We studied the connections between economic success – annual financial revenue and the number of elite athletes in the organisation, working period and the highest possible formal education of sports managers and the correlation with the development and importance of competences from the model of the of Slovenian sports managers structure (Retar, Plevnik, Kolar, 2013). In our study manager is defined as an expert having appropriate competences, personal characteristics and motivation for successful managing of sports organisations. Measurements by applying quantitative research method was carried out on the entire population of Slovenian sports managers employed in sports organisations having more than 100.000 EUR of annual revenue, more than one employee and where sports managers perform at least one year of voluntary tasks or professional work. Economic successfulness was defined by the amount of annual financial revenue of sports organisations. Based on the analysis of the collected data we have found out that managers leading economically successful sports organisations also have more categorised top level athletes and vice versa. Sports organisations employing sports managers for a shorter period of time have higher financial incomes. Sports managers with higher education manage sports organisations with higher financial incomes. They normally acquired competences through formal university education and through working experiences; the development of their competences is significantly influenced by Lifelong learning. Unexpectedly, we have found out that financially wealthier sport organisations are led by managers who assess their own social competence "Feeling responsibility for co-workers, sports environment and society for the results of their work" as the least developed. **References:** Retar, I., Plevnik, M. & Kolar, E. (2013). Key competences of Slovenian sport managers. Koper: Univerza na Primorskem, Znanstveno-raziskovalno središče, Inštitut za kineziološke raziskave, Založba Annales. WATCHING GLOBALLY PLAYING LOCALLY

Buckley, K.

Rollins College

Major sports institutions are broadening their appeal. Technological advancement has made the world of sport more accessible to owners of satellite TV, broadband and even mobile phones. The potential viewing numbers (profits) are appealing to sports owners. Sport is clearly part of the globalization process. Sports have long served as a medium through which societies and cultures learn and live – will we all end up playing and watching the same sports? This paper examines the globalization of sport beyond the mega media deals and how it will affect national sport policy development. Tradition, culture and history are intrinsically woven into a country's sport's heritage. Are mega sporting brands an opportunity for more sports enthusiasts to be entertained or an attack on local practices and ideals to benefit the wealthy? The evidence will indicate an overall global awareness of major sports leagues and teams, but a clear individual identity to local sports and customs. A classic Lexus and the Olive Tree approach to sport in the 21st century. The major American sports leagues will definitely try to maximize their product in Europe and Asia. Cricket has a great opportunity to establish itself in China, but it is going to have to be well organized and focused. Cricket authorities have not demonstrated strength in their global leadership in the last twenty or thirty years. Soccer has a phenomenal deep rooted fan base but as its Global leaders make decisions based on money and political influence so sports such as basketball will erode some of this fan base. There is also the distinct possibility of alienating traditional fans that established the brand you are promoting. It is a fine line; the new fan wants exposure, to see the product in his home town. The old fan wants to continue to see his team in his town at a reasonable price and at all costs win the game. Does globalization of Sport hurt cultural identity? The evidence suggest no. Football was exported through the world by the British in the 19th century. Countries have taken the sport, adapted it to their identity and played the game in a manner which highlighted the strengths and charac-

teristics of the country. Despite globalization, the 2012 World cup highlighted the nationalistic tendencies of the major footballing nations. Argentina plays differently than Italy who plays different than Ivory Coast who plays totally different than Morocco. Cultural tendencies will continue to be a very strong detriment of consumer behavior. Local sports culture will be the determinant force. The owners will work very hard to attract a global audience without upsetting its traditional fan base. We want to encourage more sport in more countries. Local culture will adapt to a sport and will affect how it is played. More sport more play –surely that is a good thing. KBuckley@Rollins.edu

ELECTROMYOGRAPHIC ACTIVATION PATTERNS DURING HANDBALL THROWING BY EXPERTS AND NOVICES

Rousanoglou, E.1, Noutsos, K.2, Boudolos, K.1, Bayios, I.2

National & Kapodistrian University of Athens, Greece

Introduction Knowledge of the electromyographic (EMG) activation differences between experts and novices is helpful in providing appropriate technical instructions, strength training, and injury prevention protocols (Escamilla and Andrews, 2009). This study aimed to compare the timing and intensity EMG activation pattern of experts and novices during the handball standing throw. **Methods** Surface EMG recordings were taken for the trapezius, pectoralis major, triceps brachii, and biceps brachii muscles in synchronization with EMG recordings to determine the timing of the throwing phases (tcocking, tacceleration, tfollow through). Players aimed at an illuminated target as accurate (Bayios et al., 1998) and as fast as possible (Bayios et al., 2001). The throw with the greater ball velocity was selected for further analysis (Oliver et al., 2011; Royas et al., 2009). The significance of group differences was examined with t-tests and repeated measures ANOVAs were applied for the differences among muscles and throwing phases ($p < 0.05$, SPSS version 21.0). **Results** The ball throwing velocity and throwing accuracy were significantly better in experts than novices ($p < 0.05$). No significant group difference was found for the timing of throwing phases and the timing EMG activation ($p > 0.05$). The experts showed increased intensity of EMG activation for the trapezius and the pectoralis major muscles during tcocking, with the group difference being reversed during tacceleration ($p < 0.05$). **Discussion** The group invariance in the timing pattern of throwing phases and EMG activation possibly suggests that the throwing pattern is acquired early in the learning process. The differences in the intensity pattern of EMG activation probably highlight the insufficiency of the novices to optimally store elastic energy during tcocking. Thus, from the early stages of training, care should be focused on the achievement of an optimal tcocking which is important for an effective storage of elastic energy (Roach et al., 2012;2013). **References** Bayios I, Anastasopoulou E, Sioudris D, Boudolos K. THE USE OF INSTRUMENTED STARTING BLOCKS FOR SPRINT TRAINING

Milanese, C.1, Astegno, P.2, Pirlo, M.3, Barbi, G.3, Zancanaro, C.1, Petrone, N.2

University of Verona

Introduction In order to understand the starting technique, it is necessary to measure the temporal patterns of the forces generated and their correlation with the speed achieved. Up to now, such studies have been carried out in laboratory using expensive instruments. Recently, a set of dynamometric sprint blocks has been developed and used for the kinetic analysis of elite athletes in order to develop a robotic testing bench for the validation of fault start detection criteria based on reaction time [1]. The aim of this study was to design and develop a set of instrumented starting blocks able to respect all the features of those normally used in sprint start of track and equipped with a set of load cells enabling to measure the magnitude and direction of forces generated by athletes: the blocks were used as training tool during the sprint start due to their ability to provide immediate data and information to the trainer. **Methods** The starting blocks were equipped with 4 axial load cells for each block. The force data are resolved into horizontal and vertical components for each foot. The system makes use of a portable personal computer to provide data acquisition, signal processing and graphical/textual display to the coach and athlete directly at the track after the start. Static and dynamic bench load tests were carried out to calibrate the force transducers. After validation, a series of sprint starts during training session with beginner, intermediate and expert athletes were recorded and compared to related force plate output. **Results** Several tests were performed on each part of the apparatus to ensure the validity of the results obtained during usage. Static and dynamic load tests showed good results with low error: the difference between the maximum force applied on the block and the measured force is lower than 1%; whereas the error concerning the calculated impulse is under 4%. The blocks were used on training sessions with a group of 20 athletes, ranging from beginner to expert sprinters: force profiles were analyzed in order to recognize the patterns correlated with good starts. **Discussion** The results showed that the apparatus was suitable to determine the force vector intensity and direction. Kinetic data collected with the system can be correlated with the start speed in order to classify the quality of force generation pattern. The force profiles can be displayed immediately on the screen: this feedback helped the coach in assessing the technical performance of athletes and training more effectively. **References** [1] Willwacher S, et al. 2013. *Procedia Engineering* 60, 124 Contact: chiara.milanese@univr.it

IS A SEVEN OR EIGHT-STEP START APPROACH BETTER DURING HURDLING? USING BIOMECHANICAL DATA TO DETERMINE RACE STRATEGY.

Janssen, I., de Laat, B.

*NOC*NSF/SLP*

Introduction In the sprint hurdles, eight steps are taken from the start blocks until the first hurdle. On the other hand, recent race strategies have shown seven steps to be more beneficial by decreasing the time to the first hurdle. This seven-step approach, however, requires the athlete to change their foot position in the start blocks and it is imperative that they maintain a high horizontal velocity with a short flight time over the hurdle (Salo and Scarborough, 2006; Mann and Herman, 1985). The purpose of this case study was to identify whether a particular athlete was able to demonstrate the required performance criteria when performing a seven-step approach to the first hurdle. **Methods** Over the course of several months, one elite male hurdler (age=26yrs; mass=80kg; height=1.86m) performed six trials with a seven-step approach and six trials with an eight-step approach to the first hurdle. Dependent performance parameters included horizontal velocity 2m after the first hurdle, time from the start to 3m after the first hurdle, and flight time over the hurdle. Horizontal velocity of the hip was digitised using high speed cameras and analysis software (240Hz; Quintic biomechanical software), timing gates collected time from 0.5 to 3m (Smartspeed; Queensland, Australia), and the OptoJump system (1000Hz; Microgate; Bolzano, Italy) calculated flight time. A paired samples t-test ($P < 0.05$) was used to determine which race strategy was more favourable for this particular athlete. **Results** The seven-step approach strategy resulted in similar horizontal velocity (8.15 ± 0.43 vs. 8.24 ± 0.50 m/s; $P = 0.236$) than the eight-step approach. However, the seven-step approach resulted in a significantly slower performance time (2.54 ± 0.02 vs. 2.47 ± 0.01 s; $P = 0.001$) and longer flight time (0.424 ± 0.031 vs. 0.366 ± 0.018 ; $P = 0.007$) over the hurdle. **Conclusion** Although a seven-step approach allows for a shorter sprint hurdle performance time, there is an increased risk of falling associated with this strategy. In the current study, the seven-step approach resulted in similar horizontal velocity but a slower time to 3m and over the hurdle. As a result, an eight-step approach was adopted for this particular athlete. This case study highlights how systematic biomechanical testing of a race strategy can assist coaches by determining the most beneficial race strategy for a particular athlete. **References** Mann R., Herman J. LOWER LIMB WORK-ENERGY PATTERNS IN ELITE RACE WALKING

Hanley, B., Bissas, A.

Leeds Metropolitan University

Introduction: Race walking is part of the athletics programme at the Olympic Games and all other major athletics championships. Despite this high profile, no research has measured the amount of work done at the major lower limb joints, and such data might be particularly informative in this unique form of gait given its distinctive rules. The aim of this study was to measure the work done in each of the main leg joints in elite race walkers. **Methods:** Ten elite male race walkers (stature: $1.79 \text{ m} (\pm 0.06)$; mass: $67.0 \text{ kg} (\pm 9.4)$) and 10 elite female race walkers (stature: $1.69 \text{ m} (\pm 0.05)$; mass: $53.9 \text{ kg} (\pm 5.6)$) participated in the study; in total, 10 had competed at the Olympic Games. They performed multiple trials, and ground reaction forces (Kistler, Winterthur) were recorded of the contact phase (1000 Hz) and synchronised with high-speed videography (100 Hz) (RedLake, San Diego). Sagittal plane joint powers at the hip, knee and ankle were calculated from the force and video data; the amount of work done at each joint was calculated as the time integral of the power curve using the trapezoidal rule. **Results:** Overall, the lower limb was a net generator of energy ($16.0 \pm 9.8 \text{ J}$), with most positive work done during stance ($19.3 \pm 11.0 \text{ J}$). The ankle was a net generator of energy, with most of this work occurring during stance ($7.7 \pm 5.2 \text{ J}$). The hip was also a net generator of energy, but with more positive work done during swing ($41.4 \pm 12.0 \text{ J}$) than during stance ($15.2 \pm 10.2 \text{ J}$). By contrast, the knee was a net dissipater of energy ($-50.0 \pm 12.7 \text{ J}$), with large negative work values occurring during swing ($-46.4 \pm 9.5 \text{ J}$). This led to a mean net dissipation of energy in the lower limb during swing ($-3.2 \pm 8.9 \text{ J}$). The main muscle groups that did positive work were the hip extensors ($42.3 \pm 10.1 \text{ J}$), hip flexors ($22.4 \pm 7.1 \text{ J}$) and ankle plantarflexors ($16.4 \pm 3.8 \text{ J}$). Most of the negative work was done by the knee flexors ($-38.2 \pm 7.1 \text{ J}$) and knee extensors ($-18.7 \pm 6.4 \text{ J}$). **Discussion:** The hip extensors did most of the positive work during the gait cycle and emphasised their central function in elite race walking; the hip flexors were important in late stance / early swing to drive the thigh forwards, and the extensors important in late swing / early stance in preventing too much braking at initial contact. By contrast, the amount of work done by the knee during stance was minimal, and in effect, the straightened knee rule restricted the leg to the role of a rigid lever around which the body rotated because of the forward momentum of the contralateral swing leg. The key points for coaches are that the strength and endurance of the hip muscles must be well developed for elite race walking performances, and the frequent injuries to the hamstrings in race walking are most probably due to the considerable negative work done by the knee muscles during late swing.

THE CALCULATION OF THE TRAJECTORY OF SKIER DURING ALPINE SKI RACE USING ACCELEROMETER, MAGNETIC AND GYROSCOPE SENSORS

Kazuhiko, T., Hiroshi, H., Tsutomu, S.

Hokusei Gakuen University

INTRODUCTION The measurement of forces acting on a skier during alpine ski race became possible using a compact measurement device. In our previous study, the centrifugal forces generated by turns were observed. The mean centrifugal force was approximately 0.6 G (Range 0.2-1.0 G). This force becomes the factor to change a direction of movement of skier. The trajectory of skier has an influence on the result of race. Because a skier has larger movement of vertical direction, the calculation of trajectory during skiing is more difficult than other sports. The purpose of this study is to calculate the trajectory of skier's COM during alpine ski race using accelerometer, magnetic and gyroscope sensors. **METHOD** The subject was a Japanese female alpine skier, participated in a women giant slalom race. Data collection was performed at a FIS race competition in Hokkaido, April 2013. A measurement device ($85 \times 48 \times 15$ [mm], 41[g], Logical Product Corporation, JAPAN), which combined accelerometer, gyroscope sensor and magnetic sensor, was used. These three dimensional data were sampled by 200Hz and stored in the data logger. The device was attached to her back. **DATA TRANSFORMATION** Data transformation was calculated on a excel worksheet (Microsoft). The heading angle on a horizontal plane of against magnetic north was calculated using magnetic sensor data. The acceleration and gyroscope data were processed using a smoothing filter. The pitch angle of the device was calculated by the integration of angular velocity obtained from gyroscope sensor. The 3-axis acceleration data were transformed from local to global coordinate system, using the pitch angle data. The velocity was calculated for by the integration of acceleration on global coordinate system. The trajectory of skier's COM was calculated by the velocity and heading angle data. **RESULTS**

AND DISCUSSION The acceleration and angular velocity data had high frequency component by ski vibration. The heading angle was obtained directly and exactly using magnetic sensor. The 32 ski turns were captured by the device. The range of heading angle was about -40 to 40 deg. The mean time of period of the turns was about 1.4 sec. This method using heading angle data enabled to calculate more accurate trajectory. CONCLUSION It became possible to compute the trajectory of alpine skier more exactly by using magnetic and gyroscope sensors.

THE EXTERNAL FORCES IN MALE WORLD CUP ALPINE SKIING

Gilgien, M.1, Spörri, J.2, Kröll, J.2, Crivelli, P.3, Cabri, J.1, Müller, E.2

Norwegian School for Sport Sciences

1: Norwegian School of Sport Sci. (Oslo, Norway), 2: Univ. of Salzburg (Austria), 3: WSL – Inst. of Snow and Avalanche Res. SLF (Davos, Switzerland) Introduction The external forces acting on alpine skiers determine their trajectory and, therefore, indirectly their performance. Furthermore, external forces are known to be related to injury risk. Despite decades of biomechanical research, a comprehensive understanding of forces acting in World Cup ski racing is lacking. Hence, the aim of the current study was to assess the external forces acting on male World Cup (WC) alpine skiers in the disciplines giant slalom (GS), super-G (SG) and downhill (DH). Methods During several WC races (14 GS, 5 SG and 5 DH runs) a forerunner (former WC or current Europa Cup skier) was equipped with a differential global navigation satellite system (dGNSS) tracking the skiers head trajectory at a frequency of 50Hz. The snow surface of the course was captured by static dGNSS and a digital terrain model was reconstructed (Gilgien et al., 2008). The digital terrain model in combination with a pendulum model attached to the helmet trajectory was used to derive ground reaction force (FG), ski - snow friction (FF) and air drag (FD) were derived (Gilgien et al., 2013). In addition, the parameters energy dissipation due to ski – snow friction ED(FF) and energy dissipation due to air drag ED(FD) were calculated. Finally, the differences between discipline medians were tested using an ANOVA, Kruskal – Wallis test ($p = 0.01$), followed by a Friedman's test. Results The forces are given in body weight (BW): FG was largest for GS (1.46 ± 1.04), followed by SG (1.42 ± 0.86) and DH (1.21 ± 0.53). A similar ranking was found for FF (GS: -0.20 ± 0.27 ; SG: -0.15 ± 0.19 ; DH: -0.10 ± 0.15). In contrast, the median of FD was largest for DH (0.13 ± 0.12), followed by SG (-0.09 ± 0.06) and GS (-0.07 ± 0.05). The energy dissipation values are given in BW•m: ED(FD) was largest for DH (-0.06 ± 0.07), followed by SG (-0.04 ± 0.03) and GS (-0.02 ± 0.02). No differences were observed for ED(FF) between GS (-0.07 ± 0.09) and SG (-0.07 ± 0.09), while ED(FF) was smaller for DH (-0.05 ± 0.08). Discussion This study illustrated that the athletes' loading (FG) is largest in GS, followed by SG and DH probably due to a higher turn frequency (Gilgien et al. 2014). The main factor causing energy dissipation in DH was found to be FD, while in GS and SG FF causes the major part of energy dissipation. This might be explained by the fact that in DH speed is higher and courses consist of more straight skiing (Gilgien et al. 2014). References Gilgien, M., Reid, R., Haugen, P., Smith, G. (2008). A MUSCULOSKELETAL FULL-BODY MODEL BASED ON 3D MEASUREMENTS OF ALPINE SKIING FOR ANALYZING SKIS OF DIFFERENT WIDTHS

Supej, M.1, Olenšek, A.2, Zorko, M.3, Matjačić, Z.2

1: University of Ljubljana, Faculty of Sport (Ljubljana, Slovenia), 2: SOČA (Ljubljana, Slovenia), 3: UMCL-CIOTSM (Ljubljana, Slovenia)

Introduction Recent evolution of alpine skis resulted in an increased width of ski waist. Therefore, the point of application of the ground reaction force moves medially with the increased width of ski waist and changes the knee kinematics (Zorko et al., 2013). The aim of this study was to develop a full-body musculoskeletal model for alpine skiing which can be used in combination with 3D full body measurements of alpine skiing in order to be able to investigate the effect of the ski width on knee kinetics. Methods The model of skier was generated in the Anybody Modelling System. The model was composed of three components: 1) kinematics of movement, 2) skier's body model and interaction with the ski and 3) model of the ski and interaction with the ground. We measured kinematics of movement with full-body inertial suit and GNSS technology (Supej, 2010) in six skiers while performing 3 giant slalom runs using three different skis with waist widths: 65, 88 and 110 mm respectively. Results We used an Anybody's repository of bone and muscle models to generate a model which can be used to simulate joint torques, muscle forces and muscles activation. As the models are conveyed with realistic bone properties and muscle characteristics with larger number of degrees of freedom than our dataset a compromising solution was reached that set physical constraints between neighboring body parts in such a way to account for at most those degrees of freedom that were measured and had deciding contribution to overall body posture. Final model of the skier assumed 3 rotational degrees of freedom (DOF) in the ankle, knee, hip, elbow and shoulder joints, 3 DOF of the torso, 3 neck rotations for head movement, 3 DOF of the each shoulder with respect to C7 vertebra. Ski-boot stiffness was included as a spring model with moment exerted on the ankle joint being proportional to deviation of ski shoe position from its neutral position. Discussion The results demonstrated that a model can be successfully used in combination with full-body 3D kinematics measurements. It allows analysing crucial joints' and muscles' biomechanical parameter with the main focus in the knee and hip joint of the outside leg. References Supej, M. ACUTE EFFECTS OF WHOLE BODY VIBRATION ON VERTICAL JUMPING PERFORMANCE

Pappas, A., Rousanoglou, E., Boudolos, K.

National & Kapodistrian University of Athens, Greece

Introduction The majority of studies regarding the acute effects of Whole Body Vibration (WBV) on vertical jumping performance (VJP) have mainly examined the change in jump height (JH) immediately after WBV, revealing a small but significant JH increase. Limited data exists about more detailed VJP parameters (Dabbs et al, 2012). The aim of this study is to examine the acute effects of a single bout of WBV in Ground Reaction Forces (GRF) developed during a squat jump (SJ). Methods Sixteen physically active men with no previous WBV experience were randomly assigned to the WBV-G ($n=8$, 21.3 ± 1.6 yrs, 177.3 ± 1.6 cm, 73.0 ± 6.3 kg) and to a control group (CG) ($n=8$, 20.6 ± 2.5 yrs, 182.1 ± 5.2 cm, 72.5 ± 6.4 kg). In the WBV-G, the GRF developed during SJ trials were recorded with a force platform (Kistler 9286AA, 250Hz) before (pre SJ condition-2 trials) and immediately after a WBV session (post SJ condition-2 trials). During the WBV session, the participants sustained a 3-minute vertical vibration (Power Plate, 30Hz, peak to peak amplitude at 2.5mm) while maintaining a

squatting position (knee angle: 150 degrees, 180 degrees: full extension). The CG also performed SJ trials before and after a 3-minute squatting position (pre and post SJ, respectively), without sustaining the vibration. The GRF parameters inserted in statistical analysis were the JH, the take-off velocity, the peak vertical GRF (PFz), peak anterior-posterior GRF (PFx), the peak power (PP) and the peak rate of vertical force development (PRFD) during impulse, the total impulse, and the PFz in landing. The impulse duration (timpulse) and the times to PP and to PRFD (%impulse) were also determined. Paired t-tests were applied between the pre and post SJ, separately in the WBV-G and CG (SPSS 21.0, $p < 0.05$). Results A significant WBV effect ($p < 0.05$) was found for Pfx during impulse and PFz during landing (lower values in the post SJ in the WBV-G). In the CG, no significant difference was found between the pre and post SJ ($p > 0.05$). Discussion Our findings are in agreement with previous studies examining critical VJP factors, such as JH, PFz, PP and PRFD, reporting no significant changes after a single bout of similar vertical WBV (Kavanaugh et al, 2011; Bagheri et al, 2012). The lower Pfx in impulse and PFz in landing after WBV may possibly indicate an improvement in VJ execution that should be further examined. MO-SH15 Talent & Career Development

THE ONTARIO HOCKEY LEAGUE DRAFT: DOES BIRTHPLACE AFFECT DRAFT SUCCESS?

Wattie, N., Baker, J.

York University

Introduction Research suggests that elite level North American athletes are more likely to emerge from areas that are neither too large nor too small in population (MacDonald & Baker, 2013). This 'size of birthplace effect' has largely focussed on elite professional samples of athletes and has not explored the influence of birthplace at elite developmental levels of play, nor has it considered whether birthplace influences athletes' level of skill. The purpose of this study was to describe the birthplace distribution of athletes drafted into the Ontario Hockey League (OHL; the OHL is part of the primary amateur developmental league for the most elite professional National Hockey League), and to explore whether an athlete's birthplace was related to skill level. Methods The current sample included Canadian born athletes drafted into the OHL from 2006 to 2012 ($N = 1653$). Athletes' hometowns were matched to census information to ascertain the population size of athletes' developmental environment. Population sizes were categorized into 9 census subdivisions (<2500, 2500-4999, 5000-9999, 10000-29999, 30000-99999, 100000-249999, 250000-499999, 500000-999999, >1000000) in order to facilitate comparisons with general population distributions. Skill level was determined using the draft round that athletes were selected in. Results Compared to the general population, athletes were less likely to have been from towns with populations of <2500 (OR: 0.37, 95% CI: 0.29-0.47), 2500-4999 (OR: 0.53, 95% CI: 0.41-0.69), 5000-9999 (OR: 0.62, 95% CI: 0.50-0.78), and 500000-999999 (OR: 0.87, 95% CI: 0.76-0.99). Athletes were more likely to have emerged from towns with populations of 30000-99999 (OR: 1.50, 95% CI: 1.35-1.66), 100000-249999 (OR: 1.39, 95% CI: 1.23-1.57), and 250000-499999 (OR: 1.64, 95% CI: 1.42-1.89). Spearman correlation between draft round (1 to 15) and athletes' census population category was not statistically significant ($r = -.04$, $p = .09$). Discussion Athletes drafted into the OHL were less likely to be from towns with very small and large populations and were more likely to be from locations with medium population sizes. Results were consistent with previous work reflecting advantages to athletes who come from environments of optimal size (i.e., population; MacDonald & Baker, 2013), although the precise mechanism(s) driving this effect is unknown. The persistence of this effect even in lower levels of skill development highlights the importance of understanding the influence of indirect factors in athlete development and talent identification. References MacDonald, D.J., & Baker, J. (2013). Circumstantial development: Birthdate and birthplace effects on athlete development. In J. Côté & R. Lidor (Eds). CALIBRATE YOUR JUDGMENT! HOW TO IMPROVE FAIRNESS CRITERIA IN SUBJECTIVE SERIAL TALENT EVALUATIONS

Fasold, F.1, Memmert, D.1, Unkelbach, C.2

1: German Sport University Cologne (Germany), 2: University of Cologne (Germany)

Calibration processes in subjective serial evaluations like talent tests are affected by centering biases (avoidance of extreme judgments) within the first ten judgments (Fasold et al., 2013). These biases violate fairness criteria in the beginning of such serial evaluations. A crucial prerequisite for successful calibration is the knowledge of the range of performances in a specific performance context. The aim of our study was to test the effect of a prior range-of-performance presentation (best and worst performances) on the centering bias (amount of extreme ratings) within the first ten judgments in two different talent tests in team handball. Video-material of unspecific (gymnastics) and specific motoric-tests (dribbling) of a German team handball talent center was used. In a 2x2x2 design we investigated the effect of the between-subject factors test (unspecific vs. specific) and range (with prior range presentation vs. without prior range presentation) as well as the inner-subject factor position (judgment 1-10 vs. judgment 11-20) on the frequency of extreme ratings. Participants ($N = 57$, 19 female) were randomly assigned to one of the four experimental conditions. Then participants in the with range presentation conditions were introduced to the two corresponding best and worst performances of previous tests. Afterwards, every participant watched the 20 performances one after another in a randomized order and immediately evaluated them on a grading scale (1.0-5.0). Independent of the factor test an analysis of planned contrasts shows a significant increased probability of extreme ratings with a prior range presentation among the first ten judgments, $t(38.39) = -3.39$, $p = .002$. Compared to the other conditions without this range presentation, participants showed the predicted centering bias within the first ten judgments, $t(95.03) = 3.78$, $p < .000$. The range presentation before the evaluation process seems to be an effective measure to improve the fairness-criteria in the beginning of subjective serial evaluations. Nevertheless, this measure as well as further possibilities (e.g. end-of-sequence judgments) should be discussed in the view of practitioners. Reference Fasold, F., Memmert, D., & Unkelbach, C. (2013). Calibration processes in a serial talent test. Psychology of Sport & Exercise, 14, 488-492.

THE IMPORTANCE OF PSYCHOLOGICAL CONSTRUCTS FOR TRAINING VOLUME AND PERFORMANCE IMPROVEMENT: A STRUCTURAL EQUATION MODEL FOR YOUTH SPEED SKATERS

Elferink Gemser, M.T.1,2, De Roos, I.1, Torenbeek, M.2, Fokkema, T.1, Jonker, L.1,3, Visscher, C.1

1: UMCG, RUG (Groningen, The Netherlands), 2: HAN (Nijmegen, The Netherlands) 3: KNVB (Zeist, The Netherlands)

Introduction In the process of training and reaching an expert performance level in sport, psychological characteristics play a crucial facilitating role (Starkes & Ericsson, 2003). The relation between self-regulated learning, intrinsic motivation, and goal orientation with training volume and performance improvement is still unknown. **Methods** 63 talented Dutch speed skaters (n=35 male; n=28 female) aged 11 to 22 filled in the Self-Regulation of Learning-Self-Report Scale (SRL-SRS; Toering et al., 2012), Sports Motivation Scale (SMS; Pelletier et al., 1995), Task and Ego Orientation in Sports Questionnaire (TEOSQ; Duda & Nicholls, 1992) and a questionnaire for training volume. Performance improvement over one competitive season was based on the national ranking of the Dutch National Speed Skating Association. **Results** Structural Equation Modeling in LISREL showed that the model fitted the data ($\chi^2(11)=15.49$, $p=.16$, SRMR=.089, CFI=.97, NNFI=.94, RMSEA=.077). Task orientation and intrinsic motivation were positively associated with each other (.59) and with the self-regulation learning skills planning and reflection (.25-.31). Reflection was positively related to training volume (.24) and a higher performance improvement (.22). Additionally, ego orientation was positively related to performance improvement (.31). Also a direct positive relation between training volume and performance improvement was found (.59). All relations were significant ($p<.05$). **Discussion** The present findings support the integrated view on psychological constructs in talent development, and underline the importance of psychology in talent development in sport. The clear relations between several psychological constructs and their combined importance for training volume and performance improvement over one season are relevant for those working with talented athletes. It would be valuable to monitor and develop psychological factors in talent development programs, particularly goal orientations, intrinsic motivation, planning and reflection. These factors seem to play an important role in the development of performance and in reaching a high performance level. **References** Duda J.L, Nicholls J.G. (1992). *J Edu Psych*, 89, 290-299. COLLEGE EXPERIENCE AND CAREER BARRIER AMONG STUDENT-ATHLETES: INFLUENCES OF ATHLETIC IDENTITY AND SELF-EFFICACY

Huang, C.J., Hung, T.M.

University of Taipei

Introduction College experiences are the major resources for helping student-athletes explore and formulate future career plans outside of sports. Previous research has indicated that academic support services could positively enhance levels of career self-efficacy that in turn might facilitate career decision-making. Due to investments in both the athlete and student role identities simultaneously for student-athletes, high athletic identity was considered detrimental to their exploration of non-sport career options. Few studies have investigated how athletic identity could moderate the relationships among campus experiences, self-efficacy, and career barrier in college athletes. **The aim** of this study examined the roles of athletic identity and career self-efficacy on the relationship between college experiences and career barriers of student-athletes. **Method** The participants for this study consisted of 345 varsity student-athletes (224 males, 121 females, age = 21.58 years) from 22 different sports. Participants completed the Student-Athlete Experiences Inventory (SAEI) and Student-Athlete Career Situation Inventory (SACSI). According to Baron and Kenny (1986), separate hierarchical regressions were conducted for high and low athletic-identity individuals (based upon the median split) to clarify the mediating role of self-efficacy between college experiences and career barrier. **Results** For participants who were classified as lower athletic identity, self-efficacy showed significant associations with college experiences (assorted, social interaction, academic experiences; $r = .31 \sim .42$, $p < .01$) and career barrier ($r = -.35$, $p < .01$), and hence was a qualified mediator. Further analyses revealed that inclusion of self-efficacy in the regression models indeed caused the reduction of the effect of assorted experiences, social interaction experiences, and academic experiences on career barrier. Therefore, self-efficacy was found to have a partial mediating effect between college experiences and career barrier. For those who were classified as higher athletic identity, self-efficacy was not qualified as a mediator. **Discussion** Interestingly, for participants with higher athletic identity, college experiences seemed irrelevant to their self-efficacy, indicating that campus experiences were not utilized as the sources of career self-efficacy. Previous research indicated that while student-athletes have a strong and exclusive athletic identity, they may spend a considerable amount of time participating in their sport instead of leaving time for the self-exploration needed to develop future career plans (Blann, 1985). Therefore, those college student-athletes whose athletic identities are over may tend to neglect the programming and resources provided by college departments for helping them develop transferable skills that will help them transition into the world of work. Possibly, they may develop other channels of career information rather than college experiences, which will be needed to investigate in future research.

THE ACADEMIC SUCCESS OF FLEMISH STUDENT-ATHLETES

De Brandt, K., Wylleman, P.

Vrije Universiteit Brussel

Background As the proportion of elite athletes involved in tertiary education continues to increase and only few student-athletes get sufficiently rewarded to make a living out of their sport, research on the dual career of student-athletes is of growing importance for individual nation states and institutions for higher education. Although the number of research on policies and frameworks for European student-athletes increased in the last decade, studies investigating the educational effectiveness of these frameworks are scarce. **Objective** The aim of this study was to explore the academic success of Flemish elite student-athletes. **Method** The participants were 180 student-athletes (57% men, 43% women) who studied at the Vrije Universiteit Brussel between 2004 and 2012. Data on a set of variables including gender, sport, elite sport performance level, faculty department, secondary education background and academic success rate were collected. Student-athletes were overrepresented in the faculty of Physical Education and Physiotherapy. Individual (51%) and team sport performers (49%) were almost equally distributed within the student-athlete sample. The statistical analyses included multiple independent t-tests to make comparisons a) between student-athletes and all other university students and b) within the student-athlete population. Linear regression analyses were used to evaluate how well the set of variables predicted the academic success of student-athletes. **Results** Academic success rates of student-athletes exceeded those of all 'regular' university students (76.1% vs. 71.1%). Within the student-athlete sample, secondary education type was found to be the only significant predictor of academic success. Athletes with a

'general' secondary education preparation had significantly higher academic success rates compared to athletes with a 'technical' preparation. Furthermore, male student-athletes had significantly lower academic success rates than female athletes and higher sport performance level did not impair student-athletes' academic success. Conclusion This study paints a positive image of the Flemish student-athlete. Although they performed better in the classroom than their non-athletic peers, particularly male student-athletes and student-athletes issuing from secondary education with less academic preparation are academically 'at risk' and would benefit from specific support services that help them to optimize the combination of their elite sport and academic career. Especially this group of student-athletes should receive extra assistance to adjust their study programme and planning in function of their sport programme so that they are able to train and compete in an elite sport environment with optimal support.

DOES BIRTH DATE PREDICT CAREER LENGTH IN PROFESSIONAL SPORT?

Steingröver, C.1, Wattie, N.2, Baker, J.2, Schorer, J.1

1: Institute of sport science, University of Oldenburg, Germany, 2: School of kinesiology and health science, York University, Toronto, Canada

Introduction Relative age effects (RAEs) refer to differences among individuals in annual cohorts. The effect often favors relatively older members within a cohort and seems to result from differences in maturation and experience among athletes of different chronological age. Recent results suggest that relatively younger players may not always be disadvantaged (Wattie et al., 2007; Schorer et al., 2009). Based on their advantages such as being less likely to be injured, younger players might be able to maximize their career length (CL) (Baker et al., 2013). The aim of our study was to investigate the influence of relative age on CL. We hypothesize that relatively younger players would have longer careers than relatively older ones if RAEs are occurring. **Methods** The sample included players drafted into the NBA (N = 407), NFL (N = 2380) and NHL (N = 1028) from 1980 to 1989 and who participated in one or more matches. Birthdates and number of games played were collected through the official websites of the professional associations (www.nhl.com, www.nfl.com, www.nba.com). **Results** In all sports overrepresentations of players born in Q1 were found. However, for the NBA, results were not statistically significant, $\chi^2(3, n = 535) = 0.77, p = .86, w = .04$ and only approached significance in the NFL, $\chi^2(3, n = 1924) = 7.03, p = .07, w = .06$. A clear RAE existed for the NHL, $\chi^2(3, n = 700) = 66.89, p < .01, w = .31$. A one-tailed ANOVA with number of games as dependent variable and birth quartile as between subject factor was calculated to test for differences in CL. In the NHL, a significant difference in matches played between birth quartiles was revealed, showing that relatively younger players from Q4 had the most games $F(3,696) = 2.07, p = .05, f = .10$. There were no significant effects in the NBA or NFL. **Discussion** Unlike the results for basketball and football, the significant relationship between relative age and CL in ice-hockey provides further support for the notion that relative age is an important constraint on the development of expertise in ice-hockey. Although the exact reason why relatively younger players have longer careers is not known it is possible that they may be at a lower risk of injury (Wattie et al., 2007) or have developed better playing skills (Schorer et al., 2009). **References** Baker, J., Koz, D., Kungl, A.-M., Fraser-Thomas, J., & Schorer, J. DROPOUT DILEMMA: TOWARDS A BETTER UNDERSTANDING OF YOUTH SPORT DISENGAGEMENT

Wright, E.M., Liardi, V.O.J., McCullagh, P.

California State University East Bay

Introduction Sport plays a critical role in the development of both physical competencies and social skills (Bailey, 2006). Dropout statistics for organized youth sport continue to present as a hazard for sport leaders and physical educators (Joesaar, Hein, & Hagger, 2011). Thus it is critical to examine the underlying factors that may act as a catalyst towards youth sport disengagement. **Methods** After conducting a thorough review of literature on reasons youth dropout from sport, a list of 8 factors (didn't like coach, wasn't fun, needed time for school, wasn't good enough, wanted time for non-sport activities, too much focus on winning, injured, other sports took up too much time) that may uniquely contribute to a decision to dropout of one's sport was generated (Butcher, Linder & Jones, 2002; Seefeldt & Ewing, 1989). Two hundred and sixty nine 9th graders in various high schools throughout Michigan, USA, completed questionnaires. Previous sport participation in each of grades 6 through 8 was assessed, as well as current sport participation through their first year of high school. **Results** A multiple regression analysis attempted to predict overall sport engagement through grades 6-8 from the list of dropout reasons. Results indicated that the 'other sports took up too much time' reason significantly contributed to the model. Secondly, a binary logistic regression was conducted in order to gauge if any of the 8 reasons could distinguish those who continued sport participation into high school versus those who dropped out. It was revealed that the reasons 'too much focus on winning' and 'other sports took up too much time' significantly contributed to the model. **Discussion** An overemphasis on winning was the only factor that contributed to a discontinuation of all sport. Earlier research shows that a mastery climate is associated with enduring participation, whereas a competitive climate is associated with dropout (Sarrazin et al., 2002). Self-determination theory (Deci & Ryan, 1985) is a suitable framework from which to study sport persistence, as evidence indicates that underscoring external regulators (i.e., wins) has adverse effects on sport adherence. Teens may be susceptible to developing an antipathy towards sport if extrinsic motivators are encouraged. **References** Bailey R. (2006). J Sch Health, 76(8), 397-401. RELATIVE AGE AND MATURATION OF QATARI YOUTH CLUB-LEVEL SOCCER PLAYERS

Brito, J., Paul, D., Versloot, O., Nassis, G.P.

Aspetar - Orthopaedic and Sports Medicine Hospital

Introduction In youth soccer, the relative age effect is likely to occur, favouring players born in the first months of the calendar year. Several talent development programmes use age at peak height velocity as a measure of maturity status. In Qatar, previous investigation suggested a trend for later maturation among school children and adolescents (Bener et al., 2005), but no information exists on Qatari youth club-level soccer players. This study aimed to analyse the relative age effect and maturation in a sample of Qatari youth club-level soccer players. **Methods** Birth distribution and predicted age at peak height velocity were assessed in a cohort of 290 youth club-level soccer players (age 12-16 years) from 4 clubs around Doha, Qatar. Date of birth was divided into 4 quarters of the calendar year. Predict-

ed age at peak height velocity was estimated using chronological age, stature, body mass, sitting height and estimated leg length (Mirwald et al., 2002). Results Overall, a difference in birth distribution was detected (1st quarter, 33%; 2nd quarter, 18%; 3rd quarter, 21%; 4th quarter, 28%; $X^2=15.71$; $p<0.01$). Differences were evident for players born in the first and the last quarter of the selection year compared with players born in the second quarter ($p<0.01$). The average age at peak height velocity was 14.9 ± 0.8 (95% CI, 14.8 to 15.0) years. Predicted age at peak height velocity increased from 12 to 16 years ($t=4.659$; $p<0.001$). Discussion Our analysis showed a difference in birth distribution in a sample of Qatari youth club-level soccer players. Also, a trend for late maturation among Qatari youths has been detected. The average age at peak height velocity was higher than the reference values for Caucasian boys, defined as 14.0 years (Malina et al., 2004), although the equation used to estimate age at peak height velocity has been validated primarily in Caucasian boys. Predicted age at peak height velocity was influenced by chronological age, which might question its utility in talent development programmes (Malina et al., 2013). Altogether, the results of the present study highlight the need for further investigation on maturation status during the youth development process as to establish geographical-specific long-term training programmes. IS-PM08 Muscle stem cells and skeletal muscle plasticity

SATELLITE CELLS AND SKELETAL MUSCLE REGENERATION; LEADS FROM CELL CULTURE AND ANIMAL MODELS

Harridge, S.

King's College London

Satellite cells are the muscle stem cells and have long been believed to be necessary for muscle regeneration and repair as well as involved in the hypertrophic process. However, it was not until relatively recently using lineage tracing studies on mice that it was really possible to conclude that Pax7+ve satellite cells were indeed essential for muscle repair (Lepper et al. 2011, Sambasivan et al. 2011). Further use of transgenic models, in this case to ablate muscle fibroblasts, have also recently shown the need for these connective tissue cells to act as a co-factor for optimal regeneration (Murphy et al. 2011). In human muscle we are unable to undertake experiments using such techniques. However, cell culture techniques can be used to study the behaviour of satellite cells - or 'myoblasts' or 'muscle precursor cells' as they are termed when located outside of their anatomical niche. We have used human primary cell culture models to study the behaviour of skeletal muscle derived cells with a particular focus on ageing. Our studies suggest that whilst a different phenotype can be created through replicative senescence in culture, the potential for proliferation, fusion and differentiation is preserved in cells obtained from older people (Alsharidah et al. 2013). We have also studied the possibility that satellite cells might be diverted away from their myogenic lineage and may be the origin of adipocytes contributing to the fibro-fatty phenotype characteristic of sarcopenia. We have developed cell sorting techniques that allow us to purify populations of the two main adherent cell types from muscle biopsy samples - myoblasts (CD56+ve / desmin+ve) and fibroblasts (TE7+ve). We have treated both of these cell types with physiological adipogenic cues (fatty acids) and shown that myoblasts accumulate some lipid, but remain true to their myogenic lineage (Agle et al. 2013). In contrast, fibroblasts accumulate significant amounts of lipid, extrude their fibroblast marker and express the transcription factors required for the conversion of preadipocytes into mature adipocytes (PPAR gamma and C/EBP/alpha). It seems from these experiments, that myoblasts remain robustly myogenic for their role in muscle regeneration. By contrast fibroblasts, whilst having a supporting role in satellite cell-mediated repair, also seem to act as a bi-potent stem cell population capable of transdifferentiation into adipocytes under certain conditions.

REGULATION OF SATELLITE CELLS WITH EXERCISE

Parise, G.

McMaster University

Do Satellite cells have been shown to be indispensable for skeletal muscle regeneration, and there is little debate about their role in promoting post-natal muscle growth. However the role of satellite cells in promoting exercise-induced muscle adaptation is less clear. Whether satellite cells are necessary for muscle hypertrophy has been a hotly debated topic and although animal models demonstrate that hypertrophy can be achieved in the absence of satellite cells, most human data demonstrates that when hypertrophy occurs with exercise it is usually accompanied by a nuclear contribution from satellite cells. The extent of the role of satellite cells with exercise remains relatively unknown. Typically, satellite cells are thought to contribute to exercise adaptation by promoting growth however whether satellite cells contribute to non-growth related adaptation has not been studied to any great degree. Also, common dogma is that significant satellite cell expansion is required to promote adaptation following exercise but the question has never been appropriately addressed. Finally, how satellite cells are regulated in humans following exercise remains an area of great interest. Significant strides have been made over the last few years and we gaining an appreciation for the complexity of satellite cell biology as it relates to exercise.

MUSCLE STEM CELLS IN SKELETAL MUSCLE ATROPHY AND HYPERTROPHY

Verdijk, L.

Maastricht University

The regenerative capacity of skeletal muscle tissue depends on a pool of undifferentiated myogenic precursor cells, known as satellite cells. In adult muscle, satellite cells typically remain quiescent in their niche between the basal lamina and the sarcolemma. However, in response to injury and/or exercise stimuli, satellite cells become activated. After proliferation, satellite cells can fuse together with existing myofibers (donating their nucleus to the fiber), or return to quiescence to replenish the resident pool of muscle stem cells by self-renewal. Changes in satellite cell content as well as satellite cell function have been suggested to represent key factors in regulating the skeletal

muscle adaptive response to various stimuli, such as exercise, but also in response to different (pathological) conditions, such as aging and/or disuse. At present, much of the knowledge on satellite cell biology and their role in skeletal muscle plasticity stems from extensive in vitro and animal work. Yet, translation of this knowledge toward the exact role of satellite cells in skeletal muscle adaptation in a physiological, human, in vivo situation is challenging and inconsistencies are quite common. For example, it appears evident from a number of human studies, that skeletal muscle hypertrophy in response to resistance training in both the young and old is more efficient (i.e. more robust) when satellite cell induced incorporation of new myonuclei is achieved. This is in line with the myonuclear domain theory, suggesting that myonuclei can only control a finite volume of cytoplasm, and fusion of new nuclei facilitates extensive muscle fiber hypertrophy. However, the actual requirement of satellite cells and, as such, new myonuclei, for attaining extensive hypertrophy has recently been challenged in specific experimental animal models. Likewise, the myonuclear domain theory would suggest that muscle atrophy may be associated with a reduction in myonuclear content. However, current literature remains equivocal as to whether myonuclei and/or satellite cells are lost with different models of muscle atrophy. As such, it remains to be determined to what extent potential changes in satellite cell and/or myonuclear content play a role in the extent of atrophy on one hand, and the capacity for skeletal muscle regrowth on the other hand. In this symposium, the role of muscle stem cells in skeletal muscle atrophy and hypertrophy will be further discussed. Though the focus will be on human work, evidence from animal experiments will be used to further broaden the discussion in this evolving field of science.

Invited symposia

IS-BN05 Rate of force development: methodological, physiological and practical issues

RATE OF FORCE DEVELOPMENT: METHODOLOGICAL ISSUES

Maffiuletti, N.A.

Schulthess Clinic

The rate of rise in contractile force at the onset of an explosive voluntary contraction, better known as the rate of force development (RFD), is commonly measured in one of three ways: (1) as the highest value from the first derivative of the joint torque-time curve (peak RFD), (2) as the ratio between Δ torque and Δ time at predetermined intervals (RFD 0-50 to 0-250 ms) and/or as the corresponding area (impulse) beneath the torque-time curve, (3) as the RFD-scaling factor relationship using the peak RFD (scaled to MVC) recorded during short ballistic contractions at various submaximal levels plotted against MVC torque. The EMG counterpart of RFD, the rate of EMG rise (Δ EMG/ Δ time), could also be recorded to characterize rapid muscle activation at the onset of a voluntary contraction. Besides voluntary actions, rate of force development can be quantified from electrically-evoked torque responses, which improve the reliability of RFD assessment (compared to voluntary contractions) and offer insights into the peripheral contractile determinants of RFD. Interestingly, electrically-evoked RFD largely exceeds voluntary RFD. The purpose of this talk is to present an overview of the main methodological issues in RFD quantification, which include measuring principles, considerations on the validity and reliability of RFD assessments, and recommendations for future applications in clinical and research settings.

RATE OF FORCE DEVELOPMENT: NEUROMUSCULAR DETERMINANTS

Duchateau, J.

Universite Libre de Bruxelles

The maximal rate of force development during a fast (ballistic) contraction is not only limited by muscle speed-related characteristics, but also by neural factors. Among them, the capacity of the nervous system to recruit a great percentage of the motor unit pool at the onset of muscle activation and to drive these units at a high discharge rate is an important factor. This is supported by a simulation study performed in our laboratory showing that the incidence of a few initial motor unit discharges at high frequencies (>100Hz) plays a major role in the increase of the rate of force development. Initial conditions under which the ballistic contraction is performed influences both motor unit discharge and rate of torque development. For example, the performance of a fast isometric contraction is decreased when preceded by a sustained submaximal contraction but improved when a brief unintentional (silent period) or voluntary period of relaxation is inserted between the sustained and ballistic phases of the contraction. Furthermore, chronic changes of the neuromuscular system, due to training with fast contractions and ageing, can also influence the capacity to reach high initial motor unit discharge rate and thereby the maximal rate of force development. The purpose of this keynote will be to review the neuromuscular determinants of the rate of force development and emphasize how the conditions from which fast contractions are initiated can influence motor unit activation and thereby the performance of such action. The potential mechanisms underlying chronic modulation of motor unit discharge during ballistic contraction will be also evoked.

CONTRACTILE RATE OF FORCE DEVELOPMENT: PRACTICAL IMPLICATIONS

Aagaard, P.

University of Southern Denmark

Rapid force capacity ("explosive muscle strength") is measured as the maximal contractile rate of force development (RFD), and reflects the ability of the neuromuscular system to generate fast and steep increases in muscle force at the onset of contraction. Resistance training is known to elicit significant gains in RFD due to increases in neuromuscular activity (EMG amplitude, rate of EMG rise) in the initial phase (0-200 ms) of muscle contraction, with an additional contribution from training induced gains in muscle size and tendon stiffness, respectively. The rise in RFD evoked by training allows for an enhanced acceleration of movement, elevated limb speed during short-lasting movements, and increased muscle force and power to be produced during fast movements. Consequently, gains in contractile RFD are important not only to athletes but also for elderly individuals to improve horizontal walking speed and ensure optimal postural balance. Power athletes demonstrate greater RFD along with elevated neuromuscular activity during the onset of muscle contraction

compared to age matched controls. Muscle overuse injury leads to greater acute impairments in RFD than MVC, indicating the presence of selective neuromuscular impairments. Increases in RFD and maximal muscle power have been observed following resistance training in various patient groups (hip replacement, myalgia, COPD, fall patients), including elderly sarcopenic individuals. Elevated RFD may also be observed both in young and elderly individuals with other types of high-intensity exercise, e.g. recreational soccer training. Thus, a high degree of adaptive plasticity appears to exist for RFD, which plays an important functional role for athletes, patients and frail elderly adults alike.

IS-PM04 Pacing strategy: the key to optimal endurance performance of athletes and clinical populations

MODELLING THE REGULATION OF EFFORT

Tucker, R.

MRC/UCT Research Unit for Exercise Science & Sports Medicine

The pacing strategy, or allocation of effort during the course of a bout of known distance or duration, is a critical determinant of overall performance. This is a relatively understudied area of sports performance, but it is known that for short-duration exercise, lasting under four minutes, an even or positive pacing strategy, characterized by a fast start and potential reduction in power output or speed at the end, is optimal. In contrast, optimal performance for longer duration exercise is the result of an overall negative pacing strategy, where the power output or speed increases at the end of the trial. These differences, essential for performance, also have physiological significance, for they point to the underlying physiological systems that regulate performance and fatigue. Understanding pacing strategy, and thus physiology, may shed light on the processes that cause or regulate fatigue during self-paced exercise.

PACING STRATEGIES IN CLINICAL POPULATIONS

Foster, C.

University of Wisconsin-La Crosse

Background: The pacing literature has mainly focused on athletes. However, the concept of pacing is also relevant for other populations, as pacing is organized in terms of task completion. Purpose: This study aims to compare the pacing pattern in active non-athlete older adults (many with stable cardiovascular disease) and to the pattern observed in athletes. Methods: Fifteen well-trained, non-athlete older males performed a fixed work task of 100 kCal with the instruction to finish as fast as possible. Gas exchange variables (HR, VO₂, VCO₂, BF, RER, VE, VT), blood pressure (BP), rating of perceived exertion (RPE), and power output (PO) were measured. The pacing pattern was expressed in terms of relative PO. Results: Subjects completed the time trial in a time of 531.9 ± 109.7 s, with a mean PO of 101.9 ± 26.0 W. There was a distinct pacing pattern in the relative PO, consisting of a conservative start, a fairly even paced middle part and an evident end spurt. All subjects attained a remarkably high physiological and psychological strain (VO₂ > VO₂max, RER > 1 and RPE_{peak} 8.2 ± 1.7). Conclusion: The pacing pattern was similar to the U-shaped pacing pattern described in athletes for comparable duration tasks, except for a more conservative start. The remarkably high physiological and psychological strain indicates that subjects were fulfilling the time trial with a competitive attitude and a large degree of goal organization, similar to athletes.

MANIPULATING PACING STRATEGY THROUGH PHARMACOLOGICAL AND ENVIRONMENTAL MEANS

Roelands, B., De Pauw, K., Meeusen, R.

Vrije Universiteit Brussel; Fund for Scientific Research Flanders; Lotto Sport Science Chair

Pacing is the complex feed forward and feedback mechanism that regulates power output or speed during an exercise performance. It represents the use of energetic resources during exercise, so that all energy stores are used before finishing a race, but not so far from the end of a race that a meaningful slowdown can occur. Pacing strategy depends on exercise duration, nutritional status and the previously developed performance template. Furthermore, during a time trial in the lab the strategy will also be altered by changes in climatic circumstances or brain neurotransmitter system manipulation. The pacing selected by athletes is largely dependent on the anticipated exercise duration and the presence of an experientially developed performance template. Studies investigating pacing during prolonged exercise in normal temperatures, have observed a fast start, followed by an even pace strategy in the middle and an end sprint. A reduction in pace observed at commencement of the event is often more evident during exercise in the heat. Furthermore, reductions in power output and muscle activation occur before critical core temperatures are reached, indicating that subjects can anticipate the exercise intensity and heat stress they will be exposed to, resulting in a tactical adjustment of the power output. Short duration exercise at (simulated) altitude revealed similar pacing strategies compared to normoxia and even hyperoxia, despite a reduction in power output. Recent research has shown that not only climatic stress but also pharmacological manipulation of the central nervous system has the ability to cause changes in endurance performance. Subjects seem to adapt their strategy specifically in the early phases of exercise. The heat, dopaminergic manipulations clearly improve performance. The distribution of the power output reveals that after dopamine reuptake inhibition, subjects are able to maintain a higher power output compared to placebo. Manipulations of serotonin and, especially, norepinephrine, have the opposite effect and force subjects to decrease power output early in the time trial. Interestingly, after manipulation of brain serotonin, subjects are often unable to perform an end sprint, indicating the absence of a reserve capacity or motivation to increase power output. It appears that many factors, such as ambient conditions and manipulation of brain neurotransmitters, have the potential to influence power output during exercise, and might thus be involved as regulatory mechanisms in the complex skill of pacing. IS-PM07 Ischaemic preconditioning: Impact on exercise performance and the cardiovascular system *

HISTORICAL OVERVIEW OF ISCHEMIC PRECONDITIONING AND POSITION IN SPORT AND EXERCISE SCIENCE

Redington, A.

Hospital for Sick Children

In 1986, Murry was the first to demonstrate in the laboratory that repeated, short periods of coronary artery occlusion resulted in a 75% less damage to the heart after a myocardial infarction. This phenomenon, named ischemic preconditioning, has since been applied in several animal and human models. A series of studies found that the protective effects of ischemic preconditioning were also present in: 1. areas/organs not directly exposed to the repeated, short periods of ischemia (referred to as remote preconditioning), and 2. return 24-h following the initial ischemic stimulus (referred to as the late phase of protection). The benefits from preconditioning in other areas in addition to the myocardium have opened doors for the clinical application of repeated, short periods of limb occlusion to protect organs against prolonged ischemia. In this lecture, Prof. Redington will provide an overview of ~25 years history of research in the field of ischemic preconditioning including an insight to his own early work in children. First, an overview of the proposed mechanisms of ischemic preconditioning will be provided, through the presentation of preclinical work in animals and humans. This will specifically focus on potential local and systemic pathways that contribute to the protective effects of preconditioning. Secondly, the overview will discuss studies that have applied ischemic preconditioning in clinical studies to limit cardiac or organ damage to prolonged periods of ischemia after a myocardial infarction, cardiac surgery and/or organ transplant. Finally, Prof. Redington will discuss the potential clinical application of ischemic preconditioning in sport and exercise science.

CAN ISCHEMIC PRECONDITIONING IMPROVE EXERCISE PERFORMANCE?

Jones, H.

Liverpool John Moores University

Over the past 5 years, a suite of studies have described the potential benefits of ischemic preconditioning on exercise and sports performance. The studies have shown potential benefit of ischemic preconditioning on exercise and sport specific performance in low, moderately and highly trained individuals including elite athletes. Improvement in exercise performance has also been demonstrated in different types (i.e. cycling, running, swimming) as well as different durations (sprint, middle distance and endurance) of exercise. The reported performance improvements include total exercise time, total work done, maximal power output and maximal oxygen consumption. Dr Jones will provide an in-depth overview of the potential benefits of ischemic preconditioning on sport and exercise performance. It will address the potential underlying mechanisms that may contribute to the benefits of ischemic preconditioning including circulating factors, skeletal muscle and the cardiovascular system. Generally, ischemic preconditioning has been employed prior to performance with the ischemic preconditioning stimulus on the limb being exercised (i.e. lower limb) as a potential warm-up strategy. This lecture will present the evidence for performance benefits of ischemic preconditioning acutely and up to 24 hours following the stimulus as well as evidence for the benefits when the stimulus is local and remote. Finally, this state-of-the-art knowledge will be translated to real life sporting situations; and will address how and when we can apply ischemic preconditioning and what is the most appropriate protocol.

CLINICAL USE AND EFFECTS OF SINGLE VS REPEATED PRECONDITIONING

Thijssen, D.

Radboud University Nijmegen Medical Centre

Repeated elevations in blood flow represent a key stimulus to mediate vascular adaptations. Interestingly, ischemic preconditioning also relates to the repeated exposure of the vasculature to elevations in blood flow. Therefore, repeated exposure to ischemic preconditioning may represent a potent stimulus for the vasculature to adapt. Research studies that have examined the impact of repeated, daily exposure to ischemic preconditioning in healthy subjects as well as patient groups will be discussed. These studies have provided insight into potential mechanisms that contribute to the effects of ischemic preconditioning, but also exercise training. Ischemic preconditioning has direct beneficial effects on the vasculature and protects against reperfusion injury. Prof. Thijssen will provide the evidence on which mechanisms may contribute to these protective effects, but also discuss some new data that suggests the efficacy of preconditioning may differ between clinical groups. Importantly, changes in the efficacy of preconditioning may limit the clinical applicability of the traditional preconditioning approach. As such, potential alternatives will be discussed to overcome these limitations and to provide optimal benefit from the ischemic preconditioning stimulus. Finally, Prof. Thijssen will present the evidence that supports recent suggestions that exercise training may have preconditioning effects. Accordingly, cardioprotective effects may partly be activated through similar mechanisms as those observed during ischemic preconditioning, but may also provide a strategy to improve the efficacy of ischemic preconditioning (in both healthy and diseased individuals).

16:20 - 17:50**Invited symposia****IS-BN04 Inside the Moving Brain: Different Approaches to Study the Interaction of Brain and Complex Whole Body Movements****THE NEUROBIOLOGY OF POSTURAL CONTROL AND BALANCE TRAINING**

Taube, W.

University of Freiburg

This talk presents and links knowledge obtained with different complementary approaches in order to describe postural control and adaptations in response to balance training. For instance, changes in grey and white matter (MRI) of the human brain after balance training will be discussed as well as electrophysiological findings (e.g. results obtained with TMS). Furthermore, brain activity during imagination of balance tasks (fMRI) will be presented and the long-term effects of mental balance training will be compared with the effects after observational balance training. In a further step, EEG-measurements will highlight preparatory strategies to counteract postural disturbances. Overall, the present talk tries to target postural control from different perspectives in order to provide a more comprehensive understanding.

THE CORTICAL CONTROL OF HUMAN GAIT AND ITS IMPLICATIONS FOR GAIT REHABILITATION

Knaepen, K.1, Mierau, A.2, Lefeber, D.3, Meeusen, R.1

1: MFYS-VUB (Brussels, Belgium), 2: DSHS (Cologne, Germany), 3: R&MM-VUB (Brussels, Belgium)

In order for rehabilitation robots to better assist humans in (re)learning complex whole body movements such as gait, it is necessary to understand how human gait is controlled. Both at spinal and supra-spinal level, several control networks are active to regulate human locomotion. This talk will focus on the supra-spinal control of human walking and give an overview of: 1) How the cortical control of human gait has been studied until now. We will discuss the use of different brain imagery techniques such as SPECT to look at changes in cerebral blood flow during walking, NIRS topography and fMRI to analyze changes in brain tissue oxygenation as well as EEG and MEG to look into the electrophysiological activity of the brain during walking; 2) What is already known about the cortical control of human gait? Past research resulted in distinct knowledge on cortical activation patterns during imaginary walking, repetitive foot and leg movements, gait initiation and actual gait. For example recent EEG studies suggest that the human cortex is more involved in the control of gait than previously thought: MRCPs which occur in close temporal relation with phases of a gait cycle can be distinguished as well as perturbations in spectral power over different electrocortical sources such as the primary motor cortex, the supplementary motor cortex, the cingulate cortex, the primary somatosensory cortex and the somatosensory association cortex; 3) How non-invasive brain imagery techniques are being used to study human-robot interaction in gait rehabilitation? We will present recent data of studies that looked at changes in cortical activity during different types of assistance given by gait exoskeletons and what the implications are for gait rehabilitation. Finally, we will also take a glance at how EEG adds a new dimension to human-robot interaction in the context of BCI.

NEUROPHYSIOLOGICAL CHARACTERISTICS OF SPORT-RELATED SENSORIMOTOR PERFORMANCE

Mierau, A.

German Sport University Cologne

Athletes have the ability to achieve high levels of sensorimotor skills following years of extensive training. The development of such expert performance levels is associated with a substantial reorganisation of the central nervous system. However, studying the neurophysiology of sport performance in ecologically valid settings is very challenging due to technological constraints, as well as artifacts associated with movement. Nevertheless, advances in technology and alternative experimental paradigms allow interesting approaches to reveal the neural correlates of sport performance. Research in this field has important fundamental and applied implications as it demonstrates the extent of brain plasticity and helps to advance testing and training to enhance sport performance. A growing number of studies suggest the athletes' brain is characterised by specific adaptations that facilitate information processing relevant to the sport. The aim of this talk is to present research addressing the relationship between brain activation patterns during preparation/execution of sport-related tasks and performance. In doing so, a special emphasis will be placed on elaborating the functional properties that determine this relationship. Finally, new perspectives for neurofeedback training to enhance sport performance will be established.

16:20 - 17:50**Oral presentations****OP-PM13 Muscle Damage & Regeneration****EXERCISE TRAINING RESCUES DELAYED MUSCLE REGENERATION IN AGED MICE**

Joannis, S., Baker, J.M., Iacono, C., Nederveen, J.P., Parise, G.

McMaster University

Introduction Skeletal muscle possesses the ability to regenerate following injury. This process has been shown to be affected by aging evidenced by impaired or delayed regeneration (Grounds 1998). The aged muscle, like that of young muscle, retains the ability to positively respond to stimuli like exercise (Evans 1995). Therefore, we examined whether exercise is able to improve the regenerative re-

sponse in skeletal muscle of aged mice. Methods 22 month old male C57Bl/6J mice (n=10) underwent an 8 wk progressive exercise training protocol. Mice exercised on a treadmill 3 d/wk for 40 min, training began at 8.5 m/min (wk 1) and increased to 15 m/min (wk 8); training was preceded by a warm-up at 6 m/min for 10 min and followed by a cool-down at 6m/min for 5 min. Animals were subjected to injections of cardiotoxin (CTX) (25 µl at 10 µM) into their tibialis anterior (TA) muscle. The TA were harvested before (Ex/Sed Ctl n=3) 10 (Ex/Sed D10 n=4) and 28 days (Ex/Sed D28 n=3) post-injection in exercised trained (Ex) and control sedentary (Sed) animals; mice were 24 months old at the time of sacrifice. Results Following CTX injection the proportion of muscle fibers with central nuclei increased 10 and 28 days post-injection in both Ex and Sed groups. The average fibre cross sectional area (CSA) was reduced in both Ex and Sed groups 10 days post-injection but was restored to control values in Ex 28 days post-injection (Ex Ctl: $2639 \pm 334 \mu\text{m}^2$; Ex D28: $2410 \pm 548 \mu\text{m}^2$). CSA remained reduced 28 days post-injection in Sed (Sed Ctl: $2604 \pm 167 \mu\text{m}^2$; Sed D28: $1477 \pm 351 \mu\text{m}^2$). Discussion Following a progressive exercise training program in aged mice muscle fibre CSA is restored to Ctl values 28 days post CTX injection while CSA is still reduced in Sed animals. Exercise training appears to improve the skeletal muscle's ability to regenerate following injury. References Grounds MD. (1998). *Ann. N.Y. Acad. Sci.* 854, 78-91. Evans WJ. (1995). *J. Gerontol. MUSCLE ENERGETICS ALTERATIONS RESULTING FROM ISOMETRIC NEUROMUSCULAR ELECTRICAL STIMULATION OF KNEE EXTENSORS MUSCLES: A QUANTITATIVE ³¹P-MRS STUDY.

Fouré, A.1, Wegrzyk, J.1, Le-Fur, Y.1, Mattei, J.P.1,2, Boudinet, H.2, Vilmen, C.1, Bendahan, D.1, Gondin, J.1

1: Aix-Marseille University (Marseille, France), 2: APHM (Marseille, France).

Contractions resulting from neuromuscular electrical stimulation (NMES) are associated with both a larger muscle fibres disruption and a higher inflammatory response as compared to voluntary eccentric ones (Cramer et al., 2007). Although a high inorganic phosphate accumulation ([Pi]) has been recently reported at rest and throughout a dynamic exercise after eccentric exercise inducing muscle damage (EIMD) (Davies et al., 2011), the detailed metabolic effects of NMES EIMD are still unknown. Therefore, in the present study, we aimed at investigating how and to what extent NMES EIMD altered muscle energetics at rest and during a voluntary dynamic exercise. The NMES EIMD session involved forty isometric contractions (75 Hz, duty cycle: 25%) evoked on the thigh muscles of thirteen young healthy men. Changes in concentrations of phosphocreatine [PCr], [Pi] and adenosine triphosphate [ATP] were assessed during a standardized rest-exercise-recovery protocol using ³¹-phosphorus magnetic resonance spectroscopy (³¹P-MRS) at baseline, two (D2) and four (D4) days after NMES EIMD. The 6-min dynamic exercise consisted in 180 concentric contractions (0.5 Hz) performed at 30% of maximal isometric force. Energy cost of contraction (EC) was calculated as the ratio between ATP production rate (calculated on the basis of pH and [PCr] kinetics) and power. Resting Pi/PCr ratio increased at D2 (+39%) and D4 (+29%), mainly due to the increase in [Pi] (+43% and +32%, respectively). A significant muscle alkalosis was measured at D2 and D4 as compared to baseline. Moreover, the [PCr] recovery rate decreased at D2 (-21%) and D4 (-23%). A significant decrease in total ATP production rate was observed at D2 (-21%) and D4 (-22%) mainly due to alterations of ATP production rate from oxidative pathway (-19% at D4). Given that the mean power output was similar for the three ³¹P-MRS session, EC was decreased at D4 (-21%). NMES-induced muscle damage was associated with an altered resting energy metabolism as previously reported for a voluntary eccentric EIMD (Davies et al., 2011). However, we reported for the first time that NMES EIMD led to a slower [PCr] recovery rate and a reduced rate of oxidative ATP production thereby illustrating an impaired mitochondrial function (Kemp et al., 2003). The paradoxical decreased EC might be related to compensatory mechanisms, including for instance increased muscle-tendon stiffness (Green et al., 2012) and/or changes in neural firing patterns and motor unit activity (Plattner et al., 2011). SHORT- AND LONG-TERM EFFECTS OF ENDURANCE EXERCISE ON TELOMERE LENGTH AND TELOMERE REGULATORY FACTORS IN HUMAN SKELETAL MUSCLE.

Ponsot, E.1, Högberg, R.1, Langberg, H.2, Kjaer, M.2, Kadi, F.1

University of Örebro

1: MEP-RG, Örebro University (Örebro, Sweden), 2: Institute of Sports Medicine, Bispebjerg Hospital (Copenhagen, Denmark). Introduction In skeletal muscle of athletes, repeatedly exposed to exercise-related stress, telomere length (TL), an indicator of cell proliferative potential, has been found to be dramatically shortened (overtrained athletes) or maintained compared to untrained subjects (Kadi, Ponsot, 2010). Telomerase, TRF2, POT1 and tankyrase1 have been suggested to be involved in telomere regulation during tissue adaptations to exercise (Laye et al., 2012). The impact of exercise on telomere homeostasis in skeletal muscle is poorly understood. Our study aims to investigate the short- and long-term effects of endurance activities on TL and the above cited regulation factors in skeletal muscle of healthy athletes. Methods Muscle samples were collected in 12 healthy endurance athletes (END, age 25 ± 2 years) before and 8 days after a 36km race and in 10 healthy active subjects (CON, age 25 ± 2 years) for southern-based TL determination and western blot-based analysis of telomerase, tankyrase1, TRF2 and POT1 expression. Results No differences in meanTL(END: 11.1 ± 0.3 kbp; CON: 10.5 ± 0.5 kbp) and telomerase expression were observed between groups. Longer minimumTL(END: 5.5 ± 0.1 kbp; CON: 4.7 ± 0.3 kbp) and higher expression levels of tankyrase1 (2-fold), TRF2 (3-fold) and POT-1(2-fold) were found in END vs. CON ($p < 0.05$). After the race, those expression levels were unchanged, miniTL(4.8 ± 0.8 kb) but not meanTL(10.5 ± 0.9 kbp) was decreased ($p < 0.05$). Discussion Our findings suggest for the first time that regular endurance training is associated with upregulated expression of factors involved in telomere homeostasis control in skeletal muscle of healthy athletes. Though one single endurance event can negatively alter TL, the persistent elevated expression of those factors may be consistent with the positive association between TL and long-term endurance training suggested in our study, in skeletal muscle of strength-trained athletes (Kadi et al., 2008) and in leucocytes (Cherkas et al., 2008; Ludlow et al., 2008). However, the relationship between telomere regulatory factors protein content and their activity in-vivo requires further investigations. COMPARISON BETWEEN INITIAL AND SECOND MAXIMAL KNEE EXTENSOR ECCENTRIC EXERCISE FOR MUSCLE DAMAGE, INSULIN SENSITIVITY AND LIPID PROFILE OF YOUNG VERSUS OLD MEN

Chen, T.C.1, Tseng, K.W.2, Chen, H.L.3, Nosaka, K.4

1: National Taiwan Normal University (Taiwan), 2: University of Taipei (Taiwan), 3: National Chiayi University (Taiwan), 4: Edith Cowan University (Australia)

Introduction It has been reported that knee extensor (KE) eccentric exercise improves blood lipid profile of young women (1,2). However, no previous study has investigated the effects of repeated maximal KE eccentric exercise performed by old individuals on insulin sensitivity and lipid profile. The present study compared the first and second maximal KE eccentric exercise bouts for changes in insulin sensitivity and lipid profile in young (20-25 y) and old (≥ 60 y) men to examine whether the exercise could be prescribed to elderly individuals. **Methods** Untrained 13 young (Y) and 13 old (O) men performed two exercise bouts (6 sets of 10 maximal isokinetic KE eccentric contractions of non-dominant leg) separated by 2 weeks. Several muscle damage markers were measured before, immediately and 1-5 days after exercise, 2-h oral glucose tolerance test (OGTT) was performed before and 2 days post-exercise, and blood samples for several variables (triaclylglycerols (TG), high (HDL) and low density lipoprotein cholesterol (LDL), glucose (GLU), insulin, homeostasis model assessment (HOMA), whole blood glycosylated hemoglobin (HbA1c)) were taken before, and 2 and 5 days after exercise. Changes in these variables were compared between bouts and between Y and O groups by two-way repeated measures ANOVA. **Results** Changes in KE maximal voluntary concentric contraction torque (Y: -10-31%, O: -4-25%), muscle soreness (Y: 10-38 mm, O: 3-17 mm) and plasma creatine kinase activity (Y: 551-2053%, O: 349-903%) after the first bout were greater ($P < 0.05$) for Y than O. After the second bout, the changes were smaller ($P < 0.05$) for both groups, and no differences were found between groups. OGTT showed greater increases ($P < 0.05$) after exercise for Y (1st: 13%, 2nd: 5%) than O (1st: 5%, 2nd: 0%). Greater decreases in TG and LDL, and greater increases in GLU, insulin and HOMA were found for Y than O after the first bout ($P < 0.05$). After the second bout, changes in TG and LDL were smaller for Y than O, but GLU, insulin and HOMA were similar between groups. Changes in HDL and HbA1c after exercise were similar between Y and O. Most variables showed smaller ($P < 0.05$) changes after the second than the first bout. **Discussion** These results show that insulin sensitivity was less affected by the eccentric exercise for O than Y, probably due to less muscle damage. Greater effects of exercise on blood profile were found more for Y than O after the first bout, but not after the second bout. It appears that maximal KE eccentric exercise can be used to improve wellness of elderly individuals. **References** 1) Paschalis et al. (2011) MSSE, 43, 64-73. 2) Nikolaidis et al. ONE SESSION OF WHOLE-BODY CRYOTHERAPY $<-110^{\circ}\text{C}>$ IMPROVES RECOVERY FROM EXERCISE-INDUCED MUSCLE DAMAGE

Vieira, A., Ferreira Junior, J.B., Vieira, C.A., Siqueira, A.F., Cleto, V.A., Durigan, J.L.Q., Simões, H.G., Bottaro, M.

University of Brasilia

INTRODUCTION: Exercise-induced muscle damage (EIMD) is associated to unaccustomed exercise involving eccentric actions. The symptoms included strength decrease and muscle soreness. Recently, a modality called whole body cryotherapy (WBC) using extremely cold air (-110°C) has been used to accelerate muscle recovery. However, the effects of WBC on muscle recovery are ambiguous. Hausswirth et al. (2011) showed that three sessions of WBC improve muscle damage recovery after downhill running. Nevertheless, Costello et al. (2012a) showed that one session of WBC performed 24 h after EIMD was not effective on muscle recovery. Moreover, the results reported by Fonda and Sarabon (2013) did not support completely the use of five sessions of WBC as a recovery from EIMD. Thus, the aim of this study was to evaluate the effects of one session of WBC performed immediately after EIMD on muscle recovery. **METHODS:** Twenty five untrained men (age 22.5 years, height 175.7 cm, body mass 72.0 kg) completed five sets of 20 drop jumps with 2 min of rest interval between sets. The single drop jump consisted of landing on the floor from a 60 cm box and jump immediately upward maximally. After exercise, participants were randomly assigned to two groups: 1) 3-min of WBC at -110°C ($n=13$); or 2) Control ($n=12$). Isometric knee extensors torque (KT) and ratings of perceived soreness (DOMS) were measured at baseline, immediately, 24, 48, 72 and 96 h after exercise. **RESULTS:** There was significant interaction between intervention and time on KT [$F=3.608$, $p=.005$]. The control group did not recovery KT throughout 96 h. The WBC group recovered KT 72 h after EIMD. KT was also higher after WBC at 72 and 96 h when compared to the control group. Furthermore, the WBC group recovery from DOMS at 72 h [$X^2=44.7$, $p<.001$], while the control group recovery only 96 h after EIMD [$X^2=48.3$, $p<.001$]. **DISCUSSION:** The main finding of the present study was that one session of WBC immediately after EIMD can improve muscle recovery. A possible reason for this result may be related to the decrease in core temperature during the WBC exposition (Costello et al., 2012b), which lead a vasoconstriction and then a reduction in vessels permeability to immune cells. This response would cause a decrease in edema and inflammatory process and/or pain (Hausswirth et al., 2011). In conclusion, the present study showed that WBC may be used after strenuous exercise to enhance muscle damage recovery. **REFERENCES:** Hausswirth C, Louis J, Bieuzen F, et al. (2011). EFFECTS OF ACUPUNCTURE ON SYMPTOMS AND MUSCLE FUNCTION IN DELAYED-ONSET MUSCLE SORENESS

Auerbach, K., Niederer, D., Vogt, L., Hübscher, M., Bernhörster, M., Weber, T., Banzer, W.

Goethe-University Frankfurt

Introduction Current research on effects of acupuncture on delayed-onset muscle soreness (DOMS) shows inconsistent results (Barlas et al., 2000; Lin and Yang, 1999). Also because of the studies' methodological limitations, evidence is limited. The current study was conducted to investigate the effects of standardized acupuncture treatments on symptoms and muscle function in exercise-induced DOMS. **Methods** A prospective, randomized, controlled, observer and subject-blinded trial was undertaken. In 60 subjects (\bar{x} : 38, $21.5 \pm .37$ years) DOMS of the nondominant elbow-flexors was induced through eccentric contractions until exhaustion. Afterwards, subjects were randomly assigned to five treatment groups: Verum Needle Acupuncture (VAP), Sham Needle Acupuncture (SAP), Verum Laser Acupuncture (VLAP), Placebo Laser Acupuncture (VLAP) and control group (CG). Treatment was applied immediately as well as after 24 and 48 hours after DOMS induction. The outcome measures included pain perception (visual analog scale (VAS, range: 0-10 cm), mechanical pain threshold (MPT, pressure algometry) and maximum isometric voluntary force (MIVF, force transducer) and were acquired prior to DOMS induction as well as 24, 48 and 72 hours after the induction, each time after treatment completion. Multivariate analysis of variance (MANOVA) for dependent samples using SPSS were conducted to reveal between group x time differences followed by (in case of significance) alpha-error-adjusted post-hoc testing. **Results** Following statistical testing, the mean VAS ($F(3,59)=2.0$), MPT ($F(3,59)=.4$) and

MIVF ($F(3,59) = .6$) scores were not significantly different between groups ($p > .05$). Considering female participants only, VAS-value on day 4 of the study is significantly lower in VLAP compared to PLAP and SAP (VLAP: $1.32 \pm .31$ vs. PLAP: 3.53 ± 0.93 vs. SAP: $3.44 \pm .45$, $p < .05$). Furthermore, significantly higher MIVF in VLAP in comparison to SAP and CG (VLAP: -0.14 ± 0.03 Nm, SAP: -0.23 ± 0.03 Nm, $p < 0.049$) were observed on the 2nd day. Discussion Acupuncture seems to have no effects on perceived pain, mechanical pain threshold and muscle function in subjects with DOMS. However, there seems to be a great difference between male and female subjects. In female participants, verum laser acupuncture turned out to be more effective in comparison to placebo laser acupuncture and sham needle acupuncture. IS-SH03 New perspectives with respect to the route of expertise

TALENT IDENTIFICATION AND TALENT DEVELOPMENT FROM A SIMPLE HEURISTIC PERSPECTIVE

Raab, M., de Oliveira, R., Lobinger, B.

German Sport University Cologne

Athletes use rules of thumb or heuristics which are specific to the situation and can be used rapidly without much cost. The development of heuristics occurs within the context of the athletes' natural abilities, past experiences, developed skills, and situational context, but does not pertain to any of these factors separately. Instead, heuristics pertain to the repertoire of the athlete and it is our contention that talent identification methods and talent development models should be geared towards the assessment and development of heuristics. The heuristics repertoire consists of psychological, morphological, physiological, and motor learning adaptations. The practical implication of this approach is that, for the purpose of talent identification, athletes are often assessed on general perceptual or motor skills, and for the purpose of talent development, athletes undergo training of these general abilities. Paradoxically, researchers and practitioners agree that expert athletes specialize in their sport and often use unique solutions to solve situations in the playfield and in other situations related with their sport. In this review we will introduce the concept of simple heuristics for talent identification and talent development in elite sports in contrast to ability, competence or skill approaches.

VISUAL-MOTOR STRATEGIES OF ELITE ATHLETES: MOVING MEASUREMENT INTO THE FIELD

Mann, D.

VU University Amsterdam

Elite athletes develop highly refined visual-motor strategies that help them to successfully perform fast interceptive actions. These strategies are often reflected by differences in the way that these elite performers coordinate the movement of their eyes and head. Much of what we know about expertise in the way that these eye and head movements are performed has necessarily been based on the findings of laboratory-based tasks; however, more recent technological advancements have ensured that performance can be readily evaluated in an athlete's natural environment. In this presentation I will present evidence from three studies where the direction of visual gaze was recorded to show that skilled athletes use eye movement strategies that anticipate the future state of their movement. First I will show that some of the world's best cricket batters use specific eye and head movement strategies that differentiate them from other batters (Land & McLeod, 2000; Mann, Spratford, & Abernethy, 2013). In particular, the very best batters are better able to (i) move their head in a fashion that is directly coupled to the flight-path of the ball, and (ii) use their gaze to predict the location at which they will make contact with the ball. Second, I will show that skilled football goalkeepers use a series of predictive (or catch-up) eye movements rather than simply tracking the flight-path of an approaching ball. Finally, I will show that skilled table tennis players use eye movement strategies that are highly predictive and are at times surprisingly specific to the characteristics of the flight-path of the ball. Collectively these studies help us to understand the strategies that skilled athletes use to perform time-stressed interceptive actions, and help in the development of training interventions designed to improve the interceptive skill of developing athletes. ENHANCING SKILL ACQUISITION AND EXPERTISE IN SPORT: AN ECOLOGICAL DYNAMICS RATIONALE

Davids, K.

Sheffield Hallam University

Our research programme with elite athletes has investigated and implemented learning design from an ecological dynamics perspective, examining its effects on movement coordination and control and the acquisition of expertise. Ecological dynamics is a systems-oriented theoretical rationale for understanding the emergent relations in a complex system formed by each performer and a performance environment. This approach has identified the individual-environment relationship as the relevant scale of analysis for modelling how processes of perception, cognition and action underpin expert performance in sport (Davids et al., 2014; Zelaznik, 2014). In this presentation I will elucidate key concepts from ecological dynamics and exemplify how they have informed our understanding of relevant psychological processes including: movement coordination and its acquisition, learning and transfer, impacting on practice task design in high performance programmes. The past and future of motor learning and control: What is the proper level of description and analysis? *Kinesiological Reviews* 3, 38-43.

16:20 - 17:50**Oral presentations****OP-SH04 Coaching****COACHES' VERBAL REACTIONS AND PHYSIOLOGICAL RESPONSES TO CRITICAL GAME INCIDENTS**

Knight, C.J.1, Kennedy, M.D.2, Holt, N.L.2

1Swansea University, 2University of Alberta

Introduction The current study sought to examine how coaches' verbal comments and heart rates (HR) changed in relation to game circumstances in high performance sport. **Methods** Three coaches (a head coach – HC, and 2 assistants – AC1 and AC2) of a University Hockey team participated in this study. Data were collected at 4 home games over 2 weekends. HR data, verbal comments, and critical incidents for each game were recorded. Coaches' verbal comments were recorded using a Dictaphone with a lapel-microphone attached. HR in beats/min (bpm) was recorded with Suunto T6 watches/Team pod (Suunto, Vaanta Finland). Critical incidents were documented in real time and confirmed from game recordings. Following each game verbal comments were transcribed and time stamped. Comments were then coded against the categories of the Coach Behavior Assessment System (Smith et al., 1977). **Results** Over the four games, Mean/SD HR for periods 1, 2, 3 was 109/7, 83/3, 79/2 for HC, AC1, AC2 respectively and the mean HR was not different between periods (HC: 111/6, 108/9, 108/8; AC1: 83/5, 82/4, 82/1; AC2: 78/2, 79/2, 81/2 for periods 1, 2, 3 respectively). Mean Overtime and Shootout HR was 5 and 2 bpm respectively less than mean period HR. As a percentage of age predicted HRmax coaches mean period HR were: 63%, 48% and 45% (HC, AC1, AC2). The HR response to the critical game instance "goals scored" was 110, 82, 80 and to "penalties" HR was 110, 82, 80 for HC, AC1, AC2 respectively. Verbal reactions to goals and penalties differed between the three coaches. The HC tended to react to goals scored with reinforcement and general encouragement but was often silent in reaction to goals conceded. In contrast, ACs showed less consistent reactions to goals, although general encouragement was common when goals were scored and general commentary provided when goals were conceded. Organization and mistake-contingent tactical instruction were common reactions to home team penalties, whereas organization, reinforcement, and general encouragement were more often heard in reaction to away team penalties. **Discussion** Coaches experience psychophysiological responses to competition, indicating that watching sport can induce stress-related responses in coaches. However whereas verbal responses changed to critical instances HR was not altered by critical instances of "goals" or "penalties". Thus only verbal responses change with critical incidents, likely in an attempt to increase or reduce the likelihood of a certain incident occurring again. Although further investigation is required, it seems the stress related response of increased overall HR is not influenced by occurrences to critical game incidents despite the clear change in verbal comments by coaches to these critical incidents. **References** Delashmit SJ. A MIXED METHODS EXPLORATION OF TALENT DEVELOPMENT IN TEAM SPORTS IN IRELAND: THE ROLE OF THE COACH

Sherwin, I., Campbell, M.J., MacIntyre, T.

University of Limerick

The development of talent in sport is located in the important relationship of athlete and coach (Côté et al., 2013). The current study aimed to investigate the talent development systems in team sports from a coaching perspective. By surveying expert coaches, we sought to establish their educational and athletic experience. The data collection procedure was a retrospective interview process and mirrored that proposed by Côté et al. (2005). This process focused on the "recall of factual knowledge about concrete activities they engaged in throughout their development (pp.4)" and was designed to collect information that could be verified by external sources. **Methods** Male coaches from three team sports completed the survey. Inclusion criteria for coaches were defined as those with at least 10 years' experience coaching their sport and currently coaching more than four hours per week. Consequently, 20 respondents were invited to attend a follow-up semi-structured interview. **Results** Participation in a diverse range of sports at an early age prior to specialisation in one sport through their teenage years was commonly reported. Typically, the initial introduction to coaching coincided with a highly competitive phase of their playing career. Their involvement in part-time coaching increased in their late 20s as their highly competitive participation decreased. Phenomenological experience was reported to be a contributor to learning in coaches. Our findings suggest that the coaches were highly educated with some specialisation in sport or physical education related disciplines. Additionally a minimum level of sport experience playing or coaching sports other than their primary sport, interaction with a mentor coach and some leadership role during the coach's playing career contributed to the development process. **Discussion** Criterion level experiences were deemed necessary but not sufficient to progress to high performance coaching. The attainment of these experiences did not guarantee progression to a high performance coaching level nor did it ensure success at any level. Further research is needed to gain a deeper understanding of the development of high performance coaches while some of the practical issues may be utilised to shape future coaching courses. **References** Côté, J., Ericsson, K. PERFECTIONISM AND EMOTION REGULATION IN COACHES: A TEST OF THE 2 X 2 MODEL OF DISPOSITIONAL PERFECTIONISM

Hill, A.P., Davis, P.A.

Univeristy of Leeds

The manner in which coaches regulate their emotions has implications for their own and their athletes' performance and well-being. Drawing on research that has found perfectionism to predict emotion regulation in other settings, this study adopted the 2 x 2 model of

perfectionism to examine whether subtypes of perfectionism among coaches were associated with variation in the use of emotion regulation strategies. Coaches ($N = 238$, M age = 23.92, $SD = 10.32$) from various sports completed measures of perfectionism (personal standards and evaluative concerns) and emotion regulation strategies (expressive suppression, cognitive reappraisal, and control of anger directed inwards and outwards). Moderated hierarchical regression provided mixed support for the 2×2 model. As expected, pure personal standards perfectionism (high personal standards/low concerns) was generally associated with the highest capacity for emotion regulation and pure evaluative concerns perfectionism (low personal standards/high concerns) with the lowest. Unexpectedly, mixed perfectionism (high personal standards/high concerns) was associated with the highest level of expressive suppression suggesting in some instances personal standards may exacerbate, rather than ameliorate, concerns.

THE EXPRESSION OF VICTORY AND LOSS: ESTIMATING WHO'S LEADING OR TRAILING FROM NONVERBAL CUES IN SPORTS.

Furley, P., Schweizer, G.

German Sport University Cologne

Introduction According to evolutionary accounts of nonverbal expressions (Shariff & Tracy, 2011), humans have evolved to be well-equipped for communicating important internal states non-verbally. For example, it has been suggested that primates send submissive nonverbal cues when losing a fight in order to avoid further potential life-threatening attacks. Hence, the goal of the present studies (Furley & Schweizer, 2014) was to test if humans can detect whether athletes are trailing or leading in sports based on the perception of thin slices of athletes' nonverbal behavior due to our evolutionary inheritance. **Method** In Experiment 1, participants ($n=40$) who were unexperienced in the respective sports watched short videos depicting basketball and table tennis players—who were either leading by far, leading closely, the score was tied, trailing closely, or trailing by far—and rated whether athletes were trailing or leading. Experiment 2 replicated Experiment 1 with young children ($n=44$). In Experiment 3, we replicated Experiment 1 and 2 with both expert and unexperienced participants ($n=40$) and a different set of stimuli from team handball. **Results** Experiment 1 indicated that participants could significantly differentiate between trailing and leading athletes in both team and individual sports. Experiment 2 showed that children were also able to distinguish between trailing and leading athletes based on nonverbal behavior. Comparison with the adult results from Experiment 1 revealed that the adult ratings corresponded to a higher degree with the actual scores during the game compared to the children's. Both experts and unexpert participants were able to differentiate between leading and trailing athletes (Experiment 3). **Discussion** Our findings are in line with evolutionary accounts of nonverbal behavior and suggest that humans display nonverbal signals as a consequence of leading or trailing which are reliably interpreted by others. By comparing this effect as a function of different age groups we provide evidence that although even young children can differentiate between leading and trailing athletes, the decoding of subtle nonverbal cues continues to develop with increasing experience and maturation processes. **References** Furley, P., & Schweizer, G. (2014). The Expression of Victory and Loss: Estimating Who's Leading or Trailing from Nonverbal Cues in Sports. *Journal of Nonverbal Behavior*, 38, 13-29. Shariff, A. F., & Tracy, J. L. (2011). RELATIONSHIPS BETWEEN THE MOTIVATIONAL CLIMATE CREATED BY COACHES AND ATHLETE ENGAGEMENT IN YOUTH SPORT

Curran, T., Hill, A.P., Hall, H.K., Jowett, G.E.

University of Gloucestershire

Within youth sport, understanding how coach behaviours affect the engagement of their athletes is important given high attrition in adolescence. Based on theoretical and empirical accounts of the motivation underpinning athlete engagement, we reasoned that different dimensions of the motivational climate (viz. mastery and performance structures) would be associated with the dimensions of athlete engagement (viz. confidence, dedication, enthusiasm and vigor). Two-hundred and sixty (M age = 13.53 years, $s = 1.27$) youth soccer players completed measures of athlete engagement and the motivational climate. Multiple regressions indicated that all dimensions of athlete engagement were positively predicted by perceptions of a mastery climate. Unexpectedly, the cognitive aspects of athlete engagement (viz. confidence and dedication) were also positively predicted by perceptions of a performance climate. Canonical correlation analyses further indicated that a linear composite of athlete engagement was associated with higher perceptions of a mastery climate (but not higher perceptions of a performance climate). The findings suggest that the motivational climate matters for athlete engagement in youth sport. Whereas a performance climate may only contribute to cognitive engagement, a mastery climate appears to elicit increases in all dimensions of engagement.

OP-PM14 Exercise & Training Effects

THE EFFECTS OF CONCURRENT TRAINING WITH BLOOD FLOW RESTRICTION IN INFLAMMATORY MARKERS IN ELDERLY

Souza, T.M.F., Gaspari, A.F., Brunelli, D.T., Souza, G., Nogueira, F.R.D., Lixandrao, M., Libardi, C., Conceicao, M., Berton, R., Vechin, F.C., Cavaglieri, C., Ugrinowitsch, C., Chacon Mikahil, M.P.T.

University of Campinas

The concurrent training (CT) is recommended to improve and maintain cardiorespiratory fitness, strength and muscle mass in elderly, reducing the systemic inflammation. The resistance training with blood flow restriction can improve the strength and muscle mass using low intensity (20-30% 1-RM). Then, the concurrent training with blood flow restriction (CTBFR) can be an interesting alternative to improve the healthy and reduce the inflammation offering a low muscular stress to the elderly. **PURPOSE:** Compare the effect of CT and CTBFR in inflammatory markers (TNF- α , IL-6 and CRP). **METHODS:** 26 healthy older adults (64.5 ± 4.2 y; 70.2 ± 11.7 Kg; 1.6 ± 0.1 m; ratio IL-10/TNF- $\alpha = 0.33 + 0.22$) were randomly assigned to three groups: CT ($n = 9$, 2 days/wk walking or running for 40 min, 50-80% VO_{2max} . and 2

days/wk training on the leg-press with 4 sets of 10 reps at 70-80% of 1-RM with 60 s rest), CTBFR (n = 10, similar to CT, but resistance training with blood flow restriction: 2 days/wk, leg-press with 1 set of 30 and 3 sets of 15 reps at 20-30% 1-RM with 60 s rest) and control group (n = 7, no exercise). The leg press 1-RM and VO2max were assessed before and post-experimental period (12 wk). The training-related effects were assessed using a linear mixed model with Tukey post hoc test. RESULTS: The groups CT and CTBFR showed similar increases in 1-RM (168.1 ± 53.1 to 231.6 ± 81.4 kg, $P < 0.001$ and 166.9 ± 72.6 to 200.3 ± 73.9 kg, $P = 0.001$, respectively) and VO2max. (23.5 ± 5.3 to 25.7 ± 6.1 ml/kg/min, $P = 0.04$ and 24.1 ± 3.9 to 26.4 ± 4.8 ml/kg/min, $P = 0.02$, respectively), but not showed changes in inflammatory markers (TNF- α , $P = 0.2134$; IL-6, $P = 0.1224$; CRP, $P = 0.3625$) neither in the ratio IL-10/TNF- α ($P = 0.9997$ to CT; $P = 0.9783$ to CTBFR). CONCLUSION: The CTBFR promotes similar neuromuscular and cardiorespiratory adaptations than the CT, but both training regimes did not efficient to change the inflammatory markers in healthy older adults.

TIME COURSE EFFECT OF BLOOD FLOW RESTRICTION STRENGTH TRAINING AND DETRAINING ON HAEMODYNAMICS, STRENGTH, AND MUSCLE THICKNESS

Brandner, C., Kidgell, D., Warmington, S.

Deakin University, School of Exercise and Nutrition Science

Introduction Blood flow restriction (BFR) in combination with light-load strength training (LST) provides gains in strength and muscle mass similar to traditional heavy-load strength training (HST). However, haemodynamic adaptations to BFR training are less well understood. While in addition, there is a lack of data that directly compares training responses between BFR, HST, and LST. Therefore, the purpose of this study was to examine the time course effect of combined lower- and upper-body BFR training on haemodynamics, and muscle strength and size, in comparison with both HST and LST. Methods Untrained participants (n=19 [14M, 5F]; 23 ± 0.5 yrs, 172.5 ± 2.2 cm, 68.4 ± 2.5 kg) were randomized into training groups. Either, HST (n=7; 70% 1RM), LST (n=7; 20% 1RM), or BFR (n=5; 20% 1RM with restriction pressure set at 60% total limb occlusion pressure). Training (3d/wk) comprised sets of knee extension (KE), squat (SQ), calf raise (CR), bench press (BP), seated row (SR), and bicep curl (BC) exercises. Outcome measures were taken at week 0, mid point (wk 4), end of training (wk 8), and after four weeks detraining (wk 12). Dual-energy X-ray absorptiometry (DXA) was used to measure whole body, arm, and leg muscle mass, while ultrasound was used to measure muscle thickness (MTH) at 7 sites. Heart rate (HR), blood pressure, cardiac output (Q), and stroke volume (SV) responses to KE exercise were taken at baseline, and during the final set of the exercise bout at each testing week. Results KE, SQ, and CR strength increased in both BFR and HST at wk 4 (range 8-20%) and wk 8 (range 9-28%) compared with baseline, while BP, SR, and BC strength increased only in HST (range 5-15%). DXA data were not different between groups. MTH increased in both BFR and HST for biceps brachii (range 5-10%), but additionally quadriceps (4 and 10%) and hamstrings (2 and 9%) in HST only. Baseline haemodynamic parameters were similar between groups at all measurement weeks, with training adaptations only evident during exercise for BFR and HST whereby systolic blood pressure was lower at wk 4 and wk 8 compared with wk 0. Discussion Previous BFR training interventions have typically only used single joint exercises in isolation. Therefore, a novel aspect of this study was that both upper- and lower-body training was performed. This study provides further evidence that BFR training increases muscle strength and size similar to HST, with some beneficial reductions in exercising haemodynamic stress responses over time. These data support the potential for BFR to be prescribed to clinical populations that have limited strength training capacity such as the elderly or due to muscle atrophy or weakness following injury. However, future studies should examine haemodynamic responses in populations with compromised cardiovascular health before BFR be recommended. GENDER DIFFERENCES IN THE VO2MAX-RESPONSE FOLLOWING HIGH-INTENSITY INTERVAL TRAINING AND DETRAINING?

Christensen, K., Larsen, S., Dela, F., Helge, J.W.

Copenhagen University

Introduction: High-intensity interval training (HIT) is reported to have a positive effect on VO2max, although with great variations. The sustainability of VO2max after HIT, as well as the influence of gender has not been well investigated. This study examined the effect of a 6-week HIT program and a 3-week period of detraining on the VO2max responses in healthy, but overweight and sedentary male and female adults. We hypothesized that there could be gender specific variations in the effect of HIT and subsequent detraining on VO2max. Methods 33 healthy men (n=17) and women (n=16) were included in the study based on age, activity level and BMI (Age: 38 ± 1 years; BMI: 33 ± 1 kg/m²). All subjects performed 2 incremental tests to exhaustion (VO2max) on a static cycle-ergometer prior to the 6-week HIT program (PRE1/PRE2) and then 1 test immediately after the program (POST1) and again after a 3 week detraining period (POST2). Tests were completed using a Cosmed Quark 2 system. Oxygen uptake was measured using an online gas analyzer. Subjects performed 3 sessions HIT/week consisting of 5x60s cycling sets (90s restitution) at the maximal load sustainable for one minute, corresponding to $128 \pm 2\%$ of the maximal load (296 ± 11 W) determined in the VO2max test. Data was compared using repeated measurements ANOVA (multiple comparison procedure). Results The two PRE tests did not differ significantly ($P=0.307$). VO2max was 2760 ± 103 mL/min in PRE1 and 2799 ± 99 mL/min in PRE2. Comparing the PRE tests of each subject, the mean standard deviation was 112 ± 17 mL/min and mean coefficient of variation 4.2%. When only comparing the highest measured VO2max found in the PRE tests (maxPRE) with the 2 POST tests, VO2max was significantly increased ($P<0.011$) immediately after HIT in the POST1 test ($3.5 \pm 1.3\%$). The increase did not differ (0.631) between men ($2.9 \pm 1.7\%$) and women ($4.1 \pm 1.9\%$). VO2max did not remain increased ($P=0.326$) after the 3-week detraining period (POST2) compared to the maxPRE test ($1.2 \pm 1.2\%$). However, after the detraining period, VO2max was not decreased ($P=0.127$) from POST1 ($-2.6 \pm 1.1\%$), and no difference (0.322) existed between the relative change for men ($-3.5 \pm 1.7\%$) and women ($-1.6 \pm 1.5\%$). Conclusions As expected HIT improved VO2max, but after a 3-week detraining period, VO2max did not remain higher than baseline. Yet, VO2max was not lowered compared to the values after training, implying that the HIT effect was not fully abolished after only 3 weeks of detraining. In contrast to our hypothesis, the effects of HIT and detraining were similar for men and women. Contact: kirstinek@stud.ku.dk

EFFECT ON FATIGUE AND COST-EFFECTIVENESS OF AN EXERCISE INTERVENTION DURING ADJUVANT CHEMOTHERAPY IN PATIENTS WITH BREAST OR COLON CANCER

Travier, N.1,2, Bosch, M.1, Velthuis, M.3, Steins Bisschop, C.1, van der Wall, E.4, de Wit, G.1, Peeters, P.1, May, A.1

UMC Utrecht

1Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, NL 2Unit of Nutrition, Environment and Cancer, Catalan Institute of Oncology, Barcelona, Spain 3Comprehensive Cancer Center Netherlands, Utrecht, NL 4University Medical Center Utrecht, Utrecht, NL Introduction Fatigue is a major problem of cancer patients during and after treatment. Physical exercise during cancer treatment may reduce fatigue and by that improve quality of life and decrease healthcare related expenditures and societal costs due to sick leave. The present multicenter randomized controlled trial investigated the effect of an 18-week exercise intervention during adjuvant chemotherapy for breast or colon cancer patients on fatigue and costs related to sick leave and health service utilization. Methods 204 breast and 33 colon cancer patients were randomly assigned to bi-weekly supervised aerobic and resistance exercise sessions (n=119) or usual care (n=118). In addition, the intervention group was asked to be physically active on 3 other days for 30 minutes per day. Fatigue was assessed with the validated Multidimensional Fatigue Inventory at baseline, 18 weeks and 9 months. Participants kept diaries including the EuroQol-5D to register health service utilization and sick leave. Results In colon cancer patients, the intention to treat analyses using linear mixed-effects models showed significant decreases in general fatigue in the intervention group at 18 weeks -2.19 (95% confidence interval: -4.00 to -0.38) and 9 months -2.54 (-4.38 to -0.71) when compared to usual care. For breast cancer, a significant decrease in general fatigue was only observed at 9 months (-1.00 (-1.99 to -0.01)). Comparable results were obtained for physical fatigue. For colon cancer, the cost-effectiveness analysis showed beneficial effects of the intervention with incremental costs and QALY of -4,514 and 0.049, respectively, and 100% of bootstrap simulations indicating the intervention is dominant (i.e. cheaper and more effective). For breast cancer, the results did not indicate the intervention was cost effective (incremental costs of 2,580, incremental effect of 0.006 QALY and probability of acceptance of 4% at a willingness to pay of 20,000). Conclusion An 18-week exercise program during adjuvant treatment showed significant decreases in general fatigue in breast and colon cancer patients and cost-effectiveness for colon cancer. Hence, exercise might be a beneficial addition to routine cancer care during adjuvant cancer treatment. VIBRATION TRANSMISSION TO LOWER EXTREMITY SOFT TISSUES DURING WHOLE-BODY VIBRATION

Friesenbichler, B.1,4, Lienhard, K.2,3,4, Vienneau, J.4, Nigg, B.M.4

1: Schulthess Clinic (Zurich, Switzerland), 2: I3S (Sophia Antipolis, France), 3: LAMHESS (Nice, France), 4: HPL (Calgary, Canada)

Introduction In order to evaluate potential risks of whole-body vibration (WBV) training for muscles, nerves and vascular tissue, it is important to understand the transfer of vibrations from the WBV platform to the soft tissues (Cook et al., 2011). Therefore, the purpose of this study was to quantify the transmissibility of vibrations from the WBV platform to the triceps surae and quadriceps femoris soft tissue compartments. Methods Sixteen healthy, male participants were standing upright on a side-alternating WBV platform which was vibrating at 5 mm peak-to-peak amplitude and frequencies of 10, 17 and 28 Hz. Acceleration data were collected by tri-axial accelerometers fixed to the intersection of medial and lateral gastrocnemius (triceps) and on the rectus femoris (quadriceps). The resultant acceleration vector was calculated as the sum of the three orthogonal acceleration vectors according to the three-dimensional form of the Pythagorean Theorem. The transmissibility of acceleration was calculated by dividing the values measured at the muscles by the ones measured at the platform for each participant and condition. Results Transmissibility of peak acceleration at 10, 17, and 28 Hz for the quadriceps compartment was on average 2.33, 1.17, and 0.46 and for the triceps surae compartment was 2.33, 1.88, and 1.23, respectively. The average peak acceleration at 28 Hz was 46.5 ms⁻² for the quadriceps and 125.4 ms⁻² for the triceps surae. Discussion The transfer of vibrations to the muscles is strongly dependent on the platform frequency and the muscle of interest. Especially the acceleration measured at the triceps surae was higher than the corresponding accelerations related to soft tissue injury in animal studies (45 ms⁻²; Necking et al., 1996). Neither existing regulations (ISO-2631; vibration transmission through the buttocks) nor comparison to available animal studies (anatomical differences) seem appropriate to make inferences on injury risk. However, the presented data warrants future research on long-term injury risk in WBV training and may be used for validating computer or animal models designed to assess potentially unwanted side effects. IS THE EFFECT OF 12-WEEKS SUPERVISED AEROBIC EXERCISE ON THE PROFILE OF APPETITE CONTROL DUE TO CHANGES IN GASTROINTESTINAL PEPTIDES?

Gibbons, C., Caudwell, P., Naslund, E., Finlayson, G., Blundell, J.

University of Leeds

Introduction: Exercise has been shown to affect mechanisms of appetite control. This study examined the impact of 12-weeks supervised exercise on two aspects of human appetite: postprandial effects of food (satiety) under high and low energy density conditions and satiation (meal size) and fasting levels of gastrointestinal peptides (CCK, GLP-1, PYY, insulin, leptin). Methods: Participants took part in 12-weeks of supervised exercise designed to expend 2500 kcal per week at 70% HRmax (EX - n=30) or 12-weeks of no exercise (CON - n=16). Appetite control was measured using separate validated procedures – satiety was measured using appetite ratings adjusted for energy intake (satiety quotient (SQ)) and satiation was measured using a test meal paradigm with energy density manipulated using high or low fat test meals. Appetite-related peptides and body composition were also measured. Results: When compared to CON, 12-weeks exercise led to significant reductions in body and fat mass (EX: -1.7±2.8 and -2.2±2.7 kg; CON: 0.49±2.4 and 0.06±3.1 kg; p<0.001). There was a significant increase in SQ in the EX condition compared to CON (p<0.05). This could be partially explained by exercise-induced fat loss being associated with decreases in leptin and insulin, but also increases in satiety peptides - CCK (0.46±0.13 pmol/L), PYY (25.6±12.3 ng/L) and GLP-1 (11.1±5.0 ng/L) (all p<0.05). Energy density had a significant impact on meal size and total daily energy intake (p<0.001), but there was no difference between EX and CON – exercise did not influence satiation. Conclusion: 12-weeks supervised exercise exerted a selective effect on appetite control; it strengthened post-meal satiety (SQ) but had no effect on meal-size (satiation). Meal-size was strongly determined by the external factor of energy density and not by the amount of exercise carried out. The strengthening of satiety

(SQ) could be due to measured decreases in fasting leptin and insulin but also increases in fasting levels of satiety peptides (CCK, PYY and GLP-1) brought about by exercise.

Introduction: Maximal heart rate (HR) is commonly defined as the highest HR obtained during a progressive exercise test to exhaustion. Maximal HR is considered one of the criteria to assess maximum exertion in exercise tests and is broadly used when prescribing exercise intensity. The aims of the present study were to compare peak HR measurements during maximal treadmill running and active play sessions in obese children and adolescents, and whether there was an association between peak HR and age. **Methods:** Thirty nine obese children and adolescents (7-17 years old, male/female: 18/21) participated in intensive active play sessions (60 min each) while HR was recorded (Polar Vantage, Polar Electro KY, Kempele, Finland). Children and adolescents also performed maximal running on a treadmill, starting at four kilometres per hour and an inclination of 0 %, increasing the work load (speed and inclination) until exhaustion. HR was recorded and respiratory exchange ratio (RER) and oxygen uptake (VO₂) measured during treadmill running. The criteria for having reached maximal effort was a subjective assessment by the test leader that the participants had reached his or her maximal effort, and a RER above 1.00 or reporting perceived exertion (RPE) above 17 using the Borg-RPE-Scale. **Results:** 34 children had a RER above 1.00 and 37 reported above 17 using the Borg-RPE-Scale. 32 children fulfilled both criteria. Peak HR was 4% higher and significantly ($p < 0.0001$) increased during active play (mean and 95% confidence intervals; 204 (201, 207) beats/min) compared to during maximal treadmill running (196 (194, 199) beats/min), respectively. Peak HR was not associated with age. **Discussion:** The results of the present study indicate that peak heart rate measurements during progressive running to exhaustion in obese children and adolescents cannot necessarily be determined as maximal heart rate. **Contact:** Sveinung.berntsen@uia.no

THE MAXIMAL VOLUNTARY ACTIVATION LEVEL OF THE PLANTAR FLEXOR MUSCLES ADAPTS POSITIVELY TO MECHANICAL OVERLOAD IN OBESE ADOLESCENT GIRLS

Martin, V.1, Garcia Vicencio, S.1, Kluka, V.1, Jegu, A.G.2, Cardenoux, C.2, Coudeyre, E.2, Ratel, S.1

1. Université Blaise Pascal 2. CHU Clermont-Ferrand

INTRODUCTION The effects of obesity on neuromuscular properties have been poorly investigated, in particular in youth (Maffiuletti et al., 2013). The available literature reveals that obese people have an increased ability to generate strength, which is partly accounted for by an increased muscle mass. Besides, the role of nervous factors is currently unknown, but some studies have hypothesized that the ability to maximally recruit the motor unit pool may positively adapt to chronic mechanical overloading. The purpose of this study was to verify this assumption by examining the maximal voluntary activation level (VA) of the plantar flexor (PF) muscles, which are highly involved in weight-bearing activities. **METHODS** Twelve non-obese (13.5 ± 0.8 y; BMI: 18.1 ± 1.0 kg/m²) and twelve severely obese (13.8 ± 0.9 y; BMI: 31.6 ± 4 kg/m²) adolescent girls, matched for maturation, performed isometric maximal voluntary contractions (MVC) of the PF muscles. The VA of the PF muscles, determined with the twitch interpolation technique, and the EMG activities of the gastrocnemius lateralis (GL) and soleus (SOL), normalized by the corresponding maximal compound action potentials amplitudes (M_{max}), were calculated to reflect the central mechanisms of torque production. Segmental lean mass was assessed by DXA, and used to compute the specific torque, i.e. absolute torque divided by the leg lean mass. Finally, the theoretical specific torque that could be produced with a complete (i.e. 100%) activation level (specific torque@100%VA) was estimated from the values of specific torque and VA. **RESULTS** Both absolute (73.3 ± 16.5 vs. 44.5 ± 6.2 N.m, $P < 0.001$) and specific torque (36.4 ± 8.1 vs. 28.7 ± 7.7 N.m/kg, $P < 0.05$) were higher in obese compared to non-obese girls. Accordingly, the VA (93.4 ± 2.5 vs. $85.8 \pm 4.6\%$, $P < 0.001$) and the normalized EMG activity of the SOL muscle (0.05 ± 0.02 vs. 0.02 ± 0.01 , $P = 0.01$) were significantly higher in obese girls, while no significant difference was observed on the GL muscle. Finally, the specific torque@100%VA was not different between groups. **DISCUSSION** The results of the present study reveal that the VA of the PF muscles is increased in obese girls, and this partly accounts for their increased ability to generate torque, compared to their non-obese counterparts. This up-regulation of the VA may be related to the effect of the chronic mechanical overloading on the PF muscles. The fact that this adaptation is particularly obvious on the SOL muscle, which is highly involved in posture regulation, supports this assumption. **REFERENCES** Maffiuletti NA, Ratel S, Sartorio A et al. DIFFERENCES IN KNEE EXTENSOR MUSCLES FATIGABILITY BETWEEN LEAN AND OBESE ADOLESCENT GIRLS DURING REPEATED MAXIMAL CONTRACTIONS

Garcia, S.1, Martin, V.1, Kluka, V.1, Jegu, A.G.2, Cardenoux, C.2, Coudeyre, E.2, Ratel, S.1

1: UBP-AME2P (Clermont-Fd, France), 2: CHU Gabriel Montpied (Clermont-Fd, France)

INTRODUCTION It is becoming increasingly apparent from the literature that obesity is associated with reduced physical function in adults. However, paediatric literature in this area is extremely limited. In particular, the fatigability of the knee extensor (KE) muscles, which are highly involved in ambulatory activities, has received little attention in the paediatric population. Therefore, the aim of the present study was to compare the fatigability of KE muscles between obese and nonobese adolescents during repeated maximal contractions. **METHODS** Eleven nonobese (13.5 ± 0.8 y; BMI: 18.1 ± 1.0 kg/m²) and twelve severely obese (13.8 ± 0.9 y; BMI: 31.6 ± 4.0 kg/m²) adolescent girls performed a fatigue protocol consisting in a succession of isometric 5-s maximal voluntary contractions (MVC) of the KE muscles interspersed with 5-s passive recovery periods until the generated torque reached 55% of its initial value. Single magnetic stimulations were delivered to the femoral nerve every five MVCs to calculate the maximal level of voluntary activation (VA) by means of the twitch

interpolation technique. The amplitudes of the potentiated twitch (Pt) and concomitant vastus lateralis (VL) and rectus femoris (RF) maximal compound action potentials (Mmax) were used as indicators of peripheral fatigue. RESULTS Torque reached 55% of its initial value after 52.0 ± 20.4 and 75.7 ± 23.7 repetitions in obese and nonobese girls, respectively ($P < 0.01$). However, when expressed in percentage of total repetitions, the pattern of voluntary torque loss was similar in both groups. Interestingly, VA remained unchanged in obese whereas it decreased significantly in nonobese girls over the first half of the fatigue protocol ($P < 0.05$). In contrast, Pt remained unchanged in nonobese whereas obese girls displayed a significant Pt decrement ($P < 0.001$). Finally, no significant change of Mmax was observed on VL and RF muscles in both groups. DISCUSSION The results of the present study reveal that obese adolescent girls fatigue faster than their nonobese counterparts, but that the relative pattern of torque loss over time is similar in both populations. However, the respective contributions of central and peripheral mechanisms of fatigue differ between groups: peripheral factors mainly account for fatigue in obese, whereas central factors are mainly involved in non obese girls. The higher torque produced and the higher proportion of fast-fatigable fibres in obese young people (Kriketos et al. 1997) could account for their higher peripheral fatigue. BODIPY REVEALS GREATER COLOCALISATION OF PERILIPIN 2 AND LIPID DROPLETS COMPARED TO OIL RED O.

Clark, J.A., Shepherd, S.O., Fewings, M., Wagenmakers, A.J.M.

Liverpool John Moores University

Introduction Fluorescence microscopy studies quantitating the content of lipid droplets (LD) in skeletal muscle have predominantly used oil red O (ORO) as a lipid dye. However, BODIPY has been proposed as an alternative, offering superior spectral properties. In this study we aimed to 1) investigate training-induced changes in number of LD and colocalisation with perilipin 2 (PLIN2) and 2) compare this data with earlier data generated in the same muscles with ORO (Shepherd et al. 2013). Quantitation of colocalisation of PLIN2 with LD is important as PLIN2 containing LD (PLIN2-LD) are preferentially oxidised during endurance exercise (Shepherd et al. 2013). Methods Eight sedentary males (age 21 ± 1 y, height 1.77 ± 0.03 m, body mass 70.8 ± 4.4 kg) performed 6 weeks of endurance training (40 min moderate-intensity cycling, 5 days per week). Muscle biopsies were obtained from the vastus lateralis pre- and post-training. Cryosections were stained using anti-PLIN2 as well as BODIPY and imaged using confocal microscopy. The content and colocalisation of PLIN2 and LD was investigated in a fibre type specific manner. Results BODIPY visualised LD in human skeletal muscle with better contrast and resolution than ORO. Staining revealed the existence of PLIN2-LD, but there were also LD without PLIN2 (PLIN2-null) and PLIN2 particles without BODIPY stain, confirming data of Shepherd et al. (2013). Using BODIPY, ~75% of PLIN2 colocalised with LD (pre training $73 \pm 0.04\%$; post training $78 \pm 0.02\%$ NS). Shepherd et al. (2013) reported values of ~61% for this variable without a training effect. Prior to training, there was a greater density of PLIN2-null LD compared to PLIN2-LD. Training led to a greater increase in density of PLIN2-null LD ($P < 0.05$) using the BODIPY stain (pre training 0.05 ± 0.01 LD. μm^{-2} , post training 0.08 ± 0.01 LD. μm^{-2}) compared to PLIN2-LD (pre training 0.02 ± 0.00 LD. μm^{-2} , post training 0.04 ± 0.01 LD. μm^{-2}). In contrast the ORO data detected more PLIN2-LD compared to PLIN2-null LD both before and after training. Conclusions BODIPY images of LD had better contrast and resolution than ORO and revealed greater colocalisation of PLIN2 and LD than ORO. BODIPY detected smaller LD than ORO and this may explain both the greater density of LD and higher percentage colocalisation of PLIN2 and LD than seen with ORO. The narrow emission spectrum of BODIPY may explain the ability of this stain to detect smaller LD than ORO. In summary small differences were seen in the measured variables between BODIPY and ORO. Given the superior image quality we propose that BODIPY should be the dye of choice for future studies investigating lipid metabolism in skeletal muscle. Reference Shepherd et al. THE TRAINING AND DETRAINING EFFECTS OF HIGH INTENSITY INTERVAL TRAINING IN YOUNG OVERWEIGHT/OBESE WOMEN

Terblanche, E., Bonsu, B.

Stellenbosch University

Introduction High intensity interval training is described as a super-efficient workout, especially if the goal is to lose body fat. As little as six sessions may elicit significant changes in body composition and exercise capacity, however, it is not known how lasting these effects are. There is also a paucity of studies on the effect of HIIT in young overweight women. The aim of the study was to quantify the magnitude of changes in anthropometric measures, maximal exercise capacity and blood pressure (BP) after six HIIT sessions and two weeks of detraining in young overweight/obese women. Methods Twenty young overweight/obese (21 ± 2 years; BMI: 29.0 ± 3.1 kgm $^{-2}$) untrained women volunteered for the study. Participants completed six HIIT sessions within two weeks (90–95% VO $_2$ max; exercise duration: 10 min in week 1 and 15 min in week 2). Anthropometric measures were assessed via standardized methods and bio-electrical impedance (Quadscan 4000) was used to measure %body fat. Maximal exercise capacity was tested with a graded exercise test to exhaustion on a treadmill, while ambulatory BP was monitored for one hour before and after the intervention. Cohen's d effect sizes were calculated to determine the magnitude of training and detraining effects. The study proposal was approved by the Ethics Committee of Stellenbosch University (DESC_Terblanche2012). Results Body mass (74 ± 10 kg vs 73 ± 10 kg; ES=0.12), %body fat ($35 \pm 6\%$ vs $34 \pm 6\%$; ES=0.23), waist circumference (84 ± 9 cm vs 80 ± 8 cm; ES=0.44) and maximal exercise capacity (VO $_2$ max) (27 ± 6 ml/kg/min vs 29 ± 5 ml/kg/min; ES=0.26) showed trivial to small practically significant improvements after training, however, changes were almost completely reversed after two weeks of detraining. There was only a trivial difference in the magnitude of the post-exercise BP response before and after training in SBP (10.1 ± 5.5 mmHg vs. 11.1 ± 5.3 mmHg; ES = 0.12) and a small practically significant difference in DBP (-4.3 ± 7.7 mmHg vs. -5.9 ± 5.3 mmHg; ES = 0.22). Discussion The findings show that 10–15 min HIIT induce significant changes in body composition and maximal exercise capacity and cause practically significant post-exercise hypotensive responses in overweight/obese young women. However, these positive changes are rapidly lost if training is not maintained. Nevertheless, the positive health effects that are obtained through this short duration, time efficient exercise programme, should be a major motivating factor for many individuals looking to start an exercise programme. THE INFLUENCE OF PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOURS ON BODY MASS INDEX FROM CHILDHOOD TO ADOLESCENCE

Addolorato, S.1,3, Frattini, G.1, Casolo, F.1, Galvani, C.1,2

Catholic University of the Sacred Heart

1:Exercise and Sport Science Degree Course, Catholic University of the Sacred Heart, Milan, Italy 2:Applied Exercise Physiology Laboratory, Catholic University of the Sacred Heart, Milan, Italy 3:IGOID Group, University of Castile - La Mancha, Toledo, Spain
INTRODUCTION: The prevalence of overweight and obesity among children and adolescents is rising in the European region with an increase of the onset of risk factors associated with ill health (1). Time spent in sedentary (SED) behaviour and physical activity (PA) have been both associated with adiposity (2, 3). The aim of this study was to investigate the influence of physical activity and sedentary behaviours from childhood (CH) to adolescence (AD). **METHODS:** The study population consisted of 2828 students aged between 6 and 14 years old (height, $1,45 \pm 0,16$ m; weight, $39,6 \pm 12,7$ kg; BMI, $18,3 \pm 3,0$ kg/m²) and was divided into two groups: CH and AD. Subjects were classified as normal weight (NW), overweight (OW) and obese (OB) according to Cole classification (4). Parents were asked to fill a questionnaire inquiring about time spent in PA, and SED behaviours outside school hours on a weekly basis. The amount of PA was evaluated adding leisure time PA, time spent playing sports and time spent in physically active commutes to and from school. SED activities included TV viewing, playing or working on a computer/playing videogames and any other sedentary activities. A multiple logistic regression analysis, adjusted for sex and age, was used to assess the association between BMI category and PA or SED; significance was set at $p < 0,05$. **RESULTS:** 79,9% of the cohort was classified as NW, 17,1% as OW and only 3,9% as OB. Overweight and obesity significantly decreased from CH to AD ($X^2=33,45$; $p < 0,0001$). The average amount of PA was $245,5 \pm 152,2$ min/week and the SED time reached $1739,1 \pm 809,7$ min/week, both significantly increasing from CH to AD (ANOVA; $p < 0,0001$). PA was not significantly correlated with SED in neither CH nor AD ($r = -0,031$ and $0,024$; respectively). Significant associations, were identified between SED (odds ratio (OR): 1,001; 95%CI: 1,000-1,001; $p < 0,001$) and PA (OR: 0,997, 95%CI: 0,996-0,999; $p < 0,01$) level and obesity. No associations persisted for overweight. **DISCUSSION:** According with Mitchell (2, 3) this study's data indicated that: I) more time spent in PA was negatively associated with obesity; II) spending more time in sedentary behaviour was associated with obesity. In conclusion, increasing the time spent in physical activities and reducing time spent in sedentary behaviours may help to reduce the prevalence of childhood and adolescent obesity. **REFERENCES:** (1) Branca (2007). OP-PM16 Healthy Ageing

A STUDY OF SEDENTARY BEHAVIOR IN THE OLDER FINNISH TWIN COHORT – A CROSS SECTIONAL ANALYSIS

Piirtola, M., Kaprio, J., Ropponen, A.

University of Helsinki

Introduction Sedentary behavior, measured as daily sitting time, is one of the major global public health concerns. Genetics may influence sedentary behavior as it does for physical activity. This study aimed to investigate the effects of age, sex and body mass index (BMI), but also heritability and environmental factors on total sitting time among Finnish twins. **Methods** The data is based on the fourth survey wave of older Finnish Twin Cohort (n=8406) including a comprehensive self-reported questionnaire with multiple-choice questions about sitting time in five domains: at work, at home watching TV or videos, at home using computer, in a vehicle and sitting time elsewhere. The total sum of sitting was calculated from all five sitting domains. Only those individuals, who had answered to all five questions, were included in the final analyses. The associations of age, sex and BMI on sitting time were investigated by linear regression model. Preliminary coefficients of heritability and environmental factors for total sitting time were calculated with Falconer's formula based on the pairwise correlations. **Results** The final sample of 6713 twin individuals 53 - 67 years of age (46% men) consisting of 1940 complete twin pairs (732 monozygotic and 1208 dizygotic twin pairs) were included in the analyses (80% of the total cohort). The mean total sitting time per a day was 6 hours 41 minutes (SD 2 hours 41 minutes). Of the subjects, 25% were sitting at least 8.5 hours a day. The total sitting time was less in women than in men ($p=0.002$). Older age was associated with less total sitting time ($p < 0.001$). Those with higher BMI had higher total sitting time in age and sex adjusted analysis ($p < 0.001$). MZ pairs were more similar for sitting time than DZ pairs, with initial estimates of heritability for the total sitting time of 35%. The influence of shared environmental factors was negligible (1%), while most (64%) of the variation could be ascribed to unique environmental factors; the latter including measurement error. **Discussion** The amount of sitting time in the older adult twins decreased with increasing age, but seemed to increase along with BMI. Genetic factors seem to have a moderate influence on individual differences in sitting time, whereas environmental factors may play a more prominent role. Although men tended to have higher total sitting time than women, no sex differences were evident in heritability estimates. Contact maarit.piirtola@helsinki.fi

EFFECT OF IMMOBILIZATION AND TRAINING ON INTRAMUSCULAR GLYCOGEN AND TRIGLYCERIDE STORAGE AND METABOLISM IN YOUNG AND ELDERLY

Vigelsoe, A., Gram, M., Wiuff, C., Kuhlmann, A.B., Dela, F., Helge, J.W.

University of Copenhagen

Background: Aging and physical inactivity have a negative impact on VO₂max and intra muscular storage and metabolism of glycogen and triglycerides (IMTG). This may be related to skeletal muscle insulin resistance through increased intracellular intermediates from lipid metabolism (lipotoxicity). Here we study changes in glycogen and IMTG storage and the activity of two key enzymes in metabolism: Citrate synthase (CS) and 3-hydroxyacyl-CoA dehydrogenase (HAD), after 2 weeks of unilateral immobilization followed by 6 weeks of aerobic training in average young and elderly males. We hypothesize that: 1) immobilization decreases and training increases substrate

storage and enzyme activity in both groups. 2) There is a major difference between young and elderly in substrate storage and activity of key enzymes in metabolism of glycogen and IMTG. Methods: Healthy young (Y) (n=17; age 23±1 yr (mean±SEM); 24±1 kg/m²; body fat: 20±2%) and elderly (E) (n=15; age 68±1 yr; 27±1 kg/m²; body fat: 29±2%) included to be average for their age group, underwent 14 days of one leg immobilization with a DONJOY® cast followed by six weeks of supervised bicycle training. Biopsies from m. Vastus lateralis were obtained at baseline (BA), after immobilization (IM) and after training (TR). Results: VO₂max was higher in Y (BA; 48±1, IM; 44±1, TR; 53±1 ml O₂/min/kg) compared to E (BA; 33±2, IM; 32±2, TR; 36±2 ml O₂/min/kg). In Y but not E VO₂max was decreased by IM. In both groups VO₂max was increased after TR compared to IM. E had higher IMTG compared to Y (BA; 73±10/129±26, IM; 92±11/174±39, TR; 61±6/125±34 nmol/mg for Y/E, respectively). IMTG was lower in both groups after TR compared to IM. Glycogen was lower in Y compared to E (BA; 228±17/276±22, IM; 213±23/287±47, TR; 275±22/305±27 nmol/mg for Y/E, respectively). There was no difference between Y and E in citrate synthase (CS) activity (BA; 149±7/155±10, IM; 120±5/114±6, TR; 181±9/162±8 umol/min/mg) and in HAD activity (BA; 112±5/119±6, IM; 87±5/88±6, TR; 118±6/116±8 umol/min/mg for Y and E, respectively). In both groups HAD activity was lower after IM compared to BA and TR. Conclusion: 1) IMTG was increased after IM in both young and elderly. This may partly be explained by decreased capacity to oxidize fatty acids measured by decreased HAD activity. The low initial VO₂max in the elderly may explain that VO₂max did not decrease by IM. 2) It is interesting that the elderly had higher IMTG, relatively lower HAD activity (HAD:IMTG) and lower VO₂max compared to the young. This may over time mediate an increased risk of higher production of lipotoxic intermediates – which could lead to development of insulin resistance. Contact: Avhansen@sund.ku.dk

“MORE ACTIVE AGING” PROGRAM: LONGITUDINAL EFFECTS ON FUNCTIONAL FITNESS PARAMETERS RELATED TO FALL RISK IN PORTUGUESE ACTIVE ELDERLY. FOLLOW-UP AND COMPARISON TO OTHER PROGRAMS

Ramalho, F.1,3, André, H.3, Moniz Pereira, V.2,3, Machado, M.2,3, Carnide, F.2,3, Santos Rocha, R.1,3, Veloso, A.2,3

1-ESDRM-IPS - Sport Sciences School of Rio Maior, Polytechnic Institute; 2-FMH-UL - Biomechanics and Functional Morphology Laboratory, Faculty of Human Kinetics, University of Lisbon, Portugal; 3-CIP-

Project funded by QREN-INALENTEJO 2007-2013 (ALENT-07-0262-FEDER-001883). Introduction: The aging process leads to a decline in functional fitness and therefore to an increased prevalence of falls in the elderly. Literature shows that well-designed exercise programs can prevent falls by improving physical capacities recognized as intrinsic risk factors for such accidents (1). Purpose: To evaluate the effects of the “More Active Aging” exercise intervention program on the functional fitness parameters related to fall risk and compare it to other programs. Methods: Two 24-weeks community-based exercise programs were conducted and attended by 143 senior adults (72.3±5.2 yrs). The intervention program (IG; n=72) was linearly periodized in two 12-weeks cycles and focused on postural stability, balance, mobility and strength in the lower limbs, while the control program (CG; n=71) presented a multicomponent with a non periodized design. Trained examiners administered tests of functional fitness (FF) from SFT and FAB batteries (2,3), as well as a health and falls questionnaire. ANOVA repeated measures (1X3) was performed to analyse the longitudinal changes in each of FF parameter within the IG, and ANOVA (2X2) to test the effects of group versus time interaction in the FF and fall-rate variables. Statistical significance was set as p<.05. Results: IG participants showed improvements in all FF capacities at 12 weeks, and the results were maintained over 12 weeks more. However, the interaction Group x Time was only demonstrated in the parameters of cardiorespiratory fitness and mobility (2 min p<.001; U&G p=0.021), indicating that the IG had significantly higher improvements than the CG over the 24 weeks. Conclusions: The intervention program showed to be capable of promoting improvements in elderly participants’ functional fitness after 12 weeks, and the results were maintained after another 12 weeks of intervention. The observed effects were more evident at the general mobility level, providing clues to possible effects on prevention of falls in the long term. AGING OF SKELETAL MUSCLE: A STUDY ON THE ROLE OF INTRAMUSCULAR LIPID DEPOSITION

Conte, M., Vasuri, F., Bellavista, E., Franchi, M., Degiovanni, A., Errico Grigioni, A., Trisolino, G., Martucci, E., Kovanen, V., Bertaggia, E., Sandri, M., Narici, M.V., Franceschi, C., Salvoli, S.

DIMES-Department of Experimental, Diagnostic and Specialty Medicine - University of Bologna

The etiology of sarcopenia, i.e. the age-related loss of muscle mass and strength, includes physical inactivity and inter-fibre muscle fat infiltration. Fat accumulation can also occur as intra-muscular triglycerides (IMTG) deposition in the form of lipid droplets (LDs). Little is known about the role of IMTG accumulation on muscle function. LDs are surrounded by Perilipins (Plins) and in skeletal muscle the most abundant are Plin2 and Plin5. The exact role of these proteins is not totally clear; however it is well established that Plin2 and Plin5 correlate positively with IMTG levels. Recently, we found that Plin2 expression increases with age and inactivity, and is inversely associated with muscle mass and strength. In the present study, we analysed Vastus lateralis muscle biopsies from young and old healthy donors and patients with lower limb mobility impairment, as well as post-menopausal homozygotic twins discordant for the hormone replacement therapy (HRT). We found that Plin5 is more expressed in active subjects with respect to patients, while Plin2 was confirmed to increase with age and to be more expressed in patients compared to healthy subjects. Moreover, Plin2 resulted lower in HRT-users with respect to non-users, who also resulted to have lower muscle strength. The differential expression of Plin2 and Plin5 was also confirmed in an animal model of skeletal muscle atrophy induced by denervation. In denervated mice Plin2 resulted higher with respect to the contralateral non-denervated muscle, while Plin5 remains more stable. As a whole, these data indicate that in skeletal muscle Plin2 and Plin5 are differentially regulated during aging and inactivity and have likely a different role on muscle metabolism. Furthermore, these data suggest that Plin2 at variance with Plin5 may play a role in the etiology of sarcopenia by promoting the accumulation of IMTG with possible lipotoxic effects on muscle fibers. Therefore, modifications in Plin2 and Plin5 expression and the consequent enhancement of IMTG turnover by physical activity or pharmacological intervention, could be a key factor to reduce muscle atrophy and counteract sarcopenia.

ASSOCIATION BETWEEN FUNCTIONAL DIAGNOSIS OF SARCOPENIA AND BLOOD-BASED BIOMARKERS

Hofmann, M., Halper, B., Oesen, S., Bachl, N., Wagner, K.H., Wessner, B.

University of Vienna

Introduction Based on a practical clinical definition by the European Working Group on Sarcopenia in Older People sarcopenia is diagnosed if low muscle mass is documented together with low muscle strength or physical performance (Cruz-Jentoft AJ, et al. 2010). However, there is a much effort to find suitable blood-based biomarkers which would reflect different degrees of sarcopenia. Therefore, the

aim of the current study was to investigate (i) whether members of the TGF- β superfamily such as GDF15, Activin A or myostatin and their agonist follistatin would differ between young and non-, mild and severe sarcopenic elderly females and (ii) whether these markers correlate to muscle mass and function. Methods In total 107 sedentary females participated in this study (young: 25 (21-28) years, $n=16$; elderly: 83 (65-92) years, $n=91$). Sarcopenia was defined based on the measurement of isokinetic peak torque of knee extension at 60°/s (PTE). Mild sarcopenia was defined as having a PTE between 1 and 2 SDs below the mean for the young women, while reduction in PTE by 2 SD was used as cut-off point for severe sarcopenia. In addition handgrip strength, chair rise test, 6min walking test (6MWT) and body composition were measured. Serum levels of myostatin, GDF15, Activin A, follistatin and IGF-1 were assessed using commercially available ELISA kits. Statistical differences were determined using ANOVA with Bonferroni post-hoc tests, correlations were characterized by Spearman-Rho correlation coefficients (IBM SPSS Software package). Results All functional tests (handgrip strength, chair rise test, 6MWT) differed between young and elderly women ($p<0.001$). However, only handgrip strength and chair rise tests were able to discriminate between non- and severe sarcopenic elderly ($p<0.001$). These findings were similar for muscle mass which was higher in young and non-sarcopenic in comparison to both, mild and severe sarcopenic females ($p<0.001$). The serum markers IGF-1 and GDF15 differed between young and elderly ($p<0.01$). However, these markers did not differ between non- and mild or severe sarcopenic elderly. Correlation analyses revealed that serum concentrations of follistatin, activin A and myostatin were not associated with any functional parameter. Interestingly, IGF-1 and GDF15 correlated with handgrip strength ($p=0.001$; $\rho=.352$ for IGF-1 and $p=0.005$; $\rho=-.302$ for GDF15). Discussion To our knowledge this is the first study investigating TGF- β superfamily members and IGF-1 for their suitability as biomarkers of age-related muscle loss. We were able to confirm data on age-related decline of IGF-1 (Khan et al., 2002), there aren't any data on GDF15. However, it seems that both IGF-1 and GDF15 reflect the ageing process rather than discriminating between different stages of sarcopenia. References Cruz-Jentoft AJ, et al. (2010). EXERGAMING IMPROVES FALL RISK FACTORS IN COMMUNITY-DWELLING SENIORS: A META-ANALYSIS

Faude, O., Rössler, R., Niedermayer, G., Zahner, L., Donath, L.

University of Basel

Introduction Aging is associated with functional, neural and muscular deteriorations resulting in an increased fall risk. During recent years video-based activities (exergaming) have become an attractive and feasible approach to implement balance and strengthening exercises into daily routines of independently living seniors (Jorgensen et al., 2013, Pluchino et al., 2012). The present meta-analysis aimed to summarize the existing scientific literature and to evaluate the effects of exergaming vs. traditional balance training and a control condition on fall risk factors in community-dwelling elderly. Methods A computer-based literature search was conducted in seven databases (CINAHL, EMBASE, Google Scholar, Web of Science, PubMed, Scopus, PEDro) until November 2013. Moreover, citation tracking and hand searching were carried out. Inclusion criteria were: (a) the study analyzed the effects of video-based exercises on fall risk factors, such as static balance (e.g. uni- and bilateral standing tasks), functional mobility (e.g. Berg Balance Scale, Tinetti test, Timed Up and Go test) and strength (e.g. Ten Step test, Chair Stand test) compared to a control or a balance training group and (b) the study included independently living seniors. We calculated weighted standardized mean differences (SMD with 95% CI) to compare exergaming vs. control and balance training. Statistical analysis was conducted using a random effects model. Results Thirteen studies (including a total of 347 participants) met the inclusion criteria. We found a moderate overall effect in favour of exergaming vs. control (SMD=0.47 [0.23, 0.72], $p<0.001$). In particular, moderate to large effects were present for standing balance performance (SMD=0.50 [0.15, 0.84], $p=0.005$) as well as functional mobility (SMD=0.76 [-0.10, 1.61], $p=0.08$) and strength (SMD=0.80 [0.10, 1.49], $p=0.03$). In addition, we observed trivial to moderate effects in favour of traditional balance training compared to exergaming (SMD<0.55, $p>0.17$). Discussion Our results show that exergaming might be an efficacious alternative to traditional balance training to improve fall risk factors in seniors. Particularly, static balance as well as functional mobility and strength were beneficially affected. The effects of exergaming were slightly smaller as compared to traditional balance training. However, exergaming seems highly motivating and can be conducted at home (Jorgensen et al. 2013, Pluchino et al., 2012). Thus, exergaming might enable a high compliance in the long term. OP-BN05 Balance & Training

STATIC BALANCE, HAND GRIP STRENGTH, AND FLEXIBILITY IN OLDER ADULTS, ARE THERE ANY SEX DIFFERENCES?

Lohne Seiler, H.1,2, Hansen, B.H.2, Anderssen, S.A.2

1University of Agder, Kristiansand, Norway, 2Norwegian School of Sport Sciences, Oslo, Norway

Do not insert authors here Introduction Good musculoskeletal fitness is critical for older adults' capability to perform physical activity, which is of great importance to overcome daily life activities and seem to have a protective effect on functional limitations. However, there is limited data on population levels of musculoskeletal fitness among older men and women using objective assessment methods. Therefore, the aim of this study was to assess balance, muscle strength and flexibility in a national sample of older adults, and examine whether there was any sex differences. Methods The present study is a part of a national multicenter study in Norway. Participants for the initial study were randomly selected, and the current study includes those of the initial sample aged 65-85 y. 162 older adults (85 women and 77 men) were included. Static balance was registered as the total number of sec the participants managed to keep the balancing position on one leg (one leg standing=OLS), muscle strength was registered as the best of three attempts (kg) using a dynamometer (hand grip=HG), and flexibility of lower back and hamstrings musculature was registered in number of cm the participants managed to lean forward atop of a box (sit and reach=SR). Independent sample t-test was used to assess differences between women and men. Results Mean age (SD) was 71.9 (5.7) y for women and 71.8 (5.3) y for men. No sex differences in OLS were observed: 18.6 (19.0) and 20.5 (19.8) sec, respectively. Significant differences in HG (SD) were found between women and men: 25.6 (6.0) and 42.4 (10.5) kg (<0.001),

respectively. Significant differences were also found in SR between women and men: 20.5 (10.3) and 13.4 (10.8) cm ($p < 0.001$), respectively. Discussion Norwegian older adults seem to have better grip strength and balance compared to others (Budziareck et al., 2008; Briggs et al., 1989). Otherwise, our results based on sex differences are in agreement with comparable studies (Gusi et al., 2012). In conclusion, Norwegian older men have significant better grip strength compared to women at the same age. On the other hand, Norwegian older women have significant better flexibility compared to their counterpart men. Regarding balance, no significant sex differences were observed. ACUTE EFFECTS OF 4 × 4 HIGH-INTENSITY INTERVAL RUNNING ON NEUROMUSCULAR PERFORMANCE IN YOUNG ADULTS AND SENIORS

Donath, L., Roth, R., Hanssen, H., Schmidt Trucksäss, A., Zahner, L., Faude, O.

University of Basel

Introduction High intensity interval training (HIIT) potentially increases cardiorespiratory function more than moderate endurance training (Helgerud et al., 2007). As a consequence, HIIT training has been successfully introduced in clinical and older populations (Wisloff et al., 2007; Molmen et al., 2012; Nemoto et al., 2007). However, investigations on acute effects of intense exercise - such as HIIT - on balance performance in different age-groups are scarce to date (Donath et al., 2013). Thus, the present study examined to what extent a typical HIIT session might adversely affect standing balance performance, muscle activity and balance recovery in seniors compared to young adults. **Methods** The present study was conducted as a randomized controlled crossover study. Twenty healthy seniors (age: 70 (SD 4) y) and twenty young adults (age: 27 (SD 3) y) were examined on three days. After treadmill testing to assess maximal heart rate (HRmax), either a 4×4 HIIT at 90% of HRmax or a control (CON) condition was randomly performed. Balance performance (postural sway within 10 s) was assessed during single limb-eyes opened (SLEO) and double limb-eyes closed (DLEC) stance. EMG was measured for the superficially accessible lower leg muscles (m. soleus, m. tibialis anterior, m. peroneus longus, m. gastrocnemius) at the dominant side. All measures were collected before, immediately after, 10', 30' and 45' after the HIIT and control condition. Results Compared to CON, significant increases of postural sway immediately after HIIT were observed during SLEO for both groups (adults: $p < 0.001$, $\Delta = +25\%$ sway; seniors: $p = 0.007$, $\Delta = +15\%$ sway). Increased sway during DLEC was only found for seniors immediately and 10' after HIIT (post: $p = 0.003$, $\Delta = +14\%$ sway, 10' post: $p = 0.004$, $\Delta = +18\%$ sway). Tibialis and soleus muscle activation was increased in both groups during DLEC and SLEO, particularly immediately after HIIT cessation ($p < 0.01$). **Discussion** Postural sway and muscles activity after a single HIIT session are affected up to 30 min after exercise cessation. During this time period, there might be a higher risk of falling due to deteriorated postural control ("open-fall-window"). This may be particularly relevant in seniors. As balance performance in older adults is deteriorated after an intense bout of physical exercise but not after submaximal endurance walking (Donath et al., 2013), the advantages of HIIT with regard to time efficiency are debatable. CHANGES IN POSTURAL CONTROL AFTER INDUCING FATIGUE IN JUNIOR SAILORS WEARING COMPRESSION GARMENTS.

Welman, K.E., Walker, C.N., Chamberlain, N.

Stellenbosch University

Introduction Balance is one of the critical factors that affects athletes' performances, and is recognized to have a central role in sport injury prevention. Fatigue deteriorates postural and neuromuscular control, which increases the injury risk (Paillard, 2012). Compression garments (CG) have been shown to improve fatigue and recovery, thereby indirectly benefiting performance. It is not known if this is true for sailors and in particular young individuals with poorer postural control (PC). The study endeavour to determine if lower body CG influences elite junior sailors' PC after a fatigue-inducing protocol. **Methods** Nine healthy elite sailors (Age: 13 ± 1 years; BMI: 20 ± 3 kg/m²; Professional Sailing: 3 ± 1 years) volunteered for the study. Each participant acted as their own control and randomly completed the trials without (CON) or with CG. Participants were subjected to a maximum incremental hiking fatiguing protocol (HFP) developed by Blackburn (2000). The effects on counter movement jump (CMJ) variables (jump height, power, force and velocity), lactate (LT) and postural sway (PS) variables were analysed pre- and post-HFP. Results Generally the sailors took 7 ± 2 minutes to fatigue, with a weight of 21 ± 4 kg. No differences were observed between the two HFP in Time to Fatigue ($p = 0.36$) and Weight Held at Fatigue ($p = 0.41$). CMJ performances showed a 12% and 3% reduction in jump height for CON and CG, respectively ($p = 0.15$; $d = 0.76$). Jump power after fatigue increased by 11% in the CG trial ($p = 0.06$; $d = 1.01$). Decreased jump velocity in CON trial was observed ($p = 0.09$; $d = 0.91$) with a plateau in CG ($p = 0.65$; $d = 0.23$). PS variables deteriorated in the CON trials ($p < 0.05$), whereas overall PS improved while wearing CG ($p = 0.04$). Directly after the HFP LT was significantly lower ($p = 0.04$; $d = 1.17$) in CG trial compared to CON (4 ± 2 vs. 10 ± 7 mmol/L, respectively). **Discussion** The results for the performance variables seem to correspond to the improvements in PS variables. This suggests that CG may have reduced the fatigue experienced by sailors while quasi-isometric stress was placed on the quadriceps muscles. Sailors can prolong endurance time in the hiking position by adjusting neural activity distribution among synergists, thereby minimizing the contribution of the most fatigable muscles (Cuével, 2006). CG may have improved proprioceptive feedback and, together with less fatigue, this lead to improved PS. Better PC means reduced risk for injuries and more accurate movements during fatiguing activities. References Cuével, A. (2006). *Int J Sports Med*, 27, 968-975. Paillard, T. SENSORIMOTOR FUNCTIONING IN PATIENTS WITH TOTAL HIP REPLACEMENT USING LOCAL DYNAMIC GAIT STABILITY

Hamacher, D., Schega, L.

Otto von Guericke University Magdeburg

Introduction Patients with total hip replacement (THR) suffer from proprioceptive deficits which isolated are difficult to quantify (Karanja et al., 1983; Ishii et al., 1999). Existing approaches to capture the proprioceptive status frequently use static measures (Szymanski et al., 2012) without accounting for dynamic circumstances. Local dynamic stability (LDS) of human walking has been reported to gauge sensorimotor

functioning (Dingwell & Casumano, 2000). In order to quantify possible sensorimotor deficits while walking in THR patients, we aim to compare LDS of pelvis trajectories derived from walking time series in THR patients and in their healthy counterparts. Methods 21 female patients with unilateral THR (IG, 58±10 years) and 15 healthy elderly women (CG, 65±4.2 years) were recruited at the last day of their inpatient treatment and via a local health sport club, respectively. Kinematic data were captured using a 3 dimensional (3D) motion analysis system (Moven, Xsens) during normal level-grounded walking without crutches. To quantify LDS, the largest Lyapunov Exponents of the 3D pelvis trajectories (angular velocity) have been calculated from 100 strides of each participant. Group differences were examined using Student's two-sample t-test. The level of significant was set to $\alpha=5\%$. In addition, Cohen's d was calculated. Results Compared to the healthy elderly women, reduced LDS was found in THR patients ($p=.000$, $d=1.37$). Discussion While previous research showed improvements in THR patients after an inpatient treatment regarding other relevant kinematic gait parameters (e.g. ROM of pelvis, Schega et al., 2011), our data show that THR patients exhibit decreased LDS of pelvis trajectories while walking after their inpatient treatment. This presumably quantifies decreased sensorimotor functioning in the patients' affected hip joints compared to their healthy counterparts. In a holistic point of view, however, an improved sensorimotor system is required to gain normal gait pattern and, thus, to prevent further multimorbidity. Subsequently, it should be investigated whether THR patients would develop more stable pelvis gait patterns after a longer time span. Furthermore, the dose-response effect of specific proprioceptive training on LDS is insufficiently studied and should be addressed in further research projects. WHOLE-BODY VIBRATION AND BALANCE TRAINING: A PROPRIOCEPTIVE OVERLOAD ?

Lindley, S., May, K., Richards, J.

UNIVERSITY OF CENTRAL LANCASHIRE

Introduction Whole-body vibration training (WBVT) is a neuromuscular training method that has recently been popularised and integrated into many conditioning programs. WBVT and balance training have also been used in combination as a rehabilitation and injury prevention modality (Rittweger, 2010). However, little work has investigated the effects of WBVT on the motor control system. This study explores the effects of combined Vibration Training and Balance Training using the Vibrosphere and its efficacy within an applied or clinical setting. Methods Subjects ($n=10$) participated in a single testing session consisting of 5 single dominant leg dips pre and post each intervention. The randomised interventions were standing in a double leg mini squat position for 30 seconds; on 1) Vibrosphere placed on a mat with the vibration at 45 Hz, 2) Vibrosphere on a mat without vibration, 3) on a soft mat, and 4) laboratory hard floor. 3D Joint kinematics of the Ankle, Hip and Knee joint were captured using a 10-camera Qualisys camera system and modelled using the CAST technique. Results A significant increase in the knee and hip joint angular velocities was seen in the coronal plane (-5.3 deg/s and 8.6 deg/s) and a significant decrease in sagittal knee joint velocity (5.3 deg/s) were found following the vibration intervention. Discussion The increase in the coronal plane knee and hip joint velocities could contribute to additional medial and internal rotation stresses upon soft tissue structures. This is not in agreement with other studies (Moezy et al., 2008) who have found WBVT to be a beneficial neuromuscular modality in injury prevention and rehabilitation. However previous research has not considered joint angular velocities, which are important variables in the control and stability. The increase in instability following the vibration intervention is thought to be caused by an overload to the proprioceptive receptors, therefore affecting the control mechanisms. Clinicians should consider the effects of vibration on the proprioception system and consequent joint control within the design of their rehabilitation or conditioning programs. (2008), British Journal of Sports Medicine, vol. 42, pp. 373-378.

IDENTIFICATION OF TRANSDISCIPLINARY INDIVIDUAL MOVEMENT PATTERNS

Schöllhorn, W., Beckmann, H., Janssen, D.

Johannes Gutenberg-University Mainz

Introduction Although individuality has been discussed in movement science for a long time, the phenomenon itself mostly has been considered as a side effect of extensive training in top athletes. Structurally, individuality has been neglected thru the dominance of group studies and average oriented designs without being able to draw specific consequences on training or therapy. Meanwhile individuality of single types of movement has been shown (Schöllhorn et al., 2002) and this has led to the rethinking of the traditional training approaches (Schöllhorn, 2000). Our every day experience tells us that individuality is observable in the same person for different types of movements. In a first approach to the problem individual characteristics should be recognized in several types of movements in order to transfer the individual characteristics across these movement patterns. The aim of this study was to identify intra-individual movement patterns of decathletes in shot put, discus, and javelin. Methods Within national qualification for European Athletics Junior Championships 7 right handed decathletes (mean age: 18.8 years; sd: 0.4) were recorded on two digital video cameras (200 fps; 1280 x 1024 px) located perpendicular to each other, one facing towards the flight direction of the throwing object. On the basis of a 13 segment body model the final throwing phases of 19 shot put, 19 discus, and 19 javelin trials were described by means of angular- and angular-velocity-time-courses of the main joints, except the variables of the throwing arm. Time and amplitude normalized data formed the input vectors for a classification procedure based on two Support Vector Machines (SVM) which were trained by cross-validation procedure, one for the identification of throwing disciplines and one for the identification of persons. Results The classification of all 57 trials revealed a 100% recognition rate for the disciplines with the first SVM. The second SVM led to a recognition rate of 98.5% for the athletes. Discussion The recognition rates provide strong evidence for the sensitivity of the applied movement recognition approach and for the dominance of individuality across disciplines. In expansion to the identification of individual movement characteristics in single movement trials the present investigation allows the transfer of individual information of one movement to another. The identification of transdisciplinary individual movement characteristics support the demands for more economic training by transdisciplinary training. In consequence, the results point to rethink group oriented training and suggest a more enhanced focus on individual characteristics in training even. References Schöllhorn, W. I., Nigg, B. OP-PM17 Cancer & Exercise

EFFECT OF CAFFEINE ON EXERCISE CAPACITY, FATIGUE AND FUNCTIONAL PERFORMANCE IN PROSTATE CANCER SURVIVORS

Skinner, T.L., Cornish, R.S., Bolam, K.A.

The University of Queensland

Introduction Cancer-related fatigue is a highly prevalent symptom associated with several psychological and physiological comorbidities that detract from quality of life, hindering exercise participation and activities of daily living during (Langston et al., 2013) and beyond (Goedendorp et al., 2013) cancer treatment. Whether caffeine, the world's most commonly used stimulant known to reduce exercise-related fatigue and perception of effort in healthy populations, may also be beneficial for cancer survivors has yet to be explored. The aim of this study was to examine the acute effect of caffeine on exercise capacity, exercise-related fatigue and functional performance in prostate cancer survivors. **Methods** In this randomised, placebo-controlled, double-blinded crossover study, 30 prostate cancer survivors (age 70.3 ± 7.7 yr, body mass 80.5 ± 13.0 kg, mean \pm SD) consumed 6.04 ± 0.16 mg/kg anhydrous caffeine or a placebo (calcium sulphate) one hour prior to completing a battery of exercise capacity and functional performance tests. Immediate fatigue and perceived exertion were measured directly pre- and post-exercise at both testing sessions. Results Caffeine increased exercise capacity (as measured by the 400 m walk test) by 7.93 sec ($+3.0\%$; $p=0.010$); however, post-exercise fatigue and perception of exertion were comparable to the placebo session ($p=0.632$ and $p=0.902$, respectively). Increases in isometric grip strength trended toward significance in both dominant ($+2.9\%$; $p=0.053$) and non-dominant ($+2.1\%$; $p=0.061$) hands in the caffeine trial compared to placebo. Caffeine ingestion did not result in improvements in performance for any of the remaining functional measures, including the timed up-and-go test, repeated chair stands, 6-m fast walk and 6-m backwards tandem walk. Systolic blood pressure and heart rate were significantly increased ($p=0.006$ and $p=0.040$, respectively) on completion of the testing battery when compared to placebo. **Discussion** Consumption of caffeine, one hour prior to exercise, induced improvements in exercise capacity and muscular strength in prostate cancer survivors. Furthermore, there was no change in exercise-related fatigue when compared to placebo, despite improved performance in the 400-m walk. Caffeine appears to enhance exercise tolerance through improved performance with no subsequent increase in fatigue or perception of exertion and may be an appropriate strategy to facilitate exercise participation in prostate cancer survivors. **References** Goedendorp MM, Gielissen MF, Verhagen CA, Bleijenberg G. NORDIC WALKING TRAINING IN CANCER PATIENTS: SELF-PACING AND EXERCISE INTENSITY

Schmidt, K., Bernardi, A., Vogt, L., Niederer, D., Molt, S., Hacibayramoglu, M., Banzer, W.

Goethe-University

Introduction In cancer patients maximal cardiopulmonary exercise testing (CPET) is recommended for prescribing exercise intensity. However, the feasibility of CPET and the control of exercise intensity in clinical and practical routine is often limited. Evidence indicates that sedentary middle-aged or older adults as well as cardiac patients select intensity levels within the recommended range while exercising self-paced (Ekkekakis 2009). Nevertheless, in cancer patients it is unknown if preference-based exercise induces an appropriate training load. Therefore, this study aimed to evaluate whether a self-paced Nordic Walking (NW) training in cancer patients elicits exercise intensities within the recommended range of moderate to vigorous physical activity (MVPA). **Methods** Measurement of individual exercise-induced training load was based on two methods differing in requirements of time, cost and expertise (group A: heart rate reserve (HRR); group B: oxygen uptake reserve (VO2R) determined by indirect calorimetry). 18 cancer patients with at least 3 month of NW experience participated in baseline CPET on a cycle ergometer (group A: $n=12$, 3 male, 53-75 yrs.) or a treadmill (group B: $n=6$, 3 male, 48-71 yrs.) for determining maximal exercise capacity (VO2peak) and maximal heart rate. At least 48 hours after initial testing, patients performed a self-paced Nordic Walking training session without direct feedback of their actual physiological response. **Results** Group A selected walking speeds that elicited mean HRR-values of $56 \pm 7\%$ (95%-CI: $+52$; $+61$) with a proportion of 95% (95%-CI: $+92$; $+98$) of the session within the recommended MVPA-range (40-89% of HRR or VO2R). Group B reached mean VO2R-values of $63 \pm 12\%$ (95%-CI: $+50$; $+76$) with 97.0% (95%-CI: $+91$; $+103$) proportion of MVPA. Group comparison revealed no significant differences ($p > .05$). Individual values ranged from 49% to 72% of HRR in group A and 45% to 81% of VO2R in group B. **Discussion** Both, on average and individually, participants selected an exercise intensity within the exercise intensity recommendations for MVPA. The results of the HRR-based method were confirmed by the criterion standard for measurement of exercise metabolism (indirect calorimetry). Thus, our findings suggest that a preference-based NW training might be an appropriate option to induce recommended exercise intensities in cancer patients. Future studies should compare training effects, affective responses and adherence between self-paced exercise and imposed intensities. **References** Ekkekakis, P. (2009). MAXIMAL AND SUBMAXIMAL CARDIORESPIRATORY AND METABOLIC PERFORMANCE MONITORING IN BREAST CANCER PATIENTS

Bernardi, A.I., Schmidt, K.I., Vogt, L.I., Lungwitz, A.I., Banzer, W.I.

Goethe University Frankfurt

Introduction Aerobic endurance training with moderate to vigorous intensity of at least 30% oxygen uptake reserve (VO2R) is recommended for developing cardiorespiratory fitness (CRF). For determining exercise intensity and monitoring training progress submaximal lactate or ventilatory based thresholds are widely used. However, there is insufficient knowledge about their feasibility in cancer patients. Therefore, the aim of this study was twofold: 1. to compare threshold-based exercise intensity prescription methods with the range-based guidelines according to the ACSM, and 2. to assess the sensitivity of those variables to detect changes in maximum oxygen uptake (VO2max) as the gold criterion of CRF in breast cancer patients. **Methods** 20 female breast cancer patients (51.5 ± 8.4 years, VO2max

21.8±5.0 ml/min/kg) participated in two exercise tests until exhaustion on a cycle ergometer (0 +25W, 3min). Following baseline testing, participants received individualized exercise counseling for home-based training and the opportunity to participate in a guided Nordic-Walking training. Tests were separated by 4-6 weeks (T1 and T2). Ventilatory threshold (VT) and respiratory compensation point (RCP), as well as lactate threshold (LT) and individual anaerobic threshold (IAT) were determined according to established methods. Results Work rates at LT, VT, IAT and RCP, oriented within the guideline recommendations for exercise intensity of 46-90% VO₂max (50.5%±8.1, 53.6%±9.2, 73.3%±7.8 and 83.2%±5.2), correlated significantly (r : .66 to .81, p <.01) with VO₂max. For 16 out of 20 patients every threshold induced a metabolic reaction of more than 30% VO₂R. Values of VO₂max, LT, VT, IAT and RCP showed significant improvements (p <.05) over time. VT, RCP and IAT had an efficiency in indicating the change in VO₂max of 82%, 86% and 80% respectively. Discussion Our results suggest that submaximal thresholds can be applied for prescribing individual exercise intensities according to current recommendations (Garber et al., 2011). Additionally the metabolic and ventilatory thresholds appear sufficiently sensitive to depict changes in CRF in cancer patients. As their application seems less dependent on the patients' capability to make a maximum effort they may facilitate performance monitoring in clinical practice. Further studies should focus on the implementation of submaximal markers in exercise rehabilitation. This might help to enhance patients' compliance, tailor individual training programs and evaluate performance development. FUNCTIONAL STATUS AND MORTALITY IN GASTROINTESTINAL CANCER PATIENTS

Gutekunst, K.1, Vogt, L.1, Schmidt, K.1, Bolling, C.2, Niefeld, R.1, Banzer, W.1

1:Institute of Sport Science 2:Agaplesion Markus Hospital Frankfurt/Main

Introduction Growing evidence underlines the association between motor deficits, dependence in activities of daily living (ADL) and premature mortality as well as frailty in elderly persons (Bohannon 2008). Certain studies indicate muscle degradation in patients with gastrointestinal cancer. To our knowledge no study systematically focused on ADL and functional decline in these patients. Therefore, the present study aimed to explore functional status and dependence in ADL in patients with gastrointestinal cancer during chemotherapy. Methods To assess dependence in ADL and allow for classification of independent living skills 21 gastrointestinal cancer patients (70±9 years; 8 ♀, 13 ♂; during chemotherapy) completed the Functional Independence Measure (FIM; 7 items) and Lawton's instrumental ADL (iADL; 8 items) Scale. Items are scored on an ordinal scale ranging from 1 (total dependence) to 7 or 8 (total independence). In addition, patients rated their exercise capacity on a modified 13-point Perceived Functional Ability-Scale (PFA) (George et al. 1997) via estimating the walking or running velocity they could keep up for 1.6 kilometers. Handgrip strength (dominant side) was objectively measured using the Jamar hand dynamometer. Results Corresponding to the FIM only 14% were classified as needing supervision or moderate assistance. With respect to the more specific iADL instrument, patients were categorized as: 57% independent, 19% needing supervision, and 24% being frailty and dependent in ADL. The average PFA was 4.1±2.7, corresponding to a self-estimated speed of 4.5km/h. Handgrip strength on (female: 17.2±2.1kg; male: 25.9±8.1kg) was 20.1±18.9% below age- and sex-specific reference values. Correlation analysis revealed significant relationships of ADL-score with handgrip strength (r =.58; p <.01) and PFA-score (r =.63; p <.01). Discussion The results indicate that almost half of the patients with gastrointestinal cancer suffer from restrictions of ADL and muscle strength. Low handgrip strength and dependence in ADLs generally may predict incident disabilities and poor outcomes in hospitalized older people (Bohannon 2008). Herewith, progression in functional decline in gastrointestinal cancer patients seems presumable. Future research should incorporate objective measures of motor function and ADLs to gain more detailed information of the restrictions and needs of gastrointestinal cancer patients and to provide a basis for the development of deficit orientated exercise programs. 3 MONTH FOLLOW-UP OF AN INPATIENT SPORTS THERAPY IN THE PEDIATRIC STEM CELL TRANSPLANTATION

Senn Malashonak, A., Arndt, S., Vogt, L., Rosenhagen, A., Bader, P., Banzer, W.

Medical Center of the Goethe University

Introduction: The hematopoietic stem cell transplantation (SCT) is associated with numerous therapy-related side effects and a rapid decline of physical performance. Even several years later young survivors present posttransplant life-long damages like cardiopulmonary and neuromotor impairments, reduced muscle strength or limitations in quality of life (Ness & Gurney, 2007). For adults evidence suggests that physical exercise enhances patient's fitness in all phases of treatment (Galvao & Newton, 2005). This randomized controlled trial evaluates short- and middle-term impact of an inpatient sports therapy on submaximal functional capacity. Methods: In this prospective study 17 participants (10.3 ± 2.7y) were randomized into a sport (IG) or control group (CG). During their inpatient care the IG (n=9) performed a daily supervised exercise therapy consisting of endurance, resistance and flexibility training while the CG (n=9) obtained mental training and relaxation exercises. After hospital discharge the interventions were stopped for both groups. A 6-Minute-Walking-Test (6MWT) was assessed at hospital admission (T1), discharge (T2) and day +100 (T3) after SCT. For descriptive analyses mean standard error (SE) and 95% confidence interval (CI) were calculated as well as univariate ANOVA and unpaired T-test (as post-hoc) for group comparison. Results: The percentage change data presents for the univariate ANOVA a high significant group and time effect (p =.005) together with a significant difference at T2 (p =.013) between the groups (IG: m =3.6 ± 4.2%; KG: m = -12.5 ± 7.7%). Above this the relative differences between T1 and T3 ranged for 8.4 ± 2.9% (CI: 1.6 – 15.2) vs. 6.3 ± 5.6% (CI: -6.8 – 19.5) in the IG and CG respectively. Discussion The results indicate that an inpatient sports therapy has a short- and middle-term impact on submaximal functional capacity. The children and adolescents of IG benefit from the inpatient intervention as they show a constant increase of their fitness level over time. By contrast inactive patients have a lower chance to stay above their baseline values 3 month after sct. Especially for young sct patients reintegration (peer groups, school, sports club) can be supported by a solid physical status. Further research is necessary. IMPACT OF THE INITIAL FITNESS LEVEL ON THE EFFECTS OF A STRUCTURED SPORTS THERAPY DURING STEM CELL TRANSPLANTATION

Arndt, S.1, Senn Malashonak, A.1, Vogt, L.2, Rosenhagen, A.2, Jung, M.3, Siegler, K.1, Bader, P.1, Banzer, W.2

1: Pediatric Oncology, Goethe-University Clinic (Frankfurt), 2: Sports Medicine, Goethe-University (Frankfurt), 3: Physical Therapy, Fresenius University (Idstein)

Introduction Cancer- and treatment-related side effects often lead to a reduced performance level in children and adolescents. Especially before sct a high number of patients suffer of physical and psychological limitations due to prior treatment. Exercise intervention studies present beneficial effects on e.g. muscle strength, endurance or health-related quality of life during and after sct. The following study examines initial fitness levels of pediatric sct patients and their influence on the effects of a supportive sports therapy. **Methods** 39 children and adolescents (11.1 ± 3.6 years) were randomly assigned into a sport (IG) and control group (CG). During hospitalization the IG performed a daily sports therapy based on endurance, strength and flexibility training, the CG conducted mental and relaxation exercises. A Six-Minute-Walking-Test (6MWT) was assessed before and after inpatient treatment. Baseline results were used to assign the IG into 2 subgroups (mediansplit; IGP0-50=9; IGP50-100=10). Differences between groups were analysed with Kruskal Wallis and post hoc test. Results Post inter-group comparison observed (highly) significant differences between IGP0-50 and the other groups ($p < 0.01$; $p = 0.017$). In retest the IGP0-50 increased her 6MWD by $12.4 \pm 7.2\%$. IGP50-100 and CG presented a decline in distance (-6.7% ; -14.6%). After discharge the IG with the highest pre values achieved 79.7% compared to healthy children and adolescents. Thereby, this group left the hospital with the best (submaximal) aerobic condition. **Discussion** The current results indicate that a supportive sports therapy during sct can prevent the treatment-related loss of physical function. Patients' benefit depend i.a. on their initial fitness level. Though a diminished physical capability may result in higher training effects, data support a preliminary sport therapy prior sct. Further research is needed to evaluate the physical and psychological effects of a preventive and rehabilitative exercise therapy in pediatric sct. **References** Rosenhagen, A. et al. OP-PM18 Time-trial Performance

ON THE NECESSITY OF PERFORMANCE-FEEDBACK IN THE REGULATION OF EXERCISE INTENSITY

Smits, B.L.M.1, Polman, R.C.J.2, Otten, E.1, Pepping, G.J.1,3, Hettinga, F.J.1,4

1 University of Groningen/UMCG, the Netherlands; 2 Victoria University, Australia; 3 Australian Catholic University, Australia; 4 University of Essex, UK

Introduction To complete an exercise bout and/or maximise exercise performance, exercisers have to distribute and manage their effort. This process is known as pacing. Pacing, and the subsequent exercise performance, can only be optimised if exercisers make decisions based on the most relevant information. In today's competition, athletes can consult performance-feedback (e.g. speed, heart rate, power output, etc.) on different external devices assisting the decisions they need to make regarding pace regulation during the race. But how important is this information? The aim of the present study was to examine whether instantaneous performance-feedback contributes to maximising performance and pacing in well-trained athletes, and how they pace themselves when they are blinded from it, relying on intrinsic feedback. **Methods** Three successive 20-km cycling time trials were performed. Participants were appointed to an experimental (EXP) group ($n = 10$) blinded from feedback, or a control (CON) group ($n = 10$) with the possibility to consult feedback (i.e. speed, heart rate, power output, cadence, elapsed time, elapsed distance) continuously. Results Whereas CON did not change their pacing-strategy (i.e. power-distribution) throughout the trials, the strategies of EXP varied across the trials. However, no between-group differences were found in performance time (CON: 28.86 ± 3.68 min; 29.16 ± 3.93 min; and 28.88 ± 4.12 min vs. EXP: 30.95 ± 2.77 min; 30.80 ± 3.76 min; and 30.45 ± 3.17 min; for respectively trial 1, 2, and 3) and mean power output (CON: $3.61 \pm .58$ W/kg; $3.61 \pm .56$ W/kg; and $3.70 \pm .60$ W/kg vs. EXP: $3.46 \pm .37$ W/kg; $3.49 \pm .44$ W/kg; and $3.56 \pm .42$ W/kg; for respectively trial 1, 2, and 3). When trials were analysed without end-spurt, that is excluding the last 10% of the pacing-strategy of each trial, it was demonstrated that EXP was able to adopt a pacing-strategy comparable to that of the CON-group by the third trial. **Conclusion** Pacing in well-trained athletes, and the subsequent exercise performance, does not seem to depend on provided instantaneous performance-feedback throughout the first 90% of the race. Only feedback providing precise knowledge of the end point seems profitable in maximizing performance in the last 10% of the race. We conclude that information other than external performance-feedback seems directive in decision-making in pacing throughout the largest part of the trial in well-trained athletes. DECLINE IN GROSS EFFICIENCY DURING EXERCISE EFFECTS ANAEROBIC CAPACITY IN CYCLING TIME TRIALS

Mulder, R.1, Noordhof, D.1, Malterer, K.2, Foster, C.2,1, de Koning, J.1,2

[1] VU University Amsterdam, [2] University of Wisconsin-La Crosse

Introduction Anaerobic capacity, defined as the maximum amount of anaerobic energy release during exercise, is generally calculated according to the maximal accumulated oxygen deficit (MAOD) method, gross efficiency (GE) method or the concept of critical power. All of these methods assume a constant GE during exercise. However, recent literature showed that gross efficiency (GE) declines during exercise and therefore influences the estimated expenditure of anaerobic and aerobic resources [1]. Therefore, the purpose of the current study was to compare the calculated anaerobic work (AnW) produced during cycling time trials of different length, with and without a GE correction for a decline in GE. **Methods** AnW was calculated in eighteen trained competitive cyclists during four different time trials (500-m, 1000-m, 2000-m, and 4000-m). GE was estimated at the start and finish [1] of the time trial. To give insight in the rate of decline of GE during the time trial, two time trials were reproduced (1000-m and 4000-m) and stopped at 50% of the corresponding 'full' time trial,

which provided an estimate of GE at 50% of the corresponding 'full' time trial. Results AnW during time trial exercise corrected for a decline in GE was 30% (confidence interval [25, 36%]) higher ($p < 0.001$) compared to AnW without a GE correction. A significant interaction effect between calculation method (constant GE, declining GE) and distance (500-m, 1000-m, 2000-m, 4000-m) was found ($p < 0.001$). Further analysis revealed that the calculated AnW with GE correction was different from AnW without GE correction for all time trial distances. AnW calculated without GE correction did not result in equal values for AnW calculated over different time trial distances ($p < 0.001$), which is in contradiction with the concept of a constant anaerobic capacity. However, AnW with correction for a declining GE did result in a constant value for anaerobically attributable work ($p = 0.18$). Conclusion AnW calculated during short time trials (< 4000 -m) with a correction for a declining GE is 30% [25, 36%] higher compared to anaerobic capacity calculated assuming a constant GE. The concept of a constant anaerobic capacity was only supported when AnW during time trials was calculated with a correction for a decline in GE during the race. Therefore, AnW calculated corrected for a decline in GE may represent anaerobic energy contributions during high intensity exercise better than calculating AnW assuming a constant GE. Literature 1. THE COMBINED EFFECT OF HEAT STRESS AND HYPOHYDRATION ON PACING PATTERN DURING A 40-KM CYCLING TIME TRIAL

Levels, K.1,2, De Koning, J.J.1,3, Foster, C.1,3, Daanen, H.A.M.1,2

1: MOVE, VU University (Amsterdam, The Netherlands), 2: TNO (Soesterberg, The Netherlands), 3: UWLAX (La Crosse, USA)

Introduction The effect of heat stress and hydration status on performance during aerobic exercise has been studied extensively but their interaction effect on pacing and performance is still unclear. Therefore, the main goal of this study is to investigate the combined effect of hypohydration and heat stress on pacing pattern and exercise performance during a 40-km cycling time trial. **Methods** 13 male cyclists performed 40-km cycling time trials in 25°C or 35°C in euhydrated (EU25, EU35) and hypohydrated (HYPO25, HYPO35) conditions. Relative humidity was 55±3% whereas air velocity was maintained at 7 m/s. Hypohydration was induced before starting the time trial by 50 min exercise in 30°C. Power output, heart rate, gastrointestinal temperature, skin temperature, thermal sensation and comfort, thirst sensation, and RPE were measured during the time trial. The significance of effects of experimental condition on the dependent variables was determined using two-way ANOVAs (or three-way ANOVAs to determine significance of effects over time). The practical meaningfulness of the performance effect was determined according to Batterham and Hopkins (2006). Results Body mass at the start of the time trial was 1.1% [95% confidence interval (CI): 0.94-1.23%] lower in the HYPO trials than in the EU trials ($F=267$, $P<0.001$). At the finish, hypohydration levels were 2.1% (1.8 – 2.3%) of initial body mass in EU25, 2.7% (2.5 – 2.9%) in EU35, 3.1% (2.9 – 3.3%) in HYPO25 and 3.8% (3.6 – 4.0%) in HYPO35. Heat stress increased finish time by 4:19 min (1:57 – 6:40 min; $F=14.9$, $P=0.002$) whereas a trend was observed for hypohydration (mean difference: 1:18 min (–0.15 – 2.8 min); $F=4.09$, $P=0.06$). The chances that the effects are beneficial/trivial/harmful on the finish time of a 40-km cycling time trial in real-life competition are 0/1/99% for the heat stress intervention and 0/19/81% for the manipulation of hydration status. No interaction effect was found between heat stress and hydration status on finish time ($F=0.10$, $P=0.75$) and pacing pattern ($F=0.72$, $P=0.70$). Heat storage, skin temperature, thermal sensation/comfort and RPE were higher in the hot trials, whereas RPE and thirst sensation were higher in the hypohydration trials. **Discussion** The negative effect of hypohydration on exercise performance during a 40-km cycling time trial is similar in hot and moderate conditions. Probably, the cooling provided by the high air velocity prevented hypohydration to become a performance limiting factor. References Batterham, A. M., & Hopkins, W. G. (2006). EFFECT OF ORAL NITRATE ON TIME-TRIAL PERFORMANCE IN SEVERE HYPOXIA: A RANDOMIZED PLACEBO CONTROLLED TRIAL

Bourdillon, N.1, Fan, J.L.1, Muller, H.2, Meyer, P.2, Kayser, B.1

1 ISSUL Institute of Sport Sciences, University of Lausanne, Switzerland 2 Service of cardiology, HCUg, Geneva, Switzerland

Introduction: Dietary nitrate as salt or in nitrate-rich food like beet root juice is a precursor for nitric oxide (NO). Nitrate may improve aerobic performance, through improved oxidative metabolism and contractile efficiency (Larsen et al. 2011). NO also contributes to adjust pulmonary arterial tone. Aerobic exercise in severe hypoxia (>4500 m) may be limited by hypoxic pulmonary vasoconstriction (HPV). We tested the hypothesis that oral intake of nitrate in hypoxia limits HPV, improves right heart function, and thus allows better maximum time-trial cycling performance. **Methods:** We examined the effect of 3-day oral nitrate supplementation (0.1 mmol/kg/day) vs. placebo (randomized, double blind) in 11 well-trained cyclists (VO_{2max} : 63.3 ± 6.6 mL/kg/min) on a) middle cerebral artery velocity (MCAv), cerebral and muscle oxygenation (O_2Hb & HHb), VO_2 and performance of 15 km time trial cycling (TT) in normoxia and hypoxia (FIO_2 : 0.11, 5000m) and b) right ventricular systolic pressure (RV-RA gradient) and function (TAPSE, S-wave) estimated by echocardiography at rest and during submaximal normoxic/hypoxic exercise (50, 100, 150 Watts). We further measured resting expired NO at rest. Results: Nitrate had no effect on expired NO ($P>0.05$). Hypoxia reduced TT performance by $23 \pm 9\%$, lowered VO_2 , cerebral and muscle O_2Hb and elevated MCAv ($P<0.05$). Nitrate had no effect ($P>0.05$). During steady-state exercise in hypoxia the changes in TAPSE, RV-RA gradient and S-wave were suggestive of increased pulmonary arterial pressure; Nitrate elevated systemic diastolic blood pressure by 7.5 ± 2.1 mmHg across all intensities ($P<0.05$) but had no effect on other parameters. **Discussion:** Contrary to our hypothesis oral nitrate intake in well-trained cyclists did not improve time-trial cycling performance, nor reduce the oxygen cost of exercise, either in normoxia or hypoxia. Since most other studies in the literature reporting improved oxidative metabolism with nitrate where not done with well-trained athletes, we speculate that training status of the subjects may interfere with nitrate effects. **Conclusion:** Our findings contrast with the literature and question the routine use of oral nitrate as a means to improve aerobic exercise performance, in normoxia or hypoxia, in well-trained endurance athletes. **Acknowledgements:** We gratefully acknowledge the financial support from the Swiss Society of Sports Medicine. **Reference:** Larsen FJ, Schiffer TA, Borniquel S, et al. EFFECT OF HEAT-ACCLIMATIZATION ON CYCLING TIME-TRIAL PERFORMANCE AND PACING

Racinais, S., Périard, J.D., Karlsen, A., Nybo, L.

Aspetar, Qatar Orthopaedic and Sports Medicine Hospital

Purpose: To determine the performance and pacing effects of heat-acclimatization on outdoor cycling time-trials (TT, 43.4 km) in the heat. **Methods:** Nine experienced cyclists performed 3 TTs in hot ambient conditions (TTH, ~37°C). The first TTH (TTH-1) in the heat was not

preceded by any heat acclimatization whereas TTH-2 and TTH-3 were performed on the 6th and 14th days of training in the heat. Control TTs in cold condition (TTC, $\sim 8^{\circ}\text{C}$) were obtained pre and post the heat intervention. Results: There were no differences in TTCs pre and post intervention. Irrespective of climate and acclimatization status the cyclists initiated the first 20% of all TTs with similar power output, but during TTH-1 they subsequently had a marked decrease in performance and average power ($256 \pm 18\text{W}$) was lower than TTC ($304 \pm 9\text{W}$, $p < 0.05$). However, this decrement was partly counteracted by 1 week of acclimatization (TTH-2: $280 \pm 19\text{W}$) and further reduced after 2 weeks of acclimatization (TTH-3: $294 \pm 14\text{W}$). The TTH-3 was performed with a similar speed (TTH-3 39.8 ± 2.3 vs. TTC 39.4 ± 2.0 km.h $^{-1}$) and time (TTH-3 66 ± 4 vs. TTC 66 ± 3 min) than TTC. HR was higher during the first 20% of TTH-1 than in the other TTs ($p < 0.05$), but was similar during the remaining TTs. Final rectal temperature was similar in all TTHs ($40.2 \pm 0.4^{\circ}\text{C}$, $p = 1.000$) and higher than in TTC ($38.5 \pm 0.6^{\circ}\text{C}$, $p < 0.001$). Conclusion: Cyclists initiate time-trials in the heat at a similar power output as in cold environments. When not heat-acclimatized, power output dropped to maintain similar physiological responses. This drop is partly recovered after one week and close to normalized after two weeks of heat-acclimatization allowing for a similar performance as the lower air density in a hot environment allows for faster speed at a given power output.

MIDDLE CEREBRAL ARTERY BLOOD VELOCITY IS REDUCED DURING PROLONGED SELF-PACED EXERCISE IN BOTH HOT AND COOL ENVIRONMENTS

Périard, J.D., Racinais, S.

Aspetar – Qatar Orthopaedic and Sports Medicine Hospital

Introduction The development of hyperthermia during prolonged constant-rate exercise in the heat is associated with a reduction in middle cerebral artery mean blood velocity (MCA Vmean). This reduction is attributable to a progressive decreases in cardiac output and arterial blood pressure, but mainly to a hyperventilation-induced reduction in arterial carbon dioxide pressure (PaCO₂) (Nybo & Nielsen, 2001). Interestingly, during self-paced exercise it has been suggested that a similar relative intensity is maintained in hot and cool environments, despite differences in absolute work rate, due to a reduction in maximal aerobic capacity (Périard et al., 2011). The maintenance of a similar relative intensity should result in a comparable ventilatory response, and potentially MCA Vmean. The aim of this study was to determine the extent to which hyperthermia influences cerebral blood flow during prolonged self-paced exercise. **Methods** Nine well-trained cyclists performed a 750 kJ cycling time trial in HOT (35°C) and COOL (20°C) conditions while cerebrovascular, cardiorespiratory and thermoregulatory measurements were conducted. **Results** Time trial completion was longer in HOT ($53.3 \pm 10.7\text{min}$) compared with COOL ($46.0 \pm 7.7\text{min}$; $P < 0.001$). Power output in HOT was lower from 40% of work completed onward ($P < 0.05$). Rectal temperature increased to 39.5 ± 0.7 (HOT) and $38.7 \pm 0.6^{\circ}\text{C}$ (COOL; $P < 0.05$). Skin temperature and skin blood flow were higher throughout the HOT compared with COOL time trial ($P < 0.05$), as was heart rate ($P < 0.05$). Cardiac output was lower after 90% of work completed in the HOT relative to COOL condition ($P < 0.05$). Mean arterial pressure and oxygen uptake were lower from 50% of work completed onward in the HOT condition compared with COOL ($P < 0.05$). Ventilation increased and PaCO₂ decreased similarly between conditions ($P < 0.05$). MCA Vmean increased in the first 10% of both time trials ($P < 0.05$). Although it tended to be higher in COOL ($P = 0.14$), MCA Vmean decreased similarly throughout each condition (HOT: -12.9 ± 8.8 and COOL: $-11.9 \pm 5.2\%$; $P < 0.05$). **Discussion** MCA Vmean is similarly reduced during prolonged self-paced exercise in HOT and COOL environmental conditions. This occurs despite a significantly greater increase in thermal and cardiovascular strain during the time trial in the heat. The reduction appears to be related to the maintenance of a similar relative exercise intensity during the time trials, which results in a comparable hyperventilation-induced decline in PaCO₂. **References** Nybo L & Nielsen B. OP-BN06 Sleep & Motor Performance

SLEEP RELATED IMPROVEMENTS IN MOTOR TASKS: COMPARING FINGER VS. HAND TAPPING

Erlacher, D.1, Schmidt, S.2, Blischke, K.3

1University of Bern, Switzerland, 2Karlsruhe Institute of Technology, Germany, 3Saarland University, Germany

Several studies showed better performance in sequential finger-tapping task after sleep (e.g. Walker, 2002). However, in a series of own studies we could not replicated this finding with other motor tasks, like a continuous visuo-motor Pursuit-Tracking task, or a sub-maximal force impulse (Counter Movement Jump), (Blischke et al., 2008). It seems that positive sleep effects might be specific to the original task, which required participants to tap a five-element sequence with four fingers of one hand repetitively on a standard keyboard. One possible explanation for these equivocal findings might be that finger tapping compared to tracking or jump-ing is a fine motor skill. But, it is difficult to compare the differences between fine vs. gross motor tasks because the tasks vary in several features. To test this notion, we adapted the original finger tapping task to a hand-tapping task and ran three experiments with 24 participants each. First, we replicated the original finger-tapping task used by Walker (2002). For Experiment 2 and 3, participants had to tap the sequence on a smart board, attached on a wall in front of them, using either their non-dominant hand (Exp 2) or both hands (Exp 3). Half of the participant in each study initially learned the skill in the evening and underwent two retention tests; after 12h in the morning and after 24h in the evening (EME). The other half started in the evening (MEM). Results showed significant improvement after sleep only for the finger-tapping task during both retention intervals (EME: $p = .002$; MEM: $p = .027$) 12h retention interval. For both hand-tapping studies sleep yields p-values of $p = .19$ or larger. These findings suggest that sleep-related enhancements of motor learning are not in general linked to tasks, which require sequential movements to different spatial targets. One rationale for these findings might be the different neural activations (e.g. number of involved motor units) when using fingers to perform a fine motor task versus the use of the whole arm and shoulder to perform a gross motor task.

SLEEP BOOSTS CHUNK CONCATENATION IN A COMPLEX GROSS MOTOR TASK

Malangre, A., Blischke, K.

Saarland University

Introduction Sleep-related off-line improvements in newly learned procedural skills are attributed to enhancement consolidation of an internal skill representation. Specifically, such improvements have been related to chunk formation (Kuriyama et al., 2004), enabling participants to initiate all elements comprised in a chunk as a single response, and to shortening overly long response durations typically concomitant with chunk initiation (chunk concatenation; Abrahamse et al., 2013). This notion was tested on data previously having shown sleep-related enhancement consolidation in a gross motor task. **Methods** 24 subjects, randomly assigned to two groups (12 each), initially practiced a sequence of 15 arm reaching movements differing in direction and extent either in the morning or in the evening (100 trials), and were then retested 12 and 24 hrs later (30 trials per test). As sequence elements differed in trajectory length, participants original element durations were normalized in order to compensate for different transport times. Then across all participants and trial blocks, the four longest and the four shortest normalized element durations (nEDs) were identified statistically. On these data, for each time interval (acquisition, retention1, retention2) a 2[nED] x 2[Test] x 2[Group] ANOVA was calculated. In case of significant triple interactions, for each group and that specific time interval a 2[nED] x 2[Test] ANOVA was calculated. **Results** Overall, nEDs resulted in consistent segmentation patterns of response durations, which on average proved to be quite similar in both groups. Also, during acquisition long nEDs decreased significantly more than short ones ($p < .001$, $\eta^2 = .49$) in both groups at the same rate (no triple interaction; $p = .940$). However, during each of the two retention intervals, over-proportional reduction of long nEDs took place only in those subjects who had been afforded sleep, as was revealed by significant triple interactions in the respective 3-way ANOVAs ($p \leq .019$, $\eta^2 \geq .23$). This was corroborated by nED x Test-interactions in the respective 2-way ANOVAs turning out significant again only for those groups that had slept during that specific time interval ($p \leq .026$, $\eta^2 \geq .40$), but not for the respective wake groups ($p \geq .527$). **Discussion** According to these findings sleep, but not wake, appears to support off-line chunk concatenation after initial learning in a complex arm movement sequence, which in turn plays a major part in the general sleep-related improvement of total sequence execution time observed for this task earlier. **References** Abrahamse, EL, Ruitenberg, MFL, de Kleine, E, Verwey, WB (2013). *Front Hum Neurosci*, 7:82. SLEEP AND GROSS-MOTOR SEQUENCE PRODUCTION

Blischke, K.I., Malangrè, A.1

1: Saarland University

Introduction Sleep is known to elicit off-line improvements of newly learned procedural skills (Walker, 2005). In the motor domain, however, this phenomenon has been reported almost exclusively for sequential-finger-tapping skills (Blischke et al., 2008). The aim of the present study was to extend the notion of sleep-related offline-learning to tasks closer to everyday motor skills by employing a sequence of unrestrained reaching-movements with the non-dominant arm following an irregular spatial pattern in the horizontal plane. **Methods** 24 randomly assigned participants (25.5 +/- 3.9 years) practiced a 15-element arm movement sequence for a total of 100 trials either in the evening (EME-group) or in the morning (MEM-group), and were then retested 12 (Retest1) and 24 hrs (Retest2) later (30 trials per test). For each subject, average total execution time (TET) and number of erroneous sequences (ES) were assessed. Performance measures at the end of practice were calculated from the last three acquisition blocks. Also, based on each subject's TET-acquisition data, a power function was calculated to obtain an estimate for that individual's performance during both Retest1 and Retest2, which possibly might have resulted from mere continued practice. **Results** In both groups error rate was low from the beginning on and did not change across tests ($p = .239$). However, TET significantly decreased during acquisition in both groups ($p < .001$, $\eta^2 = .81$), and decreased once more in either group following the respective sleep-filled retention intervals (EME: $F(1, 11) = 35.11$, $p < .001$, $\eta^2 = .76$; MEM: $F(1, 11) = 60.33$, $p < .001$, $\eta^2 = .84$), but remained stable throughout the wake intervals ($p \geq .127$). Also, in each group the observed actual TET proved to be significantly shorter than the predicted TET after sleep (EME[Retest1]: $t(11) = -3.90$, $p = .001$, $d = 1.13$; MEM[Retest2]: $t(11) = -5.01$, $p < .001$, $d = 1.41$), while actual and estimated TET were not dissociated by the wake interval preceding sleep in the MEM-group ($p = .427$). **Discussion** According to our results, even in a gross motor task involving a sequence of coordinated limb movements, sleep following initial learning significantly facilitates performance. This result is also maintained when controlling for possible performance improvements due to just continued practice at retention. This finding successfully extends the notion of sleep-related offline-learning beyond the standard finger-tapping paradigm. **References** Blischke K, Erlacher D, Kresin H, Brueckner S, Malangrè A (2008). *Journal of Human Kinetics*, 20, 23-35. SLEEP TO BOOST LEARNING A FINE-MOTOR SKILL

Hoedlmoser, K.1, Petzka, M.1, Birklbauer, J.2, Gruber, G.3, Benjamins, J.4, Van Someren, E.4,5

1 Laboratory for Sleep, Cognition and Consciousness Research, University of Salzburg, Austria; 2 Department of Sport Science and Kinesiology, University of Salzburg, Austria;

Introduction Relearned fine-motor skills, like typing on a mirrored keyboard, are supposed to require suppression of over-practiced motor skills, like typing on a regular keyboard. Interestingly, performance on the habitual skill often worsens after practicing such an unusual skill. The aim of our study was to investigate whether sleep modifies this interfering effect. **Methods** 25 males (25.44±4.56 years) had to practice touch typing of words with 5 letters length as rapidly and accurately as possible on a regular keyboard and on a mirrored keyboard. The training period for the regular keyboard consisted of four 3min blocks. This regular typing period was followed by 3 times four 3min blocks on the mirrored keyboard. Testing on the regular and mirrored keyboard (each typing condition was tested during two 3min blocks) occurred after 8h of diurnal wakefulness (wake group, n=11) or nocturnal sleep (sleep group, n=14). The sleep group spent two nights with polysomnography (baseline and experimental night) in the sleep laboratory. Fine-motor performance was measured by the number of correctly typed letters per 30s. Sleep was scored visually according to AASM criteria and sleep spindles were detected automatically (The Siesta Group, Vienna, Austria). **Results** A 2x2x2 ANOVA for repeated measures with the within-subject factors TIME (pre vs. post sleep/wakefulness) and CONDITION (regular vs. mirrored typing) and the between subject factor GROUP (sleep vs. wake) revealed a significant interaction between TIMExCONDITIONxGROUP ($F(1,23)=9.959$, $p=0.004$). Subjects in the sleep group showed a significant decrease in regular typing speed after nocturnal sleep whereas mirrored typing did not change. For subjects in the wake group we found a significant deterioration in mirrored typing but no change in regular typing. Furthermore, we could demonstrate a significant correlation ($r(14)=0.644$, $p=0.013$) between fast (13-15Hz) sleep spindle number during sleep stage N2 and overnight gains in mirrored typing. **Discussion** Our results indicate an increased retroactive interference during regular keyboard typing after sleep which may occur because of a

more effective consolidation of the mirrored keyboard typing skill during sleep in comparison to wakefulness. Additionally, we provide evidence that fast sleep spindle number during N2 promotes unlearning of an overlearned automated motor skill and facilitates learning of a replacement skill. Acknowledgments This study was funded by the Austrian Science Fund (P25000). Contact kerstin.hoedlmoser@sbg.ac.at

THE EFFECT OF COMPETITION ON THE SLEEP PATTERNS OF ELITE RUGBY UNION PLAYERS

Shearer, D.A., Jones, M.R., Harrington, B., Kilduff, L.P.

University of South Wales

Rugby union is physically demanding and results in disruptions to physiological and psychological functions following competition (West et al., 2013). Insufficient recovery may compromise an individual's physiological adaptation and/or maintenance. Halson (2008) suggested that good sleep practice in elite athletes might be the most efficacious recovery strategy. However, to date no published research has assessed sleep patterns of rugby union players following match-play. The aim of the present study was to examine sleep patterns of professional rugby union players, prior and post-match-play, to assess the influence of competition on sleep patterns. 28 male rugby union players (24.4 ± 2.9 years, 103.9 ± 12.2 kg) competed in 1 of 4 competitive home matches with similar kick-off times and training schedules prior and post-match. Players were monitored continuously using an Actiwatch® from two days prior to the match until 3 days post-match. Sleep behaviour variables measured included; time to bed, time in bed, sleep latency, time asleep, time awake, sleep efficiency, actual sleep percentage, percentage of time moving, and get up time, as previously described by Leeder et al. (2012). ANOVA showed significant differences for time to bed ($F = 26.425$, $\eta^2 = 0.495$, $p < 0.001$), get up time ($F = 21.175$, $\eta^2 = 0.440$, $p < 0.001$), time spent in bed ($F = 10.669$, $\eta^2 = 0.283$, $p < 0.001$), time asleep ($F = 8.752$, $\eta^2 = 0.245$, $p < 0.001$), and percentage of time moving ($F = 4.602$, $\eta^2 = 0.146$, $p < 0.05$). Post-hocs revealed a significant increase for time in bed the night before the match ($p < 0.01$; 95 % CI = 0:10 – 1:28 hrs; 9.7 ± 13.5 %) compared with the reference night sleep. Furthermore, time asleep significantly decreased post-match ($p < 0.05$; 95 % CI = -0:03 – -1:59 hrs; -19.5 ± 19.8 %) compared to two nights pre-match. Results also suggested sleep efficiency reduced post-match compared to two nights pre-match, however no significant changes were observed ($p > 0.05$). No significant changes in sleep latency, time awake, actual sleep percentage or percentage of time moving were observed on any night compared to the reference night sleep. The results demonstrate that sleep is deprived post-match which may have detrimental effects on the recovery process. The large standard deviations observed suggest a case-by-case consideration is needed for physiological and psychological monitoring. Halson SL. SLEEP-RELATED CONSOLIDATION OF CEREBELLAR-DEPENDENT MOTOR LEARNING

Onuki, Y.

Netherlands Institute for Neuroscience

It is well known that sleep improves the cognitive and motor performance after encoding through offline consolidation. It is, however, not known whether cerebellar-dependent motor learning, e.g. learning of prediction timing, is also facilitated by sleep. We created a novel task for prediction timing that reliably activated the cerebellum, and tested this task for sleep-dependent consolidation effects in a nap paradigm. We showed that subjects who slept after initial training improved above and beyond the pre-sleep level, whereas subjects who stayed awake remained at initial levels. The quality and duration of sleep correlated with the performance improvement. We conclude that cerebellar-dependent learning is also consolidated during, and facilitated after, sleep.

OP-PM19 Exercise with Blood Flow Restrictions

BLOOD FLOW-RESTRICTED VIBRATION EXERCISE INCREASES SATELLITE CELL NUMBERS IN YOUNG MEN

Toigo, M.1,2, Aguayo, D.1, Mueller, S.M.1, Auer, M.3, Jung, H.H.3, Boutellier, U.1, Flück, M.2

1: ETH (Zurich, Switzerland); 2: Balgrist (Zurich, Switzerland); 3: USZ (Zurich, Switzerland)

Introduction Myofiber hypertrophy is facilitated by myonuclear addition following skeletal muscle stem (satellite) cell proliferation, differentiation, and fusion. Thus, activation of satellite cells (SC) following exercise sets the stage for robust myofiber hypertrophy. For young healthy active individuals there is no convincing evidence that long-term vibration exercise (VIB) can effectively increase muscle mass or muscle fiber cross-sectional areas. Thus, we hypothesized that VIB is ineffective in stimulating SCs in healthy young active men. Given that VIB leads to muscle activation levels comparable to those during low-intensity exercise and that low-intensity exercise performed under blood flow-restricted (BFR) conditions can induce hypertrophy, we further hypothesized that BFR VIB would increase SC numbers. **Methods** Twenty-five young healthy moderately trained men were assigned to one of three training groups (blood flow-restriction only [BFR; $n = 8$], VIB only [$n = 8$], and VIB under BFR conditions [BFRVIB; $n = 9$]). Vastus lateralis muscle biopsies were obtained at baseline, and 24 h after one exercise bout, which consisted of three 4-min BFR, VIB or BFRVIB intervals, interspersed with 3-min rest intervals without VIB and BFR. Muscle fiber type-specific SC content and the number of differentiating SCs were determined immunohistochemically using antibodies against Pax7 and Myogenin, respectively. **Results** The mean number of SCs per muscle fiber increased (+99%, $P = 0.002$) after a bout of BFRVIB, but remained unchanged after BFR and VIB. For BFRVIB (but not BFR or VIB), the mean number of SCs per Myosin Heavy Chains (MyHC) type 1 and 2 fibers increased by 93% ($P = 0.016$) and 130%, ($P = 0.002$), respectively. The number of differentiating SCs per muscle fiber increased for BFRVIB only (+139%, $P < 0.000$), with fiber type-specific increases of 138% ($P = 0.001$) and 162% ($P = 0.002$) for MyHC-1 and MyHC-2, respectively. Similar results were obtained when SCs were expressed as a proportion of all sublamellar myonuclei. **Conclusion** In young moderately trained men, a single bout of BFRVIB significantly increased muscle fiber SC content and differentiation in

MyHC-1 and MyHC-2 muscle fibers. In contrast, both BFR and VIB alone were ineffective in increasing SC numbers. Contact mtoigo@research.balgrist.ch

HYPERTROPHY SIGNALING, MUSCLE GROWTH AND INCREASES IN STRENGTH AFTER BLOOD FLOW RESTRICTED RESISTANCE EXERCISE

Bjørnsen, T., Dalen, T., Løvstad, A., Paulsen, G., Wernbom, M., Flesche, A., Berntsen, S., Uglestad, I., Østgaard, H., Raastad, T.

Norwegian School of Sport Sciences/University of Agder

INTRODUCTION: High frequency blood flow restricted resistance exercise (BFRRE) has been shown to induce rapid muscle growth accompanied by increased numbers of satellite cells and myonuclei (1). However, the intracellular signaling behind the hypertrophic response is still largely unknown and notably, the hypertrophy plateaued after the first week of high frequency BFRRE (1). Therefore, the present study aimed to investigate the anabolic signaling pathways, muscle growth and maximal strength during and after two blocks of high frequency BFRRE interspersed by 10 days of rest. **METHODS:** Ten young men and women (22-28 yrs) completed two blocks of seven BFRRE sessions in five days, separated by 10-days of rest. The exercise protocol consisted of four sets with unilateral knee-extension to voluntary failure (30 s rest between sets) at 20 % of one repetition maximum (1RM). Both legs were exercised, and the pressure cuff was inflated to 90-100 mmHg. Seven biopsies were obtained from m. vastus lateralis; "acute" biopsies were collected 1 h after the first bout of each training week. Phosphorylation levels of eukaryotic translation elongation factor 2 (eEF2), p70S6 kinase (p70) and p38 mitogen-activated protein kinases (p38) were measured using western blotting. Muscle growth was assessed as changes in muscle fiber area (MFA) using immunohistochemistry, as well as thickness of m. vastus lateralis and cross sectional area (CSA) of m. rectus femoris applying ultrasound imaging. Strength was measured as 1RM in knee extension. **RESULTS:** Phosphorylation (p-) levels of p70 and p38 were significantly higher in the acute biopsies from the first training week compared to baseline ($p=0.02$ and $p=0.04$, respectively). There was a tendency to higher levels of p-p70 and p-p38 in the acute biopsies of the second training week ($p=0.07$ and $p=0.10$, respectively). No changes were observed in p-eEF2. CSA of m. rectus femoris and muscle thickness of m. vastus lateralis were significantly greater 10 days after BFRRE (mean \pm SD, $7\pm4\%$; $p<0.001$ and $6\pm3\%$; $p<0.001$, respectively). The MFA of type 1 and 2 fibers showed non-significant trends towards increases; $19\pm23\%$ ($p=0.06$) and $15\pm27\%$ ($p=0.20$), respectively. 1RM in knee extension increased with $6\pm7\%$ ($p=0.03$). **DISCUSSION:** Two blocks of high frequency BFRRE, interspersed by 10 days of rest, produced gains in muscle thickness, CSA and maximal strength. Furthermore, BFRRE activates intracellular signaling pathways associated with training-induced muscle hypertrophy, and the trained muscle seems to retain its responsiveness to the training stimulus when 10 days of rest intersperse high frequency training blocks. **REFERENCES** 1. IMPACT OF ISCHEMIC PRECONDITIONING ON SYMPATHETIC VASOCONSTRICTION AT REST AND DURING EXERCISE IN HUMANS

Horiuchi, M., Endo, J., Thijssen, D.H.

Yamanashi Institute of Environmental Sciences, Liverpool John Moores University

Introduction Redistribution of blood during exercise is essential for optimal exercise performance. Accumulation of metabolites in exercising skeletal muscle blunts the sympathetically driven vasoconstriction that occurs in skeletal muscles, a phenomenon termed functional sympatholysis. K-ATP channels (1) potentially contribute to this response. Repeated periods of ischemia followed by reperfusion, named 'ischemic preconditioning (IPC)', improves exercise performance and is suggested to alter ATP-sensitive potassium channels. Therefore, this study examined whether IPC alters sympathetic vasoconstriction in healthy men, which could potentially contribute to explain the effects of IPC on exercise. **Methods** Fifteen healthy males participated in this study. To assess functional sympatholysis, we continuously examined oxygenated hemoglobin (HbO₂) of the flexor digitorum superficialis muscles. Cold pressor test (CPT) was used to increase sympathetic nerve activity at rest, causing a decline in HbO₂. This protocol is repeated during a 6-min handgrip (HG) exercise at 10% and 25 % MVC, with CPT repeated during exercise. The inability of CPT to decline HbO₂ during HG exercise is indicative for the presence of function sympatholysis. This protocol was preceded by IPC or a control condition (CON). IPC consisted of 4 repetitions of inflating an upper to 220mmHg for 5 minutes, followed by deflation of 5 minutes. The control condition (CON) used a similar set-up, but used a cuff pressure of 20mmHg. **Results** CPT significantly increased mean arterial pressure in all conditions with no difference between CON and IPC. At rest, the reduction of HbO₂ to the CPT was significantly greater when preceded by IPC than CON (-11.0 ± 1.0 vs. $-13.8\pm1.2\%$; CON vs IPC, $p=0.006$, means \pm S.E.M.). Whilst we found no impact of IPC on HbO₂ responses to the CPT at 10% MVC (-8.3 ± 0.4 vs. $-8.8\pm1.5\%$; CON vs. IPC, $p=0.593$), IPC induced a significantly larger increase in HbO₂ to the CPT at 25% MVC compared to CON ($2.0\pm0.4\%$ vs. $4.2\pm0.6\%$; CON vs IPC, $p=0.027$). **Discussion** First, the results showed a greater vasoconstriction under resting conditions during the IPC-trial. This may relate to a lower a priori sympathetic activity and/or largest vascular responsiveness to an increase in sympathetic activity through IPC. At least, a stronger constriction before exercise may eventually contribute to the availability of a larger blood volume for the exercising limb. Second, we observed that IPC was associated with an attenuated vasoconstriction to CPT during moderate intensity exercise. This suggests that IPC resulted in a larger vasodilation, i.e. functional sympatholysis, in the active muscle beds. **Conclusion** Collectively, these results indicated that IPC may affect sympathetically-mediated vasoconstriction at rest and during moderate exercise, but not during light exercise. These findings suggest that IPC may contribute to a better redistribution of blood during moderate-intensity exercise. **Reference** 1.Keller et al. (2004). J Physiol 561, 273-282.

EXERCISE AT HIGH ALTITUDE IS ASSOCIATED WITH HIGHER DEGREE OF SLEEP DISCORDED BREATHING DUE TO HYPOXIA

Fernandez Tellez, H.1,2, Piacentini, M.F.3, Mairesse, O.1,2, Macdonald Nethercott, E.4,5, Neyt, X.2, Meeusen, R.1, Patten, N.1,2

1: VUB (Brussels, Belgium), 2: VIPER Research Unit RMA (Brussels, Belgium), 3: University of Rome Foro Italico (Rome, Italy) 4: PA Hospital NHS Trust (Harlow, United Kingdom) 5: IPEV (France)

Introduction At altitudes above 2.500m, nocturnal ventilation in healthy subjects commonly shows an oscillatory behavior with alternating periods of hyperventilation followed by apneas or hypopneas. This breathing pattern is called periodic breathing (PB). It has been shown to be associated with decreased daytime alertness and performance. Considering the use of the "sleep high train low" approach to

promote exercise tolerance in athletes, the influence of this chronic nocturnal exposure to hypoxia warrants additional investigation to ascertain there are no detrimental effects on recovery. On the other hand, considering the sleep-promoting effect of exercise, one could expect the effects of altitude related hypoxia to be lessened in regular exercise. To investigate the relationship between exercise and sleep during a chronic exposure to altitude, exercise and nocturnal PB were monitored at a constant equivalent altitude of 3659m over the course of a year. **Methods** The investigation took place at the Concordia Antarctic station, in the framework of the European Space Agency's Life Science campaign. 14 healthy male participants were monitored using a wireless polysomnography (BioRadio, Cleveland Inc.). Assessments of aerobic fitness (maximum aerobic uptake) and sleep quality (full polysomnography) were conducted seven times, through the whole campaign with a periodicity of six weeks and one habituation night. All recordings were analysed by a professional sleep technician. Subjects completed volitional physical activity (self-report) throughout the whole confinement period. **Results** PB was present at a clinically significant severe level during the whole campaign (Apnea Hypopnea Index=65.4 \pm 14.55). Over time, PB does not seem to show a clear trend, with subjects having both episodes of increasing and decreasing. Mean apnoea-hypopnea index scores were positively correlated to both mean exercise time ($R^2=0.4857$; $p=0.008$) and the coefficient of variation in mean night pulsed oxygen saturations (SpO_2 ; $R^2=0.3062$; $p=0.05$). **Discussion** Exposure to hypobaric or normobaric hypoxia elevates chemosensitivity, leading to PB during sleep. Exercise impacts gas exchange and may also alter chemosensitivity; however, this is the first time that interactions between sleep, exercise and hypoxia have been examined, especially over extended periods of hypobaric hypoxia in subjects used to sea level. Our data indicate exercise (i.e. physical activity) per se affects night SpO_2 concentrations, and AHI index acutely. This relationship does not improve after one year of continuous exposure. The implications for sleep quality and recovery should be taken into account in scheduling nocturnal exposure to hypobaric hypoxia in training regimens. **References** West JB. EFFECTS OF RUNNING EXERCISE COMBINED WITH BLOOD FLOW RESTRICTION ON PHYSICAL RESPONSE AND MUSCULAR FITNESS IN ATHLETES

Yun Tsung, C.

National Taiwan Normal University

Introduction Muscular fitness (strength and endurance) not only improves sports performance, but also reduces the risk of injury. Recent studies show that low-intensity resistance training (LIRT) combined with blood flow restriction (BFRE) leads to an increase in the metabolic stress. It is well known that LIRT+BFRE improves the muscle adaptations such as strength and endurance gains. However, running exercise combined with BFRE on acute physiological responses and muscle performance is still unknown. Thus, the purpose of the present study was to investigate the effect of running exercise+BFRE on blood lactate (BLA), muscle tissue O_2 saturation (MTOS), strength and endurance performance in athletes. **Methods** 12 male athletes were recruited to participate in this study. All participants received two treatments: (1) Running exercise with BFRE (RB). (2) Running exercise without BFRE (R). Following a 5 min rest after the treatment, strength and endurance were determined using a Biodex System. Ratings of perceived exertion (RPE) were recorded (pre-ex, post-ex, 5 min post-ex, post-test) using the Borg RPE Scale. BLA (pre-ex, 3 min post-ex, 3 min post-test) and MTOS (from 5 min pre-ex to 5 min post-ex) were determined using lactate meter and near-infrared spectroscopy. A one-way ANOVA with repeated measures was performed to examine the muscular fitness differences between the treatments. A two-way ANOVA with repeated measures was used to evaluate the treatment effects for the others variables. **Results** Following the treatment, isokinetic knee flexion strength (60°/s) was greater in the RB treatment than in the R treatment. There were no differences between the two treatments for isokinetic knee extension strength (60°/s, 180°/s) and knee flexion strength (180°/s). With respect to isokinetic endurance, there was no difference between RB exercise and R exercise. RPE was higher in the RB treatment than in the R treatment at post-ex. BLA was higher in the RB treatment than in the R treatment at 3 min post-ex. MTOS was lower in the RB treatment than in the R treatment during-ex and 5 min post-ex. **Discussion** In the present study showed that RB treatment has no effect on isokinetic knee extension strength (60°/s, 180°/s), knee flexion strength (180°/s) and endurance performance, because a single bout of RB treatment did not cause any change in the muscle adaptations. Previous studies suggest that LIRT+BFRE result in muscular ischemic conditions, thus increase in motor unit recruitment, such as type II fibers (Wernbom et al., 2009; Yasuda et al., 2009). Increasing in motor unit recruitment was the possible explanation for improvement on isokinetic (60°/s) knee flexion strength after the RB treatment. The RB treatment increased the RPE and muscular metabolic stress were similar to previous studies. Given the muscular fitness improvements associated with resistance training, a RB treatment may be an effective training program for promoting muscle adaptations in practical applications. MAINTAINING A GOOD VENTILATORY EFFICIENCY IN THE TRANSITION BETWEEN NORMOXIA AND HYPOXIA AT REST PREDICTS A BETTER OXYGENATION DURING EXERCISE IN HYPOXIA.

Papi Renzetti, G., Giardini, G., Mandolesi, G., Cogo, A.

University of Ferrara

INTRODUCTION Exposure to acute H induces a sudden increase in ventilation (VE) to maintain satisfactory oxygen saturation (SaO_2). It has been shown that a ventilatory pattern characterized by low respiratory rate (RR) and high tidal volume (VT) for the same amount of VE is associated to better SaO_2 (1, 2) and subjects adopting slower and deeper breathing maintain a better SaO_2 at altitude due to a better ventilatory efficiency (IE). IE is the ventilation (VE) required to achieve a given level of SaO_2 . The relative changes in VE and % SaO_2 is the index of ventilatory efficiency (IE index = SaO_2/VE corrected by height). **AIM** To assess the influence of different breathing patterns on SaO_2 during H exposure. **METHOD** We tested the ventilatory adaptation and SaO_2 in 36 mountain guides (M age 29-57) at rest in N, and at rest and during exercise in H simulating 4500m (Altitrainer, Simtec, CH; Quark, COSMED, I). For each frame we calculated the mean value of VE, VT, RR and the IE. Data during exercise refer to the same work intensity. **RESULTS** As expected, VE increased and SaO_2 decreased in H vs. N, changing further during exercise. According to the difference in IE between N and H at rest ($\Delta SaO_2/VE$) we divided the subjects into 4 groups: High Efficiency (+1.36), Moderate (-1.16), Mild (-3) and Low (-5.4). In group High, the SpO_2 during exercise is higher than in group Low (76.8 vs. 64.66 $p=0.027$) with a significantly greater increase in VT as compared to RR for the same increase in VE. A significant correlation is found between the $\Delta SpO_2/VE$ at rest and the oxygen desaturation during exercise in H ($r=0.46$ $p=0.005$). **CONCLUSION** We conclude that subjects with a better IE at rest in H, spontaneously adopting slower and deeper ventilation, have the capability to maintain a better oxygenation during exercise in H. 1) Bernardi L et al Breathing patterns and cardiovascular autonomic modulation during hypoxia induced by simulated altitude. *J Hypertens* (2001)19:947-958 2) Bernardi L et al Reduced hypoxic ventilatory response with

OP-SH05 Sociology & Gender

THE NATIONAL PROJECT FOR WOMEN AND SPORT - BARRIERS TO ACCESS FOR WOMEN TO DECISION-MAKING POSITIONS IN ISRAELI SPORT

Betzer Tayar, M.

Wingate

The study, analyses discourses about the roles and barriers to access for women to decision-making positions in Israeli sport organizations and to identify and evaluate some of the strategies and tactics adopted to overcome these barriers. In particular it focuses on the exploration of discourses of masculinity and femininity that underpin the Israeli society (such as the discourse of militarization organisations) and the institutions of sport within it (for example, the unique political affiliation system in the sporting arena). In order to understand and explore the social construction of these gendered discourses, a significant policy initiative toward gender equity in sport was explored through the perceptions and discourses of key actors. This includes the creation of the National Project for Women and Sport (NPWS). Critical Discourse Analysis was employed as a methodological approach to analyse how female and male interviewees, all considered to be 'insiders' within their organisations, explained the process of the construction of gendered roles and barriers. Included in the interview data was also the auto-ethnographical accounts of the author, who was a primary actor in the process of developing policy in the case study initiative addressed. Dominant discourses of femininity (such as the discourse of sisterhood, assertiveness, and of the processes of mentoring), and of masculinity (and how these promote uniformity) were identified as mechanisms for reproducing the gendered reality of sport leadership in Israel. The implication of a critical theoretical approach is that it should be emancipatory in its ambitions and impact, and the study is intended to contribute to enhancing the understanding of how discourse not only reflects but also creates barriers and opportunities so that the construction of such barriers can be challenged in progressive policy discourses.

USING THE STRENGTH BASED APPROACH IN THE DESERT: EXPLORING POSSIBILITIES FOR YOUNG QATARI WOMEN'S PARTICIPATION IN PHYSICAL ACTIVITY

Knez, K., Macdonald, D., lisahunter

ASPETAR-Qatar Orthopaedic and Sports Medicine Hospital

Recent years have seen Qatar's propulsion into the international economic, political and sporting communities, facilitated largely through the development and expansion of Qatar's immense natural gas and oil reserves. This has resulted in rapid urban and economic development. While these shifts have led to economic prosperity for many Qatar families, it has also been suggested as the catalyst for rapid increases in obesity, diabetes and inactivity among Qatari nationals. The current context has resulted in questions being asked by government and health officials about how to best address these 'problems'. This research is grounded in a strength-based approach to understanding young Qatari women's participation in physical activity. We argue that shifting our focus from understanding Qatari women's participation through a deficit framework to one which highlights what is possible (instead of what is not) provides a different story filled with potential and opportunity. Drawing on a social constructivist framework, this project included 10 young Qatari women, aged 18-27, who regularly participated in physical activity. Semi structured interviews were conducted with each individual participant over a two hour period. Interviews were in English, and transcribed verbatim by the interviewer. The participants selected their own pseudonyms and member checks were employed. The results of this project contrast sharply with commonly held stereotypes and assumptions about Qatari women who can be and are physically active. Whilst participation methods varied, common themes of negotiating family and cultural expectations were evident. Understanding these points of negotiation and possibilities provide a powerful and culturally relevant narrative, which looks beyond stereotypical assumptions of oppression and indulgence. Such narratives are important if we are serious in our attempts to move beyond binary viewpoints of 'east' versus 'west'.

THE IMPACT OF AGE AND GENDER ON THE SELF-IDENTITY AND ATHLETIC IDENTITY OF ELITE ATHLETES

Martin, L.A.1, Fogarty, G.J.2

1: USC (Sunshine Coast, Australia, 2: USQ (Toowoomba, Australia)

Introduction The possession of a strong and exclusive athletic identity has been suggested as playing a role in hindering the development of an individual's multidimensional self-identity. This two-part study aimed to investigate the self-identity characteristics possessed by Australian elite athletes, including athletic identity, and the impact that age and gender have upon the endorsement of multiple dimensions of their self-identity. Within the general population, clear gender differences have been found in relation to self-concept. **Methods** The SDQ III-summary items (Marsh & O'Neill, 1984) and the AIMS (Brewer et al., 1993) were administered to measure self-identity characteristics and athletic identity respectively. In the first part of the study, a total of 917 athletes (476 females) on sporting scholarships linked with the Australian Institute of Sport were surveyed in relation to these constructs. The second part of the study employed cross-validation techniques to confirm the findings of part one using a subsequent data set (N = 310; 172 females). **Results** Results indicated that both samples endorsed the same self-identity characteristics as being accurate representations of who they feel that they are as people, as well as those characteristics that they consider to be important to their self-view. Correlation analyses between AIMS and SDQ III scores indicated significant positive relationships between athletic identity and the importance placed upon sporting ability for both samples. However, no relationships were found between the AIMS and other SDQ III items. Athletic identity levels were shown to decrease significantly with age. Male athletes in both studies were shown to view themselves as having more physical ability, as being more attractive, and more emotionally stable than their female counterparts. **Discussion** Athletes with high levels of athletic identity tend

to place a high value on sporting ability, otherwise elite athletes tend to exhibit a common identity profile that operated largely independently of the extent to which they identified with the athlete role. Results suggest that age but not gender plays a role in determining athletic identity levels in the Australian elite athlete population. In relation to self-identity, gender differences in self-concept found within the general population were found to generalise across to elite athlete populations. References Brewer, B. COMPARISON OF SPORTS ACTIVITY OF WOMEN AND MEN UNDER CONSIDERATION OF PERSONALITY TRAITS

Semmler Ludwig, R., Paetz, F.

Clausthal University of Technology

Introduction Investigations of sports activities are important for organizing attractive sports programs, e.g., at universities and fitness centers. Therefore, the present study focuses on the discriminant potential of sportsmen's personality when choosing a specific kind of sport. In an empirical study we analyzed students' favored kinds of sports with regard to their personality and additionally considered gender. **Methods** Over 100 students answered a questionnaire by Semmler-Ludwig concerning their sports activities and personality. To describe students' personality, the well-established Big Five approach was used, which determines personality considering five major dimensions: Extraversion, Neuroticism, Agreeableness, Conscientiousness and Openness (e.g., see McCrae & John 1992). The subjects self-reflectively evaluated these factors (Saum-Aldehoff 2007). The results of both parts of the questionnaire (sports activities and personality) revealed correlations and therefore interesting results concerning study's purpose. **Results** The results indicated gender differences regarding the most preferred kinds of sports; while female students prefer fitness training, male students mostly like sport games. Furthermore, we detected differences in students' personality across different sports activities: Adventure sportsmen reached the highest score of the factor Openness and the lowest score of the factor Neuroticism. They showed significant differences compared to sportsmen who favored fitness training ($p=0.007$ for Openness, $p=0.017$ for Neuroticism). Openness of adventure sportsmen and dancers tends to differ ($p=0.064$), the same also holds for nature sportsmen like climbers etc. and swimmers/triathletes/runners ($p=0.056$). Differences in Neuroticism between nature sportsmen and sports fighters are also significant ($p=0.008$). Furthermore, relations between gender and personality are visible; e.g., male students revealed lower scores for Neuroticism ($p=0.021$). **Discussion** The given study shows interesting relations between students' gender, personality and sports activities. Students with the highest score in Openness especially love adventure sport. Swimmers, triathletes, runners, dancers and some others self-reflected themselves less open to experience than, e.g., climbers and wild water canoeists. The sports fighters had the biggest score in Neuroticism, nature sportsmen the lowest, fitness fans, dancers and sports players were between them. Furthermore, the investigated sportsmen were relatively relaxed and male students were less neurotic than the involved women. References McCrae RR, John OP. (1992). COMPARISON OF ARM, UPPER BODY AND WHOLE BODY DOUBLE POLING IN FEMALE AND MALE CROSS-COUNTRY SKIERS

Hegge, A., Bucher, E., Ettema, G., Sandbakk, Ø.

Norwegian University of Science and Technology

Introduction The double poling technique in cross-country skiing is a whole body movement where the arms, trunk and legs interact in producing power. When these body segments work together an increase in power output is expected compared to their isolated movements. Since previous findings show that gender differences increase with more contribution from poling, further examination regarding the different segmental contributions during double poling is required. Therefore, we examined the aerobic and anaerobic capacities and movement efficiency during isolated arm (AP), upper body (UP; arm+trunk) and whole body (WP) double poling and the associated gender effects. **Methods** Ten female and ten male elite cross-country skiers, matched by performance (FIS points 99 ± 26 and 99 ± 21), performed three submaximal stages, a 3-min and a 30-s max test on a modified Concept2 SkiErg in the three double poling modes. The regression lines of oxygen uptake vs. external power during the submaximal stages determined efficiency, and the average power output during the 3-min and 30-s tests determined performance. Body composition was measured with DXA scan. **Results** Women had a lower absolute oxygen uptake and produced less power than men (all $P<0.05$), but the oxygen uptake-power regression line did not differ between poling modes or gender. In the 3-min test UP power was more than 50% higher compared to AP, whereas WP was ~35% higher than UP (all $P<0.05$). The corresponding values for the 30-s test were ~40% from AP to UP, and 33 (women) and 18% (men) from UP to WP with a significant gender difference in the last case (all $P<0.05$). Women had a 51, 49 and 47% lower power output during the 3-min test and 53, 54 and 48% lower during the 30-s test compared to men in AP, UP and WP respectively, and these gender differences decreased to 22, 30, 29% (3-min) and 25, 37 and 30% (30-s) when normalized for the lean mass involved in each mode (all $P<0.05$). VO_{2peak} in the 3-min test was ~32% higher for UP than AP, and 29 (women) and 18% (men) higher for WP than UP with a significant gender difference in the last case (all $P<0.05$). **Discussion** The current study demonstrated large increases in power when the arms, trunk and legs work together compared to more isolated movements, with a particular importance placed on the role of the trunk in double poling. This finding also relates to the gender differences, indicating that the aerobic and anaerobic capacities of arms and trunk play crucial roles in explaining the gender gap in cross-country skiing. However, the ability to produce power for a given metabolic cost seems independent of exercise mode and gender. To extend upon these findings, the specific contributions from the upper and lower body joints in whole body double poling would be of high interest.

EFFECTS OF LIVING AREA AND SPORTS CLUB PARTICIPATION ON PHYSICAL FITNESS DEVELOPMENT IN CHILDREN

Muehlbauer, T.1, Golle, K.1, Hoffmann, M.1, Wick, D.2, Granacher, U.1

1: University of Potsdam (Potsdam, Germany), 2: University of Applied Science in Sport and Management (Potsdam, Germany)

Introduction Cross-sectional studies detected associations between physical fitness, living area (Chillon et al., 2011), and sports participation (Ara et al., 2004) in children. Yet, their scientific value is limited because the identification of cause-and-effect relationships is not possible. In a longitudinal approach, we examined the effects of living area and sports club participation on physical fitness development in primary school children from grade three to six. **Methods** One-hundred and seventy-two children (age: 9-12 years; sex: 69 girls, 103

boys) from 24 public primary schools were tested for their physical fitness using 50-m sprint, triple hop, 1-kg ball push, endurance run, stand-and-reach, and star coordination run. Living area (i.e., urban: cities > 10,000 inhabitants, rural: cities/villages ≤ 10,000 inhabitants) and sports club participation (Yes or No option) were assessed using parental questionnaire. Physical fitness parameters were analysed in adjusted analysis of variance (ANOVA) with repeated measures on grade. Additionally, effect sizes (ES) were determined. Further, odds ratios (OR) and 95% confidence interval (CI) were calculated using the chi-square test to determine associations between living area and sports club participation. Results The correlative analyses regarding living area and sports club participation revealed that living in rural areas is more likely associated with not participating in a sports club (OR = 2.7, 95% CI = 0.87-8.33) compared to living in urban areas. Furthermore, urban compared to rural children showed significantly better performance development in endurance run ($p = 0.07$, $ES = 0.12$), 1-kg ball push ($p = 0.009$, $ES = 0.16$), and triple hop ($p < 0.001$, $ES = 0.22$). Further, significantly better performance development were found for endurance run ($p = 0.08$, $ES = 0.19$) and triple hop ($p = 0.029$, $ES = 0.23$) for children participating in sports clubs compared to their non-participating peers. Discussion Findings from the present study indicate that the development of physical fitness is affected by living area and sports club participation. More specifically, children living in urban areas and children participating in sports clubs were fitter and increases in fitness were larger over time than in their counterparts. As a consequence, sports club programs should especially focus on appealing arrangements to increase physical fitness in children living in rural areas. OP-PM20 Exercise Therapy

EFFECTS OF A SIX-MONTH INTRADIALYTIC PHYSICAL ACTIVITY PROGRAM AND ADEQUATE NUTRITIONAL SUPPORT ON PROTEIN-ENERGY WASTING, PHYSICAL FUNCTIONING AND QUALITY OF LIFE IN CHRONIC HEMODIALYSIS PATIENTS

Magnard, J.1, Deschamps, T.1, Paris, A.2, Hristea, D.2

UNIVERSITY OF NANTES

1: Lab « Motricité, Interactions, Performance » (E.A 4334), University of Nantes (France), 2: Dialysis Unit, ECHO Nantes Dialysis Association (France). Introduction Protein-energy wasting (PEW), common in hemodialysis (HD) patients, is a powerful predictor of co-morbidities and mortality. In order to improve anabolic effects of classic nutritional support, some studies suggest that the combined practice of physical exercise can have a potential to reverse PEW (Pupim et al., 2004). Our purpose was to investigate the effect of intradialytic pedaling exercise combined to adequate nutritional support on PEW, functional capacities and quality of life (QOL) of HD patients. Methods Twenty-one HD patients with criteria for PEW (70.9 ± 13.5 years) were randomly allocated into nutrition and exercise (GN+Ex) or nutrition control (GN) group. In both groups, the prescription of nutritional supplements was adapted to reach goals set by the European Guidelines for Nutrition. Specifically, the GN+Ex performed a 6-months progressive submaximal individualized cycling program during the three weekly HD sessions. The primary outcome was to compare the number of patients having reached remission of PEW in both groups over 6 months. Secondary outcomes were the effects of exercise on functional performances (six-minute walk test -6MWT-, quiet standing postural control, maximal quadriceps strength), body composition (bioimpedance spectroscopy) and self-reported health-related QOL (SF36 score). Results There was no significant difference in the number of patients having reached remission of PEW between groups, and in body composition or maximal quadriceps strength. However, there were significant increases in the 6MWT (278.7 ± 144.7 vs. 339.5 ± 126.4 meters; $p < 0.001$) and the QOL (SF36 score: 50.7 ± 19.7 vs. 77.4 ± 12.1 %; $p < 0.001$) for the GN+Ex while these parameters declined in GN. The postural control worsened over time in GN and remained stable in GN+Ex ($p < 0.01$). Discussion Even if no effect was observed in the treatment of PEW, the current results suggest a positive influence of intradialytic exercise on functional performances. Indeed, the increase in walking autonomy and the stabilization of postural sway are of special interest for fundamental and clinical purposes. An improvement of functional capacities of these patients can be assumed. Moreover, the improvement of self-assessed QOL, as well as the good acceptance of exercise intervention by patients and nursing staff, encourage the setting of further larger-scale studies and clinical routine. NEW METHODS OF FUNCTIONAL EVALUATION OF PATIENTS WITH METABOLIC MYOPATHIES. THE EFFECTS OF EXERCISE TRAINING.

Porcelli, S., Marzorati, M., Bellistri, G., Morandi, L., Grassi, B.

National Research Council

INTRODUCTION Mitochondrial myopathies (MM) and myophosphorylase deficiency (McArdle's disease, McA) are genetic disorders characterized by impairments of energy metabolism which translate into reduced exercise tolerance. At present the therapeutic interventions available for these patients are very limited. Evidence has been provided that aerobic training should be considered as a treatment for these conditions. Aim of the present study was to utilize non-invasive methods of functional evaluation, specifically aimed at oxidative metabolism at the skeletal muscle level, in order to evaluate the effects of an aerobic exercise training. METHODS 7 MM and 8 McA patients underwent 12 weeks of exercise training (4v/weeks) at home at an heart rate (HR) corresponding to about 65-70% of the maximal HR. Oxygen uptake ($\dot{V}O_2$) and skeletal muscle (vastus lateralis) fractional O_2 extraction (by NIRS) were assessed during incremental and moderate and high-intensity constant-load exercises. All tests were carried out on a cycle ergometer before (BEFORE) and at the end (AFTER) of the training period. Before and about 2 months after the termination of the training period average daily energy expenditure (EE) of the patients were determined (SenseWear Armband). RESULTS $\dot{V}O_{2peak}$ increased significantly with training both in MM (from 14.7 ± 3.0 [$x \pm SD$] mL/kg/min BEFORE to 17.6 ± 3.3 AFTER) and in McA (from 17.4 ± 4.0 mL/kg/min to 20.4 ± 4.4 mL/kg/min). Peak skeletal muscle (vastus lateralis) fractional O_2 extraction increased with training both in MM (from 22.0 ± 16.5 % to 32.6 ± 14.5) and in McA (from

17.8 ± 17.9 % to 43.4 ± 17.4). During the high-intensity constant-load exercise, MM and McA patients showed, after training, clear signs of increased exercise tolerance, such as lower HR (from 134.3 ± 26.6 b/min to 121.2 ± 21.9) and lower scores at the Borg's scale of perceived exertion (from 14.5 ± 1.2 to 12.3 ± 1.5). EE was not different BEFORE (36.6 ± 9.2 kcal/day/kg) vs. AFTER (35.7 ± 13.4). CONCLUSION In MM and McA patients a 12 weeks aerobic training program significantly increased exercise tolerance. Our findings confirm that near infrared spectroscopy can effectively detect the functional improvements obtained by training, yielding insights also on the mechanisms of the improvements at the pathophysiological level. Surprisingly, the improvements in exercise tolerance obtained by the training program did not determine an increase in average daily energy expenditure.

HAPTIC FEEDBACK IMPROVES STATIC BALANCE IN INDIVIDUALS WITH MILD TO MODERATE PARKINSON'S DISEASE.

Gregory, T., Welman, K.E., Roux, L.

UNIVERSITY OF STELLENBOSCH

Introduction: Parkinson's disease (PD) is characterized by postural instability which worsens with advance stages. Poor postural stability is an indication of reduced postural control (PC), which increases individuals' fall risk (Tuunainen et al., 2014). Until recently it was believed that individuals with PD were unable to use haptic feedback to improve postural instability (Rabin et al., 2013). This study aimed to establish whether haptic feedback influence a static balance task performance in individuals with mild to moderate PD. Methods: After performing a baseline test, the 16 participants (age: 68.5±6.0 years;BMI: 26.8±3.2 kg/m²) were asked to complete a modified-tandem standing task under 6 different sensory conditions i.e. eyes open (EO), eyes closed (EC), unrestricted manual contact (UMC), light touch only (LMT) and no manual contact (NMC) as well as on (+F) or off a foam pad. The Instrumented Sway (Mobility labTM) tri-axial accelerometer was used to assess overall postural sway, as well as anterior-posterior (AP) and medial-lateral (ML) sway. According to Mancini et al. (2012) JERK is one of the best parameters for evaluating postural sway in PD and indicates the relative smoothness of postural sway. Results: Participants showed significantly less postural sway during all conditions where they received LMT compared to NMC conditions (p<0.01) as well as UMC (p<0.01) in overall, AP and ML directions. Additionally, all JERK parameters showed a larger postural sway during EC NMC conditions compared to EO conditions (p<0.01) (d=11.0). Interestingly individuals had less sway with EO NMC compared to UMC and EC (p<0.01) (d=7.4). Participants showed more AP postural sway (2.7±5.6 vs. 5.3±3.1 m-2.s-5) during EC+F conditions compared with EC while standing on a solid surface (p=0.009) (d=0.7). Conclusion: Haptic feedback improved PC in individuals with PD. Thus, benefits gained from non-supportive manual contact (e.g. fingertip touch) shows that PD subjects can use and benefit from sensory information received from LMT that is independent of mechanical support (e.g. cane or walking stick) with regards to PC. Activities that utilize haptic feedback can help individuals with PD to regain or maintain PC. Results furthermore support previous findings that individuals with PD have a visual dependency. SELECTIVITY OF CERVICAL MOVEMENT BEHAVIOUR TO DISTINGUISH IDIOPATHIC NECK PAIN PATIENTS FROM ASYMPTOMATIC SUBJECTS

Niederer, D., Vogt, L., Wilke, J., Banzer, W.

Goethe University Frankfurt/Main

Introduction Patients suffering from idiopathic neck pain are suggested to display impaired movement behaviour in comparison to asymptomatic subjects (Vogt et al., 2007). Overall, an increase in movement variability and a decrease in cervical range of motion with increasing age were described (Uthairup and Jull, 2009). To our knowledge, no study aimed to establish effective cut-off values to distinguish impaired from asymptomatic kinematic behaviour characteristics so far. Therefore, present study aims to develop and evaluate age-dependent cut-off values based on regression models. Methods One hundred twenty (120) asymptomatic subjects (model development: n= 100, 18-75 years, 36 female; model evaluation: n= 20, 23-75 years, 15 female) and 20 patients suffering from idiopathic neck pain (model evaluation, 22-71 years, 15 female) were included. All subjects performed five repetitive maximal cervical flexion/extension movements in an upright sitting position at a self-determined velocity. Cervical kinematic characteristics (maximal range of motion (ROM), coefficient of variation (CV) and mean evasive movements in rotation and flexion (EVA)) were calculated from raw 3D ultrasonic data. Then, linear regression models were developed to define cut-off ranges for each characteristic. Values of ROM, CV and EVA (for each subject included into the model evaluation) were afterwards classified as 'asymptomatic' or 'symptomatic' according to these ranges. Classifications' selectivities were finally rated using 2x2 contingency tables. Results Contingency tables showed significant discrepancies between expected and joint frequency distributions for ROM (Chi2= 6.8; p< .01) and CV (Chi2= 6.42; p< .05) but not for EVA (p> .05). Analyses of the selectivities for significant frequency distributions revealed a sensitivity of 60% for ROM and of 75% for CV. Specificity was shown to be 85% for ROM and 65% for CV. Discussion Age-related cut-off models seem to be able to classify asymptomatic subjects' and chronic nonspecific neck patients' movement characteristics with sufficient quality. By including such classifications, the present findings expand actual research stating an age-related decrease in kinematic behaviour only by using categorizing span widths across decades (Cagnie et al., 2007). Future study is warranted to reveal our results' potential applicability for assessments in prospective intervention trials for idiopathic neck pain patients. References Uthairup S, Jull G. (2009). THE EFFECTS OF RADIAL EXTRACORPOREAL SHOCK WAVE THERAPY AND EXERCISE ON PAIN AND FUNCTIONALITY IN PATIENTS WITH LATERAL EPICONDYALGIA

YURUK, Z.O.1, KIRDI, N.2

1: Baskent University, 2: Hacettepe University

Introduction Pain over the lateral humeral epicondyle associated with gripping or manipulation of the hand is generally linked with a diagnosis of tennis elbow or lateral epicondylalgia (LE) (Coombes et al., 2009). Although many treatments have been advocated, there is little clear consensus on which modality works best (Faro et al., 2007). Exercise has been claimed to have better and faster effect (Peterson et al., 2011). Radial extracorporeal shock wave therapy (RESWT) is low energy shock wave therapy frequently used in clinics. However there is a lack of evidence about RESWT in LE (Spacca et al., 2005). The aim of our study was to investigate the effects of RESWT and exercise on pain and functionality in patients with LE. Methods In the randomized controlled study, forty-five subjects with LE were randomly

divided into three groups: Group I (n=15), RESWT and exercise; Group II (n=15), placebo RESWT and exercise and Group III (n=15), only exercise. In Group I, RESWT was applied to lateral epicondyle and painful areas with 2000 pulses, once in a week, total of 3 sessions. In Group II, placebo RESWT was applied to lateral epicondyle and painful areas with 20 pulses, once in a week, totally 3 sessions. Stretching and eccentric strengthening exercises were given to the patients in all groups once daily, at least 3 times at a week for 8 weeks. The patients were evaluated before the treatment, 3rd, 9th and 15th weeks after the baseline assessment. Outcome measures were pressure pain threshold (PPT) and functionality. PPT was evaluated on lateral and medial epicondyle with using digital algometer. Functionality was assessed with The Disabilities of the Arm, Shoulder and Hand Score (DASH). Results There were significant differences in PPT and DASH scores between three groups ($p<0.05$). In the Group I, lateral epicondyle PPT score was improved in 9th and 15th weeks, but there was significant difference only at 15th week in medial epicondyle PPT score ($p<0.05$). There were no significant changes in PPT scores in Group II and III ($p<0.05$). Improvements were obtained in DASH scores at 3rd, 9th and 15th weeks in Group I and at 9th weeks in Group II ($p<0.05$). Discussion In our study, RESWT combined with exercise improved pain threshold and function compared with placebo RESWT and only exercise. We concluded that, these improvements were obtained because of the physiological effects of RESWT. References Coombes BK, Bisset L, Vicenzio B. (2009). Br J of Sports Med, 43, 252-258. EXERCISE INDUCED INSPIRATORY STRIDOR IN TOP ATHLETES

Clemm, H.1,3, Vollaeter, M.1,3, Hilland, M.2, Sandvik, L.2, Sandnes, A.3, Campos, C.1, Ellingsen, T.E.2, Halvorsen, T.1,3, Heimdal, J.H.2,4, Roeksund, O.1,2,5

Haukeland University Hospital (1,2), University of Bergen (3,4), Bergen University College (5)

Introduction Exercise induced inspiratory stridor (EIS) is common in top athletes and often misdiagnosed as asthma. EIS has been attributed to inappropriate adduction of the vocal cords (VCD), and some researchers argue that exercise induced VCD may be diagnosed from a medical history alone or with laryngoscopy performed during maximum voluntary ventilation (MVV) or similar breathing exercises at rest. From experience acquired during the last 15 years, we argue that EIS represents a broad spectrum of abnormalities and that video-recorded continuous laryngoscopy performed during maximal exercise (CLE-test) is required to make a correct diagnosis. EIS strongly influences performance, and adequate diagnostic work-up and treatment is therefore important. **Method** All patients presenting with EIS to our institution are offered a complete maximal cardiopulmonary treadmill exercise test with a CLE set-up, MVV at rest with laryngoscopic surveillance and they fill in a standardized questionnaire. We here present findings from athletes with EIS, competing at a national or international level, tested at our institution since 2012. **Results** Thirty two (19%) of 164 new referrals were top athletes, 23 (72%) females. Almost all (97 %) felt that EIS prevented them from reaching their goals, and 25% had stopped pushing themselves because of breathing problems. Seventy-four % had attempted asthma medication, and 54% stopped due to no effect. Breathing problems during low intensity exercise was reported by 10%, while 70% had problems during high intensity exercise, and 50 % had worse symptoms during competition. Despite similar symptoms, laryngeal findings varied. Moderate to severe supraglottic obstruction were seen in 69% with a secondary adduction of the vocal cords in 32%. Only 50% had moderate to severe supraglottic obstruction during MVV at rest, and 69% were able to describe this as an inspiratory problem or a problem with stridor. Primary exercise induced VCD was observed in one subject only. Epiglottic abnormalities was seen in 16%, seemingly disturbing airflow, and 80% of these had sense of being suffocated. Normal findings were seen in 18%, with symptoms probably explained by inadequate expectations or breathing patterns. **Conclusion** The origins of EIS in top athletes vary, and the symptoms influenced performance to a large extent. Adduction of supraglottic structures and not the vocal cords was the inciting event in the majority. EIS is difficult to define based on symptoms alone or with laryngoscopy at rest. A correct diagnosis requires continuous laryngoscopy during exercise, which is a safe procedure revealing findings with therapeutic consequences.

STRESS-RELATED HORMONAL CHANGES TO A YOUTH BASKETBALL GAME

Cortis, C.1, Lupo, C.2, Teixeira, A.M.3, Rama, L.3, Kraemer, W.J.4, Capranica, L.5

1University of Cassino e Lazio Meridionale; 2University of Turin; 3Coimbra University; 4University of Connecticut; 5University of Rome Foro Italico

Introduction The study aimed to investigate the effects of a youth basketball game on ratings of perceived efforts (RPE), heart rate responses (HR) and salivary hormones (cortisol-sC; alpha-amylase-sAA). To provide meaningful information regarding the activity of the sympathetic-adrenal medullary (SAM) and hypothalamic-pituitary-adrenal (HPA) axis, the ratio of sAA over sC (AOC) has been considered (Ali & Pruessner 2012; Filaire et al 2013). Therefore, the relationship between RPE and AOC has been evaluated. **Methods** Ten youth (16±1yrs) male basketball players participated in a 60-min friendly game. To evaluate game intensity, HR measured during the competition was expressed as frequency of occurrence exceeding 85% of individual HRmax. Saliva samples were collected before (pre) and after (post) the competition, at 10 (post10), 20 (post20) and 30-min (post30) of the recovery phase, and analyzed using kinetic reaction assay for sAA and ELISA method for sC. AOC was calculated as the ratio between sAA and sC area under the curve. The CR10 RPE (Borg 1998) was administered at the end of the game. Differences ($p<0.05$) between saliva samplings were tested by means of repeated measures ANOVA. Pearson's correlation was applied to AOC and RPE. **Results** During the game, the occurrence of HR >85% HRmax was 81±23%, and RPE ranged from moderate to very hard (5.8±2.2). Peak sAA was observed at post-game (319.6±35.0U/ml), with significant differences ($p<0.0001$) with respect to pre (90.3±12.1U/ml) and recovery samplings (post10: 191.4±31.9U/ml; post20: 128.0±26.6U/ml; post30:121.8±23.9U/ml). Pre sC values (6.1±1.8nmol/L) were different ($p<0.001$) from post-game (13.7±3.7nmol/L) and recovery (post10: 14.2±4.5nmol/L; post20: 12.4±3.8nmol/L; post30: 14.7±5.0nmol/L). AUC (55.2±58.0) showed a moderate relationship ($r=-0.5$; 95% CI=-0.9-0.2; $p=0.12$) with RPE. **Discussion** Eliciting high HR and significant sC and sAA increments at the end of the game, the basketball

competition posed a high stress on players, who perceived their efforts as hard. Whilst sC remains elevated during the recovery phase, sAA returns to baseline within 30-min post-game, mirroring the faster reactivity and recovery of SAM with respect to HPA. In line with previous studies, a negative correlation between AOC and subjective ratings (Filaire et al 2013) emerged, indicating a link between the two systems. Further psychobiological investigations on the impact of youth competition are needed to explore the relationship between hormonal and psychological responses. INTERRELATIONS BETWEEN MATCH CHARACTERISTICS, FIELD- AND LABORATORY TESTS IN YOUTH ELITE BASKETBALL PLAYERS

Brink, M.S., Fiechter, H., Otten, E., Lemmink, K.A.P.M.

University of Groningen, University Medical Center Groningen

Introduction To develop an effective training program, objective information about the physiological strengths and weaknesses of basketball players is needed. These physiological capacities are usually investigated using field- or laboratory tests. It is assumed that these tests reflect the physical demands of matches (Impellizzeri & Marcora 2009). The purpose of the present study was to determine if field tests and laboratory tests are related to match characteristics in youth elite basketball players. **Methods** Time motion analyses of four quarters out of two matches were carried out for twenty-one youth elite basketball players (age $17,50 \pm 1,56$ years, body mass $82,50 \pm 9,75$ kg, height $192,13 \pm 7,70$ cm and body fat $9,21 \pm 3,50$ %). Positional data was collected based on 10 Hz top-view video footage, using semi-automatic tracking software. Relative time spent on standing/walking, jogging, low speed running, high speed running and sprinting was calculated. In addition, players performed the Interval Shuttle Sprint Test (ISST), Interval Shuttle Run Test (ISRT) (Lemmink et al., 2004), a 30s Wingate test (Bar-Or, O 1987) and a treadmill test to determine maximal oxygen uptake (VO₂max). Interrelations between all exercise modes were examined using Pearson correlation coefficients. **Results** Players' peak and total sprint time on the ISST was $8,5 \pm 0,29$ s and $26,3 \pm 0,91$ s respectively and they completed $106,5 \pm 24,72$ runs on the ISRT. Wingate peak power was $17,1 \pm 2,22$ W/kg and players' VO₂max was $56,7 \pm 4,87$ ml/min/kg. Relative sprint time during matches was related to peak and total sprint time of the ISST ($r = 0,63$ and $r = 0,59$; $p < 0,05$ respectively). Furthermore, ISRT performance was associated with higher VO₂max ($r = 0,61$; $p < 0,05$). Although trends were found for the relation between match characteristics and ISRT and for the ISST and the Wingate test, none of these correlations were significant. **Discussion** This study provided evidence that the ISST, as an intermittent field tests, can be used to test the sprinting capacities of basketball players. The results did not directly support the use of the ISRT as a specific aerobic running test in basketball players but trends were found. Furthermore, it was found that, the anaerobic 30s Wingate test and aerobic VO₂max test, are not related to match characteristics. EFFECT OF DIFFERENT SETTINGS AND NUMBER OF PLAYERS ON PHYSIOLOGICAL AND TECHNICAL DEMANDS OF BALL-DRILLS IN BASKETBALL

Conte, D.I, Favero, T.2, Niederhausen, M.3, Tessitore, A.1

1 University of Rome "Foro Italico"; 2,3 University of Portland

Introduction Ball-drills (BD) are a training method that simultaneously develops basketball players' technical and tactical skills eliciting a high physical and physiological demand. Previous investigation focused on the effect of varying the number of players and court size on physiological and technical demands (Klusemann et al., 2012), while none analyzed the use of different BD settings in basketball. This study aimed to analyze the effect of different BD settings and number of players involved on players' physiological and technical demands. **Methods** Twenty-one young basketball players belonging to under 17 and under 15 teams performed two different BDs: 3 bouts of 4 minutes played continuously (BDcont) and intermittently (alternating 1 minute of work and 1 of passive rest) (BDint). Each BD was played using a different number of players: 2vs2 and 4vs4. Training load (TL) was assessed through the rate of perceived exertion (RPE), percentage of maximal heart rate (%HRmax) and Edwards' TL (Edwards, 1993). Technical actions (TAs) were also collected and classified in: dribbles, passes, shots, interceptions, steals, rebounds and turnovers. A 2x2x3 (players x drills x bouts) 3-way ANOVA with repeated measures for %HRmax and a 2x2 (players x drills) 2-way ANOVA with repeated measures for Edwards' TL, RPE and TAs were applied. The level of statistical significance was set at $p < 0.05$. **Results** Results showed higher values ($p < 0.05$) for %HRmax, Edwards TL and RPE in 2vs2 and BDcont compared to 4vs4 and BDint, respectively. A significant difference ($p < 0.05$) was also showed among bouts for the %HRmax. Moreover, a significant difference ($p < 0.05$) was found in the interaction of drills with players in the %HRmax and Edwards' TL, and in the interaction between players and bouts in the %HRmax. TA analysis showed higher ($p < 0.05$) number of dribbles, passes, shots and rebounds in 2vs2 compared to 4vs4. Furthermore, dribble activity was performed more in BDint than in BDcont ($p < 0.05$). **Discussion** This study showed that a reduction of the number of players elicit higher physiological and technical demands. The BD setting comparison showed that BDcont stimulate greater physiological load, but a lower number of dribbles compared to BDint. Basketball coaches should vary the number of players involved and the BD settings to modify the BD workload intensity. References Edwards S. (1993). *The heart rate monitor book*, 113-123. RELATIVE AGE EFFECT IN YOUNG BASKETBALL PLAYERS OF DIFFERENT COMPETITIVE LEVELS: ANTHROPOMETRICAL AND PHYSIOLOGICAL BASIS

Irazusta, J., Arrieta, H., Zarrasquin, I., Ruiz, F., Petrini, A., Gil, S., Torres-Unda, J.

University of the Basque Country

Relative Age Effect in young basketball players of different competitive levels: anthropometrical and physiological basis. Irazusta, J., Arrieta, H., Zarrasquin, I., Ruiz, F., Petrini, A., Gil, S., Torres-Unda, J. University of the Basque Country (UPV/EHU). Leioa (Bizkaia) Spain **Introduction** Relative Age Effect (RAE) is a used to describe the higher participation in sports of those boys or girls born early in the relevant selection period. While RAE has been reported in a high number of sports (Helsen et al. 2005), underlying reasons for this effect are not well understood. Due to the importance of height (Hoare, 2000), basketball is a sport where RAE may be relevant. Therefore, our aim is to describe the possible presence of this effect in young male players and teams of different levels and to ascertain the underlying causes of RAE in the above-mentioned sport. **Methods** We analyzed the data for the following: birth-date, height, weight, points scored per match

and personal performance index (PIF) of basketball players who took part in European U16 championship (15-16 year-old boys, international), Spanish ACB Mini-cup (13-14 year-old boys national), as well as of players in a regional competition in our area. In the last two tournaments, we also measured some anthropometrical and physiological characteristics of the players which could be relevant for basketball performance. Results RAE was evident in boys of every tournament analyzed and there were a decreasing percentage of players from the first to the fourth terms. RAE was more relevant in teams of international or national levels than those which took part in regional competition. In addition, there was a positive correlation between the age of the players and their height, weight, speed, agility and endurance in the regional tournament. This correlation also occurred in the Mini-cup, but the differences did not reach statistical significance. In the European U16 championship, there were also positive correlations between the date of birth and the height, PIF or points scored. Discussion Our results demonstrated that RAE is very relevant in young basketball of different competitive levels. This effect seems to be due, at least in part, to physiological and anthropometrical differences between boys born early or late in the selection year. Sport dropout can occur among relatively younger boys (Delorme et al., 2011). This way of selecting players may be shortsighted because is founded in advantages that will no longer presents when they are adults. Coaches and teams should be aware of this bias in order to carry out the selection of players properly. References Hoare DG. (2000). J Sci Med Sport, 3, 391-405 Helsen WF, Van Winckel JV, Williams M. MATURITY STATUS IS CORRELATED TO BASKET PERFORMANCE IN ELITE ADOLESCENT BASKETBALL PLAYERS

Torres Unda, J., Irazusta, A., Gravina, L., Zarrazquin, I., Kortajarena, M., Gil, J., Irazusta, J.

University of Basque Country (UPV/EHU)

Introduction Anthropometrical and physiological features are undoubtedly important factors in determining success in basketball (Hoare, 2000; Torres-Unda et al., 2013). During the course of adolescent development, there are abrupt increases in size and weight, together with a rapid improvement of physical performance (Roemmich, & Rogol, 1995). However, the processes of maturation do not occur in everyone at the same age (Borsboon et al., 1996). The difference in maturation among adolescents may be very relevant because it can influence the functional capacity in basketball (Malina et al., 2004). Methods We analyzed the relation of maturational status (measured as years from the age peak height velocity, APHV) of elite male basketball players (13-14 years old) and teams with anthropometrical and physiological parameters. We also analyzed points scored and performance index rating (PIR) in the Mini-cup tournament of the ACB. In addition, we calculated the differences in the years from APHV between different teams regarding their position in the tournament. Results Boys who took part in this elite basketball tournament had an earlier maturation than their age-mates from the general population. Height, weight, arm span, hand length, femur length and sitting height of the players were strongly correlated ($p < 0.005$) with the years from the APHV. However, sprint-time and jump capacity were not correlated with the above-mentioned parameters in the analyzed sample. Earlier maturation also correlated positively with PIR and points scored ($p < 0.05$). Accordingly, the APHV ($p < 0.005$) was highest among the finalist and semifinalist teams than for the rest of the teams. Discussion Our results seem to demonstrate that during adolescence selection criteria for elite basketball teams are based on an early development. Early maturing players have transient anthropometrical advantages which can have a great effect in basketball performance (Delorme et al., 2011). In consequence, many talented late-maturing players may be marginalized and their career stunted by a short-sighted method of selection. References Borsboon, G. J., Van Pelt, W., & Quaryer, P. H. OP-BN07 Injury Incidence

LOWER LIMB INJURIES IN THE NZ ARMY OVER 8 YEARS

Lark, S., Rousseau, J., Morton, H.

Massey University

Introduction Results of 9 months of NZ defence force injuries reports most injuries as musculoskeletal (Davidson et al 2008) of which nearly half are lower limb injuries. This has implications on overall costs of injuries to the army: loss of manpower, training time, and duty time, non-deployability, and an increase in medical costs and at times can lead to service discharge (Piasis et al., 2008). Methods Eight years of injury data was extracted through the New Zealand Defence Force Accredited Employer Programme (AEP) where all work place injuries requiring medical attention are captured ($n=2401$). Causative factors are derived from the narrative given on the AEP form completed by the soldier. Narratives were filtered using Microsoft® Excell 2010 to uncover the injury and contributing activity, e.g. "Sports session, volleyball, landed unevenly on (R) foot, rolled ankle outwards". Frequency data and Chi square analysis was carried out on injury site by activity. Results Analysis shows 43% of all NZ Army soldiers are injured annually. Lower limb injuries account for a significant proportion (42%) and this rate has remained static over the last 8 years. Of all the lower limb injury sites, the ankle has the highest injury rate at 37%, with most of these occurring during military training (i.e., PT, battle drill and pack march) and sport (i.e., indoor court sport, contact sports, running). Overall, lower limb injuries remain the highest proportion of all injuries sustained in the NZ Army, while running was the most common activity causing ankle injuries. Discussion Regardless of many interventions over the years (i.e., change of boots, introducing orthotics, change in training practices) the statistics for lower limb and ankle injuries remains a consistently high proportion of all injuries sustained. Speculation that wearing boots with high shafts to provide support and stability to the ankle joint (Bohm & Hosl, 2010) may actually be weakening, fatiguing, altering muscle activation patterns or reducing range of motion. Therefore, when not wearing the boot the ankle is weak and vulnerable to injury. The precise aetiology has yet to be elucidated during a series of studies to determine any changes in muscle activation, flexibility, or strength of the ankle joint through boot wearing. The results of these are expected to

help determine future policy of footwear in the army with a view to decrease lower limb and ankle injuries. References Bohm, H., & Hosl, M. (2010). INJURIES AND ILLNESSES DURING THE EUROPEAN YOUTH OLYMPIC FESTIVAL 2013

Van Beijsterveldt, A.1, Thijs, K.2, Backx, F.2, Stubbe, J.1,3

1 Netherlands Organization for Applied Scientific Research (TNO); 2 UMC Utrecht; 3 Amsterdam University of Applied Sciences (all institutions: the Netherlands).

Background: The European Youth Olympic Festival (EYOF) is a biennial sporting event for talented young participants (13-18 years) from all over Europe. Objective: Since knowledge about the epidemiology of injuries and illnesses of young top athletes is lacking, the aim of this study is to analyze the frequencies and characteristics of injuries and illnesses during the EYOF 2013. Design: Prospective cohort study. Setting: The International Olympic Committee (IOC) injury and illness surveillance system for multisport events was used. All National Olympic Committees (NOCs) were asked to report the daily occurrence (or non-occurrence) of newly sustained injuries and illnesses on a standardized reporting form. In addition, information on athletes treated for injuries and illnesses by the Local Organizing Committee medical services was retrieved from the medical centers at the sport venues and the Olympic villages. Participants: 2272 athletes (48% girls, 52% boys; mean age 16.0±1.0 years) from 49 countries. Main outcome measures: frequencies and characteristics of injuries and illnesses. Results: Preliminary results show that 209 injuries and 46 illnesses were reported, resulting in an incidence of 92.0 injuries and 20.2 illnesses per 1000 athletes. Injury prevalence was the highest in basketball (15.1%), tennis (15.1%) and judo (12.9%). More than two-thirds of the injuries occurred during a match. Almost 4 out of 10 (37.3%) injuries resulted in time loss. Illness frequency was highest in gymnastics, taking into account the respective number of participating athletes. Most frequently reported symptoms were diarrhea, vomiting (43.5%) and pain (37.0%). Conclusions: Ten per cent of the athletes suffered from an injury and/or illness during EYOF. The presented data can form the basis for further research on injury mechanisms. Future research is needed to gain more knowledge about risk factors, and in the final step to implement effective injury prevention measures.

ANKLE INJURIES IN THE NETHERLANDS: LONG-TERM TRENDS OF 10-25 YEARS

Kemler, H.J.1,2, van de Port, I.G.L.1,3, Valkenberg, H.2, Hoes, A.W.1, Backx, F.J.G.1

VeiligheidNL, UMC Utrecht

Introduction Ankle injuries are a common health problem, but information about ankle injury rates and time trends in the population at large are scarce. Ankle injury rates in the population at large, display the whole picture of ankle injuries, and can guide ankle injury prevention. Our aim was to investigate the incidence of and time trends in population-based and emergency department treated ankle injuries related to sports activities and other activities related to daily living. Methods Data were obtained from one national survey on accidents and injuries (2000–2010) and one based on emergency department data (1986–2010). Linear regression was used to determine linear trends in ankle injuries per 1000 person-years. Results The number of ankle injuries related to sports activities and other activities of daily living increased from 19.0 to 26.6 per 1000 person-years ($p = 0.002$). The number of sports-related ankle injuries treated in Emergency Departments decreased from 4.2 to 1.5 per 1000 person-years ($p < 0.001$), and from 3.2 to 2.1 per 1000 person-years ($p < 0.001$) for other activities of daily living. Discussion According to our data, the incidence rates of all medically and non-medically treated ankle injuries are around 5.5 times higher than those registered at emergency departments. The high incidence rates of ankle injuries stress the need for proper ankle injury treatment and ankle injury prevention. A reliable registration of physical activity and sports participation is necessary in order to put increasing ankle injury trends into perspective.

THE EPIDEMIOLOGY OF BOXING INJURIES PRESENTING TO IRI SPORT MEDICINE FEDERATION INJURY SURVEILLANCE SYSTEM

Pourkazemi, L.1, Moradi Shahpar, F.1, Ebrahimi Varkiani, M.2, Alizadeh, M.H.2

1: Sport Medicine Federation & University of Esfahan. 2: University of Tehran

Introduction Injury prevention is an important part of health care in sport. In order to plan a preventive measure, first the extent of the sport injury should be established[1]. Boxing is a contact Olympic sport which was played firstly in 688 B.C. it was one of the most high risk of injury sports in Iran[2]. Due to its contact nature, incurring injury is unavoidable. Due to the importance of injury identification in prevention, the present article aimed to study the profile of injuries in Iranian male boxers presented to the sport medicine federation injury surveillance system. Method The data for Iranian boxers from the sport medicine federation injury surveillance system of Iran during one year of Persian calendar at 21st of March 2009 until 19th of March 2012 were analyzed. The injury definition was any reportable events occurred as a result of participating in competition or practice, required medical attention by physician and resulted in restriction of the athlete's participation for at least one day beyond the injury. The type of injuries was not considered due to unavailability. All statistical analysis was done by the SPSS software (version 14). Results Among 50715 registered athletes, 815 athletes (with mean age of 28.33±10.54), presented 927 injuries. The incidence rate of 18.27 injury per 1000 registered athletes was calculated. Head & Neck (42.7%) followed by upper extremity (30.2%) were the most common body regions injured. The mechanism of 75.6% of injuries caused by contact. For about 69.2% of injuries occurred in training and the left in competition. Elderly and adults aged 45-64 and 25-44 year-old had highest injury incidence of 30.2 and 19.6 injury per 1000 registered athletes respectively. Discussion The injury rate of 18.27 injury per 1000 registered athletes was reported for 50715 boxers in 3 years. As observed, head & face (41.5%) incurred most of injuries. Wrist, hand and finger were the next body parts at high risk of injury. It may be due in part to the nature of the sport which the fighters targets each other, specially the heads with the fists. Furthermore, following these contact, contact was the main mechanism of injury obviously. Because the training session frequency is so many more than competition, most of injuries happened in training. The use of protective equipments in training session, specially the helmet may protect the boxers from incurring injury. According to the results, head and face should be in priority of preventive measures. Additionally, training session should be held with more observant. Reference 1. A SUBMAXIMAL ROWING TEST TO MONITOR TRAINING STATUS IN FIRST-YEAR COMPETITIVE ROWERS

Hofmijster, M.J.1, van de Plasse, G.J.J.1, Stubbe, J.H.2,3, van Beijsterveldt, A.M.C.2

(1) *Vrije Universiteit Amsterdam*; (2) *TNO*; (3) *Hogeschool van Amsterdam*

Introduction Rowers in their first year of competition have a high risk of overtraining, caused by a disbalance in training load and recovery. A typical week in the rowing season consists of 5-8 training sessions, and many first year ("freshmen") rowers have little previous experience in competitive sports. The risk is further increased by the fact that personalization of training load is difficult and that coaches are often inexperienced. In this study we investigated whether a standardized submaximal exercise rowing test (SERT) can be used as a tool to monitor training status and as such can help to prevent overtraining. **Methods** For a period of four weeks, the weekly training load of members of one lightweight men's freshmen crew (eight rowers) was quantified by summing heart rate scores, using the method of Edwards (Edwards, 1993). Rowers undertook the SERT on a rowing ergometer (Concept 2, USA) on a weekly basis. The SERT is an adaptation of the LSCT (Lamberts, 2011) and yields values for power output at 70, 80 and 90% of maximum heart rate, heart rate recovery (HRR, defined as the drop in heart rate in one minute after cessation of exercise) and rate of perceived exertion (RPE) on a 0-10 point scale (Foster 2001). **Results** One participant dropped out because he showed signs of overtraining already at the start of the experiment. For the remaining seven rowers, training load was significantly higher in weeks 2 and 3 compared to weeks 1 and 4 ($P < 0.01$). Consequently, these weeks were categorized as 'heavy weeks' (H) whereas weeks 1 and 4 were categorized as 'light to moderate' weeks (L). HRR was shown to be significantly lower during the heavy weeks (L: 53.8 ± 8.48 , H: 50.6 ± 6.50 , $P < 0.05$), suggesting fatigue or inaccurate recovery. No differences were found in power values or RPE scores. **Discussion** Obtaining relevant information on training status of individual team members can prove to be difficult in crew rowing. This study indicates that a standardized training such as the SERT helps to monitor individual rowers, especially when HRR is obtained. A sudden drop in HRR can act as an early warning sign and may lead a coach to adapt the training schedule. Furthermore, the participants rated the SERT with only 3.8 on the 0-10 RPE scale, indicating that the SERT is suitable to be performed on a frequent basis without interfering with the daily training. Future research should point out whether occurrence of overtraining would indeed be lower with frequent monitoring of training status. **References** Lamberts, R.P. et al., 2011, *British Journal of Sports Medicine* 45(10), 791-804 Edwards, S., 1993, *The heart rate monitor book* Foster, C. et al., 2001, *Journal of Strength and Conditioning Research* 15(1), 109-115 Contact m.hofmijster@vu.nl

OP-PM22 Critical Power

NON-DISCLOSED DURATION CONSTANT POWER TEST TO ESTIMATE ANAEROBIC WORK CAPACITY AND CRITICAL POWER

Tsai, M.

University of Toronto

Introduction Critical Power is used extensively in sport to characterize fitness by estimating anaerobic work capacity (AWC) and critical power (CP). Traditionally, estimates of CP_{trad}, AWC_{trad} require repeated, time consuming tests. Alternatively, a 3-min all-out test yields good estimates of AWC₃ and CP₃ (Burnley 2006). However, adoption of the 3-min protocol for regular fitness monitoring is deterred by the mentally/physically strenuous nature of the test. We propose a less strenuous constant power protocol that yields valid estimates of AWC_n and CP_n. **Methods** Twelve participants (2 women, 10 men; age 35.4 ± 10.6 yrs) completed 5 testing sessions over 2 weeks. In the first session, participant's AWC₃ and CP₃ were determined. Over the next four sessions subjects completed 4 bouts at randomly assigned power outputs producing exhaustion in 2-10min the continued with a non-disclosed duration all-out effort. These bouts produced multiple estimates of AWC_n and CP_n. Significant differences of parameter estimates by test protocol were identified using ANOVA with Tukey's procedure to account for type I error in multiple comparisons. Results AWC for all tests did not differ AWC_{trad}=9514±2927J; AWC₃=15994±4687J; 1 min AWC_n =14527±2775J; 2-3 min AWC_n =15290±3493J; 5 min AWC_n =16066±5533J; 10 min AWC_n =11832±6129J). CP for all tests with the exception of the 10 min constant power test did not differ CP_{trad}=296.2±56.7w; CP₃ =280.4±56.4w; 1 min CP_n =286.9±57.8w; 2-3 min CP_n =283.7±61.0w; 5 min CP_n =263.6±60.6w; 10 min CP_n =249.4±58.1w; p=0.045. **Discussion** In all the constant power tests (except for the 10-min test), the AWC and CP did not differ from the traditional AWC and CP. Therefore, a constant power protocol that is less than 5-min followed by an all out effort seems to be a suitable alternative test to determine AWC and CP for fitness monitoring. These constant power assessments of AWC and CP may facilitate more frequent monitoring of fitness and response to training programs. **References** Burnley M, JH Doust, and A Vanhatalo. (2006). THE EFFECT OF GENDER ON INDIVIDUAL ANAEROBIC THRESHOLD IN SWIMMING: A COMPARISON BETWEEN RELATIVE AND ABSOLUTE PARAMETERS

Pelarigo, J.1,2,3, Sousa, A.2,3, Ribeiro, J.2,3, Cascais, C.2, Denadai, B.4, Greco, C.4, Fernandes, R.2,3, Vilas Boas, J.P.2,3

1The Capes Foundation, Ministry of Education of Brazil, Brazil, 2Faculty of Sport/CI/F2D, University of Porto, Portugal, 3LABIOMEPE, University of Porto, Portugal, 4São Paulo State University, Brazil.

Introduction Some of the major sports performance determinant factors have been shown to be dependent on gender characteristics. Anaerobic threshold for instance is influenced by anthropometric, hormonal and genetic differences (Thibault, et al., 2010). However, researchers usually used absolute values to compare such differences, whereas relative analysis is scarce. The purpose of this study was to examine the effect of gender on absolute and relative individual anaerobic threshold (IAnT) in swimming. **Methods** Eight males (18.5 ± 3.1 yr, 1.79 ± 0.05 m, 72.1 ± 7.0 kg) and 8 females (17.6 ± 2.1 yr, 1.69 ± 0.04 m, 59.6 ± 4.8 kg) middle and long-distance swimmers, with similar mean relative performances over a 400m freestyle swim ($88.2 \pm 3.4\%$ and $88.4 \pm 2.7\%$, of the 25m WR, respectively) participated in this study. The swimmers performed a 7 x 200m front crawl incremental protocol until voluntary exhaustion (Fernandes et al., 2006) to determine the velocity (v) associated to IAnT and VO₂max. Blood lactate concentration [La-], VO₂ and heart rate (HR) were controlled during the test. The data were analyzed using one way ANOVA (p<0.05). Results The absolute IAnT values showed significant differences for v (1.34 ± 0.07 and 1.24 ± 0.06 m/s), [La-] (2.0 ± 0.5 and 1.5 ± 0.5 mmol/L), and HR (162 ± 9 and 172 ± 8 bpm) for males and females, respectively. However, VO₂ at the IAnT (50.2 ± 5.9 and 46.7 ± 4.7 mL/kg/min) was similar. Regarding relative IAnT values expressed as a percentage of VO₂max, VO₂ (84.1 ± 7.3 and $82.8 \pm 5.4\%$), v (91.2 ± 3.6 and $90.5 \pm 3.4\%$), [La-] (22.5 ± 4.3 and $22.8 \pm 7.4\%$), and HR (89.3 ± 3.9 and $90.8 \pm 3.1\%$) showed similar values between genders. **Discussion** Commonly, the scientific literature demonstrates gender differences on factors related to performance, such as the absolute variables presented in the present study. However, those variables, such as IAnT related physiological and biomechanical parameters, when expressed as a percentage of VO₂max, showed similar values. Thus, coaches and researchers may apply the same relative IAnT parameters when expressed as a percentage of VO₂max for training control and prescription in male and female swimmers. **Acknowledgments** This research was supported by grants from Capes Foundation, Ministry of Education of Brazil (BEX: 0536/10-5), and Project PTDC/DES/101224/2008 (FCOMP-01-0124-FEDER-009577). **References** Fernandes R et al. THE DISTANCE-TIME RELATIONSHIP AND OXYGEN UPTAKE KINETICS IN SWIMMING

Almeida, T.1, Espada, M.1,2, Reis, J.1, Vleck, V.1, Bruno, P.1, Alves, F.1

(1) Faculty of Human Kinetics - University of Lisbon / (2) Polytechnic Institute of Setubal

Introduction Critical velocity (CV) calculated as the slope of the distance-time (d-t) relationship, represents an important parameter of aerobic function. The y-intercept derived from this relationship is defined as a finite stock of reserve power available pre-exercise, usually termed anaerobic work capacity or D', and associated to the distance that can be completed resorting to anaerobic metabolism (Jones et al. 2010). Athletes with a relatively high anaerobic capacity will tend to have slower oxygen uptake (VO₂) kinetics than long-distance specialists (Jones & Burnley, 2009). The aim of this study was to examine the relationship between CV, D' and VO₂ kinetics in swimming.

Methods Ten trained competitive male swimmers performed maximal 200 and 400 m front crawl swims (S200, S400). CV was calculated as the slope of distance-time relationship (Sd-t) from these maximal trials. D' resulted from the linear coefficient (y-intercept) of the d-t model. 50 m competitive front crawl swimming performance was recorded for analysis (S50). Maximal aerobic velocity (MAV) was estimated from mean swimming velocity of the 400 m. The maximal oxygen uptake (VO2max) was determined through an incremental step test comprising 5 x 250 and 1 x 200-m stages and VO2 kinetics parameters were determined from two 500 m constant intensity swimming exercise bouts, at 87.5% and 92.5% of MAV. Both the incremental and the 500-m tests were performed using aquatrainer swimming snorkel® for breath-by-breath data collection, (K4b2, Cosmed, Italy). Results CV (1.41 ± 0.06 m.s⁻¹) was significantly lower than MAV (1.45 ± 0.04 m.s⁻¹). VO2max (3806.2 ± 462.9 ml.min⁻¹) was not significantly different from VO2 at 92.5 % MAV (3695.9 ± 385.9 ml.min⁻¹). CV was negatively correlated to the time constant of the primary phase (tau_p) at 87.5% MAV (19.5 ± 8.9 -sec) and 92.5% MAV (17.4 ± 6.7 -sec) (respectively $r = -0.72$ and -0.64 , $p < 0.05$). The amplitude of the primary phase (A_p) at 87.5% MAV (3090.4 ± 456.8 ml.min⁻¹) was negatively correlated to S50 (26.8 ± 0.9 -sec) ($r = -0.66$, $p < 0.05$). D' (19.9 ± 7.0 m) presented no correlations to VO2 kinetics parameters but was negatively correlated to S50 ($r = -0.67$, $p < 0.05$). **Discussion** Our results are in line with those of Reis et al. (2012), which support the notion that the primary phase of VO2 kinetics is an important determinant of aerobic swimming performance. The relation between CV and VO2 kinetics parameter highlights the pertinence of VO2 data collection in swimming for physiological profiling and training optimization. **References** Jones, A.M., Vanhatalo, A., Burnley, M., Morton, R.H., Poole, D.C. MANIFESTATION OF A PLATEAU RESPONSE IN VO2 AT MAXIMAL OXYGEN UPTAKE IS A FUNCTION OF THE ANAEROBIC WORK CAPACITY

Gordon, D., Baker, J.I, Johnstone, J.I, Barnes, R.2, Scruton, A.I, Merzbach, V.1

1Anglia Ruskin University, 2University of Cambridge

Introduction Variations in plateau incidence at VO2max are shown to be related to the size of the finite anaerobic capacity (AnC). However, the AnC only refers to substrate availability and does not reflect changes in intracellular metabolites associated with fatigue processes which are evident at VO2max. The anaerobic work capacity (AWC) (W') derived from the power-time relationship in concert with critical power (CP) defines the interaction between anaerobic substrate metabolism and metabolite accumulation, potentially providing a more plausible explanation for variances in plateau response. Therefore, the purpose of this study was to evaluate the association between W' and the incidence of plateau at VO2max in a cohort of trained individuals. **Method** Following University Institutional ethical approval, 15 males (age, 24.4 ± 5.19 yrs; height, 179.3 ± 6.7 cm; mass, 79.6 ± 12.9 kg; VO2max, 47.8 ± 6.9 ml.kg⁻¹.min⁻¹) volunteered to participate. Each participant reported to the laboratory on 5 separate occasions, visits 1 and 5 for the determination of VO2max, while for the remaining 3 visits, tests to exhaustion were completed for determination of CP and W'. All trials were completed on an electronically braked cycle ergometer at a constant cadence of 80-100 rpm with work-rate (VO2max) increasing by 0.42 W.s⁻¹ following a 60 s period at 100 W. Using a pre-calibrated metabolic cart, plateau responses were determined using the criteria of $\Delta VO2 < 1.5$ ml.kg⁻¹.min⁻¹ over the final two consecutive 30 s sampling periods. For CP trials, intensity was assigned on Pmax from VO2max 1 with individual trials completed at ~120, 100 and 95% Pmax. CP and W' were derived using a linear P -1/t model and solving the equation $P = AWC.(1/t) + CP$. **Results** Seven participants exhibited a plateau response (RE), $\Delta VO2$ ml.kg⁻¹.min⁻¹ (0.73 ± 0.53) compared to non-responders (NRE) (n= 8) of 2.4 ± 0.4 ml.kg⁻¹.min⁻¹ (P= 0.005). For RE a significant inverse correlation was observed between $\Delta VO2_{dif}$ ml.kg⁻¹.min⁻¹ (difference between criterion and actual response) and W' (P= 0.030) but not for NRE (p> 0.05). Additionally there were no differences for VO2max, CP or Pmax for RE and NRE (p> 0.05). CP was however significantly correlated to VO2max for RE (P= 0.064) and NRE (P= 0.008). **Discussion** These data suggest that the manifestation of the plateau at VO2max as expressed as a function of the AWC, representing the balance between the finite anaerobic capacity, accumulation of the fatigue induced metabolites and O2 bound to haemoglobin and myoglobin. The findings lend support to the classical interpretation for a cardiac limitation to VO2max and offer further insight into the issues surrounding plateau attainment. dan.gordon@anglia.ac.uk

LACTATE PRO VS LACTATE PRO2

Mamen, A.

University College of Health Sciences-Campus Kristiania

Introduction The Lactate Pro LT-1710 from KDK (now Arkay Global Business Inc, Kyoto, Japan) quickly became a popular «credit card» size blood lactate analyser. Now a new model is on the market, Lactate Pro2 LT-1730. The new model requires a smaller volume of blood, 0.3 micro litres, and thus has a shorter analysing time, 15 s, compared to 60 s in the old model. The measuring range is a whole blood lactate concentration (BLC) from 0.5 to 25.0 mmol/L. The weight is 45 g and it has a memory capacity of 330 measurements. Since the measuring sticks are different for the two models, users of LT-1710 at some time must change to the new LT-1730 if they wish to continue using Arkay products. For this reason, it is of importance to establish how well the two models compare in measuring BLC. **Methods** To do so, we had 40 subjects to exercise on the treadmill or cycle ergometer with a step protocol until exhaustion, measuring the BLC at each step. Altogether 174 parallel measurements were taken. **Results** Mean (SD) BLC was 4.6 (3.6) and 4.4 (3.9) for the LT-1710 and LT-1730 respectively. The 95% confidence interval was 0.5 and 0.6 for the two analysers. A Bland-Altman plot gave a bias of - 0.2, with a 95% confidence interval of -0.3 to -0.1. At high BLC (>12 mM), the LT-1730 gave significantly higher results than its predecessor, mean (SD) for the LR-1710: 13.4 (0.9) vs 14.2 (1.4) for the LT-1730, $p < 0.05$. 95% confidence interval was 0.5 and 0.8 respectively. For the lower BLCs (>3.0 mM) the opposite was true, LT-1710: 2.0 (0.7) and 1.7 (0.6) for LT-1730, $p < 0.01$. 95% confidence interval was 0.1 for both units. Pearson product moment correlation was 0.99. To see if the analysers would give different results in practical work, 40 lactate profile tests on cycle ergometer were analysed. Two threshold determinations were used, a delta approach where 2.0 mmol/L was added to the resting BLC value, and a fixed concentration method that uses 4.0 mmol/L BLC. With the delta method, the mean threshold power was 210.3 (39.8) W vs 211.9 (38.1) W for LT-1710 and LT-1730, $p = 0.86$. 12 of the 40 tests (30%) had a difference between 10 and 18 W. This difference may be considered as an important difference. The rest of the tests showed only minor differences, less than 10 W. For the 4 mmol/L approach the threshold power was 211.1 (40.1) and 217.2 (39.6) W respectively, $p = 0.53$. Thirteen results differed with more than 10 W, with 22 W as the largest deviation. **Discussion** The smaller volume of blood possibly makes the measurements more prone to variation due to contamination of the blood drop. Our results show that the LT-1730 performed well against its predecessor and on a group level gives comparable results. In about one third of the lactate threshold tests the analysers deviated so much that it may have practical importance for athlete diagnostics. asgeir.mamen@nhck.no

THE EFFECTS OF ACUTE VERSUS CHRONIC SODIUM BICARBONATE SUPPLEMENTATION ON HIGH-INTENSITY INTERMITTENT SPRINT PERFORMANCE IN RUGBY UNION PLAYERS

Fitzpatrick, P., Warrington, G.

Dublin City University

Introduction Exogenous ingestion of alkalis agents, such as sodium bicarbonate (SB), has been shown to enhance muscle buffering capacity, thereby delaying the metabolic acidosis associated with high-intensity exercise and potentially improving performance. The aim of this research was to examine the effects of acute and chronic SB supplementation in comparison to a placebo (PLA) on high-intensity intermittent sprint performance in trained rugby union players. **Methods** Using a double-blind, randomised, cross-over design, ten trained male rugby union players (age 28 ± 5 years) completed four separate trials – two acute and two chronic supplementation trials. For the acute trials, subjects ingested either 0.3g/kg body mass (BM) of NaHCO₃ (SB-A) or a placebo (PLA-A) separated into three equal doses at 90, 60 and 30 minutes prior to the performance test. Chronic supplementation consisted of ingesting 0.3g/kg BM of NaHCO₃ (SB-C) or a placebo (PLA-C) each day for five consecutive days prior to the performance test. Using a resistance of 7.5% body mass, the performance test protocol consisted of 6 x 10s maximal sprints on a cycle ergometer followed by 50 seconds active recovery prior to each subsequent sprint. Peak power output (PPO) and mean power output (MPO) were recorded for each 10s sprint. Blood bicarbonate (StdHCO₃-), pH, base excess (BE-Ecf), blood lactate, PCO₂ and PO₂ were also measured. **Results** Acute SB supplementation demonstrated significant elevations in pre-exercise levels for blood bicarbonate (StdHCO₃-), pH and base excess (BE-Ecf) but no significant improvement in peak power output (PPO), mean power output (MPO) or total work (TW). Chronic SB supplementation exhibited a significant increase in StdHCO₃- following Sprint 1 only. However, no significant differences in performance parameters were recorded for either acute or chronic SB supplementation when compared to the PLA trial. **Discussion** The major findings of this work suggest that pre-exercise metabolic alkalosis may be induced following acute but not chronic SB ingestion. However, results are inconclusive regarding the efficacy of acute or chronic SB ingestion to enhance performance in high intensity, intermittent performance indicative of the physiological demands associated with rugby union. Results also appear to indicate a high degree of individual variability, which, in part, may be due to potential gastrointestinal side effects of SB ingestion. **Conclusion** Neither acute nor chronic SB supplementation had a significant impact on performance as measured by power output in a high-intensity intermittent sprint test. Although metabolic alkalosis was induced with acute SB ingestion, identified by increases in blood StdHCO₃-, pH and BE-Ecf, no ergogenic benefit was observed. The highly individual response elicited by SB supplementation warrants further research to examine the efficacy of acute and chronic SB supplementation on high-intensity intermittent exercise.

IV IRON SUPPLEMENTATION REDUCES PERCEIVED FATIGUE IN DISTANCE RUNNERS

Thompson, K.G.¹, Garvican Lewis, L.A.^{1,2}, Woods, A.¹, Saunders, P.², Gore, C.J.^{1,2}

University of Canberra¹, Australian Institute of Sport²

Introduction Recently, intravenous (IV) iron supplementation was shown to improve fatigue in non-anaemic pre-menopausal women without altering total body haemoglobin (Hb) (Krayenbuehl et al, 2011), indicating potential non-haematological benefits of iron supplementation. In athletes, the 'optimal' level of iron for training and wellbeing is uncertain. IV iron supplementation improved Hb mass and VO₂max in trained runners with 'low' iron levels but no effects were observed in those with an initial ferritin >35µg/L (Garvican et al 2013). Performance and perceptions of fatigue were not assessed therefore; this study aimed to investigate the effect of IV iron supplementation on performance, and perceived fatigue in distance runners without clinical iron deficiency. **Methods** 14 distance runners with initial ferritin of 30-100 µg•L⁻¹ were randomly assigned to receive 3 x 2ml blinded injections of either IV ferric carboxymaltose (IRON) or normal saline (PLACEBO) fortnightly over four weeks (week 0, 2, 4). Athletes performed a 3000m time trial and 10 x 400m monitored training set at baseline (PRE) and on consecutive days following each injection with a follow up two week after the final injection. Perceived fatigue was determined PRE and fortnightly thereafter via Total Fatigue Score (TFS) and Total Mood Disturbance (TMD) using the Brief Fatigue Inventory and Brunel Mood Scale, respectively. Data were analysed using magnitude-based inferences with 90% Confidence Limits and Cohen's Effect Sizes. **Results** At week 6, serum ferritin was substantially increased in IRON only (% change; 90% CL, Effect Size: 90.6%; 35.1 to 168.7%, 1.51). No clear improvements in 3000m performance were observed in either group, IRON reduced average time for the 10x400m training set (-0.7%; -1.6 to 0.3%, -0.07) at week 4. TFS and TMD substantially decreased in IRON but not PLACEBO at week 6 (TFS: -59.1%; -78.1 to -23.7%, -1.77, TMD: -10.2%; -19.5 to 0.2%, -0.52), with the difference in change score greater in IRON than PLACEBO for both parameters (TFS: -54.0%; -77.3 to -6.9%, -1.26; TMD: -11.2%; -23.2 to 2.6%, -0.88). **Discussion** IV iron supplementation may improve perceived fatigue of trained athletes with normal ferritin levels but does not appear to acutely affect running performance. The long term effect of IV iron supplementation on health and training status warrants further investigation. **References** 1. Krayenbuehl P, Battegay E, Breyman C, et al. PHYSIOLOGICAL CORRELATES OF COMPETITIVE PERFORMANCE IN PORTUGUESE ELITE MIDDLE DISTANCE RUNNERS

Reis, J.¹, Manuel, B.¹, Reis, V.M.², Almeida, T.¹, Vleck, V.¹, Alves, F.¹

1. CIPER, University of Lisbon (Lisbon, Portugal); 2. CIDESP, UTAD (Vila Real, Portugal)

Introduction Middle distance performance in running is dependent on the ability of deriving high amounts of muscle power from both the aerobic and the anaerobic metabolic energy systems. The purpose of this study was to identify the physiological correlates of the 1500 m performance in elite middle distance Portuguese runners. **Methods** All tests were completed two to five days after the main races of the season where every athlete ran the 1500m event. The time obtained was registered as the season best time (SBT). 28 national and international level male Portuguese middle distance runners (SBT: 3:45.20±5.8 min:s) participated in this study (age: 24.1±3.9 yr.; body mass:

64.5±5.8 kg; height: 177.5±7 cm). All tests were conducted on a standard 400-m outdoor athletics track. Subjects initially completed an incremental test of 5x6 min duration and constant velocity steps, in order to estimate submaximal energy cost of running, VO₂peak and maximal aerobic velocity (MAV) and lactate threshold. In a subsequent session, a supramaximal test of 600 m was performed, to complete the estimation of maximal anaerobic oxygen deficit (MAOD) and to analyze VO₂ on-kinetics. Time constant of the primary phase (τ) and amplitude were calculated using a mono-exponential model. Respiratory data was collected breath by breath (K4b2, Cosmed, Italy) and blood lactate concentrations were measured with the Lactate Pro LT-1710 analyser (Arkay KDK). Results Only MAV (5.73±0.46 m.s⁻¹) showed a significant correlation with the 1500 m race performance ($r=0.40$; $p\leq 0.05$). VO₂peak (65.43±6.33 ml.kg⁻¹.min⁻¹) showed a small interindividual variability (coefficient of variation= 9.7 %), contrarily to MAOD (34.61 ± 11.23 mlO₂.kg⁻¹; coefficient of variation=32.4 %). In spite of this, MAOD was poorly related to SBT ($r^2=0.16$). However, the five best race time runners showed MAOD values lower than the average of the total group (26.04 ± 8.35 mlO₂.kg⁻¹). On the other hand, MAOD was negatively correlated with MAV ($r=0.42$; $p\leq 0.05$), confirming the tendency for lower anaerobic capacity in the faster 1500 m runners. Supramaximal τ (9.62±2.21s) was negatively associated to VO₂peak ($r=-0.60$; $p\leq 0.05$). Discussion Best middle distance Portuguese runners, in spite of a good international competitive level, have a markedly aerobic profile, possibly lacking muscle power and sprint adaptations. VO₂ on-kinetics time constant, measured in a supramaximal track running test of 600 m, was not confirmed as a predictor of 1500 m performance. The fast VO₂ responses observed, however, when compared with data from different training status age matched populations (Bosquet et al., 2007), in similar duration and intensity exercises, indicate that this parameter is influenced by aerobic training. ASSESSING STRIDE PARAMETERS AND VERTICAL STIFFNESS WITH GPS-EMBEDDED ACCELEROMETERS

Buchheit, M.1, Gray, A.2, Di Salvo, V.1, Morin, J.B.3

1: Aspire (Doha, Qatar), 2: Athletic Data Innovations (Sydney, Australia), 3: Exercise Physiology Lab (Saint-Etienne, France)

Introduction Classical time-motion analyses in soccer include distance covered into specific speed zones, accelerations, decelerations and accelerometer-derived measures of 'body load'. While these data may be useful to assess match (locomotor) demands, they are very likely dependent on game pace. They might therefore lack of sensitivity to detect neuromuscular fatigue per se. The aim of the present study was to examine the ability of GPS-imbedded accelerometers to assess stride parameters and vertical stiffness (K), which are related to neuromuscular fatigue during repeated high-intensity runs [1]. The ability to detect stride imbalances was also examined. **Methods** A team sport player performed a series of 30-s runs on a motorized treadmill (ADAL3D-WR, MD, Andrézieux, France, 6 @10 km/h, 6 @17 km/h and 6 @24 km/h) with or without his right ankle taped (aimed at creating a stride imbalance), wearing on his back a commercially-available GPS system (VX Sports, VX340a, Lower Hutt, New Zealand) with an embedded 100-Hz accelerometer. Contact (CT) and flying (FT) time, and K [2] were computed from both treadmill and accelerometers (Athletic Data Innovations) data. The agreement between treadmill (criterion measure) and accelerometer-derived data was examined. We also compared the ability of the different systems to detect the lateral imbalance. Data were analyzed using magnitude-based inferences. Results Biases were small (CT, -10.4%; 90CI: -12.3, -9.8; K -13.3%; -14.6, -11.9) and moderate (FT, -25.8%; -18.8, -27.7). The typical error of the estimate was trivial (CT: 3.9%, 3.4, 4.6), small (K: 6.3%; 5.5, 7.5) and moderate (FT: 15.7%; 13.5, 18.9), with nearly perfect (CT: $r=0.98$; 90%CI 0.97, 0.99; K: 0.98; 0.97, 0.99) and large (FT: 0.68; 0.55, 0.78) correlations for treadmill vs. accelerometer. The tape induced very large increase in the right - left foot Δ in CT (4.5%; 4.2, 4.9), FT (7.0%; 2.3, 11.3) and K (10.3%; 8.6, 12.0) on the treadmill. The tape effect observed with the accelerometers on CT (3.7%, 2.3, 5.0) and K (6.4%, 3.8, 9.2) were also very large but of lower magnitude than with the treadmill (Δ in the Δ CT: -0.9%, -2.4, 0.7 and K: -3.9%, -7.5, -0.3). The accelerometer-derived tape effect on FT was unclear (0.3%, -3.7, 4.3). **Discussion** Present data highlight the potential of GPS-embedded accelerometers to assess CT and K during ground running. Since CT and K are two important determinants of high-intensity running performance [1], our results open new perspective for the field monitoring of neuromuscular fatigue. References 1. EFFECT OF FOOTSTRIKE PATTERN ON RUNNING ECONOMY AT A FAST SPEED

Terasaki, N., Suzuki, T., Ogane, R., Shioda, K., Kinugasa, R.

Kanagawa University

Introduction No difference in running economy between rearfoot and forefoot strike patterns has been observed in four previous studies (Ardigò et al. 1995; Cunningham et al. 2010; Gruber et al. 2013; Perl et al. 2012). However, these previous studies comparing running economy between footstrike patterns were limited by over a range of a slow to medium (~ 15 km•h⁻¹) speeds. The present study was therefore to determine whether there were differences in running economy between footstrike patterns at a fast speed. **Methods** Six male habitual forefoot runners performed the rearfoot and forefoot patterns on a treadmill at 10 and 18 km•h⁻¹ while wearing standard running shoes. Steady-state rate of oxygen consumption was determined for each footstrike and speed conditions. After 2 min of habituation, subjects performed four trials in a random order. Each trial lasted a minimum of 3 min, with at least 1 min of running after VO₂ levels reached a steady-state. Running economy was expressed as the rate of VO₂ (ml•kg⁻¹•min⁻¹). Results No significant difference in VO₂ was observed between footstrike patterns at a slow and fast speeds. VO₂ was 33.7 ± 1.3 ml•kg⁻¹•min⁻¹ for the forefoot strike and 34.3 ± 2.2 ml•kg⁻¹•min⁻¹ for the rearfoot strike at the slow speed while VO₂ was 56.9 ± 4.4 ml•kg⁻¹•min⁻¹ for the forefoot strike and 57.1 ± 3.4 ml•kg⁻¹•min⁻¹ for the rearfoot strike at the fast speed. **Discussion** We predicted that foot strike types affect running economy at a fast speed. This hypothesis is based on idea that performing the nonhabitual pattern resulted in artificially high rates of VO₂ given that performing a novel task typically causes an increase in the rate of VO₂ and requires habituation to observe any improvement in economy (Cavanagh & Williams 1982). Differences in running economy may be results of the different muscle activation patterns, elastic energy utilization in the Achilles tendon (Lieberman 2010), and force exerted by a muscle fibers that probably take longer to adapt to a new gait pattern than kinematic adjustments (Duchateau et al. 2006). However, the potential for predicted high VO₂ as a result of performing a nonhabitual footstrike pattern was eliminated in our investigation, indicating the acute response to switching footstrike patterns in habitual forefoot runners may not appear to be any impact on running economy regardless of running speed. A long accommodation period may thus be required when examining metabolic differences between footstrike types. BAREFOOT VS. SHOD: A COMPARISON OF LOWER LIMB MOTION DURING RUNNING USING SYMMETRY ANALYSIS

Langley, B., Morrison, S., Cramp, M.

University of East London

Introduction Previous research (Sinclair et al., 2013; De Wit et al., 2000) has assessed kinematic differences between barefoot and shod running and reported differences in sagittal plane hip, knee and ankle motion at discrete points within the gait cycle. Further information may be gained about kinematic differences by analysis of the entire kinematic waveform. The aim of this work was to examine differences in barefoot and shod lower limb kinematics during running using symmetry analysis. **Method** Fifteen males (27 ± 5 years, 1.77 ± 0.04 m, 80 ± 10 kg) ran at a self selected pace (2.8 ± 0.5 m.s⁻¹) on a treadmill in barefoot and shod conditions (standardized ASICS running shoes). Kinematic data were collected using an eight camera VICON MX motion analysis system (sampling at 200Hz). Hip, knee and ankle angles were calculated using the Plug in Gait model (Davis et al., 1991) and averaged over 5 gait cycles. Trend symmetry (TS) analysis (Crenshaw & Richards, 2006) was used to compare kinematic curves for the two conditions. A TS score of 1 equals perfect symmetry and > 0.95 highly symmetrical waveforms. TS values were calculated for each subject and averaged across subjects. Additionally, joint angles at initial contact (IC) and stance phase range of motion (ROM) were compared between conditions using paired t-tests and Wilcoxon matched pairs analysis. Results TS analysis revealed highly symmetrical ($TS > 0.95$) kinematic patterns for barefoot and shod conditions at the hip, knee and ankle in the sagittal plane, hip and ankle in the frontal plane and the knee and ankle in the transverse plane. Knee joint motion in the frontal plane was the least symmetrical ($TS = 0.87$). Significant ($p < 0.05$) differences between conditions at IC were recorded at the ankle in all three planes. Sagittal plane knee, and transverse plane knee and ankle motion were significantly ($p < 0.05$) greater in the shod condition. Sagittal plane ankle joint motion was significantly ($p < 0.05$) greater in the barefoot condition. Discussion The kinematic patterns recorded within this study are consistent with those reported by Sinclair et al., (2013) for barefoot running. Overall TS analysis revealed that barefoot and shod running patterns are highly similar. However, there are significant changes in lower limb orientation at IC and the ROM at the knee and ankle. **References** Crenshaw SJ, Richards JG (2006) *Gait Posture*, 24, 515-521 Davis RB, Öunpuu S, Tyburski D, Gage JR (1991) *Hum Mov Sci*, 10, 575-587 De Wit B, De Clercq D, Aerts, P (2000) *J Biomech*, 33, 269-278 Sinclair J, Greenhalgh A, Brooks D, Edmundson CJ, Hobbs SJ (2013) *Footwear Science*, 5, 45-53 Contact langley@uel.ac.uk

FOOD-INTAKE BY ULTRA-MARATHON RUNNERS DURING TRAINING AND COMPETITION: CROSS-SECTIONAL SURVEY AND CASE-REPORT

Wardenaar, F.1, Ceelen, I.1, De Vries, J.2, Mensink, M.2, Witkamp, R.2

1: HAN University of Applied Sciences (Nijmegen, NL), 2: Wageningen University (Wageningen, NL).

Introduction Athletes competing in ultra endurance activities can have difficulties to meet nutrition recommendations due to a variety of reasons. We questioned whether general guidelines as stated in the IOC consensus (2010) are feasible for this discipline. The present field study focused on carbohydrate (CHO) and fluid intake of ultra-marathon runners competing in the 60 km or 120 km of Texel in April 2013. The purpose was to determine dietary intake during a training period, and during the day of the race. **Methods** 68 male and female ultra-marathon runners completed 2-3 24h-recalls with an additional questionnaire regarding sports nutrition and supplement intake during a training period several weeks before the race. Dietary intake of a small group of 120 km runners ($n=4$) was continuously observed and registered during the race (mean finish time 11:01:05h). Finally, dietary intake before and during the race of 60 km was assessed a day after the race ($n=42$), using a questionnaire (mean finish time 6:04:32). The Dutch food composition table (NEVO 2011) was used for conversion of dietary intake into energy and nutrients. If an Estimated Average Requirement value (EAR) was available group dietary intake was evaluated by SD-corrected % probability of inadequacy (POI). If not, dietary intake was evaluated qualitatively based on the median vs Adequate Intake (AI). Data are presented as mean \pm SD or median(25th-75th). **Results** During training males ($n=54$) consumed on average 11.3 ± 2.6 MJ per day. Mean CHO intake was 4.4 ± 1.3 g/kg/day. POI was 2.7% based on an EAR of 2.9g/kg, 77% had an intake lower than 5g/kg and 100% had an intake below 7g/kg. Females ($n=14$) consumed 8.8 ± 2.1 MJ. Mean CHO intake was 4.5 ± 1.3 g/kg. POI was 0.3% based on EAR of 2.9g/kg, and 83.4% had an intake lower than 5g/kg. All had an intake lower than 7g/kg. The prevalence of inadequate fluid intake with an AI of 2.5L/day for both groups was considered low, based on the estimated median fluid intake of 2.9(2.3-3.3) L and 2.7(1.7-3.3) L for males and females, respectively. Before the race, 87.8% of the runners reported consumption of >1 g/kg CHO, and 70.6% reported a consumption of >8 ml/kg of fluid. During the race 24.4% of the group met the recommendations of >60 g/h CHO and 14.6% consumed >500 ml/h of fluid. The mean intake of 120 km runners for carbohydrate was 67.2g/h (range 31-108), with only one subject below 60g/h. Observed mean hourly fluid intake was 529.5ml (range 392.3-608.8 ml/h). Mean weight loss during the race was 1.5% but with large individual differences (-4% up to +1%). In conclusion, daily habitual CHO intake of ultra-marathon runners is above EAR, but more than 75% has an intake <5 g/kg/day, which is considered the minimum for endurance athletes. Based on self-reported intake, recommended CHO and fluid intake pre-race was met by $>70\%$ of the runners. During the race fewer than one quarter of the athletes reported an adequate CHO and fluid intake. However, CHO and fluid intake in four 120 km runners observed during the race seemed adequate.

08:30 - 10:00**Oral presentations****OP-PM23 Obesity & Exercise****IMPACT OF ADRB3 SNP ON ABDOMINAL FAT IN OVERWEIGHT AND OBESE WOMEN**

Szendrei, B.1, Cupeiro, R.1,2, Amigo, T.3, Gonzalez Lamuno, D.3, Gomez, C., Lopez Plaza, B., Peinado, A.B.1, Calderon, F.J.1

1: Technical University of Madrid 2: University of Francisco de Vitoria 3: IFIMAV- University of Cantabria 4. IdiPAZ, University Hospital La Paz, SPAIN

Introduction The β -3 adrenergic receptor takes part in lipid metabolism and the Trp64Arg polymorphism of the gene has been associated with metabolic risk factors and obesity. The aim of this study was to analyze the effect of the Trp64Arg polymorphism of the ADRB3

gene on the android adipose tissue (AAT) and the abdominal visceral fat (VAT) during a controlled exercise and diet program in overweight and obese healthy women. Methods 101 women (38.28 ± 8.11 years, 1.62 ± 0.06 m, 80.21 ± 10.23 kg) followed a 24-week weight loss intervention of a controlled training program (supervised exercise group, S; 3 times/week; 38-60 min/session; strength, endurance or combined training) or exercise recommendations (non-supervised group, NS) and a caloric restriction (30% of the total daily energy expenditure). AAT (kg) and VAT (kg) were determined by dual-energy X-ray absorptiometry before and after the intervention. Genotyping of the overweight subjects was done based on the PCR and RFLP techniques according to previously used protocols, and of the obese subjects using Real Time PCR [1, 2] Results Genotype distribution was 84 Trp64Trp and 17 Trp64Arg subjects. In the NS group we found higher AAT in Trp64Trp women than in Trp64Arg only after the intervention (2.94 ± 0.320 vs 2.26 ± 0.13 kg, $p=0.049$). Pooling NS+S we observed a tendency toward the same (2.64 ± 0.18 vs 2.29 ± 0.07 kg, $p=0.070$). Trp64Arg NS group tended to have higher AAT after 24 weeks than S group (2.94 ± 0.32 vs 2.33 ± 0.15 kg, $p=0.083$). Regarding VAT, within NS group Trp64Trp and Trp64Arg significantly differed before and after the program (1.35 ± 0.22 vs 0.74 ± 0.09 kg, $p=0.01$ and 1.21 ± 0.19 vs 0.51 ± 0.08 kg, $p=0.001$). Pooling NS+S we found a borderline significance between Trp64Trp and Trp64Arg at baseline (1.02 ± 0.12 vs 0.78 ± 0.05 kg, $p=0.056$) and significant difference at the end (0.87 ± 0.11 vs 0.55 ± 0.04 kg, $p=0.007$). Trp64Arg women of the NS group did not improve significantly these parameters during the weight loss program in contrast to the other groups. Discussion Previous studies mentioned the importance of the Trp64Arg polymorphism of the ADRB3 gene [3,4]. Our data confirm that it has an influence on android and visceral adipose tissue and that controlled exercise combined with diet seems to be the best tool to reduce them. DOES SERUM IL-6 CONCENTRATION EXPLAIN THE RELATIONSHIPS BETWEEN ADIPOSITY AND MUSCLE SIZE AND STRENGTH IN YOUNG AND OLDER ADULTS?

Erskine, R.M.^{1,2}, Tomlinson, D.J.², Morse, C.I.², Winwood, K.2, Onambele Pearson, G.L.²

(1)Liverpool John Moores University, UK; (2)Manchester Metropolitan University, UK

Introduction Sarcopaenia, the age-related loss of muscle mass, has been associated with elevated markers of chronic inflammation, such as interleukin-6 (IL-6). However, it is not clear how increased adiposity influences skeletal muscle properties in both young and older individuals, and how circulatory inflammatory cytokines may explain potential relationships between body fat and muscle size and strength. The purpose of this study was to investigate the relationships between adiposity and skeletal muscle size, architecture and maximum strength in healthy young and older adults, and to examine whether serum [IL-6] could explain these relationships. Methods One hundred and forty-two healthy, untrained men and women aged 18-80 yr (BMI: 17-49 kg/m²) performed isometric and isokinetic plantar flexor maximal voluntary contractions (MVCs) on a Cybex dynamometer. Voluntary muscle activation and antagonist muscle co-activation were assessed using the interpolated twitch technique and EMG, respectively. Achilles tendon moment arm, volume (Vm), fascicle length and pennation angle (AoP), and physiological cross-sectional area (PCSA) of m. gastrocnemius medialis (GM) were measured using ultrasonography. GM specific force was calculated as GM fascicle force/PCSA. Body fat mass (BFM) and lean mass (LM) were assessed using dual-energy X-ray absorptiometry. Serum [IL-6] (n=67) was measured using ELISA. Results Isometric and isokinetic MVC torque correlated with LM, Vm, PCSA and AoP ($r \geq 0.426$; $p < 0.001$). Isokinetic MVC torque also correlated with BF% ($r = -0.245$; $p = 0.003$), and [IL-6] ($r = -0.280$; $p = 0.023$). BFM correlated with Vm, PCSA, AoP and LM ($r \geq 0.312$; $p < 0.001$), and with [IL-6] ($r = 0.380$; $p = 0.002$), muscle specific force ($r = -0.296$; $p = 0.011$). In addition to isokinetic MVC and BFM, [IL-6] correlated with BF% ($r = 0.358$; $p = 0.003$). Discussion Our data show that positive relationships exist between fat mass and precise measures of muscle size and architecture in young and older adults, which suggest a loading (hypertrophic) effect of chronically elevated adiposity on skeletal muscle. However, the inverse relationships between BF% and dynamic strength, and between fat mass and muscle specific force, suggest that any hypertrophic effect of increased adiposity is countered by a decrease in muscle quality (possibly by an increase in intramuscular fat content). Moreover, the positive relationships between [IL-6] and fat mass and BF%, and the inverse relationship between [IL-6] and isokinetic strength indicate a role for inflammatory cytokines in further reducing skeletal muscle quality, possibly by chronically elevating muscle protein breakdown. EFFECTS OF TWO DIFFERENT TYPES OF EXERCISE ON CIRCULATING IRISIN LEVEL IN OBESE ADULTS

Song, W., Lee, H., Kim, H., Yoon, D., So, B., Son, J., Lee, Y., Seo, D., Chang, H

Health and Exercise Science Laboratory, Institute of Sports Science, Seoul National University., Dongguk University., Seoul Womens University

Objective. The novel myokine irisin has been reported as a therapeutic target for obesity and diabetes. Irisin is induced by exercise and activation increases gene expression of brown fat thereby elevates energy expenditure. However, only a few study investigated the effect of exercise on expression of circulating irisin level. In addition, there is no study how different exercise effects circulating irisin level in obese adults. Therefore, the objective of this study is to reveal the effects of aerobic exercise (AE) and resistance exercise (RE) training on expression of circulating irisin level in obese adults. Material/Methods. Participants were randomly assigned into exercise groups. Twenty eight obese adults (20-30 yrs) were included in this study. The final participants were AE(n=10), RE(n=10) and control (n=8). The samples were analyzed before and after 8 week of 60 min exercise program. Results. The subjects, in both aerobic and resistance training, showed significant improvement in anthropometric parameters, maximal oxygen uptake and muscle strength. Interestingly the circulating irisin was significantly increased in resistance training group but not in aerobic training and control groups. Furthermore, the exercise-induced change of the circulating irisin was positively correlated with muscle mass. On the other hand, the exercise-induced change of the circulating irisin was negatively correlated with fat mass and body fat percentage. Conclusion. These findings suggest that resistance training might play important role in improvement of circulating irisin level in obese adults.

ACUTE PHYSIOLOGICAL EFFECTS OF A SINGLE BOUT OF AEROBIC INTERVAL AND CONTINUOUS MODERATE INTENSITY CYCLING IN OBESE INDIVIDUALS.

Koh, F.J.1, Newton, R.U.1, Watson, G.2, Baker, M.3, Lin, Z.Y.1, Abbiss, C.R.1

(1)Edith Cowan University, (2) University of Tasmania, (3) Australian Catholic University

Introduction There are informal reports that obese participants prefer aerobic interval (AI) training to continuous moderate (CM) intensity exercise (Tjønnna et al., 2008). While both AI and CM exercise are effective in the treatment of many chronic diseases, it is possible that the

acute physiological effects of the last exercise session in training studies may persist beyond 24h and thus confound results (Whyte et al., 2010). The aims of this study were to examine the physiological effects and perceived enjoyment of an acute bout of AI and a CM in an obese population. Methods In a randomised and counterbalanced order, eight obese (waist: 103 ± 10 cm) participants performed bouts of CM (40 min at 50% peak power output (PPO)) and AI cycling (13 x 1 min at 85% PPO: 2 min at 30% PPO). CM and AI were isocaloric and matched for duration. Salivary cortisol was measured before, 10 and 30 min post exercise and analysed using ELISA kits. Participants completed the Physical Activity Enjoyment Scale (PACES) at the end of each trial. Blood pressure (BP) and resting metabolism were measured at baseline, post 24, 48 and 72h in a fasted state. Peripheral BP was measured in duplicate using manual sphygmomanometer and central BP was derived from the radial pulse wave using a sphygmocardiogram (Sphygmocor). Resting metabolism was determined from gas exchange (TrueOne® gas analyser) measured in a supine and rested state over 40 minutes. Results Salivary cortisol increased in both trials and was significantly (mean \pm SD) 1.89 ± 0.35 times higher at 30 min post exercise. Peripheral diastolic BP averaged over time points was lower in the AI trial (82 ± 5 vs. 84 ± 5 mmHg) and it was lower than baseline (86 ± 12 mmHg) at post 24h (-3 ± 1 mmHg) and at 72h (-4 ± 2 mmHg). Resting mean arterial BP were lower than baseline (102 ± 14 mmHg) at post 24, 48 and 72h (-4 ± 1 , -5 ± 2 , -4 ± 2 mmHg, respectively) with the average over four time points lower in AI (98 ± 6 mmHg) than CM (100 ± 5 mmHg). Similar observations were found in derived central BP parameters. Resting carbohydrate oxidation rates were higher at 72h post exercise (0.16 ± 0.02 g/min) than baseline (0.10 ± 0.06 g/min), with no difference between trials. PACES scores were significantly higher for the AI than the CM trial (109 ± 13 vs. 96 ± 10). Discussion We have shown that physiological effects after a single exercise bout can persist up to 24 - 72h. Also, AI elicited greater decrease in diastolic pressure and is enjoyed more by obese individuals. References Tjønnå, A. E., Lee, S. J., Rognmo, O., Stølen, T. O., Bye, A., Haram, P. M., . . . EXERCISE TRAINING COMBINED TO WELL-BALANCED DIET INCREASES NRG1 CLEAVAGE AND ADAM17 EXPRESSION IN SKELETAL MUSCLE OF OBESE RATS.

Ennequin, G.1, Boisseau, N.1, Caillaud, K.1, Chavanelle, V.1, Gerbaix, M.1, Metz, L.1, Etienne, M.1, Walrand, S.2, Masgrau, A.2, Guillet, C.2, Courteix, D.1, Capel, F.2, Sirvent, P.1

1: AME2P (Clermont-Ferrand, France); 2: UNH Laboratory (Clermont-Ferrand, France)

Introduction Recent studies have shown that Neuregulin 1 (NRG1) is secreted during exercise and favors glucose consumption in skeletal muscle cells. Furthermore chronic exposure to NRG1 increases oxidative capacity in L6E9 and C2C12 cells. From this data, it appears relevant to hypothesize that metabolic disorders could be associated with alteration of NRG1 signalling pathway and that chronic exercise could induce an improvement of NRG1 signaling in skeletal muscle of obese rats. Protocol 72 male Wistar rats (7-month-old) were assigned in 2 groups: 12 rats were fed with a well-balanced diet (Control) and 60 rats fed with high fat/high sucrose (HF/HS) diet for 4 months to induce obesity. After obesity induction, the totality of the Control group and 12 rats of the HF/HS group were sacrificed (T1). The other 48 rats were randomly assigned into four groups for 8 weeks. Two groups pursued the HF/HS diet and were attributed to exercise (HF/HS+E) or sedentary schedule (HF/HS). The two others groups followed a well-balanced diet and performed exercise (ND+E) or not (ND) (T2). Endurance training was performed on treadmill 5 days/wk at 15 m/min. Gene expression of NRG1 isoforms and its receptors (ErbBs) was assessed by RT-PCR and protein expression of NRG1 isoforms and a metalloprotease (ADAM17, involved in NRG1 cleavage and activation) was assessed by Western-Blot in gastrocnemius. Results After HF/HS diet, weight gain was significantly higher in HF/HS compared to Control. Obesity induced a significant increase of NRG1- α mRNA in HF/HS compared to Control. We did not observe changes in HF/HS group regarding ErbBs and NRG1- β mRNA levels. After training and a return to well-balanced diet, ErbB4 gene expression was increased in ND+E group compared with HF/HS, HF/HS+E and ND groups. Cleaved NRG1 isoform was significantly enhanced in ND+E group compared to other groups. Consequently, the NRG1 cleavage ratio was more elevated in ND+E group compared to the other groups and this was associated with an up-regulation of ADAM17. Conclusion Taken together, these results suggest that endurance training combined with a well-balanced diet leads to an increased expression of ADAM17 which could induce a NRG1 cleavage, leading to an increase in NRG1 active form. Combined with the increased expression of ErbB4 receptor, these results indicate a potential activation of NRG1/ErbB signaling pathway in skeletal muscle, which could lead to improvements of cellular carbohydrate metabolism in metabolic disorder context.

EFFECTS OF EXERCISE AND FOOD RESTRICTION IN ADULTHOOD ON BODY COMPOSITION AND ENERGY METABOLISM-RELATED ENZYMES IN THE SKELETAL MUSCLES OF OTSUKA LONG EVANS TOKUSHIMA FATTY RATS

Daisuke, S.

The Jikeikai University School of Medicine

【Purpose】 Our previous study showed that pre-pubertal onset of exercise enabled sustained maintenance of a lower body weight (BW) in obesity-diabetes model Otsuka Long Evans Tokushima Fatty (OLETF) rats whose age corresponded to middle age in humans. However, the lowered BW was regained quickly after the food restriction regimen was stopped. It needs to be confirmed if the maintenance of the lost BW is acquired only through pre-pubertal onset of exercise. Therefore, this study examined the effects of exercise and food restriction conducted on OLETF rats aged between 20 and 34 week on BW, body composition, and glucose-fat metabolism in their later life.

【Methods】 Twenty-four OLETF rats were divided into exercise (Ex), food restriction (Diet), and sedentary control (Sed) groups. The Ex group exercised every day on a rotating wheel. The food intake of the Diet group was roughly 60-70% that of the Sed group. Both interventions were conducted at 20-34 weeks of age; subsequently, the rats were kept sedentary and allowed ad libitum food intake until 45 weeks of age. Fasting blood glucose (FBG) and serum leptin (SLept) levels were measured every 7 weeks. Whole-body subcutaneous fat mass (SFM), visceral fat mass (VFM), and lean body mass (LBM) were measured every 7 weeks by CT scan. At 46 weeks of age, after the experiment concluded, the rats were placed on an overnight fast and then anesthetized with pentobarbital. Blood samples were taken for measuring serum lipid concentrations. All rats were euthanized by performing bloodletting, after which one quadriceps femoris muscle per animal was removed for later measurement of citrate synthase (CS), succinate dehydrogenase (SDH), phosphofructokinase (PFK), and uncoupling protein 3 (UCP-3) mRNA expression. 【Results】 BW in the Ex and Diet groups decreased rapidly from the start of the intervention. However, the lowered BW in both groups increased again from 7 weeks after intervention onset. After the intervention ceased, BW in both groups gradually increased. At 45 weeks of age, there was no difference in BW among all the groups. SFM and VFM in the Ex and Diet groups were significantly lower than in the Sed group, but no significant difference was seen among the three groups at 35 weeks of age. No significant differences in serum lipids, FBS, and SLept concentrations as well as the CS, SDH, PFK activities, and UCP-3 mRNA expression in the skeletal muscle were seen among all groups after the intervention ceased. 【Conclusion】 To maintain

better BW, body composition, and glucose-fat metabolism indices, exercise and/or restriction of food intake should continue in adulthood and middle age in OLETF rats.

2 DAYS OF BOVINE COLOSTRUM SUPPLEMENTATION DID NOT BLUNT THE EXERCISE INDUCED INCREASE IN INTESTINAL PERMEABILITY

March, D.S.1, Thatcher, R.1, Marchbank, T.2, Playford, R.J.2, Davison, G.3

1: AU (Aberystwyth, UK), 2: PU (Plymouth, UK), 3: UoK (Chatham, UK)

Introduction Bovine colostrum (BC) has previously been shown to reduce the exercise-induced increase in intestinal permeability following 14 d of supplementation (Marchbank et al., 2011). However it is not known whether BC can induce similar effects following shorter supplementation periods. Therefore the aim of this study was to compare a shorter supplementation period (2 d) with the previously proven 14 d period. **Methods** A randomised crossover design was used. Participants undertook two baseline intestinal permeability measurements (5 h urine L/R ratio) separated by 48 h. A further 48 h later, participants peak oxygen uptake was determined. Following this, they ingested 10 g of either BC or a macronutrient-matched Placebo twice daily for 14 d. On day 2 and 14 of the supplementation period participants performed 20 min of treadmill running at 80% peak oxygen uptake after which intestinal permeability was again assessed (Post-Ex). This was then followed by a 2 week 'washout' period and all procedures were repeated. A two-way repeated measures analysis of variance (ANOVA) (trial x time) was performed to compare temporal (Baseline 1, Baseline 2, 48 h Post-Ex, 14 d Post-Ex) responses between trials (Placebo and BC). Post hoc paired t-tests with the Bonferroni correction were used where necessary. **Results** Significant main effects of trial, time and trial x time interaction were evident (all $P < 0.001$). Post Hoc analysis revealed significant Post-Ex increases in intestinal permeability in the Placebo arm (308% and 314% increases at 2 d and 14 d time points, $P < 0.001$ and $P < 0.001$). This was significantly blunted after 14 d of BC supplementation (168% increase, $P < 0.001$ compared to Placebo). However 2 d of BC supplementation did not significantly blunt the exercise induced increase (315% increase, $P > 0.05$, compared to Placebo). **Discussion** In support of previous findings (Marchbank et al., 2011) 14 d of BC supplementation significantly blunted the exercise-induced increase in intestinal permeability. However no effect of BC supplementation was observed after 2 d. It is likely that the supplementation period is too short to allow the bioactive substances within the colostrum to confer their benefit. Further study is warranted to determine whether higher doses, or BC in combination with other substances, can confer benefits with a shorter supplementation period. **References** Marchbank, T., Davison, G., Oakes, J. R., Ghatei, M. A., Patterson, M., Moyer, M. P., & Playford, R. J. (2011). The nutraceutical bovine colostrum truncates the increase in gut permeability caused by heavy exercise in athletes. *Am J Physiol Gastrointest Liver Physiol*, 300(3), G477-484. EFFECT OF WHEY PROTEIN HYDROLYSATE ON ADAPTATION TO ENDURANCE TRAINING IN WELL-TRAINED RUNNERS

Sondergaard Thomsen, L.1,2, Madsen, K.3, Bangsbo, J.4, Jensen, J.5, Rokkedahl Lausch, T.1, Ortenblad, N.2, Hansen, M.1

1 Aarhus University, Denmark; 2 University of Southern Denmark, Odense, Denmark; 3 University of Gothenburg, Sweden, 4 University of Copenhagen, Denmark, 5 Norwegian School of Sport Science, Oslo, Norway

Introduction: There is limited knowledge about the effect of protein on adaptation to endurance training. We aimed to examine effect of carbohydrate plus whey hydrolysate intake vs. isocaloric carbohydrate before and after each exercise session on endurance performance and mitochondrial adaptation in athletes during six weeks of endurance training. **Methods:** 30 well-trained endurance runners (aged 30.15y \pm 8.65; maximum oxygen uptake 60.75 ml O₂ kg⁻¹min⁻¹ \pm 3.73) participated in a block-randomized controlled intervention trial including six weeks of endurance training. Half of the runners ingested a protein beverage before (0.3 g kg⁻¹) and protein-carbohydrate beverage (0.3 g protein kg⁻¹ and 1 g carbohydrate kg⁻¹) after each exercise session (PRO+CHO). The other half of the group ingested energy matched carbohydrate beverages (CHO). The groups were matched two and two for age, training and performance status and maximal oxygen uptake (VO₂max). Before and after the intervention period a muscle biopsy and blood samples were obtained and the runners performed a VO₂max test, a 6 K performance test and had body compositions determined. Each participant kept diary 24 hours before each test to ensure nutritional status was identical before and after each test. Food registration diary was obtained for four days in the beginning and end of the intervention period. **Results:** Performance in 6 K-run test improved from baseline ($p=0.001$). No difference in improvement was detected between CHO+PRO and CHO at any time (midway: $p=0.68$, $n=9$ matched pairs; after the intervention: $p=0.98$, $n=8$ matched pairs). No overall change in VO₂max (ml O₂/kg¹/min¹) was detected during the intervention period ($p=0.47$) or between the groups ($p=0.46$). In line, Vo₂max (L/min) was not effected during the intervention period ($p=0.30$) and nor changed between intervention ($p=0.48$, $n=9$ matched pairs). **Conclusions:** Preliminary results show no observed difference in VO₂max, but an overall improvement in performance was observed in 6 K-run test after six weeks of endurance training. Ingested PRO+CHO beverages before and after each training session did not have any additive ergogen effect on adaptation to training compared to isocaloric CHO. ENHANCING ENDURANCE PERFORMANCE BY NUTRITIONAL MANIPULATION: A SLEEP LOW STRATEGY

Marquet, L.A., Louis, J., Tiollier, E., Hawley, J., Burke, L., Brisswalter, J., Hausswirth, C.

INSEP

Introduction For several years, a growing interest is brought on the manipulation of carbohydrate (CHO) availability before and after specific training sessions. This strategy could promote the physiological adaptations to training and enhance endurance performance (Burke, 2010). Within this context, the purpose of this study was to test the effects of a low glycogen availability doubly induced by training and nutrition manipulation. A new "sleep low" strategy was experimented, including blocs of variable intensity training sessions per-

formed at night and after an overnight fast. **Methods** During 3 consecutive weeks, 23 well-trained triathletes (age: \pm years;; maximal oxygen uptake: 61.2 ± 4.8 ml.min.kg⁻¹) volunteered to follow a standardized training program and specific nutritional guidelines according to the group where they were assigned. Each week, all participants performed the same standardized training program, including low intensity training sessions (LIT) in the morning and high intensity training sessions (HIT) at the end of the afternoon over 4 consecutive days. Only one LIT session per day was prescribed for the others days of the week in order to maintain a 12-15h training volume. In the "sleep low" group (SL=13), no CHO intake was authorized for all HIT and LIT sessions. The dinner was also CHO-free and the LIT sessions were performed after an overnight fast so that they trained with a low CHO availability. At the opposite, the CHO availability was regularly maintained in the "sleep high" group (SH=10) by consuming sports drinks during training sessions and CHO at every meals. Finally all groups ingested the same amount of CHO per day (6 g.kg⁻¹.d⁻¹) but divided differently over the day. Performances in cycling (submaximal and supramaximal tests) and running (10km test), perceived exertion, cycling efficiency and body composition were recorded before and after the 3 weeks of modified training and nutrition. Changes in studied variables over time and between groups were assessed by using a magnitude-based inference approach recommended for studies in sports medicine and exercise sciences. **Results** A significant enhancement in cycling (+7.2% time to exhaustion) and running performances (-56s on 10km) were recorded at the end of the protocol only in the SL group. These changes in performances were associated with a 1% reduction in fat mass (-795g). We hypothesized potential beneficial changes in cycling efficiency by lowering the oxygen consumption at a given intensity, and a preservation of glycogen stocks in the SL group. (The present study is still running and data presented in this abstract are preliminary results). **Conclusion** A chronic "sleep low" training strategy is effective in enhancing endurance performance in cycling and running. Training with low glycogen availability may enhance physiological adaptations involved in endurance performance. **Reference** Burke LM (2010) Fueling strategies to optimize performance: training high or training low? *Scand J Med Sci Sports* 20 (Suppl 2):48-58

PROTEIN INGESTION PRIOR TO SLEEP INCREASES MUSCLE MASS GAIN DURING PROLONGED RESISTANCE TYPE EXERCISE TRAINING IN YOUNG MEN

Snijders, T.1, Res, P.T.1, Smeets, J.S.J.1, van Vliet, S.1, van Kranenburg, J.1, Kies, A.K.2, Maase, K.3, Verdijk, L.B.1, van Loon, L.J.C.1

1. Maastricht University, the Netherlands 2. DSM Biotechnology Center, the Netherlands 3. NOC*NSF, the Netherlands

Introduction It has been demonstrated that protein ingestion prior to sleep stimulates the muscle protein synthetic response during post-exercise overnight recovery. However, it remains unknown whether the application of dietary protein ingestion prior to sleep will further augment the skeletal muscle adaptive response to prolonged resistance type exercise training. In the present study we assessed the impact of dietary protein supplementation prior to sleep on muscle mass and strength gains in response to prolonged resistance type exercise training. **Methods** Forty-four healthy young men (22 \pm 1 y) were randomly assigned to a progressive, 12-wk resistance type exercise training program (3 sessions/wk). One group consumed a protein supplement containing 27.3 g protein, 15 g carbohydrate, and 0.1 g fat every night prior to sleep. The other group received a non-caloric placebo. Muscle hypertrophy was assessed on a whole-body (DXA), limb (CT), and muscle fiber (biopsy) level prior to and after 12 weeks of training. Strength was assessed regularly by one-repetition maximum (1RM) strength testing. **Results** Total 1RM muscle strength increased following 12 wks of resistance type exercise training to a greater extent in the protein compared with placebo supplemented group (164 \pm 11 kg and 130 \pm 9 kg, respectively; $P < 0.001$). In addition, quadriceps muscle cross-sectional area increased in both groups over time ($P < 0.001$), with a greater increase in the protein compared with the placebo group (+8.4 \pm 1.1 vs +4.8 \pm 0.8 cm², respectively; $P < 0.05$). Both type I and type II muscle fiber size increased following resistance type exercise training ($P < 0.0001$). However, the type II muscle fiber size increased to a greater extent in the protein (+2319 \pm 368 μ m²) compared with the placebo supplemented group (+1017 \pm 353 μ m²; $P < 0.05$). **Conclusion** Protein ingestion prior to sleep represents an effective dietary strategy to augment muscle mass gain during prolonged resistance type exercise training in healthy young males. **Contact** Tim.snijders@maastrichtuniversity.nl

AMINOACIDEMIA AFTER INGESTION OF EQUAL AMOUNTS OF PROTEIN FROM FOUR DIFFERENT WHEY PROTEINS AND MILK

Raastad, T., Larssen Laahne, J.A., Østgaard, H.N., Paulsen, G., Børsheim, E.

Norwegian School of Sport Sciences

Introduction Milk proteins, and especially the whey fraction of milk protein, have gained interest because of their effectiveness in stimulating muscle protein synthesis in the hours after ingestion (1). Whey protein is rapidly digested and absorbed; giving a rapid aminoacidemia, which seems to be one of the triggers of muscle protein synthesis (2). However, whey protein can be produced and processed in several ways that probably affects the biological response, but so far there have been little focus on effects of different whey products. Consequently, the purpose of this study was to compare the aminoacidemia after ingestion of a whey protein isolated by a new filtration technique that preserve the proteins in a more native form against the conventional whey concentrate (WPC-80; a byproduct in cheese production). Furthermore, the aminoacidemia after ingesting processed WPC-80 and low fat milk was also investigated. **Methods** Ten healthy men (18-45 years) participated in five trials separated by one week, in which each of the whey products or milk was tested. The whey products tested were WPC-80, native whey (filtration technique), and two types of processed WPC-80; hydrolyzed WPC-80 (HWP) and microparticulated WPC-80 (MWP). All products were standardized on volume (636 ml) and the total content of protein (21 g), fat (6.5 g) and carbohydrates (40 g). The protein drinks and milk were ingested immediately after completing a standardized strength training session and blood samples were drawn at 0, 30, 45, 60, 90 and 120 min after ingestion. The concentrations of amino acids, glucose and insulin were measured in plasma and peak concentrations and the area under the curve (AUC) were used for comparison between trials. **Results** Peak concentration and AUC for leucine was 20-25% higher after ingestion of native whey compared to the other whey products. There were no significant differences in the aminoacidemia between the three WPC-80 products, but it tended to be slower after MWP ingestion. After ingestion of milk, the aminoacidemia was slower, and the peak concentrations of branched chained and most essential amino acids were 15-40% lower than after ingestion of the whey products. There were no differences between the products in the glucose and insulin response. **Discussion** The main finding in this study was that the leucine concentration in plasma reached higher values after ingestion of native whey than after ingestion of the conventional whey products. Because this difference was observed for leucine only, it is likely caused by a higher content of leucine in the native whey fraction. Interestingly, the processed WPC-80 products did not show faster aminoacidemia than the intact WPC-80 product. **References** (1) Hulmi, Lockwood, and Stout. *Nutr.Metab.*7:51, 2010. SPECIFIC SUPPLEMENT AND SPORT NUTRITION PRODUCT USE IN THE DUTCH GENERAL POPULATION

Steennis, J.1, Wardenaar, F.2, Van den Dool, R.3, Ceelen, I.2, Witkamp, R.1, Mensink, M.1

1: Wageningen University, Division of Human Nutrition (Wageningen, NL), 2: HAN University of Applied Sciences, Sport and Exercise (Nijmegen, NL), 3: MUIR Institute (Utrecht)

Introduction Previous studies indicate that a typical consumer of sport specific supplements and products is a young (<35 years) male, frequently active in sports (>1 time/week), and member of a club. In the Dutch active general population, the use of sport specific nutritional supplements (5,8%) and sports nutrition products (21,6%) was found to be lower than previously reported in elite athletes (Wardenaar et al., 2012). However, data for the recreationally- active part of the general population is still limited. Therefore, as part of the Dutch National Sport Investigation (NSO 2013) we investigated the self-reported consumption frequency of sport specific nutritional supplements and sports nutrition products. **Methods** In a representative sample of the Dutch population aged 15-80 with an equal number of females and males (n=1544 subjects), 6 questions were asked about the use of nutritional supplement and sports nutrition products. Chi-square test was used to determine differences in supplement and product use between sexes. Level of significance was set on $P \leq 0.05$. **Results** 74,03% of the total population was involved in sports (of which 89,76% without competition). 21% used both dietary supplements and sports nutrition products, 28% only used supplements, 12% only used sports nutrition products and 38% used no products. The total frequency of supplement intake of the last 12 months was estimated at 49% and sports nutrition product use was estimated on 34%. The use of dietary supplements only, was higher in women than in men (36% vs. 20%) whereas men used sports nutrition products more often than women (17% vs. 7%). Females used more frequently: multivitamin/minerals (32%), Vitamin D (20%), ess. fatty acids /fish oil (6%), iron (7%), Magnesium (10%), Calcium (11%) and probiotics (9%). Men used more frequently: Thirst-quenchers (23%), energy drinks (27%) and recovery drinks (5%). There were no differences between men and women for: caffeine (5%), protein shakes (5%), zinc (3%), creatine (1%), b-alanine (1%), beetroot juice (1%), energy gels (1%), HMB (0,4%) and quercetin (0,2%). Of the subjects that were not engaged in regular sports activities, 51% used no supplements or sports nutrition, 35% only used supplements, 8% only used sports nutrition products and 7% used both dietary supplements and sports nutrition products. **In conclusion**, almost two-thirds of the recreationally- active part of the Dutch general population indicated to use sport specific nutritional supplements and/or sport nutrition products. Females used more frequently dietary supplements, while males used more frequently sports nutrition products. The use of ergogenic supplements, except caffeine, is limited to only 1%. **Reference** Wardenaar, F., Ceelen, I., Witkamp, R., Mensink, M., Sports Nutrition: Supplement and Product use in the Dutch General Population. 17th Annual ECSS-Congress, Bruges 2012

Oral presentations**OP-BN09 Neuromuscular Activation****MODULATION OF MOTOR UNIT ACTIVITY IN BICEPS BRACHII IN RESPONSE TO NEUROMUSCULAR ELECTRICAL STIMULATION APPLIED TO THE CONTRALATERAL ARM**

Amiridis, I., Mani, D., Almklass, A., Gould, J.R., Matkowski, B., Enoka, R.M.

Aristotle University - Thessaloniki, University of Colorado - Boulder

Introduction Neuromuscular electrical stimulation (NMES) elicits action potentials in intramuscular branches of peripheral nerves. Because the time constant for the strength-duration relation is longer for sensory axons than motor axons, narrow pulse widths (0.2-0.4 ms) preferentially activate motor axons, whereas wider pulse widths (0.5-1 ms) recruit relatively more sensory axons (Bergquist et al. 2011). The purpose of the study was to determine the influence of NMES pulse width on the modulation of motor unit (MU) activity in a contralateral limb. The hypothesis was that wide-pulse NMES would cause greater modulation of MU activity due to augmented activation of sensory axons. **Methods** The discharge of action potentials by MUs in left biceps brachii of young adults was recorded with subcutaneous fine-wire electrodes. The protocol involved subjects performing submaximal isometric contractions (≤ 30 s in duration) to maintain the discharge of an isolated MU. In the middle 5 s of each contraction, NMES was applied to the right biceps brachii with either of two pulse durations (0.2 or 1 ms) or three currents (80% motor threshold, 10%, and 20% of MVC force). The primary outcome was the influence of NMES on the discharge characteristics (mean and coefficient of variation) of the isolated MUs. **Results** There are two general findings on the influence of NMES applied to the right biceps brachii on the discharge of low-threshold MUs in the left biceps brachii: (1) Both NMES pulse widths elicited a variable number of longer interspike intervals (ISIs) during the steady contractions, even when the NMES current was less than motor threshold; and (2) Wide pulses increased the coefficient of variation (CoV) for ISI of some MUs, but not others. An NMES-evoked contraction at 20% MVC force, for example, did not change the CoV for ISI (29.2%) of one MU during narrow-pulse NMES, whereas the CoV with wide-pulse NMES was 15.3% before, 28.8% during, and 18.1% after. **Discussion** The differential influence of NMES pulse width on the discharge characteristics of a MU may depend on its recruitment threshold. Continuous electrical stimulation of the index finger, for example, elicited opposing effects on the recruitment threshold of low- and high-threshold MUs in first dorsal interosseus (Garrett & Stephens, 1981). The capacity of NMES to modulate MU activity in the contralateral arm may depend on pulse width. **References** Bergquist AI, Clair JM, Lagerquist O, Mang CS, Okuma Y, Collins DF. (2011). DIFFERENT NUMBER OF MUSCLE SYNERGIES DURING TREADMILL WALKING BETWEEN YOUNG AND ELDERLY ADULTS

Kibushi, B.1, Hagio, S.1, Kimura, T.2, Kouzaki, M.1

1: Kyoto university, 2: Ritsumeikan University

Introduction Aging leads to a lot of kinetic and neurophysiological changes during walking (Murray et al., 1969; Monaco et al., 2010). However, it has not been revealed how the various muscles related to walking were controlled as changing some neurophysiological factors caused by aging. It is suggested that the central nervous system achieve such a redundant motor control via muscle synergies, modular organization grouping functionally similar muscles (Torres-Oviedo and Ting., 2007). The purpose of this study was to reveal the

age-related neurophysiological changes by comparing muscle synergies between young and elderly adults during treadmill walking. Methods In this study, 12 young adults (2 females / 10 males, age: 24.3 ± 4.2 years) and 20 elderly adults (10 females / 10 males, age: 66.3 ± 6.4 years) participated, and they walked on a treadmill at preferred walking speed. Surface electromyograms (EMGs) were recorded from 8 muscles in right lower limb. Muscle synergies were extracted from filtered, rectified, integrated into 8 muscles \times 30 walking cycles-sized, and variance-normalized EMGs of each subject using the non-negative matrix factorization (NMF) algorithm (Lee and Seung, 1999). The NMF models EMG data matrix as a linear combination of time-invariant muscle synergies, each activated by a time-dependent activation coefficient. We iterated the analysis by varying the number of synergies between 1 and 8 and then selected the least number of synergies that could adequately reconstruct the original EMG data matrix. Results For each subject, a few muscle synergies were found, and it revealed that mean number of synergies in elderly were significantly fewer than young adults (young: 5.1 ± 1.0 , elderly: 4.1 ± 0.8 , $p=0.004$). We found that synergies of triceps surae and quadriceps muscles in elderly adults were generated from merging of synergies observed in young adults. Discussion We suggested that the different number of synergies between young and elderly adults due to the merging of synergies in elderly. Merged synergies during walking were recognized in post-stroke subjects who have severe motor dysfunctions (Clark et al., 2010), which might lead to reduce a degree of joint motion. Hence, the merging of synergies in triceps surae and quadriceps muscles might cause walking dysfunctions, such as decreasing ranges of ankle dorsiflexion extension or hip flexion-extension (Murray et al., 1969). Therefore, it suggested that merged synergies in elderly adults lead to these walking dysfunctions. References Clark DJ, Ting LH, Zajac FE, Neptune RR, Kautz SA. (2010). TIMING OF MUSCLE ACTIVATION DURING DOUBLE POLING ERGOMETER TESTING IN DIFFERENT SITTING POSITIONS—PILOT TEST FOR DISABLED SIT SKIERS

Rapp, W., Lappi, T., Ohtonen, O., Lindinger, L., Linnamo, V.

University of Jyväskylä

Introduction In Paralympic sit ski athletes core stability is essential for forward propulsion. As these athletes can only use arm and trunk for double poling, well-coordinated muscular activation is necessary. Depending on the level of impairment, sit skiers can take different sitting positions which may affect athletic performance. Whether the timing of muscle activation and performance is affected by sitting position is not clear at present. The aim of the present study was to examine muscular activation of trunk and arm muscles with healthy subjects in sitting positions commonly observable in disabled sit skiers. Methods 10 healthy male XC skiers (20 ± 3 y) participated in an ergometer test (concept2 ski ergometer, USA), simulating double poling in sit skiers. Poling forces were recorded synchronously with surface EMG from triceps brachii (TRIC), m. rectus abdominis (REcab) and m. erector spinae (ES) muscles. EMG was normalized to MVC and mean EMG amplitude (m%MVC) was calculated 200ms before (PRE) and during poling (POL). Maximum velocity poling at 4 sitting positions (P1-P4) on an adjustable chair was tested. P1 represent normal, P2 with knees higher than hip, P3 kneeling and P4 with straight leg. Results Maximum poling velocity was achieved in P3 with 6.6 ± 0.24 m/s and slowest in P2 with 4.2 ± 0.27 m/s ($P < 0.05$). Mean values over all 4 positions show that the REcab was activated -136 ± 16 ms before poling. TRIC was activated little bit earlier (-10 ± 1 ms) whilst ES is activated at the end of poling (187 ± 12 ms). Differences between sitting positions did not show any statistical significance in muscle onset in any of the muscles. M%MVC for TRIC showed a range from 8% (P1) to 13% (P2) in PRE and 46% to 60% during POL. REcab showed 19% (P1) to 25% (P3) in PRE and 16% to 26% during poling POL. Discussion Kneeling (P3) seems to be the most effective position to achieve the highest velocity and highest EMG at the ergometer. The onset of muscle activation, however, was in all positions the same. Higher activation of abdominal muscle before starting of poling s underlines the importance, that core stability is one requirement to achieve best poling performance. It is hypothesized, that such a movement pattern should also be claimed in disabled athletes sitting in sledges. This result may also have impact to the classification process and performance related categories (Van de Vliet, 2012) which are required to guaranty a fair competition among persons with equal or similar levels of impairment. CHILD-ADULT DIFFERENCES IN SPECIFIC STRENGTH ARE ATTRIBUTED TO VOLUNTARY ACTIVATION LEVEL ONLY AT LONG MUSCLE LENGTH

Kluka, V.1,3, Martin, V.1, Garcia Vicencio, S.1, Jegu, A.G.2, Cardenoux, C.2, Morio, C.3, Coudeyre, E.2, Ratel, S.1

1: University of Blaise Pascal-AME2P (Clermont-Fd, France), 2: CHU Gabriel Montpied (Clermont-Fd, France), 3: Oxyrane Research (Ville-neuve d'Ascq, France)

Introduction It has been shown that the ability to produce maximal strength with respect to muscle size is lower in children than in young adults. That difference may be attributed to the lower ability of children to fully activate their motor units (O'Brien et al. 2009). However, other studies reported comparable levels of voluntary activation (VA) in children and older subjects (Belanger and Mc Comas, 1989). Part of these controversies could be attributed to discrepancies in the mechanical conditions of muscle contraction, i.e. muscle length. Therefore, the aim of the present study was to compare the effect of muscle length on the level of VA at short and long muscle lengths between children and adults. Methods Thirteen prepubertal boys (10.2 ± 1.1 y) and ten men (23.9 ± 2.9 y) performed isometric 5-s maximal voluntary contractions (MVC) of the knee extensor (KE) muscles at three muscular angles (20° , 90° , 100° ; 0° = full extension) interspersed with at least 60-s passive recovery periods. Single magnetic stimulations were delivered to the femoral nerve to calculate the maximal level of VA by means of the twitch interpolation technique. The specific torque was calculated as the absolute torque divided by thigh muscle mass, as assessed using DXA. Finally, the theoretical specific torque that could be produced with a complete (i.e. 100%) activation level (specific torque@100%VA) was estimated from the values of specific torque and VA. Results Specific torque was higher in adults at 90° (60 ± 11 N.m/kg vs. 48 ± 10 N.m/kg, $P < 0.05$) and 100° (48 ± 8 N.m/kg vs. 41 ± 7 N.m/kg, $P < 0.05$) but not at 20° . Accordingly, VA was significantly higher in adults at 90° ($94 \pm 4\%$ vs. $88 \pm 8\%$, $P < 0.05$) and 100° ($93 \pm 6\%$ vs. $86 \pm 8\%$, $P < 0.05$), while no significant difference was observed at 20° . Interestingly, the specific torque@100%VA was not different between groups, whatever the joint angle. Discussion The results of the present study reveal for the first time that the level of VA is only lower in children at long muscle length. This lower ability of children to fully activate their motor units at long muscle length could account for their lower specific torque since no difference in theoretical specific torque was observed between groups at 90° and 100° . Further studies are however required to identify the mechanisms underlying the effects of muscle length on specific strength and VA in children. References Belanger AY, McComas AJ. (1989). ACUTE UPPER BODY COMPLEX TRAINING WITH ACCOMMODATING RESISTANCE IN COLLEGIATE MALE WRESTLERS

Jones, M.T.1, Oliver, J.M.2, Delgado, J.I, Robison, C.E.1

1:George Mason University, VA, USA; 2:Texas Christian University, TX, USA

Introduction Upper body power (UB-P) is essential to success in wrestling. Post-activation potentiation, in the form of complex training (CT), has been shown to elicit greater lower body power production in explosive movements when heavy strength movements are performed prior. Accommodating resistance (AR), in the form of bench pressing with chains, has been purported to increase UB-P. Research on UB-CT is limited and results are inconclusive. The aim of this study was to determine if acute UB-CT with AR would enhance UB-P. **Methods** Participants were 13 wrestlers (20.5 ± 1 yr, 174.3 ± 4.2 cm, 76.5 ± 8.3 kg, 8.5 ± 2.6 %BF) with > 1 year of formal strength training. Baseline testing included 3-RM bench press (BP) and %body fat (BF). Prior to testing, participants were randomly assigned to one of two protocols: chain BP or plate BP. One week after baseline testing, participants performed the assigned protocol, which consisted of a warm-up and determination of UB-P during the performance of the plyometric push up (PPU). Participants performed a baseline PPU then benched 1 x 6 reps at 60% 1RM followed by a PPU. After a 3-min rest, participants performed a second set of 1 x 6 reps at 60% 1RM followed by a PPU. All PPU were performed on a force plate for determination UB-P. All were familiar with and performed the PPU regularly in training. Independent samples t-tests were used to analyze physical characteristics and UB strength. A 2 x 3 repeated measures ANOVA was used to analyze UB-P (alpha level: p<0.05). **Results** Participants in the plate BP group were older (21.4 ± 0.8 yr) than the chain BP group (19.9 ± 0.7 yr; p = 0.005). No other differences were observed in physical characteristics or baseline measures. Despite an observable difference in decline of UB-P following initial set (chain BP, -10.9 ± 5.3%; plate BP, -17.4 ± 5.7%) and set 2 (chain BP, -8.6 ± 6.6%; plate BP, +1.0 ± 7.2%), no group interaction was observed (p = 0.166). A time effect was observed in which both chain BP and plate BP resulted in a decrease in UB-P following the initial set (-14.1 ± 3.9%; p = 0.004), with a return to baseline levels after set 2. **Discussion** AR did not result in improvement in UB-P over traditional plate loaded resistances when performing an acute UB-CT. While AR of chains appeared to have attenuated the loss of UB-P following an initial set, traditional plate loaded resistance appeared to attenuate this following a second set. Further testing using a larger sample and crossover is recommended to delineate the influence of the two training methods on UB-P during the PPU. **References** McCurdy, K, et al. (2008). POST-ACTIVATION POTENTIATION INDUCED IN THE KNEE EXTENSORS AFTER 'COMPLETE' WARM-UP INCLUDING TASK PRACTICE

Blazevich, A.J., Trajano, G.S., Haff, G.G., Seitz, L.B.

Edith Cowan University

Introduction There is significant practical interest in the idea that the performance of a set of voluntary contractions (i.e. a conditioning activity) might evoke an increase in force production in a subsequent contraction (i.e. post-activation potentiation; PAP), even after no further torque could be achieved with standard warm-up and task practice procedures. Whilst the development of muscle forces or joint torques that exceed the expected 'maximal' muscle force has been achieved by others during electrically-elicited contractions (by varying nerve stimulation frequency and pulse-width characteristics), it remains to be determined whether such 'extra torque' can be elicited under voluntary conditions. In the present study, the effect of performing conditioning activities at different velocities (and therefore loads), total contraction durations and total work on voluntary and twitch PAP was examined after no further improvement in contractile performance could be elicited by a task-specific warm-up. **Methods** After completing a 5-min cycle warm-up and two isokinetic knee extensions at 180°/s at 20, 40, 60 and 80% of perceived maximum exertion, 17 strength-trained men performed single maximal knee extensions at 180°/s (45-s rest) until peak torque production varied <2% (i.e. no further improvement was attained). Voluntary isokinetic and electrically-evoked isometric knee extension torque were then measured before and 1, 4, 7, 10 and 13 min after performing each of five conditioning activities on separate occasions: 4 knee extensions at 60°/s, 4 and 12 at 180°/s, and 4 and 20 at 300°/s. **Results** Significant improvements in voluntary (for 7 min; peak 3.2 - 5.2% at 4 min) and electrically-evoked (for 4 min; peak 10.1 - 13.5% at 1 min) torque production were elicited in the 4 x 60°/s, 12 x 180°/s and 20 x 300°/s conditions only. Thus, conditioning activities of longer total contraction duration (6 s) with a minimum total work of ~750-900 J elicited increases in voluntary torque regardless of movement velocity. **Discussion** Voluntary and twitch PAP can be elicited with a conditioning activity even when no further improvement in muscle contractile capacity can be elicited by continued task-specific practice. Furthermore, a minimum conditioning activity contraction duration and total work appear important to elicit voluntary and twitch PAP, however movement velocity appears unimportant. Therefore, 'extra torque' can be elicited under voluntary contractions and is clearly a physiological phenomenon rather than being a warm-up or familiarisation effect. Contact a.blazevich@ecu.edu.au

OP-PM25 Molecular Training Responses

TRAINING-INDUCED TENASCIN-C EXPRESSION REGULATES CAPILLARY GROWTH

Valdivieso, P., Hoppeler, H., Flück, M.

University of Zurich

Introduction Tenascin-C is an anti-adhesive extracellular matrix protein which expression is induced in (muscle) tissues being subjected to a high degree of tension (Järvinen et al 2003; Flück et al. 2008). Elevated tenascin-C expression has been shown to promote capillary growth (Ballard et al., 2006; Flück et al., 2008). A Single Nuclear Polymorphism (SNP rs2104772, 44513A/T) in exon 17 of the tenascin-C

gene, which leads to the substitution of isoleucine at position 1677 with leucine, has been found associated with tissue defects (Matsuda et al., 20005). We hypothesized that SNP rs2104772 affects the angiogenic response of skeletal muscle to endurance training in line with altered tenascin-C expression. Methods 36 healthy, non-specifically trained male Swiss subjects (age: 32.9 ± 1.6 kg, weight: 77.4 ± 2.3 kg, height: 177.6 ± 1.2 cm, VO_{2max} : 42.4 ± 1.6 mlO₂/min/kg) performed bicycle type endurance training at 65% peak aerobic power output (5-times a week over 6 weeks). Biopsies were collected from the knee extensor muscle, vastus lateralis, 2 days before and 2 days after endurance training. Micro-anatomical characteristics of (muscle) cells and organelles were assessed by morphometric analyses of electron micrographs. Genomic DNA was isolated and rs2104772 assessed with High Resolution Melt PCR combined with sequencing. Tenascin-C protein was quantified in total homogenates using immunoblotting. Pre-post changes were compared with ANOVA for the factor 'genotype rs2104772' (A/T heterozygote or homozygote) and the repeated factor 'training' (yes, no) and a false-discovery rate-adjusted post-hoc test of Fisher. Results Endurance training improved systemic VO_{2max} ($+9 \pm 1\%$) and local components of aerobic fitness (capillary density $+10 \pm 4\%$, mitochondrial density $+22 \pm 4\%$ and capillary-to-fiber ratio $+8 \pm 3\%$) and elevated the concentration of the large ($77 \pm 29\%$) and small tenascin-C isoform ($128 \pm 54\%$). 22 subjects demonstrated A/T heterozygosity of rs2104772. Changes in capillary-to-fiber ratio passed the level of significance for a genotype effect ($p=0.013$). It was $13 \pm 3\%$ ($p=0.0003$) increased in volunteers being homozygous as opposed to those being heterozygous for rs2104772 ($-1 \pm 5\%$, $p=0.94$). No influence of rs2104772 was identified at baseline. Discussion Our data support the involvement of an amino acid substitution in the fibronectin type III-D domain of Tenascin-C in exercise-induced angiogenesis. The involved cellular mechanism and functional relevance for activity-induced metabolism remains to be explored. Contact mflueck@research.balgrist.ch

SKELETAL MUSCLE SIGNALING DURING SPRINT EXERCISE IN SEVERE ACUTE HYPOXIA: ROLE OF FREE RADICALS

Morales Álamo, D., Ponce González, J.G.1, Guadalupe Grau, A.1, Perez Suarez, I.1, Santana, A.1, Cusso, R.2, Cadefau, J.2, Guerra, B.1, Dorado, C.1, José, A.L., Calbet, J.A.L.1

1. Las Palmas University, 2. Dep. Of of Physiological Sciences I, University of Barcelona, Spain.

Compared to normoxia, sprint exercise in severe acute hypoxia elicits a much greater glycolytic rate, lower muscle pH at exhaustion and higher oxidative stress leading to a paradoxical blunt of the AMPK Thr172 phosphorylation. To determine if free radicals could play a role in blunting Thr172-AMPA phosphorylation, nine volunteers performed a single 30s sprint (Wingate test) in two occasions while breathing hypoxic gas (PIO₂=75 mmHg): one after the ingestion of a placebo (P) and another following the intake of antioxidants (A) (α-lipoic acid, vitamin C, and vitamin E), with a double blind design. Vastus lateralis muscle biopsies were obtained before and immediately after, 30 and 120 min post-sprint. Compared to the control condition, the ingestion of antioxidants resulted in lower plasma carbonylated proteins, lower elevation of AMP/ATP molar ratio, and reduced glycolytic rate ($P<0.05$) without significant effects on performance or VO_2 . The ingestion of antioxidants did not alter the basal muscle signaling. Thr172-AMPA and Thr184/187-TAK1 phosphorylation was not increased after the sprint regardless of the ingestion of antioxidants. Thr286-CaMKII phosphorylation was increased after the sprint, but this response was blunted by the antioxidants. Ser485-AMPA1/Ser491-AMPA2 phosphorylation increased immediately after the sprints coincident with increased Akt phosphorylation. In summary, this study shows that antioxidants attenuate the glycolytic response to sprint exercise in severe acute hypoxia and modify the muscle signaling response to exercise. Ser485-AMPA1/Ser491-AMPA2 phosphorylation, a known mechanism of Thr172-AMPA phosphorylation inhibition, is increased immediately after sprint exercise in hypoxia by a mechanism independent of free radicals. THE EFFECT OF ACUTE ENDURANCE EXERCISE FOLLOWED BY STRENGTH EXERCISE ON MOLECULAR RESPONSE IN HUMAN SKELETAL MUSCLE

Popov, D.V.1,2, Lysenko, E.A.1, Bachinin, A.V.1, Miller, T.F.1, Vinogradova, O.L.1,2

1: Institute for Biomedical Problems of Russian Academy of Sciences (Moscow, Russia), 2: M.V. Lomonosov Moscow State University (Moscow, Russia).

Introduction Endurance exercise activates mitochondrial biogenesis in skeletal muscle and, on the other hand, does not induce noticeable activation of muscle protein synthesis. Moreover, high intensive endurance exercise activates catabolism in skeletal muscle by up regulation of the ubiquitin-proteasome pathway. On the contrary, strength exercise up regulates muscle protein synthesis. The aim of the study was to investigate the effect of endurance exercise followed by short strength exercise on regulation of mitochondrial biogenesis, protein synthesis, and degradation in human skeletal muscle. Methods Seven amateur endurance trained males carried out two test sessions: endurance exercise (70 min) and endurance exercise (70 min) followed by short strength exercise session (4×12 75% of 1RM) in randomized order. Blood insulin and cortisol levels were evaluated before exercise session and during 2 h of recovery. Biopsy samples from m.vastus lateralis were taken before, 40 min, 5 h and 21 h after termination of endurance exercise. Expression of metabolic (PGC-1α, TFAMs) and catabolic (Myostatin, Atrogin-1, MuRF) genes were evaluated by real-time PCR. Expression of anabolic and catabolic signaling regulators (p70, EF2 and FOXO1) as well as PGC-1α in cytoplasmic and nuclear fraction were measured by Western blot. Results Blood hormone levels did not differ between groups before and after exercise sessions. The expression of metabolic genes increased after both exercise sessions and no differences between trials were found for metabolic genes, as well as for PGC-1α protein content. The activation of catabolic pathways was more pronounced after endurance exercise compared to combined endurance and strength exercise session. Discussion The combined endurance and strength exercise session induced changes in mitochondrial biogenesis similar to those after endurance exercise alone. Short strength exercise session might be used for suppression of catabolic response after acute endurance exercise. Contact Email address [danil-popov@yandex.ru]

PURINERGIC RECEPTORS P2X7, P2Y2 AND P2Y6 ARE INHIBITED BY AEROBIC EXERCISE TRAINING IN EXPERIMENTAL ALLERGIC LUNG INFLAMMATION

Greiffo, F.R., Custodio, R.W.A., Oliveira, N.C.R., Cipriani, F., Sousa, A., Pereira, P.R., Oliveira, A.R.A., Aquino-Junior, J.C.J., Damasceno-Rodrigues, N.R., Albertini, R., Ligeiro-Oliveira, A.P.

Nove de Julho University and University of Sao Paulo

Introduction The aim of this study was investigated the effects of aerobic exercise training (AET) in asthma phenotype in an experimental model of asthma and the possible involvement of ATP and P2X7, P2Y2 and P2Y6 receptors in this response. Methods Adult C57Bl/6 ($n=5$ /group) were distributed in Control, Exercise, Asthma and Asthma+Exercise groups. AET was performed in a treadmill, 5x/week, 1hour/session, 60% of maximal exercise capacity, during 5 weeks after the establishment of allergic airway inflammation. The ovalbumin

model of asthma was used. The total and differential cell number in the bronchoalveolar lavage (BAL) was analyzed and, the levels of IL-5, IL-10 and IFN-gamma in BAL and serum were analyzed by ELISA. The number of eosinophils, collagen content and the mucus production in the airways wall were analyzed. The extracellular levels of ATP in BAL and the expression of P2X7, P2Y2 and P2Y6 receptors in the lungs were analyzed by western blotting and immunohistochemistry. Results AET in asthma group significantly reduced the number of total cells ($p<0.01$) and eosinophils ($p<0.01$) in BAL as well as the levels of IL-5 in BAL ($p<0.01$) and serum ($p<0.01$) while increased the levels of IL-10 in BAL ($p<0.01$) and serum ($p<0.01$). In addition, AET reduced the expression of purinergic receptors P2X7 ($p<0.05$), P2Y2 ($p<0.05$) and P2Y6 ($p<0.05$) in the lungs, as observed through western blotting and immunohistochemistry. Discussion This study suggested that the AET reduces asthma phenotype, which was followed by decreased ATP accumulation in the lungs and also reduced expression of P2X7, P2Y2 and P2Y6 receptors. Recently it has been reported that purinergic receptors P2X7, P2Y2 and P2Y6 contributes to the development of allergic airway inflammation (Müller et al., 2010; Müller et al., 2011; Vieira et al., 2011). Some studies showed that the AET decreases asthmatic lung inflammation and the involvement of purinergic signalling may be involved (Vieira et al., 2007; Vieira et al., 2013). NEITHER LOW INTENSITY NOR HIGH INTENSITY SWIM TRAINING AFFECTS ADAPTIVE IMMUNE FUNCTION IN YOUNG ADULT HEALTHY MICE

Horstman, A.1, Balder, A.1, Baan, G.1, Veninga, H.2, Kraal, G.2, den Haan, J.2, Jaspers, R.1

1 Laboratory for Myology, MOVE Research Institute, Fac. of Human Movement Sciences, VU University Amsterdam - 2 Dept. of Molecular Cell Biology and Immunology, VU University Medical Center, Amsterdam

Introduction: Whereas both prolonged exhaustive exercise and physical inactivity have been associated with a compromised immunity, regular moderate intensity exercise training may improve adaptive immune responses under healthy conditions. Here we tested whether the adaptive immune function is improved by high and/or low intensity swim training. Methods: 64 male C57Bl/6J mice of 6 weeks old were assigned to a progressive, low intensity endurance exercise training (60 min/day, LIET), a progressive, short duration high intensity exercise training (2x10 min/day, HIST), a control swim group (3 min/day, CS) or a control group without exercise training, 5 d/wk for 4 weeks ($n=16$ /group). Additional loads of 50 and 80% of the maximal sustainable weight were attached to the tail of mice in LIET and HIST, resp. After 3 weeks, 8 mice of each group were challenged with antigen ovalbumin (OVA) in order to elicit an adaptive immune response. The other 8 mice were injected with a vehicle. 24 hrs after the last training, mice were sacrificed. Spleen, serum and plantarflexor muscles were excised to examine OVA specific CD8+ T cell responses of splenocytes, serum OVA-Ig response and adaptations in m. triceps surae. Results: Swim performance improved considerably with increases in load attached to the tail in both LIET and HIST ($1.1\pm0.3\%$ and $2.1\pm0.3\%$ in bodyweight, resp., $p<0.001$). Percentage type I fibers in SOL of HIST was lower than LIET ($35.5\pm0.9\%$ vs $39.9\pm1.1\%$, $p<0.05$), while CSA of GM myofibers in HIST was 19.7–28.7% higher. Both types of training resulted in a mean decrease in percentage B cells (LIET: 2.2%, HIST: 2.4%, $p<0.05$), while that of CD8+ T cells was increased (LIET: 1.1%, $p<0.05$) compared to CS. Despite the training effect (increased load and muscle adaptations), the frequency of CD4+ T, CD4+CD25+ regulatory T, and NK cells, neutrophils, and dendritic cells was not affected ($p>0.05$). Although total percentages of B and CD8+ T cells were affected by training, no significant changes were observed in the generation of OVA-specific CD8+ T cells (on average 0.7% of the CD8+ T cells) and OVA-specific antibody responses following immunization. Discussion: Both progressive low intensity endurance and short duration high intensity swim training increased swim performance in mice. However, the specific (adaptive) immune function remained unaltered. We conclude that additional exercise does not alter the early immune response against a single exposure to a neoantigen in healthy, normally active young adult mice.

EXPRESSION ANALYSIS OF MECHANOSENSITIVE GROWTH FACTORS IN DUCHENNE MUSCULAR DYSTROPHY MOUSE MODELS

Hoogaars, W.M.1,2, Weijer, F.1, Spierenburg, A.1, Aartsma Rus, A.2, Jaspers, R.T.1

1: MOVE Research Institute Amsterdam, VU, Amsterdam, the Netherlands 2: Leiden University Medical Center, Leiden, the Netherlands

Introduction Mechanical stress/damage in muscle results in upregulation and release of mechanosensitive growth factors such as IGF1Ea, MGF and HGF, which play a vital role in muscle plasticity by stimulating muscle fiber growth and satellite cell activity. Mutations resulting in loss-of-function of dystrophin cause Duchenne Muscular Dystrophy (DMD). Dystrophin has been implicated in mechanotransduction in muscle and importantly loss of mechanotransduction and decreased levels of MGF have previously been suggested to contribute to the progressive muscle weakness in DMD muscle (De Bari 2003, Goldspink 1999). To determine if dystrophin is important for the expression of mechanosensitive growth factors, we here determined the expression levels of different mechanosensitive growth factors in two DMD mouse models. Methods Muscles of wildtype mice and two DMD mouse models, mdx (mild dystrophic pathology) and mdx utr^{-/-} (severe dystrophic pathology) mice, were isolated for gene expression analysis. qPCR analysis was performed for Igf1Ea, Mgf, Hgf, Vegf and regeneration marker Myog on gastrocnemius muscle samples. In addition, immunofluorescence was performed to determine muscle fiber size, fiber type and percentage of fibers containing centrally located nuclei. Results qPCR analysis showed that Igf1Ea expression increased 1.9-fold in mdx mice and 4.5-fold in mdx utr^{-/-} mice. Mgf expression increased 2.6-fold in mdx mice and 6-fold in mdx utr^{-/-} mice. Hgf expression was elevated 4.1-fold in mdx mice and 11.3-fold in mdx utr^{-/-} mice. Elevated expression levels of these growth factors corresponded to higher expression of muscle regeneration marker Myog and percentage of fibers with centrally located nuclei. Discussion Surprisingly, in mdx and mdx utr^{-/-} mice Mgf expression was elevated. This was in contrast to the decrease of Mgf expression in mdx mice reported previously (De Bari 2003, Goldspink 1999). Similar increases were observed for the expression of Igf1Ea and Hgf, which correlated with the elevated levels of regeneration marker Myog. Our results suggest that loss of dystrophin in mice does not result in impaired expression of mechanosensitive growth factors as previously has been suggested. 08:30 - 10:00**Oral presentations****OP-SH06 Sports Management****FACTORS INFLUENCING MEMBERSHIP SATISFACTION AND MEMBERSHIP RETENTION OF THE EUROPEAN COLLEGE OF SPORT SCIENCE**

Hokkanen, T.

German Sport University Cologne

Introduction There is an excessive amount of research covering the topic of membership satisfaction and retention. However, nonprofit associations (NPO) have often been neglected in this respect. Acquiring new members and keeping the old ones are as important goals for membership associations as they are for business entities. Nonetheless, only a few studies focused on paid memberships for NPOs (e.g. Bhattacharya, Hayagreeva, & Glynn, 1995; Bhattacharya 1998). Membership satisfaction has often been studied within customer satisfaction hence its unique features have been dismissed (Ancarani & Kamann, 2010). The purpose of the current study was to examine the factors influencing membership satisfaction and retention of a professional NPO, namely the European College of Sport Science (ECSS). Methods 662 paying and 610 not paying members participated an online survey in 2013 using convenience sampling. Satisfaction was evaluated by confirmatory factor analysis (CFA), and drivers for satisfaction were identified using structural equation modeling (SEM). t tests were utilized to assess the differences between those members paying and those not paying. Results The CFA ($X^2=944.275$, $DF=335$, $p=0.000$, $X^2/DF=2.819$, $SRMR=0.068$, $CFI=0.624$, $RMSEA=0.052$, $Pclose=0.150$) revealed that the membership satisfaction was strongly influenced by service delivery ($\beta=0.92$) service quality ($\beta=0.58$) and value ($\beta=0.75$). The SEM ($X^2=385.493$, $DF=1142$, $p=0.000$, $X^2/DF=2.715$, $SRMR=0.045$, $CFI=0.96$, $RMSEA=0.051$, $Pclose=0.391$) showed a relatively strong impact of satisfaction ($\beta=0.67$) on future behavior. R^2 for future behavior was 46%. For both models all factor loadings were significant ($C.R. \geq 1.96$, $p \leq 0.000$). The t tests proved that the paying members were supposedly more satisfied ($t(1162)=3.518$; $p \leq 0.05$). Overall, services were more highly valued than they were perceived to be delivered ($t(1271)=10.468$, $p \leq 0.05$). **Discussion** The results emphasized that the annual congress and benefits related to the congress had a strong impact on membership satisfaction. These results were in line with the results by Ancarani and Kamann (2010). The managerial focus of a membership association should be on delivering high quality services and gaining comprehensive knowledge on members' needs and reasons for joining the association. This will help to keep the members satisfied, create an affiliation with the members and acquire new members as well as keep the old ones. **References** Ancarani, A. & Kamann, D.-J. POST RETIREMENT EXPERIENCES OF FORMER SWEDISH ELITE ATHLETES

Straalman, O.1, Patriksson, G.1, Fahlström, P.G.3

(1 & 2) DEPARTMENT OF FOOD NUTRITION AND SPORT SCIENCE, FACULTY OF EDUCATION, GOTHENBURG UNIVERSITY (3) Faculty of Social Sciences, Linnaeus University

Introduction Previous studies have shown that successful sport careers are often based upon the notion that athletes are living a life in harmony, and that positive adjustment to retirement is dependent on the athletes coping strategies and adjustment skills adapted during the sport career (Patriksson, 1995; Stråhlman, 2006). The aims of this study are to describe; (1) the perceptions and experiences of the road through the elite sports career, (2) experiences of the transition from elite sport to a post retirement life. Method 36 athletes were interviewed (26 men -10 women) all with experience of top-level sport on international basis. One third of the group had finished their career before or during the 1990s and the others in the 2000s. The respondents represented various sports. The issues discussed highlight the aims of the study, and the questions were formulated to grasp the essence of the respondents' experiences. Results The career ended for many of the respondents as a conscious planned decision, even if one third made a comeback. Only a few ended in an abrupt way. The decision to end the sport career was often a combination of reasons; lack of motivation, injury - health problems and age. The transition from elite sport went for the majority smoothly and the respondents enjoyed their retirement lives, although a small portion of them experienced problems as a direct result of their career ending. Sport still played a central role and sport related properties were important for the respondents' lives. No one regretted their elite sports career but they underlined the importance to prepare for the post retirement life. The majority of the respondents found new jobs, most sport related, and they were satisfied with their lives. **Discussion** It is important not only to focus on the elite sport career, but on career support in general, especially for those with problematic adjustment. Unproblematic voluntary adjustment is often linked to the possibility to prepare in advance for retirement. Since no one reported having severe injuries that predominantly affected their post retirement life, they could put their new ambitions in other areas. Sport organisations, public authorities and individuals are all responsible for the athlete's retirement. **References** Park, S., Lavallee, D. & Tod, D. (2013). ECONOMIC EVALUATION OF A PHYSICAL ACTIVITY INTERVENTION USING ACTIVITY TRAILS

Schöner, M.1, Beck, V.2, Vogt, L.1, Niederer, D.1, Maulbecker-Armstrong, C.3, Banzer, W.1

1: Goethe University (Frankfurt, Germany) 2: University of Applied Sciences Darmstadt (Darmstadt, Germany) 3: Ministry of Social Affairs of Hessen (Wiesbaden, Germany)

Introduction As health care resources are spare, it is important to evaluate the costs and benefits of health-promoting interventions enabling policy makers to compare alternative interventions and take informed investment decisions. The aim of this observational study is to evaluate the potential health-related economic benefit of a three-month intervention for elderly subjects using activity trails. Methods A three-month guided physical activity intervention program was set up on two separate activity trails in Germany. A total of 47 participants (68 ± 10 years, 31 women, 16 men) completed the SF 36 questionnaire prior to and 12 weeks after the initiation of the intervention. In

order to calculate a single-index utility score for economic evaluation, we used the SF 6D to translate SF 36 data into a preference-based measure of health-related quality of life (hrQoL), using general population values. The single-index utility score of each participant was multiplied by the participant's number of life years remaining according to statistical life expectancy data to calculate quality-adjusted life years (QALYs) before and 12 weeks after the initiation of the intervention. The change in QALYs is aggregated across all subjects to determine the social impact. Results During the 12 week intervention period, the mean measure of hrQoL increased from .69 (± 1.1 ; $p < .05$) to .73 (± 1.3 ; $p < .05$). The mean remaining expected life years of all participants was 16 years (± 4.3 ; $p < .05$). The number of QALYs gained was .6 (± 1.8 ; $p < .05$). According to the QALY maximization rule, we aggregated individual health gains across all subjects and found an economic benefit of 27 QALYs. Discussion Participating in the three-month guided physical activity intervention using activity trails appeared to be beneficial for elderly subjects. The increase in hrQoL supports the use of activity trails as part of a public health program. QALYs provide a common measure to quantify health-related benefits resulting from a variety of interventions. When combined with costs, comparisons can be made between alternative interventions according to the cost-utility ratio (cost per QALY). For diligent resource allocation decisions, it is crucial to understand the underlying model, since alternative instruments (e.g. SF-6D, EQ-5D) appear to provide different utility scores. KINEMATIC PARAMETERS AND OXYGEN UPTAKE KINETICS DURING SUB-MAXIMAL EXERCISE IN SWIMMING

Espada, M.1,2, Reis, J.1, Almeida, T.1, Vleck, V.1, Bruno, P.1, Alves, F.1

(1) Faculty of Human Kinetics - University of Lisbon / (2) Polytechnic Institute of Setubal

Introduction Performance excellence in swimming is strongly influenced by physiological profile and swimming technique (Psycharakis et al. 2008). Faster oxygen uptake (VO₂) kinetics is associated to a better tolerance to fatigue (Bailey et al. 2009) which begins to markedly manifest above maximal lactate steady state velocity (MLSSv) in swimming. The purpose of this study was to analyze the relationship between VO₂ kinetics and kinematic parameters around MLSSv in swimming. **Methods** National level portuguese swimmers (n = 14; 16.6 \pm 2.5 yrs) completed a 400-m all-out test for maximal aerobic velocity (MAV) estimation and 30-min at constant swimming velocity at 87.5, 90 and 92.5% of maximal aerobic velocity (MAV) for MLSSv determination. Two square-wave transitions of 500-m, 2.5% above and below MLSSv were completed to determine VO₂ on-kinetics, using two exponential functions. All the tests were performed in front-crawl and data was collected during all tests, except the 400-m all-out test, using a respiratory snorkel and a breath-by-breath analyser (K4b2, Cosmed, Italy). Stroke rate (SR) was determined as the number of cycles per min (registered by the number of strokes in each 25 m), stroke length (SL) was calculated by dividing velocity by SR. **Results** SR was significantly lower below than above MLSSv (respectively, 34.3 \pm 3.6 Vs. 38.0 \pm 3.8 cycles.min⁻¹), the contrary was observed for SL (2.29 \pm 0.22 Vs. 2.16 \pm 0.19 m.cycle⁻¹). The amplitude of the primary phase (Ap) was significantly higher above than below MLSSv (respectively, 49.5 \pm 6.9 Vs. 45.9 \pm 6.7 ml.kg⁻¹.min⁻¹) and the time constant of the primary phase (taup) was not significantly different below and above MLSSv (21.2 \pm 8.6 Vs. 19.0 \pm 7.7-s, respectively). SR at 97.5% MLSSv was negatively correlated to Ap at the same exercise intensity (r = - 0.60, p < 0.05), a positive correlation was observed for SL and Ap at 97.5% MLSSv (r = 0.67, p < 0.01). MLSSv was negatively correlated with taup at 97.5 and 102.5% MLSSv (respectively, r = - 0.64 and r = - 0.55; p < 0.05). MAV was also negatively correlated to taup at 97.5 and 102.5% MLSSv (r = - 0.67, p < 0.01; r = - 0.56, p < 0.05). **Discussion** MLSSv seems to represent the upper limit of stroke mechanics efficiency and the relationship between kinematic parameters and the primary phase of VO₂ kinetics highlight the importance and pertinence of technical quality training in day-to-day swimming practice. Since 98% of the total VO₂max is attained at four times taup (Burnley & Jones, 2007) and swimmers evidenced a taup of around 20-s, coaches may prescribe training sets below 80-s to endure VO₂max. **References** Bailey, S.J., Wilkerson, D.P., DiMenna, F.J., Jones, A.M. A PROMISING PROCEDURE TO ASSEMBLE MORE O₂ UPTAKE RESPONSES AT EXERCISE ONSET

Francescato, M.P.1, Cettolo, V.1, Bellio, R.2

University of Udine

Introduction Great interest is devoted to the parameters (e.g. the time constant) describing the phase II pulmonary O₂ uptake kinetics at exercise onset. Since the O₂ uptake data are "noisy", more responses of the same transition are assembled to enhance the signal-to-noise ratio. The reliability of a new method to assemble more responses ("stacking") was investigated as compared to the usual "re-sampling" method. **Methods** The environment R (R Core Team, 2013) was used for the whole simulation. Ten sets of 10000 simulated noisy responses were generated (Francescato et al., 2014) and the first one was then progressively assembled over an increasing number of sets (from 2 to 10) using both methods. For the "re-sampling" method, all the responses were re-sampled at 1 s time intervals, re-aligned to the starting time, and then averaged. For the "stacking" method, the responses were simply stacked up. The kinetic parameters and their approximate confidence intervals were estimated by non-linear regression with a simple mono-exponential model on all the assembled responses; only the data usually assumed to pertain to phase II pulmonary O₂ uptake were considered. The percentage responses for which the approximated confidence intervals included the true parameter were calculated. **Results** Simulations showed that the average estimated parameters were close to the correct ones for both the assembling methods. Results of the "re-sampling" method showed that the widths of the approximated confidence intervals were artificially narrower than the correct ones (it was about the half for the time constant). This condition yielded a low probability of including the true parameter within the approximated confidence interval (~70% for the time constant), independent of the number of assembled responses. Results of the "stacking" method showed that the widths of the approximated confidence intervals were practically equal to the correct ones. Consequently, the probability of including the true parameter within the approximated confidence interval was higher (>94% for the time constant), independent of the number of assembled responses. **Discussion** Our simulation demonstrated that the simple "stacking" of the O₂ uptake responses required the less

effort for the assembling of more responses. Moreover, this method allowed maintaining the precision and the accuracy of the native data, thus yielding the highest probability of including the true parameter values within the estimated uncertainty. We conclude that the "stacking" method should be preferred, because of its high reliability. References Francescato MP, Cettolo V, Bellio R (2014), *Exp Physiol*, 99, 187-195. R Core Team (2013). RELATIONSHIP BETWEEN V'O₂PEAK AND CARDIORESPIRATORY KINETICS IN GROUPS OF DIFFERENT EXERCISE CAPACITY

Koschate, J., Drescher, U., Hoffmann, U.

German Sport University Cologne

Introduction A significant relationship between cardiorespiratory kinetics and peak oxygen uptake (V'O₂peak) is assumed. Cardiorespiratory kinetics are one of the factors determining V'O₂peak. Using pseudo random binary sequences (PRBS) as a moderate work rate pattern combined with cross correlation functions (CCF), kinetic assessment can be reduced to a single test session, contrary to other kinetic test procedures. By use of a backward calculation method (BCM), muscular V'O₂ (V'O₂musc) can be calculated. Especially in populations where V'O₂peak tests could be risky or time is restricted, short, submaximal, reliable tests are important. To evaluate BCM using PRBS and CCF, groups with different exercise capacities were tested. It was assumed that V'O₂peak would show a correlation with cardiorespiratory kinetics. Method 26 active young (AY) (age: 31.1±8.3 years; weight: 71.9±12.5 kg), 12 active middle aged (AMA) (age: 48.3±4.3 years; weight: 76.6±15.7 kg) and 29 inactive elderly (IE) (age: 72.5±2.8 years; weight: 82.2±9.2 kg) subjects were tested for V'O₂peak and cardiorespiratory kinetics on a bicycle ergometer. For assessment of cardiorespiratory kinetics PRBS WR patterns in combination with CCF were applied. Higher peaks in CCF imply faster system responses (Hoffmann et al., 2013). To control for effects of age on V'O₂peak, the percentage of target V'O₂peak (%targetV'O₂peak), considering age and bodyweight, was calculated. Correlations were calculated two-tailed via Spearman-Rho, stepwise linear regression was applied as well. Results The AY, AMA and IE subjects achieved 158.23±24.2%, 113.7±17.8% and 69.6±13.3% of target V'O₂peak, respectively. Mean CCFpeaks for AY were 0.45±0.12 for heart rate (Hpeak); 0.33±0.07 for respiratory V'O₂ (Rpeak) and 0.41±0.07 for V'O₂musc (Mpeak). Hpeak for AMA was 0.37±0.09, for Rpeak 0.39±0.15 and 0.37±0.1 for Mpeak. For IE Hpeak was 0.32±0.11, Rpeak 0.3±0.1 and Mpeak was 0.32±0.07. A significant correlation with %targetV'O₂peak was calculated for the peaks of R, M and H (r=0.383, p=0.001; r=0.557, p<0.001; r=0.439, p<0.001). Performing a stepwise linear regression, including Hpeak and Mpeak as independent and %targetV'O₂peak as dependent variable, Mpeak showed the most important influence (p<0.001). Discussion The results show that the developed method to assess cardiorespiratory kinetics correlates well with V'O₂peak in groups of different exercise capacity. The calculated value Mpeak shows the most important influence on V'O₂peak. The applied test leads to the opportunity to estimate some influencing factors of exercise capacity irrespective of the subjects maximal effort or motivational aspects. PHYSIOLOGICAL ACUTE EFFECTS OF CONSTANT VERSUS INTERMITTENT CYCLE ISO-WORKLOAD EXERCISE BELOW VENTILATORY THRESHOLD

Abrantes, C., Pinto, G., Sousa, N.

University of Trás-os-Montes and Alto Douro

Introduction It may be assumed that intermittent exercise by itself can change the exercise and post-exercise energy output. The aim of this study was to compare the acute effects of cycle exercise intensity fluctuation, with the same total workload (iso-workload) below ventilatory threshold, on physiological responses during and after exercise. Methods The sample comprised nine voluntary male (age mean = 22.2, s = 1.8 years; height mean = 170.1, s = 4.4 cm, weight mean = 68.8, s = 4.7 kg, peak oxygen uptake = 57.5, s = 9.9 mL.Kg⁻¹.min⁻¹ and fat mass mean = 11.07, s = 1.66%) who performed three exercise protocols lasting 30 minutes each, followed by twenty minutes of post-exercise passive period. The anaerobic ventilatory threshold was tested during an incremental test (25 Watts.min⁻¹) to exhaustion. In the constant workload protocol (CON) the exercise intensity was set at 65% of the ventilatory threshold. The intermittent protocols were divided in lower intermittent intensity (LO-INT) and higher intermittent intensity (HI-INT). The LO-INT was comprised by 1 minute at 85% of ventilatory threshold, followed by 2 minutes at 57% of the ventilatory threshold repeated 10 times. The HI-INT was comprised by 1 minute at 100% of ventilatory threshold, followed by 4 minutes at 57% of the ventilatory threshold repeated 6 times. Oxygen uptake (VO₂), heart rate (HR), perceived exertion (RPE) and energy expenditure (kcal) were measured during exercise, and excess post-exercise oxygen uptake (EPOC), HR and Kcal after exercise. Results During exercise, no differences were found in VO₂, HR, RPE and Kcal between CON, LO-INT and HI-INT protocols. The exercise VO₂ values were 2.3±0.2 L.min for CON, 2.2±0.2 L.min for LO-INT and 2.1±0.2 L.min for HI-INT. The amount of oxidative energy expenditure was 11.4±0.9 Kcal.min⁻¹ for CON, 10.9±1.1 Kcal.min⁻¹ for LO-INT and 10.7±0.9 Kcal.min⁻¹ for HI-INT. In post-exercise responses, no differences were found in EPOC, in HR neither in Kcal. The amount of energy output during the post exercise period was 2.4±0.3 Kcal.min⁻¹ for CON, 2.5±0.4 Kcal.min⁻¹ LO-INT and 2.4±0.3 Kcal.min⁻¹ for HI-INT. Discussion The iso-workload intensity fluctuation, below the anaerobic ventilatory threshold, by itself did not promote a different response neither during nor after exercise. A higher EPOC associated to intensity fluctuation protocols at similar total workload (Kang et al., 2007) may be dependent of intensities above ventilatory threshold. The global exercise perceived exertion was not affected by exercise fluctuation. It appears that when the workload is similar and below ventilatory threshold, the exercise fluctuation would not change per se the physiological profile. A RANGE FOR THE "REAL" VALUE OF INTERNAL MECHANICAL POWER IN CYCLING

Giorgi, H., Andrews, M., Gray, A., Osborne, M.

The University of Queensland

Introduction A number of complex frameworks have been developed for considering metabolic energy supply and various energy demands during cycling. None of these, however, adequately account for the cost of moving the limbs against inertial and gravitational forces, i.e., the internal mechanical power (IP). Previously, IP has been determined using either a physiological or a biomechanical approach. The physiological approach is valuable because it quantifies the energy state of the entire system where changes to whole-body energy metabolism with changes in energy demands are relatively indisputable. This approach, however, generally determines IP by subtracting external mechanical power (EP), the power applied externally on the pedals, and the metabolic cost of rest from the total

energy expenditure. This simple relationship has been rebuked by biomechanists, who have instead argued that there is some degree of energy transfer from IP to EP, i.e., they do not have independent metabolic costs. The biomechanical approach can determine the potential and kinetic energies of the separate body segments and can largely distinguish the muscle groups from which the energy was sourced. The greatest limitation to this approach, however, is that it does not account for the dissipation of energy to heat, a significant destination of metabolic energy in the human body. The purpose of this study was to consider the approaches together to calculate a range of values for IP during cycling at 200 W and 80 and 110 rev/min. Methods Ten elite cyclists completed five-minute bouts of cycling at 0 W (no chain attached) and 200 W, at 80 and 110 rev/min. Oxygen consumption during unloaded cycling was converted to metabolic power and then transformed to its mechanical counterpart by multiplying by delta efficiency. This represented the physiological estimate of IP. The biomechanical estimate of IP at 200 W was taken as the summed muscle joint powers, determined from inverse dynamics analysis, in excess of that required to apply power to the pedals. Results The range of IP estimates at 80 rev/min was constrained at the lower limit by the biomechanical estimate of 28 ± 11 W and at the upper limit by physiological estimate of 56 ± 9 W. At 110 rev/min, the biomechanical estimate was 34 ± 17 W and the physiological estimate was 96 ± 13 W. Discussion The proposal for a range of values for IP is novel and represents a more comprehensive description of the flow of metabolic to mechanical energy than when only one approach is used. Future efforts to refine the models that predict the upper and lower limits should see these limits move closer together and toward the real value of IP. Such an improvement may have implications for improved cycling performance predictions.

MAXIMAL CARDIORESPIRATORY RESPONSES IN EXHAUSTIVE TANDEM-BICYCLE ERGOMETER EXERCISE - COMPARISON OF THE SUBJECTS WITH THE DIFFERENT PEAK OXYGEN UPTAKE-

Onodera, S.1, Katayama, K.2, Ogita, F.3, Saito, T.4, Hayashi, S.4, Murata, M.4, Wada, T.4, Goto, M.4, Watanabe, Y.4, Yoshioka, A.5, Nishimura, K.6, Kremenec, M.J.1

Purpose: We have reported that the tandem-bicycle ergometer is a suitable apparatus to give an equal load to two subjects from sub-maximal exercise to exhaustion in the viewpoint of cardiorespiratory responses (Onodera S. et al., ECSS 2012, 2013). This time, we tested whether maximal cardiorespiratory responses of two subjects obtained during tandem-bicycle exercise are the same as those during single-bicycle exercise, even when two subjects with different peak oxygen uptake (VO₂peak) performed exhaustive tandem-bicycle exercise. Methods: First, fourteen healthy young Japanese males performed incremental single-bicycle exercise until exhaustion (SIN), and VO₂peak and peak heart rate (HRpeak) were recorded. Then, the subjects were divided into two groups; one was high VO₂peak group (high group; n=7), and the other was low VO₂peak group (low group; n=7). The difference in VO₂peak between groups was around 10%. Next, the incremental exhaustive tandem-bicycle exercise was carried out in two different conditions, i.e., the former saddle (FOR) and the rear saddle (REA) trial. Two subjects for tandem-bicycle exercise were randomly selected for each group. In the test, VO₂peak and HRpeak were determined. Results and Discussion: VO₂peak and HRpeak in the SIN trial were 46.6 ± 2.7 ml/kg/min and 195.1 ± 9.5 bpm in the high group, and 41.2 ± 3.0 ml/kg/min and 193.0 ± 9.5 bpm in the low group. In the FOR and REA trials of the high group, VO₂peak and HRpeak were 45.4 ± 2.8 ml/kg/min and 191.1 ± 8.2 bpm (FOR), and 44.8 ± 3.5 ml/kg/min and 190.9 ± 8.6 bpm (REA), respectively. In the low group, VO₂peak and HRpeak were 41.5 ± 2.9 ml/kg/min and 190.6 ± 9.2 bpm (FOR), and 41.7 ± 3.6 ml/kg/min and 191.1 ± 7.9 bpm (REA). When VO₂peak and HRpeak among three conditions, i.e. single-trial, the FOR and REA in tandem-bicycle trial, were compared within each group, no significant differences were found. In conclusion, it is suggested that even if there are 10% difference in VO₂peak between the subjects, maximal cardiorespiratory responses of the two subjects during tandem-bicycle exercise are the same as those during single-bicycle exercise. PEAK OXYGEN UPTAKE EVALUATION IN WHEELCHAIR BASKETBALL PLAYERS: CONTINUOUS OR INTERMITTENT PROGRESSIVE FIELD TEST?

Leprêtre, P.M.1, Faupin, A.2, Borel, B.3, Weissland, T.1

1) Université de Picardie Jules Verne; 2) Université du Sud-Toulon-Var; 3) Université Lille 2

Introduction A continuous progressive multistage field test (MFT) was validated to assess wheelchair mobility and estimate peak of oxygen uptake (VO₂peak) (Vanderthommen et al. 2002). However, intermittent nature of wheelchair basketball game (Spörner et al. 2009) raised the question about continuous or intermittent incremental test to estimate VO₂peak (Castagna et al. 2006). In able-body athletes, Buchheit (2008) observed a lesser inter-individual variation of aerobic performance during an intermittent (IFT) compared to continuous incremental exercises. Hence, this study aimed to compare the physiological responses of wheelchair basketball players (WBP) measured during IFT and MFT. Methods 18 trained WBP (32.0 ± 5.7 y, IWB classification: 2.9 ± 1.1 points) performed on two separate days, MFT and IFT in random order. For both test, initial rolling velocity was set at 6 km.h⁻¹ and increased by 0.37 km.h⁻¹ per min or 0.5 km.h⁻¹ per 45s for MFT and IFT, respectively. For both tests, VO₂peak and peak values of breath frequency (RF), pulmonary ventilation (VEpeak), heart rate at VO₂peak (HR@VO₂peak) the peak recovery – rest blood lactate values difference (Δ Lact), and the perceived rating exertion (RPE) were measured. Results Student's t-test did not show any difference in VO₂peak, VEpeak and RF between both tests. IFT was shorter (12.4 ± 2.4 vs. 14.9 ± 5.1 min, $P < 0.05$) but induced higher values of FRV and Δ Lact compared to MFT (14.2 ± 1.8 vs. 11.1 ± 1.9 km.h⁻¹ and 8.3 ± 4.2 vs. 6.9 ± 3.3 mmol.L⁻¹, $P < 0.05$). However, HR@VO₂peak and RPE values were higher during MFT than IFT (166.8 ± 13.8 vs. 172.8 ± 14.0 bpm and 13.8 ± 3.5 vs. 15.3 ± 3.8 , respectively, $P < 0.05$). Discussion Buchheit (2008) earlier reported that IFT led to significantly higher peak of lactate values and final velocity than continuous exercise without significant VO₂peak. Braking, accelerate and change direction induced by IFT could explain a greater anaerobic solicitation but also the lesser RPE in our subjects compared to MFT. MFT imposed to turn in a

single direction and a longer time duration, which could produce discomfort and higher RPE compared to IFT. Finally, rest periods of IFT would delay cardiac adaptation in our population including spinal cord injury WBP (Schmid et al. 1998). IFT could be used for design interval training sessions in order to increase VO₂peak in WBP. Reference Buchheit M. (2008) J Strength Cond Res. 2008 22:365-74. Castagna C et al. THE EFFECTS OF HYBRID CYCLE VERSUS HANDCYCLE EXERCISE ON METABOLIC SYNDROME, INFLAMMATION AND VISCERAL ADIPOSITY IN PEOPLE WITH SPINAL CORD INJURY

Bakkum, A.

VU University

Purpose: The purpose of this study was to examine the effects of a hybrid cycle versus handcycle training program on metabolic syndrome, inflammatory status and visceral adiposity in people with long-term spinal cord injury (SCI). **Methods:** Nineteen inactive wheelchair-dependent individuals (aged 28-65 years; age at onset SCI \geq 18) with paraplegia or tetraplegia for at least 9 years have completed this 16-wk multicenter randomized-controlled trial. The hybrid group (N=9) performed a hybrid cycle (functional electrical stimulation (FES)-induced leg exercise combined with voluntary arm exercise) training program, while the handcycle group (N=10) performed a handcycle program. Both groups trained twice a week, 30 min at 70% heart rate reserve. Outcome measures obtained pre and post the program were metabolic syndrome components (waist circumference, blood pressure, high-density lipoprotein cholesterol (HDL-C), triglycerides (TG) and insulin resistance), resting inflammatory status (C-reactive protein (CRP), interleukin-6 and -10 (IL-6 and IL-10), and visceral adiposity (trunk and android fat). Differences between pre and post measurements were examined using a two-factor (time x group) mixed measures ANOVA. **Results:** Overall significant reductions were found for waist circumference (3.5%, $p=0.001$), diastolic blood pressure (7%, $p=0.03$), insulin (26%, $p=0.004$), homeostasis model assessment-estimated insulin resistance (HOMA-IR; 26%, $p=0.006$), CRP (16%; $p=0.05$), IL-6 (26%; $p=0.04$) and IL-6/IL-10 ratio (32%; $p=0.03$). In contrast, no significant main effects for time were observed for systolic blood pressure, TG, HDL-C, glucose, IL-10, and trunk and android fat. For all outcome measures, there were no significant differences between groups. **Conclusion:** Since both the hybrid cycle and handcycle group showed similar positive effects on metabolic syndrome components and resting inflammatory status, there was no notable benefit of FES-induced leg exercise above handcycle training alone.

PHYSICAL CAPACITY OF PERSONS WITH A SPINAL CORD INJURY FOR AT LEAST 10 YEARS

de Groot, S., van der Scheer, J., Bakkum, A., Adriaansen, J., Smit, C., Dijkstra, C., Post, M., van der Woude, L.

Reade

Introduction A good physical capacity is important for people with a spinal cord injury (SCI) since it is positively related to participation and quality of life. Therefore, the purpose of this study was to study the impact of time since injury (TSI) on the physical capacity of persons with SCI for at least 10 years. **Methods** Cross-sectional study. Persons with SCI (N=208) in three strata: 10-19, 20-29 and 30 years or more after SCI, age at injury 18-35 years and dependent on a wheelchair for longer distances. Physical capacity (peak power output (POpeak) and peak oxygen uptake (VO₂peak)) were assessed with a wheelchair on a treadmill. **Results** Of the participants, 25% was not able to perform the exercise test. Non-participants in the exercise test (N=52) were significantly older (51 ± 9 vs. 48 ± 8 years, $p=0.04$), had a longer TSI (27 ± 10 vs. 24 ± 8 years, $p=0.03$), had more often a motor complete lesion (88% vs. 76%, $p=0.05$), and tetraplegia (76% vs. 55%, $p=0.01$). In the group with tetraplegia, no significant differences were found between TSI strata in VO₂peak (10-19yrs: 1.1 ± 0.5 l/min; 20-29yrs: 1.3 ± 0.4 l/min; >29yrs: 1.1 ± 0.4 l/min, $p=0.40$) or POpeak (10-19yrs: 40 ± 25 W; 20-29yrs: 42 ± 22 W; >29yrs: 45 ± 27 W, $p=0.83$). This is in contrast with the group with paraplegia, which showed a significant difference in POpeak between TSI strata (10-19yrs: 68 ± 24 W; 20-29yrs: 67 ± 25 W; >29yrs: 62 ± 23 W, $p=0.03$) but not in VO₂peak (10-19yrs: 1.7 ± 0.6 l/min; 20-29yrs: 1.5 ± 0.5 l/min; >29yrs: 1.3 ± 0.2 l/min, $p=0.07$). After controlling for confounders, no significant associations were found for the group with tetraplegia. In the group with paraplegia, TSI was significantly associated with POpeak ($p=0.001$) and VO₂peak ($p=0.002$), after controlling for confounders. Those with the longest TSI had the lowest POpeak and VO₂peak. **Conclusion** TSI did not seem to have an effect on the physical capacity of people with a tetraplegia, which might be explained by the high percentage of people with a tetraplegia that was not able to perform the exercise test. In people with paraplegia the physical capacity was significantly lower in those with a TSI longer than 30 years, indicating that the group with a long TSI needs extra attention to keeping them fit. LEARNING WITH A LEVER-PROPELLED WHEELCHAIR: THE EFFECT OF THREE WEEKS OF PRACTICE ON EFFICIENCY AND TECHNIQUE

Jaspers, E.G.1, Hettinga, F.J.3,1, van der Woude, L.H.V.1,2

University of Groningen

1University of Groningen, University Medical Center Groningen, Center for Human Movement Sciences, 2Center for Rehabilitation, University Medical Center Groningen, The Netherlands, 3University of Essex, School of Biological Sciences, Centre of Sport and Exercise Science, Colchester, United Kingdom **Introduction** Lever-propelled wheelchairs are alternatives to hand-rim propelled wheelchairs that could potentially be used to prevent overuse injuries. The NuDrive is a detachable lever-propulsion system that enables an upright posture, potentially beneficial in preventing back problems. It also provides a continuous grip, very suitable for users with a limited hand function. These advantages make the NuDrive an interesting option for rehabilitation. However, using the NuDrive adequately is suggested to require a process of adaptation, i.e. motor learning. Therefore, we investigated the effects of three weeks of practice on technique and efficiency. **Methods** Inexperienced able-bodied male participants were randomly divided over an experimental (EXP, n=8) and a control group (CON, n=8). Pre- and posttest for both groups were three weeks apart and consisted of three consecutive 4 min bouts of sub-maximal exercise, with 2 min rest in between. EXP performed seven practice trials spread over the three weeks, to become more and more familiarized to the lever-propulsion. These trials consisted of two consecutive 4 min bouts of sub-maximal exercise, with 2 min rest in between. All tests and trials were performed on a motorized treadmill (0.30 W/kg, 1,11 m/s). Changes in technique were measured using: stroke frequency, push time(PT), cycle time(CT), hand-speed and lever range of motion (lever ROM). Learning effects were quantified using gross mechanical efficiency (GME). **Statistics:** ANOVA $p>0.05$ **Results** PT(EXP:CON; $+0.11(\pm 0.10)$ s; $+0.02(\pm 0.02)$ s) and lever ROM ($+12.8(\pm 14.1)$ deg; $+1.1(\pm 4.3)$ deg) increased, where maximal hand-speed during the push phase (EXP:CON; $-0.17(\pm 0.14)$ m/s; $0.0(\pm 0.09)$ m/s) decreased more in EXP compared to CON, indicating that EXP participants shifted to a movement pattern with a longer stroke range and slower movement of the hands: a longer-slower movement pattern. Some indication of an increased GME was found, however, nothing

conclusive, potentially due to a low participant number in the GME analysis (EXP, n=5; CON, n=7). Conclusion EXP participants adopted a longer-slower movement pattern after three weeks of practice. Maximal hand-speed only decreased during the push phase. This indicates that participants might be more inclined to change their technique during the active push phase compared to the more passive pull phase. Inexperienced new users of the NuDrive might benefit from a focus on a longer-slower movement pattern early in their learning trajectory, although more research is needed to establish the effect of practice trials on GME.

TRAINING FOR A HANDCYCLING MOUNTAIN TIME TRIAL; PILOT STUDY ON THE BENEFITS FOR FITNESS IN PERSONS WITH SPINAL CORD INJURY

Valent, L., Postma, K., Van Vliet, L., Gobets, D., Groot, S.

Helimare Rehabilitation centre

Introduction: In persons with a spinal cord injury (SCI) it is difficult, but very important, to exercise in order to stay fit and healthy (De Groot et al, 2013, Nash et al, 2005). For this reason the HandbikeBattle; a hand cycling mountain time trial (20 km, 1000 Hm+), was organized to offer a challenge to train for. The aim of the current research project is to study the effects of a training period, prior to the HandbikeBattle, on physical capacity and to monitor possible adverse effects due to training or the event. **Methods:** 47 Persons, predominantly with SCI (n=40), were medically approved to participate for the event. All were former patients participating in teams of eight Dutch rehabilitation centers. 10 out of 47 subjects were familiar with the sport hand cycling, the others were new to the rigid frame hand cycle and started training with it especially for this event. Laboratory peak graded exercise tests were performed in 6 out of 8 rehabilitation centers at the start (T1) and after 3 months semi-controlled training (T2) just prior to the time trial. Outcome measures were peak oxygen uptake (VO2peak) and peak power output (POpeak). Participants had to fill out a questionnaire about upper-extremity pain. Two weeks after the race the participants had to fill out a questionnaire about their recovery. **Results:** VO2peak improved on average 12% from 2.11 ± 0.60 L/min to 2.30 ± 0.59 L/min (n=28, p=0.007) and POpeak improved on average 21% from 120 ± 44 W to 141 ± 48 W (n=31, p<0.001). Participants with relatively large improvements (> 15%) in POpeak were those with a significantly lower POpeak at T1 and who were less hampered by injuries. All participants finished the time trial. Two weeks after the time trial 34 out of 40 reported complete recovery; 4 still had to recover from minor to moderate upper-extremity (shoulder) complaints; 2 had serious chronic complaints, which were already present before the time trial. **Discussion:** This study involved many inexperienced but motivated persons for whom this event was their first serious sport training goal. A large improvement in fitness is seen after the training period especially in those with a low physical capacity. A key factor for success in training for such an event is preventing overload (injuries) and, therefore, we advise an optimal ergonomic handcycling set-up, custom-made training protocols and monitoring with a diary. Moreover, participants learned from each other and from the professionals about optimal preparation and training but also how to overcome barriers (Scelza, 2005) that prevent them from training. **References:** de Groot S, Valent LJ, van Koppenhagen CF, Broeksteeg R, Post MW, van der Woude LH. FAT CONTRIBUTION OF EXERCISE ENERGY EXPENDITURE IN PARALYMPIC ATHLETES WITH LOCOMOTOR IMPAIRMENTS.

Bernardi, M.1, Marini, C.2, Duca, A.3, Lanzano, R.1, Squeo, M.R.1, Parisi, F.1, Dante, D.1, Righi, M.3, Gallozzi, C.2

1 Sapienza University of Rome (Italy), 2 Italian Olympic Committee (Italy) 3 University of Messina (Italy)

Introduction The study is aimed at assessing energy expenditure (EE) and relative contribution of fat (Fat%) during arm cranking ergometer (ACE) steady-state exercises carried out at different sub-maximal intensities in Paralympic athletes (PA) with locomotor impairments competing in summer and winter sports with different EE (Bernardi et al. 2010; Bernardi et al. 2012). We evaluated the hypothesis that PA with spinal cord injury (PA-SCI) had a lower FAT% than PA with other locomotor impairment (PA-OLI). **Methods** Sixty-four male PA, including 29 PA-SCI and 35 PA-OLI (age 35.4 ± 8.86 and 37.1 ± 8.46 years old, height 1.77 ± 0.099 and 1.74 ± 0.134 m; mass, 68.9 ± 10.17 and 71.4 ± 8.25 kg, respectively) gave an informed consent to participate to the study. All PA were tested both at rest and during an incremental ACE (E400, Cosmed, Italy) cardiopulmonary maximal exercise test through a breath by breath metabolic monitoring (Quark CPET, Cosmed, Italy) to assess rest oxygen uptake (VO2) and VO2peak, respectively. In a following day, with the same material and methods, PA were submitted to three sub-maximal constant power exercise tests (S-CPET) at intensity equal to ~30%, 50% and 70% of VO2 reserve (VO2R), to assess S-CPET EE and Fat% at different intensities. **Results** Rest VO2 ($\text{ml} \cdot \text{min}^{-1}$) was equal to 241 ± 35.6 and 250 ± 28.9 in PA-SCI and PA-OLI, respectively. VO2peak ($\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$, $\text{l} \cdot \text{min}^{-1}$) were equal to 35.6 ± 10.67 (2.4 ± 0.60) and 36.9 ± 6.35 (2.6 ± 0.52) in PA-SCI and PA-OLI, respectively. S-CPET were carried out at VO2 values ($\text{ml} \cdot \text{min}^{-1}$ and corresponding intensities as %VO2R) equal to 978 ± 214.1 (32.2 ± 0.06), 1292 ± 303.3 (48.3 ± 5.42) and 1793 ± 524.2 (69.2 ± 8.54) and 1030 ± 196.3 (32.3 ± 0.06), 1473 ± 321.9 (51.6 ± 8.26) and 2014 ± 441.7 (73.7 ± 11.64) in PA-SCI and PA-OLI, respectively. Based on EE at rest and during S-CPET VO2 ($\text{ml} \cdot \text{min}^{-1}$) was 361.5 ± 16.19 power (watts) ($r^2=0.952$). Fat% at the three intensities were equal to 27.8 ± 13.45 , 17.5 ± 12.54 and 9.6 ± 9.75 and 29.5 ± 12.46 , 15.7 ± 12.08 and 8.5 ± 9.15 in PA-SCI and PA-OLI, respectively, resulting in $\text{Fat}\% = 43.17 - 0.467 \cdot \% \text{VO2R}$ ($r^2=0.39893$). **Discussion** No significant differences were found in Fat% assessed in different exercise intensities in trained PA with different locomotor impairments. These data can be used to calculate maximal lipid oxidation. **References:** Bernardi M, Guerra E, Di Giacinto B, Di Cesare A, Castellano V, Bhambhani Y. (2010). 08:30 - 10:00**Oral presentations****OP-PM28 Endurance & Performance****BRAIN TRAINING IMPROVES ENDURANCE PERFORMANCE**

Marcora, S.M., Staiano, W., Merlini, M.

University of Kent

Introduction It has been demonstrated that mental fatigue (MF) has a negative impact on perception of effort and endurance performance (EP) (Marcora et al., 2009). Therefore, interventions that increase resistance to MF should reduce perception of effort and improve EP. The aim of this study was to test the efficacy of Brain Endurance Training (BET), a new kind of brain training specifically designed to improve EP. BET is based on the hypothesis that systematic repetition of mentally fatiguing tasks would increase resistance to MF and, thus, improve EP. **Methods** 28 healthy and physically active males were randomly assigned to two different training groups: BET and control. Both groups trained on a cycle ergometer for 60 min at 65% of VO₂max. Whilst cycling, the BET group (N = 14) performed a mentally fatiguing task on a computer (60 min of the AX-CPT task). The control group (N = 14) was not involved in any mentally fatiguing task whilst cycling. Both groups trained three times a week for 12 weeks. Peak power output (PPO) and VO₂max (incremental test), and EP (time to exhaustion [TTE] test at 75% of current PPO) were measured at baseline (pre-test), after six weeks of training (mid-test) and after 12 weeks of training (post-test). Rating of perceived exertion (RPE) was measured every minute during the TTE test. **Results** VO₂max increased similarly in both the BET group (pre 40 ± 5; mid 48 ± 6; post 52 ± 7 ml/kg/min) and the control group (pre 40 ± 6; mid 48 ± 6; post 52 ± 6 ml/kg/min) (p < .001). However, TTE increased significantly more in the BET group (pre 27 ± 10 min; mid 38 ± 11 min; post 51 ± 15 min) than in the control group (pre 19 ± 6 min; mid 24 ± 7 min; post 30 ± 13 min) (p < .05). Analysis of covariance to adjust for baseline differences in TTE revealed an even larger improvement in the BET group (113%) compared to the control group (43%) (p < .01). This substantial effect of BET on TTE was associated with a significant reduction in RPE (p < .05). **Discussion** The results of this study provide experimental evidence that the addition of BET to a standard aerobic training program is highly effective in reducing perception of effort and improving EP. Future studies should investigate the brain adaptations underlying the positive effects of BET, and its efficacy in elite endurance athletes for which BET may provide a novel training stimulus without overloading the musculoskeletal system. **References** Marcora S.M., Staiano W., Manning V. EFFECTS OF LIGHT DEPRIVATION IN PERFORMANCE AND PSYCHOPHYSIOLOGICAL RESPONSES IN OPEN-LOOP EXERCISE

Pires, F.O.1, Ugrinowitsch, C.1, St-Clair-Gibson, A.2, Micklewright, D.3, Noakes, T.4, Pinheiro, F.

University of São Paulo

1: University of São Paulo (BR), 2: Northumbria University (UK), 3: University of Essex (UK), 4: University of Cape Town (SA). **Introduction** The visual system is suggested to play an important role for the recognition of external environments and to be involved in motor performance during exercise. Previous study observed that light deprivation affected neither performance nor psychophysiological responses in a closed-loop exercise, a 40-km cycling time trial (Kriel et al., 2007). However, there are no evidences of light deprivation effects during open-loop exercises. The aim of this study was to verify if light deprivation affects performance and psychophysiological responses in an open-loop exercise. **Methods** After a preliminary maximal incremental test, comprised of 25 W/min increments until exhaustion twelve men (VO₂peak of 35.0 ± 4.8 ml/kg/min) performed counterbalanced trials in the presence (control; CON) and absence (experimental; EXP) of light. CON and EXP trials were a time to exhaustion exercise set at 80% of the peak power output obtained in the preliminary test. Pulmonary VO₂, heart rate (HR) and electromyography (EMG) of vastus lateralis muscle were continuously recorded throughout the tests while ratings of perceived exertion (RPE) were obtained every 60 sec. Responses between CON and EXP trials were analyzed at matched absolute time of exercise (referenced by the shortest time to exhaustion), and at 100% of the time to exhaustion. The rate of increase in RPE (RPESLOPE) was calculated. CON and EXP conditions were compared by a paired T-Student test (P < 0.05). **Results** Time to exhaustion was lower (5.0 ± 1.6 min; P = 0.02) and RPESLOPE (P = 0.04) was greater in EXP, than in CON condition (6.4 ± 2.4 min). Comparisons using matched absolute time of exercise showed that VO₂ (P = 0.02) and RPE (P = 0.03) were greater in EXP than CON condition, but no difference was observed in EMG and HR. At 100% of the time to exhaustion EMG was lower (P = 0.03) in EXP than in CON condition, but no difference occurred for VO₂, HR, and RPE. **Discussion** Contrary to closed-loop exercise (Kriel et al., 2007) light deprivation impaired performance and induced greater psychophysiological (VO₂ and RPE) disturbance during an open-loop exercise. However, responses at the EXP exercise endpoint were similar to those observed in CON. These results may be interpreted according to the internal clock model (St Clair Gibson et al., 2006) in which exercise termination was anticipated in light-deprived environment, thereby preserving the body from harmful psychological and physiological disturbance. **References** 1. CONSECUTIVE DAYS OF PROLONGED TENNIS MATCHPLAY AFFECT PHYSIOLOGICAL, PERFORMANCE, AND PERCEPTUAL RESPONSES

Gescheit, D.T., Cormack, S.J., Reid, M., Duffield, R.

Tennis Australia

Purpose: To determine the performance, physiological, and perceptual responses to consecutive days of prolonged tennis matchplay. **Methods:** Seven well-trained male tennis players completed 4 h competitive tennis matches on 4 consecutive days. Pre- and post-match measures included tennis (serve speed and accuracy), physical (20m sprint, countermovement jump, shoulder rotation maximal voluntary contraction, isometric mid-thigh pull), perceptual (Training Distress Scale (Main and Grove, 2009), soreness), and physiological (body

mass, Creatine Kinase, Testosterone, Cortisol) variables. Activity profile was assessed by heart rate, and three-dimensional load (sum of the mediolateral, anteroposterior, and vertical vector loads), while Rating of Perceived Exertion (RPE) was collected every 30 minutes. Statistical analysis compared within and between day values. Changes ($\pm 90\%$ confidence interval (CI)) equal to or greater than 75% likely to exceed the smallest important value were considered practically important. Results: Three-dimensional load (mean reduction \pm SD; 1064.8 ± 83.6) and effective playing time reduced on days 2-4 compared to day 1 ($28 \pm 3\%$). Total strokes hit and RPE did not change. Post-match 20 m sprint (mean percentage change $\pm 90\%$ CI; $3.0 \pm 3.7\%$) and countermovement jump ($-15.6 \pm 15.4\%$) performance declined on days 2-4 compared to pre-match day 1. Although serve velocity was maintained, compromised post-match serve accuracy was evident (days 2: $23.6 \pm 32.0\%$ and 3: $20.4 \pm 17.8\%$ as compared to pre-match day 1). Cortisol declined and Creatine Kinase increased on all days, whereas changes in Testosterone were more variable. Conclusions: Four-hours of matchplay over 4 consecutive days realised declines in total movement, which may have been impacted by changes in tactical approach. Increases in perceptual and biochemical markers of muscle damage, decrements to sprinting and jumping ability, and reduced mood states, also highlight probable neuromuscular and perceptual fatigue. PROFESSIONAL ROAD CYCLING SPRINTS: QUANTIFYING THE DEMANDS OF THE FINAL HOUR

Menaspà, P., Martin, D.T., Quod, M., Abbiss, C.R.

Edith Cowan University

Introduction The demands of uphill and time trial performances and the physiological characteristics of professional road cyclists have been well documented. Despite the importance of sprinting to the overall outcomes of a race and the high number of sprint finishes within professional road cycling (Menaspà et al. 2013a), research examining the demands of professional road sprint cycling is limited to a couple of preliminary studies (Menaspà et al. 2013a; Menaspà et al. 2013b). The aim of this study was to examine and describe the demands of road cycling sprint competitions in professional male cycling, with particular focus on the lead-up phase prior to the final sprint. **Methods** Seventeen road race files from 6 professional male cyclists who placed in the top 5 (age, 27.0 ± 3.8 y; height, 1.76 ± 0.03 m; weight, 71.7 ± 1.1 kg) were analysed. Power, cadence, speed and total elevation gain (TEG) were recorded throughout the race using an SRM power meter. Data were averaged over the final 60, 10 and 1 min prior to the sprint finish. Exposure Variation Analysis (EVA) was used to quantify variations in power during the final 10 min of the race. **Results** The average (\pm SD) of all variables measured in this study significantly increased as athletes approached the finish line ($p < 0.001$). Power, cadence, speed and TEG were 233 ± 33 W, 89 ± 4 rpm, 45.4 ± 2.9 km·h⁻¹ and 218 ± 192 m in the 60 min; 316 ± 43 W, 95 ± 4 rpm, 50.5 ± 3.3 km·h⁻¹ and 27 ± 37 m in the last 10 min; and to 487 ± 58 W, 102 ± 6 rpm, 55.4 ± 4.7 km·h⁻¹ and 3 ± 6 m in the 1 min. EVA revealed a significantly greater number of short duration and high intensity efforts (> 6.6 W·kg⁻¹ and < 3.8 s) in the final 5 min, compared with the penultimate 5 min ($p = 0.010$). **Discussion** As expected, race intensity significantly increased as sprinters approached the finish line. Aerobic fitness is likely to be extremely important to road sprint cycling performance as evidenced by the elevation gain (up to 600 m·h⁻¹ of vertical ascension rate), high intensity and variability of the power output in the final hour leading-up to the sprint. These results expand upon previous research, highlighting that aerobic fitness is important for road sprinting. Therefore, coaches and cyclists interested in improving sprinting in road races should focus on aerobic as well as anaerobic qualities. **References** Menaspà P, Abbiss CR, Martin DT. REGULAR MODERATE OR INTENSE EXERCISE PREVENTS DEPRESSION-LIKE BEHAVIOR WITHOUT CHANGE OF HIPPOCAMPAL TRYPTOPHAN CONTENT IN CHRONICALLY TRYPTOPHAN-DEFICIENT AND STRESSED MICE

Mikami, T., Lee, H., Ohno, M., Ohta, S.

Nippon Medical School

Introduction Regular exercise has an antidepressant effect in human subjects (Carek et al., 2011). Studies using animals have suggested that the antidepressant effect of exercise is attributable to an increase of brain 5-hydroxytryptamine (5-HT); however, the precise mechanism underlying the antidepressant action via exercise is unclear. In contrast, the effect of 5-HT on antidepressant activity has not been clarified, in part because the therapeutic response to antidepressant drugs has a time lag in spite of the rapid increase of brain 5-HT upon administration of these drugs (Deltheil T et al., 2008). This study was designed to investigate the contribution of brain 5-HT to the antidepressant effect of exercise. **Methods** Mice were fed a tryptophan-deficient diet and stressed using chronic unpredictable stress (CUS) for 4 weeks with or without the performance of either moderate or intense exercise on a treadmill 3 days per week. **Results** The findings demonstrated that the onset of depression-like behavior is attributable not to chronic reduction of 5-HT but to chronic stress. Regular exercise, whether moderate or intense, prevents depression-like behavior with an improvement of adult hippocampal cell proliferation and survival and without the recovery of 5-HT. Concomitantly, the mice that exercised showed increased hippocampal noradrenaline. Regular exercise prevents the impairment of not long-term memory but short-term memory in a 5-HT-reduced state. **Discussion** These findings suggest that: (1) chronic reduction of brain 5-HT may not contribute to the onset of depression-like behavior; (2) regular exercise, whether moderate or intense, prevents the onset of chronic stress-induced depression-like behavior independent of brain 5-HT and dependent on brain adrenaline; and (3) regular exercise prevents chronic tryptophan reduction-induced impairment of not long-term but short-term memory. **References** Carek PJ, Laibstain SE, Carek SM (2011) *Int J Psychiatry Med* 41, 15–28. EFFECT OF CADENCE AND WORKLOAD ON RESPIRATORY MECHANICS DURING ARM-CRANK EXERCISE

Tiller, N.B., Campbell, I.G., Romer, L.M.

BRUNEL UNIVERSITY

Introduction: High cadence arm-ergometry increases O₂ uptake (VO₂) and heart rate compared to low cadences at similar workloads. We reasoned that changes in cadence and workload might influence the relationship between central respiratory drive and mechanical ventilatory response during upper-body exercise. **Aim:** To assess the influence of cadence and workload on respiratory mechanics during arm-crank exercise in healthy subjects. **Methods:** Eight recreationally-active men (VO_{2peak}[arms] 29.9 ± 6.9 ml/kg/min) performed arm-crank ergometry at moderate (80% of gas exchange threshold) and severe (65% of the difference between gas exchange

threshold and VO_2peak workloads, each separated by 10 min. For each workload, subjects exercised for 4 min at three different cadences (50, 70 and 90 r/pm); the order of workloads was sequential whereas the order of cadences was randomised and counterbalanced. Measurements included baseline pulmonary function, cardiorespiratory indices, central respiratory drive via diaphragm EMG (multi-pair oesophageal electrode catheter), pressure-derived indices of respiratory mechanics and respiratory-locomotor coupling via whole- and half-integer ratios. Results: Baseline pulmonary function was within normal limits (FEV_1 : 4.3 L [99%], VC: 5.2 L [102%], TLC: 7.1 L [102%], DLCO: 12.1 mmol/min/kPa [102%]). During moderate exercise, VO_2 and heart rate were highest at 90 r/pm ($p < 0.05$) relative to 70 and 50 r/pm (VO_2 1.19 \pm 0.25 vs. 1.05 \pm 0.21 vs. 0.97 \pm 0.24 L/min; heart rate 116 \pm 11 vs. 101 \pm 13 vs. 101 \pm 12 b/min). Furthermore, ventilation was highest at 90 r/pm ($p < 0.05$) due primarily to an increase in tidal volume ($p < 0.05$). During severe exercise, there were no differences in VO_2 , heart rate, ventilation or breathing pattern across cadences. Diaphragm activation during severe exercise (EMG root-mean-square amplitude) was greatest at 90 r/pm (86 \pm 25% MVC) and 70 r/pm (87 \pm 10% MVC) vs. 50 r/pm (76 \pm 17% MVC), yet there were no corresponding differences in intrathoracic pressure swings or operating lung volumes across cadences or workloads. Respiratory-locomotor coupling during moderate exercise was most prevalent at 70 vs. 50 r/pm (27 \pm 10 vs. 13 \pm 9%) and during severe exercise at 90 vs. 50 r/pm (24 \pm 7 vs. 18 \pm 5%). Conclusion: Increased isometric contractions of the diaphragm for torso stabilisation may contribute to the elevated cardiorespiratory stress noted at high cadences during arm-crank exercise, although an effect of respiratory-locomotor coupling on respiratory drive cannot be excluded. Furthermore, arm exercise appears to disrupt the causal relationship between central respiratory drive and thoracic volume displacement.

IS-PM10 Concurrent training for peak power and endurance

MUSCLE GROWTH/STRENGTH VERSUS ENDURANCE SIGNAL TRANSDUCTION PATHWAYS AND THEIR INTERACTION

Wackerhage, H.

University of Aberdeen

In many sports athletes need to train for both strength/muscle mass and endurance. Equally muscle mass/high strength and high endurance are associated with health and longevity. This provides a rationale for athletes and fitness-orientated exercisers to increase strength/muscle mass and endurance at the same time. The aim of this presentation is to introduce a) a general theory of adaptation to exercise, b) to introduce the signal transduction pathways that mediate skeletal muscle growth and endurance adaptations in response to specific types of exercise and c) to highlight the interaction between these pathways. Key muscle growth pathways are the mTOR and Smad pathways whilst endurance adaptations are regulated by the AMPK/CaMK-PGC-1 α and calcineurin NFAT pathways. These evolutionary highly conserved pathways also interact with each other and there is the evidence for circadian behaviour.

MYOCYTE SIZE AND POWER: METABOLIC CONSTRAINTS

van der Laarse, W.J.

VU University Medical Center

Training improves muscle performance, but only to a limited extent. It is important to know the limits of adaptation to develop optimal training protocols in sports, but also in rehabilitation and chronic disease. Muscle fibres from the toad *Xenopus laevis* resemble human muscle fibres with respect to cross-sectional area and metabolic fluxes. These fibres can be isolated by dissection and have been used to identify metabolic limitations of performance. Determination of oxygen consumption during fatigue protocols in single fibres demonstrated that oxidative capacity of myocytes is limited by mitochondrial capacity and by the physiological extracellular oxygen tension. A VO_2 slow component is absent in single fibres. Oxidative capacity is a main determinant of endurance, producing over 70% of steady metabolic power (depending on the fibre type). In turn, oxidative capacity is inversely related to the cross-sectional area of myocytes over a hundredfold range, suggesting that oxygen diffusion limits steady state mechanical power at the level of the myocyte. Steady glycolytic power is less than 30% of metabolic power and is limited by the lactate flux across the sarcolemma and into the T-tubules. The larger part of this flux is via transporters. Manipulating the lactate flux via transporters has considerable effects on fatigue resistance. Net phosphocreatine splitting and lactate accumulation serve as short-term energy buffers and are limited by initial concentration and buffer capacity, respectively. All of these metabolic limitations can be manipulated, for instance by training and nutrition, but this may also have adverse effects. For instance, pressure and volume overload can lead to myocardial hypertrophy and heart failure and high creatine and phosphate concentrations and lactate accumulation can increase myocyte osmolarity, leading to water influx and increased blood viscosity. Training protocols can benefit from basic knowledge on metabolic constraints. However, we are still far from the design of optimal training protocols on the basis of science.

CONCURRENT STRENGTH AND ENDURANCE TRAINING: CONCEPTS AND PRACTICAL APPLICATION IN ELITE SPORTS

Vogt, M.

Federal Institute of Sports, Dept. of Training Science, Magglingen, Switzerland

Introduction: Concurrent training for both strength and endurance is relevant in many sports. A prominent example is alpine skiing in which the mechanical and metabolic demands are very high during competition. Over the 45 to 150 seconds duration of a race, required power output is by far in excess of sustainable power levels in this sport. Hence there is a decline of muscle function, in particular a decrease of available muscle strength. It would thus seem that it is of advantage to have the capability of a very high initial power output combined with the metabolic capacity to maintain this power output as much as possible over the duration of the race. These requirements are in an important part related to maximal strength as well as oxidative capacity of muscle tissue. Methods: An overview on the physiological underpinning of modern alpine skiing will be given leading to a discussion on molecular mechanisms involved in the adaptive response to concurrent strength and endurance training. Considering this and according to the Docherty & Sporer's interference

model, concepts are developed with the aim to optimize the training process in elite alpine skiers in view of conflicting training goals. Results: From a molecular perspective there is evidence that the adaptive response of muscle to strength and endurance training is mediated by different signalling pathways. There is crosstalk between these pathways resulting in interference of adaptive signals with competing training stimuli. This can result in an interference and attenuation of the functional response to endurance and/or strength training. Manipulating training intensity in strength and endurance training is decisive to the degree by which central or peripheral (muscle) systems are affected by the stimuli. By this and/or by temporally separating strength from endurance sessions the interference effect can be diminished. Conclusion: Based on the molecular and functional insights as well as on practical experience it is concluded that training organization concepts like block periodization allows for efficient improvement of both strength and endurance in competitive alpine skiers. IS-BN06 Core stability: What is it, does it matter, how can it be assessed?

CORE STABILITY: WHAT IS IT?

van Dieën, J.H.

VU University Amsterdam

In a recent review, core stability was described as a hot topic, but a vague concept (Borghuis et al. 2008). There appears to be a reasonable consensus on what the core is. A well-defined anatomical and therefore preferable synonym would be the trunk. However, definitions of the term stability in sports science are vague and operational definitions used diverge quite widely. Nevertheless, using different operational definitions, several studies found evidence for the importance of measures of trunk stability for injury prevention in athletes (e.g. Leetun et al. 2004; Zazulak et al. 2007). The aim of this presentation will be to provide clear definitions of stability and related concepts derived from control theory. In control theory, stability is a dichotomous concept, with instability being defined as the inability to tolerate infinitely small perturbations. Since perturbations are always present an unstable system cannot function and hence it is useful to focus on performance, which encompasses the speed or accuracy with which effects of finite perturbations can be counteracted by a stable system, and/or robustness, the margin of safety that the system has to becoming unstable, either in terms of perturbation magnitude, or in terms of reduced functioning of one of the stabilizing mechanisms. The trunk is controlled by parallel mechanisms, comprising the stiffness and damping provided by passive tissues, such as the intervertebral discs, and by muscles driven by feedforward and feedback control mechanisms. Different operational definitions of trunk stability used in literature, e.g. focusing on neural control or muscular capacity, can be shown to fit within this conceptual framework, either as reflections of performance or robustness, or as potential determinants thereof, i.e. reflecting the functionality of one or more of the stabilizing mechanisms. It will be shown that trunk control is highly adaptable to environmental conditions. Due to which the contribution of different control mechanisms is context dependent. In addition, the relevance of different measures of performance may be context dependent. This suggests that methods of testing trunk control should be sports specific. Borghuis J, Hof AL, Lemmink KAPM (2008) The importance of sensory-motor control in providing core stability: Implications for measurement and training. *Sports Med* 38 (11):893-916 Leetun DT, Lloyd Ireland M, Wilson JD, Ballantyne BT, McClay Davis I (2004) Core stability measures as risk factors for lower extremity injury in athletes. *Med Sci Sports Exerc* 36:926-934 Zazulak BT, Hewett TE, Reeves NP, Goldberg B, Cholewicki J (2007) Deficits in neuromuscular control of the trunk predict knee injury risk - A prospective biomechanical-epidemiologic study. *Am J Sports Med* 35 (7):1123-1130

CORE STABILITY: DOES IT MATTER?

Chaudhari, A.

The Ohio State University

Anecdotal data throughout the scientific literature and popular press advocate for improved trunk control for injury treatment and, more importantly, prevention of injury involving the lower extremity as well as low back and upper extremity. Despite this widespread assertion that "you need to work on your core," a critical barrier to progress in the prevention and treatment of musculoskeletal injuries is the lack of understanding of what trunk control does to modulate known biomechanical predictors of injury risk and whether altering trunk control alters injury incidence. The aim of this presentation is to present the recent evidence linking trunk control to injuries and performance in sport, including prospective observational studies, clinical trials of rehabilitation programs, video observations of injury, and biomechanical laboratory studies.

CORE STABILITY: HOW CAN IT BE ASSESSED?

Cholewicki, J., Reeves, N., Popovich, J., Priess, M., Choi, J., Radcliffe, C.

Michigan State University

1: MSU Center for Orthopedic Research, Michigan State University, USA 2: Department of Osteopathic Surgical Specialties, Michigan State University, USA 3: Department of Mechanical Engineering, Michigan State University, USA 4: Department of Electrical and Computer Engineering, Michigan State University, USA Introduction There is ample evidence that fine motor control and core stability are essential for avoiding injuries in high-level athletic performances (Cholewicki et al. 2005; Zazulak et al. 2007). A variety of methods have been developed to assess core stability, such as balance performance and trunk response to random perturbations (Borghuis et al. 2008). While these methods quantify performance in a specific task, they are generally not suitable for assessing system's control in response to a variety of inputs. Therefore, we developed a systems engineering-based method for assessing trunk motor control using position and

force tracking and stabilization tasks. Methods Tracking tasks involved following a time-varying input signal displayed on a screen by changing the sagittal trunk angle with respect to the pelvis (position tracking) or by changing force exerted with the trunk against a force transducer (force tracking). Stabilization tasks involved maintaining a constant trunk angular position (position stabilization) or constant trunk force (force stabilization) while a sagittal plane disturbance input was applied to the pelvis using a robotic platform. Ten healthy subjects performed six tasks on two separate days: trunk position tracking and stabilization in the sagittal plane, and force tracking and stabilization in trunk flexion and extension. Additionally, ten subjects with low back pain (LBP) also executed this battery of tests to determine their feasibility. Error for each task was computed in time and frequency domains (root mean square and H2 norm, respectively). Intra-class correlation coefficients (ICC) for error and coefficients of multiple correlations (CMC) for frequency response curves were used to quantify reliability of each task. Results Reliability coefficients (intraclass correlation coefficient (ICC) and coefficient of multiple correlations (CMC)) for all tasks were excellent (between-day ICC ≥ 0.80 and CMC ≥ 0.75 , within-day CMC ≥ 0.85). LBP did not significantly increase immediately or 1-3 days after the testing session(s) in any of our participants. Discussion Position and force control tasks used for assessing trunk motor control appear to be reliable and safe. References Borghuis et al. (2008). *Sports Med* 38(11):893-916. Cholewicki et al. (2005). *Spine* 30(23):2614-2620. Zazulak et al. (2007). *Am. J. Sports. Med.* 35(7):1123-1130.

Invited symposia

IS-PM05 Exercise in cancer patients - study approaches and results from 3 European countries *

EXERCISE IN BREAST CANCER PATIENTS DURING THERAPY IN GERMANY. RESULTS FROM TWO PROSPECTIVE, RANDOMIZED EXERCISE INTERVENTION TRIALS

Steindorf, K., Wiskemann, K., Klassen, O., Beckhove, P., Oelmann, J., Hof, H., Schneeweiss, A., Ulrich, C.M., Pothhoff, K., Schmidt, M.E.

German Cancer Research Center (DKFZ) + National Center for Tumor Diseases (NCT)

Introduction Breast cancer patients during and after chemo- or radiotherapy often suffer from cancer-related fatigue (CRF) which frequently impairs aerobic capacity, strength, muscle mass, and, ultimately, quality of life (QOL). Despite the severe impact on the physical and emotional well-being, effective treatment methods are scarce. Physical activity has been reported to decrease fatigue, to improve emotional wellness and to increase physical strength. However, only very limited evidence exists from randomized studies on resistance training during treatment. **Methods** In two recently completed prospective, randomized, controlled intervention trials we compared the effects of a 12-week supervised progressive resistance training (2 x 1h per week) with a 12-week group-based muscle relaxation training (2 x 1h per week) in breast cancer patients stage 0-III during adjuvant chemotherapy (BEATE, n=101) and radiotherapy (BEST, n=160). The primary endpoint fatigue was assessed with a 20-item questionnaire, muscle strength via isometric and isokinetic testing. The two studies were designed to determine the effect of exercise training beyond group-related psychosocial effects. Statistical analyses were based on analysis of covariance models for the individual changes from baseline to week 12. **Results** Intention-to-treat analyses showed significant between-group differences favoring the intervention group for total fatigue and the subscale physical fatigue. Significant between-group differences in favor of resistance training were also noted for subscales of quality of life. Significant improvements in upper and lower muscle strength were observed in the exercise group, whereas no significant effect was observed for VO2peak. **Discussion/Conclusions** A 12-week resistance training program is an effective strategy to maintain or improve physical fitness and fatigue in breast cancer patients during adjuvant chemo- and/or radiotherapy. These results are highly relevant for health care professionals who are working with breast cancer patients. They should encourage and support breast cancer patients already during adjuvant therapy to exercise. **References:** 1. EXERCISE DURING AND AFTER CANCER TREATMENT: RESULTS, EXPERIENCES AND METHODOLOGICAL CONSIDERATIONS FROM THE PACT AND A-CARE STUDY

Buffart, L.M., May, A.M.

1. VU University Medical Center, 2. University Medical Center Utrecht

For many patients, cancer and its treatment are associated with physical and psychosocial problems, including reduced physical fitness and function and increased risk of anxiety, depression and fatigue, which has a negative influence on quality of life. Exercise is suggested to have beneficial effects on these outcomes, but previous studies had methodological weaknesses related to trial design, sample size, comparison group, outcome measures, short follow-up durations and program content. Currently, in the Netherlands, large randomized controlled clinical trials are conducted to evaluate the effectiveness and cost-effectiveness of state-of-the art physical activity and exercise programs that meet the Dutch cancer rehabilitation guidelines in various patient groups during and after medical treatment. The Physical Activity during Cancer Treatment study and the Alpe d'HuZes Cancer Rehabilitation study consists of four randomized controlled trials in patients with different types of cancer: after chemotherapy, during chemotherapy, after stem cell transplantation, and during childhood cancer. We will present the results of these studies on fatigue, physical fitness and quality of life and will also discuss results across studies. These results are very interesting for sports physicians, physical therapists, rehabilitation physicians, exercise physiologist, medical oncologists, general practitioners and epidemiologists who are working with cancer patients.

TITLE: EXERCISE AS A STRATEGY FOR REHABILITATION IN ADVANCED STAGE LUNG CANCER PATIENTS UNDERGOING CHEMOTHERAPY IN DENMARK. RESULTS FROM A PROSPECTIVE RANDOMIZED EXERCISE INTERVENTION TRIAL

Quist, M.

The University Hospitals Copenhagen

There are approximately 4400 new cases of lung cancer in Denmark per year. The one, three and five years survival after diagnosis of lung cancer is 32%, 13% and 10%, for patients with inoperable lung cancer (NSCLC III-IV SCLC ED), the mean survival after diagnosis 10-13 months. Even though lung cancer patients report more symptoms and side effects, impaired quality of life (HRQOL), increased anxiety and depression levels in comparison to patients with other cancer diagnoses, the vast majority of studies to date, have examined the effects of exercise training in patients diagnosed with early-stage (non-metastatic) cancer disease. Only a few studies have examined the safety and potential efficacy of exercise training in patients with advanced (metastatic) cancer disease. Recently, studies have suggested a relationship between functional capacity and prognosis, as well as functional capacity as a strong independent predictor of survival which may have a clinical relevance, improve risk stratification and prognostication in advanced stage lung cancer patients. In a prospective, randomized, controlled trial we compare the effects of a 12-week group based supervised intervention consisting of cardiovascular training, progressive resistance training and relaxation training in advanced stage lung cancer patient during chemotherapy (EX-HALE) with standard care. Results for physical capacity, functional capacity, fatigue, QOL, anxiety and depression will be presented. Overall, the results of this study (positive effect or not) will contribute with new knowledge of advanced stage lung cancer patients' physical capacity and quality of life throughout the illness and treatment.

IS-PM13 JSPFSM-ECSS Exchange lecture: Physical Activity Guidelines: Japan and Europe by the example of the Netherlands

EVIDENCE-BASED PHYSICAL ACTIVITY GUIDELINES FOR JAPANESE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Motohiko, M.

National Institute of Health and Nutrition

Background: It is necessary to revise the physical activity guidelines for Japanese people for the prevention of not only non-communicable diseases (NCD) but also frailty. Procedure and Methods: A research group comprised of eight specialists was formed to revise Exercise and Physical Activity Reference 2006, and a literature study and review from March 2011 to December 2012 was conducted. The revision aimed to: (1) review the necessity to change reference values; (2) focus on prevention of cancer and frailty in addition to prevention of NCD; (3) set new references for the elderly (≥ 65 years old); (4) provide reference values even in a simple form of expression; and (5) establish reference values for amounts of physical activity to be added to the current physical activity level based on the dose-response relationship. Based on the above, a systematic review and meta-analysis were performed. Results: We read and analyzed 267 prospective studies, and proposed five reference values as described below. • 23 metabolic equivalents (METs)-hour/week as moderate to vigorous physical activity exceeding 3 METs (60 min of physical activity a day with intensity level equivalent to walking) for young and middle-aged men and women under 65 years old. • 4 METs-hour/week as moderate to vigorous exercise exceeding 3 METs (60 min of exercise that causes accelerated breathing and sweating every week). • 10 METs-hour/week for the elderly ≥ 65 years old, including physical activities under 3 METs (40 min of physical activity every day; this can be any motion as long as one is not sitting). • Walk 10 min longer than yesterday, based on the dose-response relationship. • Gender- and age group-specific reference values of fitness (cardiorespiratory fitness): Male < 40 years old, 11.0 METs; 40 – 59 years old, 10.0 METs; ≥ 60 years old, 9.0 METs; Female < 40 years old, 9.5 METs; 40 – 59 years old, 8.5 METs; ≥ 60 years old, 7.5 METs. Physical Activity Guidelines for Japanese: Based on these reference values and the trans-theoretical model, the following physical activity guidelines were developed by the Ministry of Health, Labour and Welfare. 1. Be aware! Take your agenda, identify the spots, there are many opportunities around you to move your body. Please think about it! 2. Do it! Just a little bit longer and more vigorous! +10 will bring you one step closer to your goal. 3. Keep-it up! Your goal is 60 min of moderate to vigorous physical activity per day (40 min for the elderly). This way, you will be able to develop your physical fitness. 4. Stay together! Share your +10 with you friends or family. In addition to revision of the guidelines, it will be necessary to consider measures to promote the new standard.

NATIONAL POLICY ON SPORTS AND PHYSICAL ACTIVITY IN THE NETHERLANDS

Gelinck, R.

Netherlands Institute for Sport and Physical Activity

Introduction Only since the last quarter of the 20th century the Dutch government became more active in sports policy. The main goal was to stimulate citizens to participate in sport. In 1996 the first integral sports memorandum was presented. Sport and PA was seen as an instrument for achieving goals in other sectors as welfare, youth policy, health and integration. In 1998 the Dutch Guideline for PA was established. In 2005 a new sports memorandum was published. The three main themes from the previous memorandum: elite sports, health and participation were the basis for this memorandum. The sports budget has now been doubled compared to 1996. The government wants to invest in the social values of sports. The current policy is still based on the principles of 2005. The latest policy letter 'Sports and PA in a Olympic perspective' (2011), states the following priorities: 1. Sport and PA in the neighbourhood. This focuses on more high-quality sports and a new type of professional that connects sports with other sectors (education, care, elderly or other target groups). 2. Working towards a safer sport environment. This focuses on more (social) safety within the sports club. 3. Excel in sport. This focuses on elite sport events and better conditions for elite sport athletes and talents (including disabled elite sport). At central government level, responsibility for sports and PA policy lies with the Ministry of Health, Welfare and Sport. In 2010 for the first time it became the direct responsibility of the Minister. Before that sports policy was the responsibility of a State Secretary. This indicates that sports still is an im-

portant issue for the government. Spendings on sports The relative spendings on sports by the government haven't changed a lot the recent years, but increased considerably in absolute terms. In 2000 the net spendings were 60 million and in 2010 this increased to 111 million. The municipal spendings have almost doubled in the same period, from 660 million to 1,115 million (of which 922 million on accommodation). Participation in sport and PA In the Netherlands we use 2 indicators for sport participation. One is monthly participation (at least 12 times a year) and the other is weekly sports participation (at least 40x a year). It seemed as if we had reached a 'ceiling' in sports participation. But it still increased slightly again the last 2 years. This is mainly caused by increased participation by the elderly. In 2000, the inactivity among adults was 9.2% and this is considerably reduced to 3.5% in 2011. Youth inactivity fluctuated in recent years between 12% and 16%, and there is not really a trend to discover. Approximately 50-55% of the Dutch population meets the Dutch Guideline for PA and that is fairly constant over the years.

IS-BN07 Physiological characteristics of small-sided games

THE PHYSIOLOGICAL CHARACTERISTICS OF SMALL SIDED GAMES IN SOCCER

Rampinini, E., Connolly, D.

MAPEI Sport Research Centre, Olgiate Olona (VA)

Small-sided games (SSG) are one of the most commonly used exercise modes during soccer training. Utilizing SSG imposes both technical/tactical elements and a significant physiological load on the players. The exercise intensity of SSG can be monitored by heart rate (HR), blood lactate and ratings of perceived exertion (RPE). A combination of these parameters is recommended to describe the players internal load. In addition, recent technological advances (i.e. GPS with a sampling frequency >5Hz) facilitate monitoring the movement characteristics of the players. The external load can be quantified by measuring distances covered at different running speeds, number of accelerations and decelerations, as well as calculating the metabolic power. Several variables have been suggested to influence the intensity of SSG, for example, number of players involved, field dimensions, rule modifications, coach encouragement and work:rest ratios. By reducing the number of players (e.g. 2v2 or 3v3) it is possible to reach high levels of exercise intensity (HR >85-90% HRmax and RPE CR10 >7 au). Whereas by increasing the relative pitch area per player the HR and RPE responses are elevated (1-3% and 0.5-1.0 au, respectively). Furthermore, active coach encouragement has also been found to positively impact upon the training intensity (Rampinini et al, 2007). Comparisons between SSG and more traditional running interval training carried out in literature, have demonstrated that smaller format SSG played using large pitch dimensions can elicit similar intensities to both long and short interval running exercise (Dellal et al., 2008). However it appears that variability in exercise intensity is greater during SSG. Similar mean exercise intensity (HR%) and weekly training load (session RPE) have been noted between the two training methods, indicating that SSG training can be utilized as a valid alternative to generic interval training. In addition, SSG can induce similar aerobic adaptations (VO₂peak +7-8%, lactate threshold +11-13 % and running economy +3%) and football specific performance enhancements to interval training over a 12 week period (Impellizzeri et al., 2006). In conclusion, SSG can be an effective training tool, however strict control of the variables influencing the intensity is necessary. Systematic monitoring of the individual responses of players is important for providing a consistent training stimulus across the entire season. TACTICAL PERFORMANCE IN SMALL-SIDED SOCCER GAMES

Sampaio, J.1,2, Travassos, B.1,3, Marcelino, R.1,2, Gonçalves, B.1,2, Coutinho, D.1,2, Leite, N.1,2

1 Research Center for Sports, Health and Human Development, 2 University of Trás-os-Montes e Alto Douro, 3 university of Beira Interior

We will describe how soccer players' dynamic positional data can be used to assess tactical performance during small-sided games (SSG). The data will be used to calculate overall, sectorial and position-specific centroids and, afterwards, the players' and dyads distances, angles and coupling to these collective attractors will be presented. Several examples of different small-sided games formats will be presented, such as: (i) 2-, 3-, 4- and 5-a-side; (ii) SSG with different number of goals; (iii) SSG with unequal teams. Data analysis will be processed with non-linear statistical procedures, such as normalized approximate entropy, to identify the amount of randomness in each time series; and relative phase, to identify different modes of coordination (in-phase, anti-phase and transitions) during the small-sided games dynamics'. At the end, several practical applications and future research directions will be presented and discussed.

REPRESENTATIVENESS OF SMALL-SIDED GAMES FOR FULL-SIZED MATCHES

Frencken, W.G.P.1,2, Lemmink, K.A.P.M.3

1:Hanze University of Applied Sciences (Groningen, The Netherlands), 2: FC Groningen (Groningen, The Netherlands), 3: UMCG/RUG (Groningen, The Netherlands)

Small-sided games (SSG) are played on smaller pitches with a smaller number of players with regular or adapted rules and are normally implemented in training programs. SSG's expose players to situations they encounter frequently in real matches. Therefore, it is likely to be an effective training exercise for improving players' physical, technical, and tactical capacities required in real matches. Technological developments facilitate in-game data collection via high-quality positional data obtained through video- or sensor-based tracking technologies. Yet, limited evidence is available for the actual 'representativeness' of SSG's for full-sized matches. Several variables have been proposed to quantify the interaction process based on positional data, including length-width ratios, stretch indices, centroid positions and inter-team distances (e.g. Folgado et al., 2014; Frencken et al., 2013). A recurrent observation is that teams' positions are most strongly entrained in longitudinal direction (goal-to-goal) in SSG's and real matches. As such, this direction seems to be the dominant direction of play. In addition, prior to goals and goal-scoring opportunities a swapping of centroid positions occurs in 53% of the occa-

sions. The same, less prominent pattern was found prior to 21% of goal-scoring opportunities in a full-sized soccer match. These findings indicate tactical representativeness between SSG's and full-sized matches. Contrastingly, research demonstrates that pitch size affects the spatio-temporal interaction pattern between teams, i.e. a shorter pitch increases longitudinal in-phase movement of teams' centroids. In addition, a crossover effect of length and width manipulations of pitch size was observed, i.e. changes in pitch length or width initiate a response by teams' behaviour both longitudinally and laterally. Moreover, differences are observed in interaction patterns between age-categories (U19 vs U17 and U13 vs U11 vs U9) when controlled for pitch size (e.g. Folgado et al., 2014). No such evidence has been provided at match level. Therefore, it can be concluded that current evidence is inconclusive and incongruent. Research towards tactical, technical and physical representativeness is warranted and should focus on the relative contribution of individual players in tactical team performance and comparisons of team-tactical interaction patterns. OP-PM29 Health & Fitness (ESSA Exchange)

ACTIVE VIDEO GAMES HAVE SIMILAR PHYSIOLOGICAL RESPONSES BUT RESULT IN MORE POSITIVE PSYCHOLOGICAL STATES WHEN COMPARED TO A MODERATE INTENSITY BOUT OF EXERCISE.

Monedero, J., O'Gorman, D.J.

Dublin City University

Introduction In spite of the known benefits of physical activity, there are high drop-out rates from structured exercise interventions and only a minority attain the recommended targets (Dishman, 1982). One of the main reasons cited is that regular exercise is not enjoyable. An alternative strategy is to increase leisure time physical activity by playing active video games. The purpose of this study was to determine if the physiological, psychological and affect responses during an entertainment or fitness based video game were comparable to a traditional bout of exercise. **Methods** Twenty-three sedentary subjects (12F/11M) completed 30-mins of (i) a self-selected intensity bout of treadmill exercise, (ii) treadmill exercise at 55% of VO2Reserve, (iii) an entertainment-themed video game (ETVG) and (iv) a fitness-themed video game (FTVG) in random order with a minimum of 48 h between each trial. Energy expenditure and oxygen consumption were measured by indirect calorimetry. Enjoyment, psychological well-being and state of flow were determined during and after each trial. **Results** The active video games attained the criteria for moderate intensity exercise but resulted in significantly higher enjoyment ratings than both exercise trials ($p < 0.05$). The FTVG trial had a similar %VO2Reserve and rate of energy expenditure to the moderate intensity bout at 55%VO2Reserve but both were significantly lower than the self selected trial ($p < 0.05$). The % heart rate reserve was similar between FTVG and self-selected exercise and significantly greater than the other two trials ($p < 0.05$). While the ETVG was moderate intensity activity, the physiological responses were significantly lower than those of the other three trials ($p < 0.05$). However, state of flow was significantly higher during ETVG than during all other trials ($p < 0.05$) and psychological well-being was significantly higher than during both exercise trials. **Discussion** The main finding of this study is that active video games can have physiological responses comparable to those of traditional moderate intensity exercise but are more enjoyable and result in more positive affect states that may increase adherence. The fitness based games are more likely to attain higher physiological responses but the ETVG are more enjoyable while still meeting moderate intensity activity guidelines. **In conclusion**, active video games offer a viable strategy for meeting physical activity guidelines and reducing sedentary time. **References** Dishman RK. (1982). Compliance/adherence in health-related exercise. *Health Psychology* 1, 237-267.

EFFECT OF SELF-PACED EXERCISE ON HR, RPE, AND EXERCISE INTENSITY IN ADOLESCENT MALES AND FEMALES USING THE EXERBIKE, A STATIONARY CYCLE CONNECTED TO A VIDEO GAME CONSOLE.

Gabel, K., Larson, J.

Montana State University Billings

Introduction Recently, the Exerbike, a stationary bicycle connected to a Microsoft Xbox 360 gaming console, has been introduced as a stratagem to increase physical activity in young people. Little research has been published about exercise intensity produced during a session on an Exerbike; therefore, the aim of this research was to determine if adolescents' self-paced intensity of exercise on a Motion Fitness Exerbike GS V2 equaled moderate intensity exercise or a value of 3 to 6 METs. This level is recommended by ACSM. **Methods** Participants between the ages of 10 and 18 were recruited from the local YMCA organization to participate in two modalities of self-paced Exergaming exercise (single player and multi-player). After consent forms were signed by children and guardians, trials using both modalities commenced. Exercise intensity was assessed using Polar heart rate telemetry and the OMNI pictorial scale for rating of perceived exertion (RPE). Participants' height, weight, and age were measured and recorded. The Exerbike console screen depicted repetitions per minute (RPM), distance (miles), speed (Miles per Hour), and Watts. **Methods** were approved by the institutional review board for ethical and safe treatment of participants. **Results** Results were obtained from 26 participants. No significant difference was found in RPE, distance, speed, RPM, Watts, calculated VO2 and MET values for the multi-player modality when compared to single player modality. Average HR for each trial mode ranged from 116 to 136 bpm in single player and from 136 to 149 bpm in multi-player mode. On average, MET values for each of the 6 minute periods varied from 4.6 to 5.2 METs in single player mode and between 5.1 to 5.3 METs in the multi-player mode. **Discussion** Results are relevant to previous research on active gaming, e.g. Nintendo Wii and Dance Dance Revolution (DDR). Daley (2009) determined that the energy expenditure of playing a dance-simulation game was comparable to medium-intensity aerobic dance. Conversely, Jordan et al. (2011) concluded that Nintendo Wii generated an increase in energy expenditure; however, the increase was not sufficient to be considered moderate intensity by ACSM standards. For this study, self-paced exercise on Exerbikes while playing a video game was of sufficient intensity to meet the ACSM recommendation of greater than 3 to 6 METs, which is considered moderate intensity exercise. In general, this form of exercise may be of potential benefit to promote physical activity in adolescents. Daley AJ. (2009).

WAIST DECREASE LINKED TO REDUCED DYSLIPIDAEMIA FOLLOWING STRENGTH TRAINING POST-MENSES

Viljoen, J., Christie, C.

Rhodes University

Purpose: A randomized controlled trial was conducted to assess the efficacy of 12 weeks of strength training on cardiovascular risk factors in females, post-menses. The effect of progressive strength training on the waist circumference and blood lipid profile was assessed. **Methods:** Post-menopausal females, aged 55-65 years, not taking hormone replacement therapy or bio-identical derivatives thereof, not taking cholesterol-lowering medication, sedentary at recruitment, with no heart, lung, liver or kidney disease and non-smokers were randomly assigned to an exercise group (n=30) and a control cohort (n=18). At baseline and every four weeks thereafter body mass, waist circumference, upper and lower body strength were measured. Full, fasted lipid profiles were obtained at similar time points by qualified staff at a registered laboratory. Dietary intake was not manipulated and was monitored via three-day diet recall diaries. The exercise group trained at an intensity of >80% on five days of the week. All sessions were supervised and a minimum attendance criterion was set at 80%. Repeated measures analysis of variance and Tukey post-hoc tests were used to evaluate the variables, using the SPSS version 21 statistical programme. Microsoft Excel spreadsheets and functions were utilised for further analysis of the data. **Results:** Upper and lower body strength increased significantly ($p<0.01$) in the exercise group but did not change in the control cohort. While body mass and dietary intake remained constant, waist circumference decreased significantly ($p<0.01$) in the exercise group but remained unchanged after 12 weeks in the control sample. There was no change to plasma lipoprotein levels in either the exercise or the control samples, however 'responders' (n=13) who recorded a 3.9 – 9.5% ($\mu=6.1\%$) decrease to waist circumference were identified from the exercise group and for these participants a significant ($p=0.003$) positive association ($r^2=0.71$) with LDL-C and with Tot-C ($p=0.04$; $r^2=0.50$) was noted. **Conclusions:** Strength training resulted in significant ($p<0.01$) strength improvement in this sample. This dose of physical activity resulted in clinically relevant decreases to waist circumference in the intervention cohort (-5%). No positive effect was noted for the plasma lipoproteins, however when 'best responders' were identified a significant and positive association between reduced waist circumference and LDL-C as well as Tot-C was identified. A minimum intervention period of 12 weeks appears necessary for this association to come into effect.

CHARACTERISATION OF CHLOROFORM INSULT TO HUMANS FOLLOWING A 30 MIN SWIMMING INTERVENTION

Heaney, L.M., Kang, S., Turner, M.A., Lindley, M.R., Thomas, C.L.P.

Loughborough University

Introduction Swimming is often recommended to those with respiratory issues. Exercising in a warm and humid environment reduces the likelihood of an exacerbation episode. It is postulated that the inhalation, ingestion and absorption of disinfection by-products (DBP), such as chloroform (CHCl₃), may have a negative impact on the respiratory system. As swimming is the most popular recreational sport in the UK [1], it is important to assess whether those who participate are becoming over-exposed to these potential poisons. **Methods** Sixteen males (age 25 (2) yr, body mass index 24.8 (3.0); mean (standard deviation)) completed a 30 min self-paced swim (rating of perceived exertion = 15), with a free choice of stroke. All participants were confident swimmers and completed a mean distance of 48 (11) 25 m lengths. Exhaled breath samples (2 L) were collected prior to swimming and at 5, 90, 300, 510 and 600 min after cessation of exercise; a potential washout period calculated from preliminary work. An adaptive breath sampling protocol [2] enabled the participants to breathe normally while distal breath samples were collected on to a dual-bed thermal desorption tube and subsequently analysed by thermal desorption-gas chromatography-mass spectrometry. All samples were post-loaded with a 20 ng Toluene-d₈ internal standard. Resultant chromatograms and mass spectra were analysed for the presence and intensity of CHCl₃. **Results** At 5 min post-swimming, exhaled CHCl₃ concentration increased by a factor of 57 ($p<0.05$) from baseline and returned to baseline at 300 min (a factor of 2 increase, $p=0.06$). Two washout profiles were observed; 16% of participants showed peak CHCl₃ intensity at 90 min post-swimming, all other cases peaked at 5 min post. Estimated concentration of CHCl₃ followed a linear log vs log relationship ($r^2=0.96$). Calculation of the area under the curve allowed the total mass of exhaled CHCl₃ over a 300 and 600 min washout to be estimated to be 2.7 and 4.3 µg, respectively. Poolside air samples were estimated to measure 0.7 ± 0.3 µg/L CHCl₃. **Conclusion** This is the first study of its kind to measure multiple breath levels of DBP after swimming. Increased levels of exhaled CHCl₃ are measured immediately post-swimming and maintain at 90 min, returning to baseline by 300 min. This study involved infrequent, recreational swimmers and the DBP exposure was a transient insult. Further studies are required with swimming athletes who are subject to chronic long term exposure to DBP, in order to establish if accumulative build-up of the compounds and their associated metabolites is occurring. The extended internal exposure to CHCl₃ may cause negative impact to the biological system, a potential mechanism that should be explored. **References** [1] Active People Survey 7, Sport England (2013) http://archive.sportengland.org/research/active_people_survey/active_people_survey_7.aspx (accessed 11/02/2014) [2] Basanta et al. A TAILORED PHYSICAL ACTIVITY INTERVENTION IN A GROUP OF FEMALE WORKERS AT RISK OF DEVELOPMENT OF NECK AND UPPER LIMB MUSCULOSKELETAL DISORDERS

Bergamin, M., Gobbo, S., Zanutto, T., Bullo, V., Rasotto, C., Zaccaria, M., Ermolao, A.

University of Padova

Women showed a larger risk factor than men in neck pain, especially while engaged in repeated movements with hands or arms. Gender anthropometric features, like differences in strength, fatigue and muscle fiber characteristics, may be responsible of the higher prevalence work related musculoskeletal disorders (WRMDs) on the neck and the upper arm. The aim of this study is to evaluate a tailored physical activity protocol performed in a work environment on a group of female workers who are employed in manual precision tasks. **Methods:** Sixty subjects were recruited and randomly assigned to an intervention group and a control group (CG). Intervention consisted in a 6-month, twice-a-week, tailored exercise program. Outcome measures were gathered with visual analogue scales referred to pain on neck (VASneck), shoulder (VASshoulder), elbow (VASElbow) and wrist (VASwrist). Upper limb strength and flexibility were measured with handgrip dynamometry and back scratch test. Finally, DASH and NPDS-I questionnaires were administered to quantify upper arm and neck disability. **Results:** The personalized approach administered to the female workers induce a distinct reduction especially on shoulder pain ($p=0.018$) accompanied with increases on range of motion. Additionally, reductions in upper-limb ($p=0.007$) and neck

disability ($p=0.006$) have been detected with concomitant increases in grip strength ($p=0.013$) and shoulder flexibility ($p=0.008$) for the intervention group. Conclusions: This study indicated positive effects of a tailored workplace exercise protocol in female workers exposed to moderate risk for WRMDs showing clinically meaningful reductions of pain symptoms and disability on upper limb and neck regions.

DOES ABDOMINAL OBESITY MEDIATE THE ASSOCIATION BETWEEN TYPE 2 DIABETES MELLITUS AND BRAIN ATROPHY?

Climie, R., Moran, C., Callisaya, M., Blizzard, L., Sharman, J., Venn, A., Phan, T., Beare, R., Srikanth, V.

University of Tasmania

Objectives. Type 2 diabetes mellitus (T2DM) is associated with brain atrophy. T2DM is also associated with abdominal obesity and lower physical activity, important factors that may contribute to brain atrophy. We aimed to examine whether the association of T2DM with gray matter volume (GMV) is mediated or modified by measures of abdominal obesity and physical activity (PA). **Research Design and Methods.** In this cross-sectional study we measured waist-hip-ratio (WHR), average daily number of steps determined using 7-day pedometer measurement (habitual PA), GMV using high-resolution magnetic resonance imaging (MRI), and other mechanistic factors (APOE $\epsilon 4$ genotype, vascular risk factors and inflammatory cytokines). Using multivariable linear regression, we examined for mediation or modification of the association between T2DM and GMV by WHR and habitual PA. **Results.** There were 260 participants with T2DM (mean age 67 ± 7 years) and 302 non-T2DM participants (mean age 72 ± 7 years) included in the study. After adjusting for age, sex and total brain volume, T2DM was associated with lower GMV ($\beta = -9.91$, 95%CI = $-15.78, -4.05$, $p=0.001$), greater WHR ($\beta = 0.047$, 95%CI = $0.04, 0.06$, $p<0.001$) and less habitual PA ($\beta = -889.54$, 95%CI = $-1438.11, -340.97$, $p=0.002$). The strength of the association between T2DM and GMV was attenuated by 46% when adjusted for WHR, independent of age, sex, APOE $\epsilon 4$, vascular risk and inflammatory cytokine levels, but was unchanged when adjusted for body mass index (4%) or habitual PA (7%). **Conclusions.** Abdominal obesity mediates some of the adverse association between T2DM and brain atrophy. Interventions targeting abdominal obesity may protect against brain atrophy in T2DM.

ASSESSING HEALTH-RELATED PHYSICAL ACTIVITY: DOES QUESTIONNAIRE DATA FIT ACCELEROMETER DATA WITH REGARD TO DIFFERENT AGE GROUPS?

Eckert, K., Lange, M.

University of Leipzig

Introduction Assessing the level of physical activity (PA) is highly relevant when talking about health related behavior. Although self-report questionnaires (PAQ) are the most commonly used method for measurement population PA, this type of assessment has limitations. PAQs have to primarily consider the change in PA behavior over lifespan and secondarily to handle the bias, that the results are dependent of a person's ability to accurately recall and record all PA (Warren et al., 2010). The aim of the study is to compare objectively measured PA levels gathered using accelerometry (ActiGraph GT3x) with two PAQs (IPAQ-long and FFKA; Craig et al., 2003, Frey et al., 1999) relative to participants' age. While a number of validity studies on the IPAQ exist, such studies on the FFKA are scarce. **Methods** ActiGraph GT3x accelerometers were worn by 200 individuals aged 20-79 years (mean=38,1; sd=16,3), 48% female, BMI 24,3 (sd=3,5) for seven days during all waking periods, except swimming and showering. Right after this period participants recalled their activity behavior and filled out the International Physical Activity Questionnaire (IPAQ-long) and a German PAQ (FFKA). **Results** Activity level is decreasing with increasing age (GT3x; $p<0.001$). Self-reported data of IPAQ correlates with objective measured data by middle-aged persons (30-59 yrs.) ($r=.424^{**}$) and active people (≥ 300 min/week active) ($r=.436^{***}$) only. There were no correlations between FFKA and GT3x. Men seem to be able to recall their activity more accurately. **Discussion** The results indicate that not age seems to influence recall ability leadingly. It is more probable that the accuracy of PAQs is directed by quantity and context of items (e.g. domains of activities). Researchers and practitioners need to choose the best fitting tool according to research question, aim of study, target group and outcome. **References** Craig, C.L., Marshall, A.L., Sjöström, M., Bauman, A.E., Booth, M.L., Ainsworth, B.E., Pratt, M., Ekelund, U.L., Yngve, A., Sallis, J.F. & Oja, P. PHYSICAL ACTIVITY - MORE THAN JUST HEALTH: PHYSICAL ACTIVITY BEHAVIOUR AND MEDICAL COSTS RELATED TO HOSPITAL CLAIMS

Wilders, C.

North West University (Potchefstroom)

Introduction: Research has shown that physical inactivity can lead to an increase in medical cost, even modest reduction in inactivity levels can result in substantial cost savings. Studies have shown that physical inactivity is linked to an increase in medical cost. In this regard the aim of this study is to determine physical activity behaviour related to medical costs in a population of South African employees. **Methods** A total of 9 860 employees of the same financial institution in South Africa, between the ages of 18 and 64 ($\bar{x} = 35.3 \pm 18.6$) years participated voluntarily in the study. No differentiation was made between race groups. The assessment of physical activity behaviour was done by using the Health Risk Assessment (HRA) methodology developed. Medical expenditure data was obtained from 'Moni-

tored Health Risk Management Pty (Ltd)'. Pharmaceutical and general practitioners (GP's) claim included all costs incurring during a six-month period. Results The results show that a minority of the sample group participates in moderate to high levels of physical activity (moderate= 4.42% and high=17.80%). The results show statistically and practically significant differences between the groups that do not use chronic medication and the groups that use chronic medication. The data shows that men have higher pharmaceutical costs than women in all the physical activity categories. Women who use chronic medication and participate in moderate physical activity show lower hospital costs. The men's profile indicates that medical costs due to hospital claims rise with higher levels of physical activity. Discussion Previous research in South Africa has shown that physical activity reduces the prevalence of hospital admissions and reduces hospital costs (Lambert et al., 2009; Patel et al., 2011). Hospitalisation costs per member were lower in each activity group (low, moderate and high) when compared with the inactive group, and the same pattern was demonstrated for admission rates. Patel et al. (2011) gained similar results in a study and found that individuals who were highly active had a lower probability of hospital admission and thus cost compared to those who were inactive. INCREASING ENGAGEMENT IN PHYSICAL ACTIVITY AND THE ROLE OF BEHAVIOURAL ECONOMICS IN AN INCENTIVIZED WELLNESS PROGRAMME FOR PRIVATELY HEALTH-INSURED PERSONS: VITALITY INSURED PERSONS COHORT

Lambert, E., Kolbe-Alexander, T., Patel, D.

University of Cape Town

The World Health Organization (1) estimated that 1.9 million deaths and 19 million disability life years were attributable to physical inactivity. Equally, there is compelling evidence for the beneficial effects of physical activity in the primary and secondary prevention of a large number of chronic diseases (2). Some health insurers have begun to offer incentive-based health promotion programmes, in an attempt to change the health behaviour of their members. Vitality is an incentivised health promotion programme linked to the Discovery Health medical plan. Membership is voluntary, for a nominal monthly fee of approx. \$15-20 per family. There are currently approx. 1.3 million Vitality members in South Africa. Participation in the various wellness activities of the Vitality programme permits members to accumulate points, that denote tier status. Status, in turn, allows members to claim discounts (ranging from 15-45%) on a range of store purchases and services (subsidized gym memberships, cash back on purchases on healthy food items, etc.). In a cross-sectional study of nearly 1 million Discovery members, we demonstrated a significant and inverse relationship between levels of participation in fitness-related activities and hospital admissions, as well as length of stay (3). More recently, we showed that increasing engagement in fitness-related activities, over a 3-yr period was associated with a significantly lower probability of hospital admissions and inpatient claims, in the subsequent 2 years (4). Thus, a comprehensive, incentive-based health promotion programme, offered as part of a medical plan, may increase participation in physical activity behaviour, and result in a concomitant decrease in claims and the probability of hospital admissions. IS-SH06 Perceptual training in sport

VISUAL CONTROL TRAINING IN BASKETBALL SHOOTING

Oudejans, R.R.D.

MOVE Research Institute Amsterdam, VU University

In this presentation I will present our work on visual control training in basketball shooting. In general perceptual training may provide an addition to training that may be used to speed up the acquisition of perceptual-motor expertise in sport settings. In our research on basketball jump shooting we investigated visual control training to improve shooting performance of elite basketball players. In several studies vision of junior male, wheelchair male, and female basketball players was manipulated during shot training in such a way that they were forced to use the information that has been shown to be most relevant for visual control of their basketball shot. Vision was initially manipulated by screens that occluded the vision of the basket during the early parts of the shot, while information became available during the final instances just before ball release (players could look over or from underneath [wheelchair] the screen), providing the shooters with a time window of vision that was necessary and sufficient for accurate shooting. In recent studies vision was manipulated during shot training using Plato liquid-crystal goggles that were wirelessly and manually controlled by the experimenter using a sender/receiver system. During the training the goggles were only open during the final instances of each shot forcing players to use optimal information. Generally the visual control training led to higher shooting percentages showing that visual control training in which vision is systematically manipulated, either using screens or special occlusion goggles, provides a promising tool to be used in sports practice to improve performance.

QUIET EYE TRAINING IN SPORTS.

Wilson, M.

University of Exeter

Recent research has demonstrated that quiet eye (QE) training interventions provide a performance advantage over traditional, technique focused interventions. Following early work by Vickers and colleagues (e.g., Adolphe et al., 1997; Harle & Vickers, 2001), recent research by Causer and colleagues in shotgun shooting (Causer et al., 2010, 2011) and our own team in basketball (Vine & Wilson, 2011), football (Wood & Wilson, 2011, 2012) and golf (Moore et al., 2012; Vine & Wilson, 2010; Vine et al., 2011) has supported the efficacy of such training. The premise of these training interventions is that if a performer can optimise the information they receive from their eyes, they can optimise movement (without having to explicitly focus on the control of movement). The research has followed three main lines of enquiry: (1) Training expert performers to fine-tune skills, (2) training novices to acquire new skills, and (3) in both cases, trying to determine if the learning is more resilient to pressure. Consistent findings show that quiet eye training is more effective than traditional scripts focusing on movement control across all three areas. What has been less well understood is why such training is beneficial. The current talk will focus on potential visuomotor, attentional and psychological control explanations as explored in our most recent studies. Furthermore, the implications of applying quiet eye training outside of sport to other performance domains (including, surgical technical skills, military marksmanship, and children with coordination difficulties) will also be discussed.

IMPROVING REFEREEES' DECISIONS IN SPORTS BY VIDEO-BASED TRAINING

Plessner, H.

University of Heidelberg

Referees' decisions play an important role in sports like soccer and basketball. Among other decisions, referees have to discriminate between foul and legal play and they have to judge the severity of foul play. As a substantial proportion of referees' decisions is wrong, training methods for referees' decisions are needed. We suggest that understanding referees' decisions can be improved by using the Brunswikian lens model framework. Based on these considerations we developed a video-based training method. Several experimental studies using control groups as well as different training groups indicate that the training method is indeed able to improve referees' decisions. First, referees who participate in the training program improve their ability to discriminate between options (e.g., foul play or legal play) and to judge the severity of foul play. Second, video training can influence referees' response tendency, leading to predictable decisions in ambiguous situations. The presentation provides an overview of these studies and discusses the possibilities and boundaries of this approach.

10:20 - 11:50**Oral presentations****OP-PM30 Heart Rate Recovery & Variability****PARADOXICAL RELATIONSHIP BETWEEN HEART RATE RECOVERY AND EXERCISE PERFORMANCE FOLLOWING DIFFERENT TRAINING PERIODS**

Thomson, R.1, Bellenger, C.1, Howe, P.2, Karavirta, L.3, Buckley, J.1

1:University of South Australia, 2:University of Newcastle, 3:Polar Electro Oy

Introduction The recovery of heart rate (HR) after exercise is the result of a coordinated interaction between sympathetic withdrawal and parasympathetic re-activation and has been shown to respond to changes in training. Previous studies have shown improvements in exercise performance and faster reductions in heart rate recovery (HRR) following adaptation to training and that these improvements were related. This study investigated the within-individual changes between HRR and exercise performance following three training periods of different intensities. **Methods** 17 male cyclists or triathletes underwent two weeks of light training, two weeks of heavy training and two days of recovery and were tested after each training period. Exercise performance was measured during a five minute maximal cycling time-trial and was classified as the amount of work completed during the time-trial (in kJ and kJ/kg body weight). Peak HR is the maximum HR value obtained during the time-trial. HRR was classified as the decrease in HR 60 seconds following the maximal time-trial. **Results** 11 participants (32.5±10.1 yrs, 77.5±9.7 kg) completed the study. Compared with post light training exercise performance decreased 2.6±3.1% following heavy training ($P=0.02$), and then increased 4.0±4.2% following recovery ($P=0.01$), whereas HRR increased 6.5±8.3 bpm (17%) following heavy training ($P=0.03$) and decreased 6.6±8.2 bpm (13%) following recovery ($P=0.02$). HRR was not different between post light and recovery testing ($P=0.9$). There was a moderate inverse within-subject relationship between HRR and exercise performance across all time points ($r=-0.6$, $P\leq 0.004$). Peak HR decreased 3.2±5.1 bpm following heavy training ($P=0.06$) and significantly increased 4.9±4.3 bpm following recovery ($P=0.004$). There was a moderate within-subject relationship between peak HR and absolute and relative exercise performance ($r=0.7$, $P\leq 0.001$). **Discussion** This study demonstrated that HRR tracks exercise performance when analysed within individual participants, but the direction of the tracking indicated that the greater the HRR, the worse the exercise performance, which contrasts previous studies that have shown increases in HRR following training programs designed at improving exercise performance. The paradoxical relationship found in the present study may be due to a potential decrease in sympathetic drive following heavy training. If this is the case it would make it difficult to utilise HRR as a marker of athletic training status. Peak HR also tracked exercise performance more strongly than HRR when analysed within individual participants. Contact rebecca.thomson@unisa.edu.au

PARASYMPATHETIC REACTIVATION; A PRACTICAL TOOL TO PREDICT CYCLING PERFORMANCE.

Lamberts, R.

University of Cape Town

Introduction It is well established heart rate recovery (HRR) is able to reflect training status in a heterogeneous population and reflect changes in training status both in untrained as in high performance athletes (Daanen et al., 2013). However in a homogeneous group of similarly trained subjects, HRR loses its power to accurately predict training status due to genetic polymorphisms (Hautula et al., 2006). More recently parasympathetic reactivation has shown to be an alternative method to predict and monitor training status (Buccheit et al., 2007). Therefore the aim of this study was to determine the reliability and predictive value of parasympathetic reactivation after a sub-maximal cycle test. **Methods** Both HRR and parasympathetic reactivation were captured as part of the part of the LSCT (Lamberts et al., 2014). The study consists of two parts. In part I, 15 trained cyclists (4.9 ± 0.4 W/kg; 57.5 ± 6.0 ml/min/kg), were asked to perform the LSCT over 6 consecutive days to establish the reliability and associated typical error of measurement (TEM) of the parasympathetic reactivation measured over time frames of 30, 60 and 90 seconds. In part II, 50 trained to elite cyclists ($3.8-7.1$ W/kg; $47.8-76.8$ ml/min/kg) performed the LSCT followed by a Peak Power output (PPO) test and 2 days later a LSCT followed by a 40km time trial (40km TT). Results The reliability and associated TEM of the parasympathetic measurements were the lowest over the 60 second period (RMSSD60s) (ICC: 0.99; TEM: 7.7%) in comparison to 30 and 90 second periods (RMSSD30s: ICC: 0.98, TEM: 11.1% and RMSSD90s: ICC: 0.99, TEM 14.0%). Very good relationships were found between RMSSD60s and PPO ($r = 0.94$, SEE: 11W), VO₂max ($r = 0.71$, SEE: 4.5 ml/min/kg) and, 40km TT time ($r = 0.88$, SEE: 81 seconds). Substantially weaker relationships were found between HRR and PPO ($r = 0.69$, SEE: 24W), VO₂max ($r = 0.67$, SEE: 4.7 ml/min/kg) and, 40km TT time ($r = 0.76$, SEE: 109 seconds). **Discussion** The measurement of parasympathetic reactivation measurement (TEM: 7.7%) was reliable, but slightly lower than the reliability of HRR (TEM: 4.1%). In contrast, parasympathetic reactivation was able to predict PPO, VO₂max and 40km TT time more accurately than HRR. Parasympathetic reactivation shows great potential to further improve the capacity to accurately predict, monitor and prescribe training to cyclists. Future research should aim to determine if parasympathetic reactivation can also reflect a change in training status or not. **References** Daanen HAM et al. DO POST-MATCH RECOVERY MARKERS RELATE TO NEXT MATCH PERFORMANCE IN PROFESSIONAL AUSTRALIAN FOOTBALL?

Coutts, A.J.1,2, Cianciosi, M.1,2, Sullivan, C.J.1,2, Bilsborough, C.J.1,2, Moreira, A.3

1: UTS (Sydney, Australia), 2: Carlton FC (Melbourne, Australia), 3: USP (São Paulo, Brazil).

Introduction Poor recovery following matches in Australian football (AF) players may negatively impact on subsequent training quality and match performance. This study aimed to determine: 1) the time course of recovery in muscle damage, perceptual measures and neuromuscular performance following AF matches; and 2) if these post-match recovery measures were related to subsequent match performance. **Methods** Change in blood creatine kinase (CK) concentration, countermovement jump (CMJ) performance and perceptual questionnaires following match-play in the Australian Football League were assessed in 34 professional AF players. CK and perceptual measures were taken 24 h prior to, and 24, 48 and 96 h following matches, whilst CMJs were completed 24 h prior to, and 48 and 96 h following matches. Physical activity measures (total and high speed running distance and body load) were assessed with microtechnology devices and performance measures (i.e. skill involvements) were collected during matches. Results Blood CK, and perceptual measures were all significantly elevated post-match, before returning to near baseline measures by 96 h ($P < 0.05$). In contrast, the CMJ height, mean power and relative power were reduced 48 h following match play but had not yet returned to baseline levels after 96 h. Correlation analysis revealed moderate-to-strong relationships between the perceived pain, recovery and fatigue and changes in CK concentration. Factor analysis revealed four factors: 1) fatigue and recovery, 2) force related to time, 3) force and 4) stress and mood (eigenvalues: 5.48, 3.19, 2.29 and 1.53, respectively). A canonical analysis identified that pre-match monitoring values explained 14% of subsequent match performance, as defined by previous research. **Discussion** All recovery indicators, except CMJ performance, returned to near baseline levels at 96 h following matches. Factor analysis revealed four different constructs of post-match recovery, which provides a smaller battery of measures that can be included in an athlete monitoring system. The canonical analysis showed that whilst these four factors were related to match performance, they did not explain sufficient variance to predict subsequent match performance. However, since the perceptual measures have strong correlations with CK and CMJ performance, and also contributed two main factors in the factor analysis, these may be appropriate low cost recovery indicators for AF players. We suggest a multi-dimensional approach to monitoring post-match recovery be applied to AF. **References** 1. Sullivan C, Bilsborough JC, Cianciosi M, et al. MONITORING FATIGUE AND RECOVERY BY USE OF THE LAMBERTS AND LAMBERT SUBMAXIMAL CYCLE TEST

Hammes, D., Skorski, S., Schwindling, S., Meyer, T.

Saarland University

Introduction Monitoring of performance, fatigue and recovery is considered as crucial to prevent non-functional overreaching and overtraining. The Lamberts and Lambert Submaximal Cycle Test (LSCT) is a novel test which was designed to monitor performance as well as fatigue and recovery in cyclists (Lamberts et al., 2011). Few studies have shown the ability of the LSCT to predict performance; however, there is a lack of studies in which accumulated fatigue was systematically induced. The aim of this study was to determine the effect of an intensive training phase and a following recovery period on the LSCT results. **Methods** 23 trained male cyclists (31 ± 9 years; 9900 ± 4832 annual km) completed an 11-days training camp. The LSCT was conducted on a cycle ergometer (Cyclus 2) at day 1 (d1), before the onset of training, day 8 (d8) and day 11 (d11). After d1, a 6-day training period consisting of two cycling sessions per day was performed: in the morning: 1h at 95% of individual anaerobic threshold (IAT) or 3x5x30s sprints; in the afternoon: 3h at 80% IAT. Between d8 and d11, a 72h recovery period without training was realized. For the LSCT, participants were asked to cycle at three stages with fixed predetermined heart rates of 6 min at 60%, 6 min at 80% and 3 min at 90% of maximum heart rate (HR_{max}). During the stages, power output and rating of perceived exertion (RPE) were determined. Immediately after stage 3, the participants had to stop cycling and sit straight for 90 s to measure heart rate recovery (HRR). Results Total session RPE (Foster et al., 2001) of the 6-day training period was 11690 ± 2618 . Power output for the stages changed between testing days (d1, d8, d11): stage 1: 102 ± 35 W, 118 ± 33 W, 120 ± 35 W ($p = 0.001$); stage 2: 205 ± 37 W,

244±33W, 231±39W ($p<0.001$); stage 3: 267±49W, 286±36W, 280±37W ($p=0.08$). The same applies for RPE at stages 2 (3.7±0.9; 5.2±1.9; 3.8±1.1; ($p<0.001$) and 3 (5.6±0.9; 8.1±1.7; 6.3±1.7 ($p<0.001$)), whereas stage 1 remained unchanged ($p=0.71$). At d8 we observed that most of the athletes were not able to reach the target HR of stage 3 ($n=15$ out of 23). HRR showed no difference between tests ($p=0.20$). Discussion The main finding of the study was that the LSCT can be used for monitoring fatigue and recovery in cyclists, as power output and RPE measured during submaximal stages based on HRmax were responsive to a fatiguing training and a following recovery period. However, HRR as a part of the LSCT did not show its utility as a marker of fatigue. Changes in workload and RPE corresponding to fixed submaximal HR are presumably due to effects of training load on cardiac autonomic activity. References Foster, C., Florhaug, J. SESSION-RPE IN SOCCER: THE RETROSPECTIVE RATING

Fanchini, M.1,2, Beato, M.2, Ghielmetti, R.3, Schena, F.2,4, Impellizzeri, F.M.5

1 FC Inter, Milan, Italy. 2 University of Verona, Italy. 3 AC Spezia Calcio, Italy. 4 CeRISM, Italy. 5 Schulthess Clinic, Zurich, Switzerland

Introduction The session-RPE is a valid method to measure the internal training load (TL) in soccer. The RPE has been suggested to be collected 30 min after the end of the session (Impellizzeri et al. 2004). However after the matches players could be not too collaborative. Is it possible to collect RPE after 48 hours? Response shift (RS) concerns a change in perception after a period of time due to reconceptualization, reprioritization, scale recalibration (Schwartz et al. 1999, Sprangers et al. 1999). The aim of this study was to investigate the RS in session-RPE. Methods Twenty-one amateur soccer players (age 25±5 yrs, height 176±6 cm, weight 71±7 kg) participated in a randomized crossover design study. Players were blinded to the aims of the study, matched by distance reached in the Yo-Yo Intermittent Recovery L1 test and divided in two groups: condition 0 was asked for RPE at the end of the session while condition 48 after 48 hours. Sessions consisted in a warm-up, interval training running and cool down. The same structure and intensity (controlled by heart rate) has been proposed after 10 days and RPE (Borg CR100 scale) collected inverting the conditions. Internal TLs were measured with heart rate based methods (Edward's and Bannister TRIMP). External TLs were assessed with a GPS system (SPI-ProX, 15Hz) and total distances (TD) and distance covered higher to 15 km·h⁻¹ (HIR) considered as outcomes. Results No significant differences were found between condition 0 and 48 in percentage of peak heart rate ($p=0.36$, 71±3 and 72±3%, respectively), Edward's TLs ($p=0.36$, 151±20 and 154±11 AU), Bannister TRIMP ($p=0.46$, 67±13 and 68±12 AU), RPE ($p=0.72$, 53±15 and 54±12 AU), TD ($p=0.70$, 6091±408 and 6044±217 m) and HIR ($p=0.15$, 691±446 and 795±372 m). Conclusions The crossover avoided any possible effect of previous RPE memory. In addition, given the existing relationship between internal TL and session-RPE in soccer (Impellizzeri et al. 2004), the same loads were imposed to the athletes using two standardized training sessions. The absence of RS suggested that the RPE could be collected also after 48 hours without influencing the TL. However, until there is more evidence, this strategy should be used only when the abovementioned situations occur (not collaborative conditions). References Impellizzeri, F. M., E. Rampinini, A. J. CONSECUTIVE DAYS OF 5-SET MATCHPLAY IN TENNIS; THE INFLUENCE OF FATIGUE AND PACING.

Duffield, R.1, Gescheit, D.2, Cormack, S.3, Brydon, N.4, Skein, M.4, Reid, M.2

1:University of Technology Sydney (Australia), 2: Tennis Australia (Australia), 3: Australian Catholic University (Australia), 4:Charles Sturt University (Australia).

Introduction Notwithstanding descriptions of matchplay activity profiles (1) and that skeletal muscle function has been reported to reduce following prolonged match-play (2), there is a distinct lack of insight regarding the manifestation of fatigue for tennis-specific outcomes. Consequently, the current study compared movement and technical outcomes over consecutive days of prolonged matchplay. Methods Seven well-trained, nationally ranked players performed 4 consecutive days of 4h matchplay (ie. 5 set matches) against an opponent of a comparative ability. During each indoor match, players wore a Global Positioning Satellite device that housed a 100Hz accelerometer (Catapult, Australia) to measure 2D and 3D Loads (sum of accelerations in respective planes). Further, each match was filmed and coded for matchplay and technical performance indicators by a trained analyst. Performance indicators consisted of game statistics, stroke and error counts and qualitative descriptors of hitting position ie. closeness to ball. Mean and SD values for each measure were compared between days by Cohen's d effect size analyses. Results Player movement was reduced each day, as inferred from reductions in 2D and 3D accelerometry loads (5-8% each day; $d>1.50$). Despite the daily reduction in movement characteristics, total games played tended to be higher on day 2 ($d=0.92$), though total games and games per set were comparable on ensuing days ($d<0.20$). Interestingly, non-playing time increased on day 2 (with a corollary reduction in playing time; $d>1.00$) without changes between days thereafter ($d<0.25$). However, total strokes played each day did not differ in volume or type of shot between respective playing days ($d<0.25$). That said, qualitative descriptors of stroke positioning suggest an increase in shots played 'at stretch' on days 2-4 ($d>0.90$). Discussion The decrement in accelerometry load over consecutive days' matchplay suggests the accumulation of fatigue affecting the capacity for on-court movement. However, the increased non-playing time for an unchanged total stroke and game volumes suggest tactical alterations to the style of matchplay. Accordingly, motivation aside, consecutive days of prolonged matchplay (ie. 5 set matches) results in altered ability to position appropriately for shot selection and consequent alterations in tactical approaches to ensuing matchplay, resulting in changed movement patterns. 10:20 - 11:50**Oral presentations****OP-PM31 Energy Balance & Expenditure****HIGH BODY DISSATISFACTION IS ASSOCIATED WITH HIGHER BMI, REDUCED AEROBIC FITNESS, RESTRAINED EATING BEHAVIOR, AND LOW ENERGY AVAILABILITY IN YOUNG, EXERCISING WOMEN**

Koehler, K., Mallinson, R.J., Allaway, H.C., Williams, N.I., De Souza, M.J.

The Pennsylvania State University

Previous studies have shown that a high drive for thinness and high cognitive dietary restraint (CDR) are associated with energy deficiency (ED) in exercising women [1,2]. While high body dissatisfaction (BD) is considered a risk factor for extreme weight-controlling behaviors, little is known about the role of BD in the development of ED in exercising women. The purpose of the study was to assess the association among BD and body composition, aerobic fitness, eating behavior phenotypes, and energy status as determined by energy availability (EA) and metabolic markers of ED in exercising women. Ninety-seven young, exercising women (22.2 ± 3.9 y) with regular menstrual status (39%) or menstrual disturbances (61%) completed the Eating Disorder Inventory. They were divided into quartiles based on their BD scores (Q1: $BD=0$; Q2: $1 \leq BD < 4$; Q3: $4 \leq BD < 7$; Q4: $BD \geq 7$). Body composition was assessed using dual x-ray absorptiometry. Indirect calorimetry was used to assess resting metabolic rate (RMR) and aerobic fitness (VO_{2max}). 3-day diet logs were used to assess energy intake (EI), and exercise energy expenditure (ExEE) was determined using 7-day exercise logs and heart rate monitors. EA was calculated as $EI - ExEE$ divided by fat-free mass (FFM). Serum concentrations of triiodothyronine (T3), peptide YY (PYY), and ghrelin were determined from fasting blood samples. CDR and disinhibition (DIS) were assessed using the Three-Factor Eating Questionnaire. Differences among quartiles were assessed using one-way analysis of variance. A higher BD score was associated with a higher BMI (20.3 ± 1.9 (Q1) vs. 20.9 ± 1.9 (Q2) vs. 21.0 ± 2.0 (Q3) vs. 22.3 ± 1.9 kg/m² (Q4); $p=0.004$), a higher body fat percentage (22.9 ± 5.4 (Q1) vs. 23.9 ± 3.8 (Q2) vs. 26.2 ± 4.2 (Q3) vs. 28.6 ± 4.1 % (Q4); $p<0.001$), and lower VO_{2max} (50.6 ± 8.5 (Q1) vs. 47.8 ± 7.9 (Q2) vs. 45.1 ± 7.5 (Q3) vs. 43.1 ± 7.5 ml/kg/min (Q4); $p=0.036$). CDR ($p<0.001$) and DIS ($p=0.042$) were higher in women with high BD. Higher BD scores were further associated with low EI ($p=0.003$) and low EA (46.9 ± 23.0 (Q1) vs. 40.2 ± 13.4 (Q2) vs. 42.8 ± 13.0 (Q3) vs. 32.8 ± 15.1 kcal/kg FFM/d (Q4); $p=0.018$). RMR and serum concentrations of T3, PYY, and ghrelin were not significantly associated with BD ($p>0.26$). This study shows that high BD in young-exercising women is associated with unfavorable body composition and lower fitness. An eating behavior phenotype that includes high BD, CDR and DIS is likely indicative of weight cycling and overweight, as indicated by a higher BMI and higher body fat. Interestingly, EI and EA were lower in these women, but the presence of low EA was not indicative of chronic ED, as demonstrated by metabolic hormones and RMR. This finding suggests that EA is not a good marker of energy status in exercising women with high BD, and that these women likely underreport energy intake when being assessed in a controlled setting. CHANGES IN ENERGY EXPENDITURE, ENERGY INTAKE, ENERGY IMBALANCE, AND BODY COMPOSITION AND OVER A SEASON

Silva, A.M., Matias, C.N., Santos, D.A., Thomas, D., Heymsfield, S.B., Sardinha, L.B.

Faculty Human Kinetics, Technical University Lisbon

Changes in resting (REE), total (TEE), and physical activity energy expenditure (PAEE), energy intake, and energy imbalance are expected to occur over a season but the magnitude is still unknown. Purpose: This study aims to explore changes in body composition, REE, PAEE, TEE, energy intake, and energy imbalance over a season in athletes of different sports and varying in body weight (BW) alteration. Methods: A total of 61 handball, volleyball, basketball, triathlete, and swimmer athletes (41 males and 20 females) were evaluated in the beginning of the season and at the main stage of the competition (7-8 month apart). REE and TEE were assessed by indirect calorimetry and doubly labeled water, respectively, while PAEE was assessed as $TEE - 0.1TEE - REE$, assuming 10% of TEE is thermic effect of food. Body composition was determined by dual-energy X-ray absorptiometry and energy imbalance was calculated through average changes in stored energy over time as $1020(\Delta FFM/\Delta time) + 9500(\Delta FM/\Delta time)$, where FFM and FM represents fat-free mass and fat mass, respectively. The sum of TEE with energy imbalance was used to calculate energy intake. Body weight changes were divided into those who lost $>1.5\%$ BW, changed $\leq 1.5\%$ BW or gained $>1.5\%$ BW. Changes were calculated as a percentage from the baseline value. Results: For the whole sample TEE, PAEE, REE, energy intake, and FFM significantly increased by $15.7 \pm 11.2\%$, $29.2 \pm 31.9\%$, $7.0 \pm 22.2\%$, $15.2 \pm 11.5\%$ and $1.9 \pm 2.9\%$ while FM reduced by $2.3 \pm 13.1\%$ but no significant mean changes were found for energy imbalance. Basketball, handball, volleyball, swimmers, and triathletes significantly increased TEE ($12.7 \pm 11.7\%$, $18.8 \pm 8.5\%$, $10.7 \pm 7.7\%$, $14.0 \pm 9.1\%$ and $26.3 \pm 10.3\%$) and PAEE ($12.3 \pm 30.5\%$, $34.3 \pm 16.1\%$, $24.2 \pm 12.5\%$, $41.5 \pm 23.0\%$ and $54.2 \pm 39.8\%$), respectively, while REE only increase by $20.5 \pm 23.6\%$ in basketball players. Energy intake significantly raised by $12.9 \pm 11.7\%$, $19.6 \pm 9.0\%$, $13.7 \pm 9.7\%$, $25.4 \pm 10.1\%$ in basketball, handball, swimmers, and triathletes, correspondingly. Only volleyball players showed a significant decrease in adiposity by $-17.6 \pm 7.9\%$ with a negative energy imbalance of -164.2 ± 92.0 kcal/day whereas FFM increased in basketball and handball players by $3.5 \pm 2.3\%$ and $3.5 \pm 1.5\%$, respectively. A FM reduction of $-15.6 \pm 10.7\%$ was observed in athletes that lost $>1.5\%$ BW with a significant increase of $4.6 \pm 11.0\%$ in those that gained $>1.5\%$ BW. FFM did not significantly differ in athletes that lost $>1.5\%$ BW but increased by $0.9 \pm 1.4\%$ and $3.9 \pm 2.1\%$ in those that changed $\leq 1.5\%$ BW or gained $>1.5\%$ BW, correspondingly. Conclusion: Overall energy balance was maintain through an increase in energy expenditure with a compensated energy intake along with an improved body composition profile though differences by sport and weight changes were observed over the season. Athletes that lost weight, significantly decrease adiposity while maintaining lean mass.

ENERGY INTAKE AND ENERGY EXPENDITURE ASSESSMENT OF MALE ADOLESCENT ACADEMY-LEVEL FOOTBALL PLAYERS

Briggs, M., Cockburn, E., Stevenson, E.

Northumbria University

The purpose of the study was to provide further insight into the limited amount of data that exists on both the dietary practices and energy expenditure of adolescent academy-level football players. Ten male adolescent football players, representing a professional club at academy level (mean \pm SD: 15.4 \pm 0.3 years; height 1.7 \pm 0.1m; weight 57.8 \pm 7.8kg and BMI 19.8 \pm 1.6kg/m²) participated in the study. All players recorded their 7 day dietary intake using the combined method of self-reported weighed food diary and 24 hour recall. In addition energy expenditure was calculated for the 7 days directly using a tri-axial accelerometer (ActiGraph GT3X+, Pensacola, FL). The 7 day period was conducted during the second half of the 2012/2013 competitive season and included 4 training days, 2 rest days and a match day. Results identified a difference between mean daily energy intake (2169 \pm 134 kcal) and mean daily energy expenditure (2555 \pm 300 kcal), $t(6) = -4.17$, $p < 0.05$, $ES = 1.78$. Mean deficit between energy intake and energy expenditure was -389 \pm 273 kcal. The mean macronutrient composition of the dietary intake was 318 \pm 24 g•d⁻¹ carbohydrate, 86 \pm 10g•d⁻¹ protein and 70 \pm 21g•d⁻¹ fats, representing 55.0 \pm 3.3, 16.2 \pm 1.5, 28.7 \pm 2.3% of mean daily energy intake respectively. In conclusion, the findings of the study indicate that within this population of adolescent academy-level footballer players, energy intake is insufficient to sustain the energy requirements. This may have both a short and long term negative impact on performance during training and match-play as well as implications for a player's physical development.

THE VARIABILITY OF ENERGY AND NUTRIENT INTAKES USING THREE DIFFERENT DIETARY STANDARDISATION TECHNIQUES IN ATHLETES

El-Chab, A., Simpson, C., Lightowler, H.

Oxford Brookes University

Introduction Many dietary factors, such as energy and carbohydrate, can influence exercise and sports performance which require controlling and standardisation (Jeacocke and Burke, 2010). If uncontrolled, these dietary components can affect the performance being monitored and make it more difficult to detect changes associated with the intervention (Simonsen et al., 1991). The aim of this study was to assess the ability of athletes to replicate a diet when a controlled diet (CDiet), food record (Fdiary) and dietary recall (DRecall) were used as dietary standardisation techniques. **Methods** Thirty moderately trained athletes completed six visits to the laboratory with three days between visits. At all visits, a DRecall of the preceding 24-hours was completed to provide quantitative information about actual dietary intake. We captured one period of ad libitum food intake before Visit 1 as a written record which subjects then used before visit 2 in an attempt to replicate the same diet. Next, subjects completed another 24-hour ad libitum food intake. However, on this occasion, subjects completed a written Fdiary, which was presented at Visit 3. We then informed subjects to use this Fdiary for the 24-hours before Visit 4. Lastly, we provided subjects with a pre-packaged diet of known composition which subjects consumed for 24-hours before Visits 5 and 6. We then measured the difference in energy and macronutrient intakes between both visits for each method. This complex design provided us with insight into the ability of athletes to achieve dietary standardisation. **Results** Mean energy and macronutrient intakes between visits within each technique were not statistically significant. However, the within-subject variability of energy and macronutrient intakes was significantly higher in DRecall and Fdiary techniques compared to CDiet (Energy: 6.2%, 8.0%, 2.3%; Carbohydrate: 8.0%, 7.1%, 1.9%; Protein: 5.0%, 7.6%, 2.2%; Fat: 8.3%, 13.2%, 4.1%, respectively). **Discussion** At group level, there were no differences in mean energy and macronutrient intakes between visits for any method which suggested good subject reproducibility. Nevertheless, important within-subject differences were apparent, particularly in DRecall and Fdiary methods. These differences may influence primary measurements by increasing signal noise and reducing experimental power. Traditional statistical methods may obscure important individual variability in pre-experimental standardisation. **References** Jeacocke A, Burke L. (2010). *Int. J. Sport Nutr. Exerc. 12:00 - 13:15**Plenary sessions****PS-PL02 Interaction between thermal environment, mental and physical status of the athlete and power output *****BEHAVIOURAL ADAPTATIONS DURING EXERCISE IN EXTREME AMBIENT TEMPERATURES**

Flouris, A.D.

Centre for Research and Technology Hellas

This invited lecture will discuss how thermal homeostasis is defended via behavioural responses and the resulting effects on performance. It is well known that the human capacity to perform prolonged exercise is profoundly impaired in hot or cold environments. What is less known is that the thermoregulatory system relies primarily on behavioural adaptation and secondarily on autonomic and endocrine responses for the maintenance of thermal homeostasis. Despite the challenges involved in effectively isolating human behavioural responses, a number of studies have demonstrated that behavioural thermoregulation is a major determinant of performance. Changes in ambient temperature affect our heat balance and lead to behavioural responses that are translated to changes in the work produced. In this light, evidence shows that behaviour is primarily driven by thermal (dis)comfort, while autonomic thermoregulation is mainly stimulated by thermal sensation. Suggestions for training and event days will be provided aimed towards maximising the athlete's wellbeing and performance.

PERFORMANCE IN THERMAL EXTREMES - ADAPTATION TO HEAT AND COLD

Daanen, H.

VU University

Introduction Humans increasingly participate in endurance sports in extreme environments. In order to prepare for such events, the athletes try to adapt not only to endurance exercise by physical training, but also to the expected extreme climate. Heat Acclimation Humans can effectively adapt to heat. Decreased heart rate, rectal temperature and perceived exertion are observed in repeated fixed-intensity exercise as well as increased plasma volume and sweat rate. In order to acquire the physiological adaptations, the core temperature should be elevated above 38°C daily for at least an hour and preferably two hours. De-acclimation and Re-acclimation to heat Since athletes generally taper prior to the match, it is important that the acclimation status is maintained and does not decline during the tapering period. It was generally assumed that the decline of acclimation status took twice as long as the acquisition of acclimation. More recent studies show that the acclimation status is maintained for a much longer period, even two months, in particular for Rating of Perceived Exertion and rectal temperature adjustments (Weller et al. 2007). These results suggest that, once acclimation has been attained, the time that individuals may spend in cooler conditions before returning to a hot environment could be as long as a month, without the need for extensive re-acclimation to heat. When insufficient time for recovery is provided, the adaptations can be postponed to after the acclimation period (Daanen et al. 2011). Cold acclimation Repeated whole body exposure to cold leads to minor adaptations only compared to heat acclimation. The metabolic heat production increases, insulation by skin vasoconstriction improves and cold-acclimated subjects are better able to tolerate the cold. However, the major physiological textbooks describe that repeated local cold exposure of the extremities leads to considerably improved peripheral blood flow. A recent review (Cheung and Daanen, 2012) and experimental work (Daanen et al. 2012) showed that the extremities also do not adapt to cold. 14:00 - 15:00**Mini-Orals****MO-PM42 NU Ergogenic Supplements 2****SODIUM BICARBONATE INGESTION AUGMENTS PGC1-ALPHA EXPRESSION DURING RECOVERY FROM INTENSE INTERVAL EXERCISE IN HUMAN SKELETAL MUSCLE**

Percival, M.E.1, Martin, B.J.1, Gillen, J.B.1, Skelly, L.E.1, Tarnopolsky, M.A.1, Gibala, M.J.1

1: McMaster University, Hamilton, Ontario, Canada

INTRODUCTION Sodium bicarbonate ingestion (NaHCO₃) during 8 wk of interval training reduced the accumulation of H⁺ ions during each session, and was associated with improvements in endurance capacity and lactate threshold (Edge et al., 2006). Further supporting these observations, rats supplemented with NaHCO₃ prior to each exercise bout over a 5 wk training period demonstrated greater training-induced increases in mitochondrial respiration and time to exhaustion (Bishop et al., 2010). A potential mechanism may be through an augmented transient up-regulation of gene expression that over successive exercise bouts leads to greater adaptations. The purpose of this study was to provide insight into how NaHCO₃ ingestion may alter human muscle metabolism, signaling and gene expression in order to help explain the observations after training. METHODS Nine active men (22 ± 2 y; 78 ± 13 kg, VO_{2peak} = 48 ± 8 mL/kg/min; mean ± SD) performed an acute session of high intensity interval exercise on two occasions. Exercise involved 10 x 60 s cycling efforts at an intensity that elicited 88 ± 5% of maximal heart rate (263 ± 40 W), interspersed by 60 s of recovery. Prior to exercise, subjects ingested either NaHCO₃ or a placebo that consisted of an equimolar dose of NaCl in a randomized, double-blind, crossover manner. Needle biopsies (v. lateralis) and venous blood samples were obtained before and immediately after exercise and after 3 h of recovery. RESULTS NaHCO₃ increased blood bicarbonate, pH and post-exercise lactate content, compared to NaCl (p < 0.05). The exercise-induced decrease in muscle glycogen content was 16% greater in the NaHCO₃ treatment (Pre: 451 vs Post: 325 mmol/kg dry mass) compared to NaCl (Pre: 449 vs Post: 396 mmol/kg dry mass). The increase in PGC1-alpha mRNA expression 3 h post-exercise was significantly greater following NaHCO₃ ingestion compared to NaCl (~7-fold vs ~5-fold; p < 0.05). DISCUSSION NaHCO₃ ingestion alters skeletal muscle metabolism during intense interval exercise and augments the expression of PGC1-alpha mRNA during recovery. These results provide novel insights into the potential mechanisms responsible for enhanced mitochondrial respiration after chronic NaHCO₃ supplementation in rodents (Bishop et al., 2010) and improved aerobic exercise performance in humans (Edge et al., 2006). CITRULLINE ENHANCES NEITHER BLOOD FLOW, MICROVASCULAR CIRCULATION, NOR MYOFIBRILLAR PROTEIN SYNTHESIS IN ELDERLY MEN AT REST OR FOLLOWING RESISTANCE EXERCISE

Churchward Venne, T.A., Cotie, L.M., MacDonald, M.J., Mitchell, C.J., Prior, T., Baker, S.K., Phillips, S.M.

McMaster University

Introduction Ageing is associated with resistance of myofibrillar protein synthesis (MPS) to postprandial hyperaminoacidemia, particularly with low protein doses, a term coined 'anabolic resistance'. Impairments in postprandial skeletal muscle blood flow and/or nutritive microvascular perfusion with hyperaminoacidemia and hyperinsulinemia may contribute to anabolic resistance. Thus, we examined whether providing citrulline, a precursor for arginine and nitric oxide synthesis, would increase arterial blood flow, skeletal muscle microvascular perfusion, MPS, and signalling through mTORC1. Methods In a parallel group design, twenty one elderly males (73 ± 1 y) com-

pleted acute unilateral resistance exercise prior to ingestion of either a: high dose (45 g) of whey protein (WHEY), or a low dose (15 g) of whey protein supplemented with 10 g of citrulline (WHEY+CIT), or with 10 g of non-essential amino acids (WHEY+NEAA). A primed continuous infusion of L-[ring-¹³C₆] phenylalanine with serial muscle biopsies was used to measure MPS and protein phosphorylation, while Doppler and contrast enhanced ultrasound respectively were used to measure femoral arterial blood flow and muscle microvascular circulation under basal and postprandial conditions in both a rested (FED) and exercised (EX-FED) leg. Results Arginemia was greater in WHEY+CIT vs. WHEY and WHEY+NEAA from 30-300 min post-exercise ($P < 0.001$), but there were no treatment differences in blood flow, or microvascular perfusion (all $P > 0.05$). Phosphorylation of p70S6kThr389 was greater in WHEY vs. WHEY+NEAA ($P = 0.02$). Postprandial MPS was greater in WHEY vs. WHEY+CIT and WHEY+NEAA under both FED (WHEY: ~128%; WHEY+CIT: ~56%; WHEY+NEAA: ~38%) and EX-FED (WHEY: ~251%; WHEY+CIT: ~124%; WHEY+NEAA: ~108%) conditions ($P = 0.003$). Discussion Citrulline co-ingestion with a low quantity of protein was ineffective in augmenting the anabolic properties of protein compared to non-essential amino acids. A three-fold greater dose of whey protein was markedly more anabolic towards elderly skeletal muscle under resting and post-exercise conditions. Contact E-mail: churchta@mcmaster.ca

NITRATE SUPPLEMENTATION WITH BEETROOT JUICE BEFORE REPEATED SPRINT BOUTS

Lipski, M.1, Zinner, C.1,2, Mester, J.1,2

German Sport University Cologne

NITRATE SUPPLEMENTATION WITH BEETROOT JUICE BEFORE REPEATED SPRINT BOUTS Introduction In several studies it has been shown that chronic pharmacological and dietary nitrate supplementation (3-6 days) decreases oxygen cost of sub-maximal and continuous exercise, improves exercise tolerance and time trial performance (Bailey et al., 2012). Studies investigating high-intensity interval exercise show inconsistent results. This study is the first to examine the effects of an acute dietary nitrate supplementation on exercise performance and physiological parameters during repeated sprint bouts. Methods Moderately trained athletes ($\text{VO}_{2\text{max}} 55.2 \pm 3.8 \text{ ml/kg/min}$) were assigned to a double-blind, randomized and crossover design. On two different days they consumed 500 ml of beetroot juice (BE: 830 mg nitrate/kg) or placebo (PLA: 8 mg nitrate/kg) 3 hours prior to repeated sprint bouts consisting of four 30 s isokinetic cycling sprints intercepted by a 5 min passive rest phase. Following physiological parameters were measured during both repeated sprint bouts sessions. Breathing gases were measured continuously, as well as local muscle oxygenation using NIRS. Power output was recorded by the isokinetic ergometer. Additionally capillary blood samples were taken at several time points for blood lactate and blood gas analysis. Results There were no significant differences between conditions for exercise performance, oxygen uptake and local muscle oxygenation. RER (best $p=0.004$) and BF ($p=0.039$) were significantly higher in BE for certain time points. The pH, PCO_2 , base excess and sodium were significantly lower in some time points. Discussion The main findings of this study are that an acute dietary nitrate supplementation does not improve exercise performance and oxygen uptake during repeated sprint bouts. Mechanisms assumed to be altered by nitrate supplementation (Bailey et al., 2010; Hernández et al., 2012) seem less important during high intensity exercise. The results of this study suggest that there might be other mechanisms, regarding the reduction of hydrogen ions that might be influenced by nitrate supplementation. NITRATE SUPPLEMENTATION, EXERCISE AND KIDNEY FUNCTIONS: ANY DETRIMENTAL EFFECTS?

Stragier, S.1, Carpentier, A.1, Bréjeon, C.1, Gulbis, B.2, Poortmans, J.R.1

Université Libre de Bruxelles

Introduction: Recently, dietary supplementation with inorganic nitrate (NO_3^-) has been proposed to endurance athletes to increase their performance. However, it has been suggested that an excess of (NO_3^-) might be harmful. Few publications point out that nitrate and nitric excess exposure is associated with increased risk of renal cell carcinoma (Ward et al., 2007) and acute kidney injury (Mian et al., 2011). The present study investigated the impact of (NO_3^-) supplementation on kidney functions. **Methods:** Thirteen young males performed a 20-min cycling exercise at 85% of the maximal oxygen capacity. Seven days prior to exercise the subjects ingested either a placebo (PI) or 450 mg potassium nitrate (PN) per day. Venous blood samples and urine collections were collected prior to and immediately after exercise, and after 60 min of recovery. Glomerular filtration rates (GFR) and clearances (CI) were calculated from serum content and urine output for creatinine (Crn), albumin (Alb) and urea. **Results:** Under resting conditions, GFR and all clearance measures did not differ between PI and PN. Immediately after exercise, GFR and CI-urea decreased significantly (-11% and -44% respectively; $p < 0.05$) in PI and only CI-urea in PN (-49%), whereas Alb urine output were enhanced by 18 and 19 fold in PI and PN respectively. After the recovery period, GFR (except in PI +63%) and CI-urea returned to initial values. Alb output and CI-Alb remained enhanced both under PI and PN conditions. **Discussion:** These results suggest that dietary nitrate supplementation over a week period does not induce any specific kidney function modifications either at rest or during sustained submaximal exercise, as compared to PI. **References:** 1. EFFECTS OF ACUTE INGESTION OF P-SYNEPHRINE ON SPRINTERS' PERFORMANCE

Gutiérrez Hellín, J., Salinero, J.J., Gallo Salazar, C., Abián Vicén, J., Areces, F., Lara, B., Del Coso, J.

Camilo Jose Cela University

Introduction P-syneprine has become a commercially-available substance in most countries and its use has significantly increased in sports during the last years. In 2009, the World AntiDoping Agency (WADA) included p-syneprine in the Monitoring Program (a list of substances which are not prohibited but under the control of WADA). However, p-syneprine has received much less scientific attention than other stimulants used in sports (e.g., caffeine, ephedrine, etc.) and to the date, there is no reliable information about the ergogenicity and safety of this substance. The aim of this study was to test the effectiveness of p-syneprine to increase physical performance of elite sprinters. A second objective was to evaluate side-effects derived of the intake of this substance. **Methods** A double-blind, placebo-controlled and randomized experimental design was used in this investigation. Thirteen elite sprinters (age = 22 ± 2 years) performed two experimental trials: in one occasion, the athletes ingested 3 mg/kg of p-syneprine and in another occasion they ingested an isocaloric placebo (cellulose). The treatments were provided in unidentifiable opaque capsules. The substances were provided 1-h before performing a 60-m maximal running test, a 100-m maximal running test, a maximal squat jump, a maximal countermovement jump and

a 15-s repeated-jumps test. Time in the running tests was measured by using photocells and jump variables by using a force platform. After this, sprinters completed a questionnaire about self-perceived running velocity and muscle power during the tests (1-10 point scale) and side-effects derived from the ingestion of the experimental substances. Results In comparison to the placebo, the intake of p-synephrine neither modified the time to complete the 60-m test (8.18 ± 0.35 vs 8.20 ± 0.36 s; respectively) nor the time to complete the 100-m test (12.94 ± 0.71 vs 12.90 ± 0.65 s). The p-synephrine did not improve jump height in the squat jump (33.9 ± 3.7 vs 34.4 ± 3.6 cm), countermovement jump (36.7 ± 3.3 vs 37.4 ± 4.2 cm) or the mean jump height during the 15-s repeated jump test (32.1 ± 3.6 vs 31.7 ± 4.1 cm). During the tests, participants did not perceive increased running velocity (6.6 ± 1.9 vs 7.1 ± 1.3 points) or higher prevalence of headaches (7.7 vs 15.4%) and insomnia (0.0 vs 7.7%). Conclusion The acute intake of 3 mg/kg of p-synephrine did not improve physical performance of sprinters during short-term maximal intensity tests. Besides, the p-synephrine did not produce measurable side-effects during the following hours to the ingestion. This information suggests that this substance should not be included in the WADA list of prohibited substances. Contact: j.hellin@alumno.ucjc.edu

EFFECTIVENESS OF PHYTOTONIC SUPPLEMENT ON SIGNIFICANT PHYSIOLOGICAL FACTORS OF THE ENDURANCE

Ataei, L.

University of Nicosia

Do not insert au1-Introduction Herbal medicines have been used throughout history to enhance various parameters of immune function, treat a variety of cardiovascular diseases, and to improve physical performance (1, 2). Herbal dietary supplements are marketed to physically active individuals for a variety of reasons, including increasing energy, inducing weight loss, promoting muscle growth, or inducing other physiological or metabolic responses that may enhance exercise performance(3). 2. Materials and methods The research material included 30 competitive (boys) kayaker with average age 18.2 ± 2.8 years and body height 170.2 ± 6.7 cm, body mass 70.3 ± 4.3 kg, which divided into 2 groups of 15 subjects. Experimental group received a supplement called Phytogenic include of Ginseng, Ginkgobiloba, fenugreek seed, sour orange peel, Tribulus terrestris; and Echinacea and Glucose; another group received a placebo. Both groups were advised to take 10 gm of supplement or placebo 3 time a day for 30min before each meal for 4 weeks. All subjects performed six sessions training weekly and four specific strength workouts. VO2max and blood profile Lactate were evaluated before and after the cessation of the experiment. The Spss17 software was used for analyzing the data. In addition, t-student tests were done to compare the groups. 3. Result The results indicate that the blood lactate levels of the experimental was lower than the control group ($P < 0.05$) and the mean VO2max value increased scientifically after the 4 weeks Phyto tonic consumption as compared to the control group ($p < 0.05$). 4. Discussion: Clinical studies conducted on the Phytotonic Supplementary have shown ingredients of this product is able to increase erythropoietin therefore increase synthesis of Red Blood Cells and oxygen transfer in blood and finally Vo2max. 4-hydroxy Isoleucine Aminoacid (4-OH-Ile) in this supplement can be increased glycogen synthesis and decreased blood lactate level after sport .In conclusion, Phytotonic Supplement enhanced the general endurance of kayakers by increasing Vo2max and by delaying the accumulation of plasma lactate. However further study is needed to elucidate the more exact mechanism of effect of the Phyto tonic on exercise durability. 5. Reference 1. BRANCHED-CHAIN AMINO ACIDS AND ARGININE IMPROVE PERFORMANCE IN TWO CONSECUTIVE DAYS OF SIMULATED HANDBALL GAMES IN MALE AND FEMALE ATHLETES

Chang, C.K., Chang Chien, K.M., Chang, J.H., Wu, C.L., Huang, M.H., Liang, Y.C., Liu, T.H.

National Taiwan University of Physical Education and Sport

Introduction The central nervous system plays a crucial role in the development of physical fatigue. One of the proposed mechanisms that contribute to central fatigue is the increase in blood concentration of free tryptophan and hence the neurotransmitter serotonin in the brain during exercise. Branched-chain amino acids (BCAA) have been proposed to alleviate central fatigue due to their ability to compete with tryptophan in crossing blood-brain barrier. However, BCAA supplementation would result in elevated cerebral uptake and accumulation of NH₃, leading to central fatigue. Arginine has been suggested to be able to reduce exercise-related accumulations of NH₃ by increasing urea cycle. The purpose of this study is to investigate the effect of combined supplementation of BCAA and arginine on intermittent sprint performance by alleviating central fatigue in simulated handball games on 2 consecutive days. Method Fifteen male and 7 female handball players consumed 0.17 g/kg BCAA plus 0.04 g/kg arginine (AA trial), or placebo before exercise. Each trial contained 2 60-min simulated handball games on consecutive days. A 20 m all-out sprint was performed every 2 min. Results The performance, measured by percentage changes of sprint time between day 1 and 2, was significantly better in the AA trial in sprint 21-25 in males, and sprint 21-25 and 26-30 in females. The improved performance on day 2 in the AA trial was concurrent with reduced plasma tryptophan/BCAA ratio in both genders and the lower ratings of perceived exertion in males. The post-exercise urea concentration was significantly elevated on day 2 in the AA trial in males, indicating increased NH₃ removal. Discussion This study showed that BCAA and arginine could improve performance in intermittent sprints on the second half of the second consecutive day of simulated games by potentially alleviating central fatigue.

EFFECT OF β-ALANINE-INDUCED PRAESENSATION IN COMPETITIVE CYCLISTS

Bellinger, P., Minahan, C.

Griffith University, Gold Coast 4222, Queensland, Australia

Introduction: β-alanine is a common ingredient in supplements consumed by athletes (Kelly et al., 2013). Indeed, athletes may believe that the β-alanine induced praesensation, experienced shortly after ingestion, is associated with its ergogenic effect despite no scientific mechanism supporting this notion (Kelly et al., 2013). Thus, the effect of an athlete's "belief" on exercise performance warrants further consideration (Clark et al., 2000). The present study examined changes in cycling performance under conditions of β-alanine induced praesensation. Methods: Eight competitive cyclists (Age = 27.7 ± 5.9 yr; Peak O₂ uptake = 61.8 ± 4.2 mL/kg/min) performed one familiarization, one baseline, & four experimental trials. The experimental trials comprised a 1-km cycling time trial (TT) under four conditions with varying information (i.e., athlete informed β-alanine or placebo) & supplement content (athlete received β-alanine or placebo) delivered to the cyclist: 1. β-alanine trial/β-alanine received, 2. Control trial/β-alanine received, 3. β-alanine trial/Placebo received, & 4. Control tri-

al/placebo received. Questionnaires were undertaken exploring the cyclists' experience of the effects of the experimental conditions. Performance variables were compared using repeated measures ANOVA & magnitude-based inferences (Batterham et al., 2006). Results: A slight increase in mean power (\pm 95% confidence limits) was associated with conditions in which β -alanine was administered ($1.8 \pm 4.0\%$), but these results were inconclusive for performance enhancement ($p=0.22$, $ES=0.18$, $SWC=56\%$ beneficial). A possibly harmful effect was observed when cyclists were correctly informed that they had ingested a placebo ($-1.0 \pm 1.9\%$). β -alanine ingestion resulted in a slightly faster 1-km TT (β -alanine trial/ β -alanine received: 70.2 s; $-0.8 \pm 1.2\%$) & (control trial/ β -alanine received: 70.3 ; $-0.7 \pm 1.1\%$). There was an unclear effect of belief in the β -alanine trial/placebo received condition: 70.6 ; $-0.3 \pm 0.4\%$). No meaningful changes relative to baseline were observed in peak power or physiological variables. Questionnaire data suggested that both β -alanine conditions produced evident sensory side-effects & six cyclists experienced placebo effects. Discussion: Acute ingestion of β -alanine is not associated with improved 1-km TT performance in competitive cyclists. These findings are in contrast to the athlete's "belief" as cyclists reported improved energy & the ability to sustain a higher power output with β -alanine ingestion & the presence of β -alanine induced paraesthesia. Thus, the conditions under which β -alanine induced paraesthesia may have an effect on performance remain unclear. The elements that could be important include the timing & dose of β -alanine, the intensity & duration of the performance test & the training status of the participant. EFFECTS OF A NUTRITIONAL SUPPLEMENT ON MAXIMUM STRENGTH IN RESISTANCE TRAINED MALES.

Konstantaki, M., Eltahawy, S.

BUCKINGHAMSHIRE NEW UNIVERSITY

Introduction Jack3d is a powder based nutritional supplement that according to its manufacturers it can boost energy levels, increase endurance, improve focus and enhance the ability to lift more weight. The supplement is designed for those engaging in regular resistance training. However there have not been any published research studies investigating the supplement's effectiveness in athletic or other populations. Therefore, the aim of this study was to investigate the effects of Jack3d on mental and physical strength. Methods Sixteen resistance trained males (mean \pm s; age: 23.88 ± 3.73 years, body mass: 74.06 ± 7.73 kg, stature: 174.63 ± 5.0 cm) signed an informed consent and participated in the study. Participants first performed a 1RM bench press test to establish upper body muscle strength and were randomly assigned to one of two groups; experimental group who would consume the supplement (Jack3d) and control group who would consume a placebo drink (PLA). Six days later, Jack3d consumed a drink containing 5.5 g of the Jack3d supplement diluted in 230 ml of water, whereas PLA consumed the same quantity of diluted peach juice. Both groups ingested the drink 40 minutes prior to testing to allow for gastric emptying. Following a standardised warm up, participants performed a re-test 1RM bench press test. A self reported questionnaire was used to assess states of mental strength under the two conditions. Results Following consumption of Jack3d there was a $1.90 \pm 0.03\%$ improvement in the 1RM (82.18 ± 15.08 kg and 83.75 ± 14.07 kg, for first and second lift, respectively, $P=0.04$). There was no significant improvement ($0.3 \pm 0.03\%$) in PLA (85.31 ± 9.0 kg and 85.62 ± 9.13 kg, $P=0.11$). Participants in the Jack3d group reported increased alertness, competitive drive and aggressive feelings. Discussion These results indicate that the amount of Jack3d consumed in our trial is adequate to increase maximum strength of resistance trained males. The improvements were small however this might be due to the trained subjects we used in the study. Jack3d contains a number of ingredients such as creatine, caffeine, beta-alanine, arginine and dimethylamylamine (DMAA) that have been shown to improve muscular strength, increase alertness, buffer waste products or mobilise fatty acids. The exact mechanism of how Jack3d induced changes in muscular strength calls for further investigation. However, the ingredient DMAA is currently a listed drug in New Zealand and is also a banned substance on the World Anti-Doping Agency list (WADA, 2012). This study aims to raise awareness among the athletic populations regarding the short term effects of Jack3d use, but also the possible implications for yielding a positive drugs test. THE EFFECTS OF A 6-MONTH VEGETARIAN DIET ON CARNOSINE, CREATINE AND CARNITINE

Baguet, A.1, Bex, T.1, De Henauw, S.2, Petrovic, M.3, Derave, W.1

University Ghent

1 Department of Movement and Sports Sciences, Ghent University, Belgium 2 Department of Public Health, Ghent University, Belgium 3 Department of Internal Medicine, Ghent University, Ghent, Belgium INTRODUCTION Creatine, carnosine and carnitine are essential nitrogen-containing compounds for skeletal muscle's metabolic, homeostatic and contractile function, and they markedly determine exercise capacity. Meat and fish (animal skeletal muscles) are the main or sometimes only dietary sources of these metabolites, and it is uncertain whether endogenous synthesis pathways are able to compensate for a near-complete lack of dietary intake of carnosine, creatine and carnitine inherent to a vegetarian condition. Cross-sectional studies have shown moderately reduced muscle stores of all three metabolites in vegetarians as opposed to omnivores. The current study will test this interventionally in omnivores switching to an ovo-lacto-vegetarian diet for 6 months. METHODS Twenty-four female omnivores participated in this long-term intervention study. Ten women continued their omnivorous diet for 6 months and 14 switched to an ovo-lacto vegetarian diet. At baseline and after 3 (3M) and 6 months (6M) muscle carnosine content was measured by proton magnetic resonance spectroscopy (1H-MRS) in the calf. Fasted venous blood samples were collected to determine serum creatine, creatinine and total carnitine. Urinary creatinine was measured after 24h urine collection. RESULTS Muscle carnosine did not change ($p=0.972$) in the omnivorous (from 4.56 ± 0.77 to 4.91 ± 0.62 mM) or vegetarian group (from 4.34 ± 1.11 to 4.73 ± 1.49 mM) over a 6-month period. Plasma creatine significantly decreased ($p=0.020$) from 33.82 ± 21.00 $\mu\text{mol/L}$ to 16.75 ± 10.14 $\mu\text{mol/L}$ after 3 months ($p=0.008$) and did not further decrease after 6 months ($p=0.650$; 17.22 ± 8.65 $\mu\text{mol/L}$) in the vegetarian group, while it remained stable in the omnivorous group ($p=0.114$; 3M: 35.68 ± 19.81 $\mu\text{mol/L}$ and 6M: 40.64 ± 21.57 $\mu\text{mol/L}$). Both serum ($p=0.223$) and urinary ($p=0.685$) creatinine did not change during the study in both groups. Serum total carnitine of both the omnivorous and vegetarian group remained stable ($p=0.823$) from baseline to 6 months. CONCLUSION Surprisingly, an ovo-lacto-vegetarian diet for 6 months had no impact on the muscle carnosine content nor plasma total carnitine concentration. Plasma creatine on the other hand was already halved after a 3-month ovo-lacto-vegetarian diet, without influencing plasma or urinary creatinine content. CONTACT audrey.baguet@ugent.be

14:00 - 15:00**Mini-Orals****MO-BN15 Muscle Strength****BICEPS FEMORIS LONG HEAD MYOSIN HEAVY CHAIN ISOFORM COMPOSITION AND KNEE FLEXION MAXIMAL AND EXPLOSIVE STRENGTH**

EVANGELIDIS, P.E., MASSEY, G.J., FERGUSON, R.A., WHEELER, P.C., PAIN, M.T., FOLLAND, J.P.

LOUGHBOROUGH UNIVERSITY

Introduction Hamstring strain injuries are common in many sports and are typically sustained during conditions of eccentric loading. The biceps femoris long head (BFlh) accounts for ~70% of total hamstring strains (1) and it has been suggested that the hamstrings contain predominantly type II fibres (2), which are more susceptible to eccentric exercise induced muscle damage (3). BFlh muscle composition data is exclusively from cadavers and not all data support that BFlh is composed primarily of type II fibres (4). Myosin heavy chain (MHC) isoform content determines the contractile properties at a single-fibre level, but how muscle composition influences BFlh performance in vivo is unknown. The aim of this study was to identify the BFlh MHC isoform distribution in healthy, active males and examine the relationship between BFlh MHC composition and knee flexor maximum and explosive isometric strength. **Methods** Thirty-one healthy, recreationally active young males (age 20.6 ± 2.5 years; height 178.8 ± 7.1 cm; body mass 71.8 ± 7.3 kg; mean \pm SD) were familiarised and performed voluntary maximal and explosive isometric contractions with their dominant leg in a prone position (hip joint angle: 140° , knee joint angle: 150° ; full extension: 180°). Maximal isometric torque (MIT), maximal rate of torque development (RTDmax) and time to 15, 30, 45, 75% MIT were measured. To determine the BFlh MHC isoform composition, muscle tissue samples were obtained with the micro-biopsy technique from the mid-section of the dominant leg and analysed with SDS-PAGE electrophoresis. Results BFlh MHC isoform distribution was $47.1 \pm 9.1\%$ MHC-I, $35.5 \pm 8.5\%$ MHC-IIA and $17.4 \pm 9.1\%$ MHC-IIX (mean \pm SD). No relationship was found between BFlh total MHC-II and MIT ($r = 0.03$, $P = 0.87$) or any measure of explosive strength ($-0.241 < r < 0.272$, $P > 0.139$). **Discussion** The BFlh muscle on average had a balanced, mixed MHC isoform distribution in healthy, recreationally active population, and MHC composition was not related to knee flexor maximal or explosive isometric strength. The results of the present study do not support the suggestion that BFlh muscle composition may contribute to the muscle's susceptibility to strain injuries. Also, BFlh MHC content does not seem to be a determining factor of the knee flexor performance in vivo. **References** 1. Woodley & Mercer (2004). *N Z J Physiother.* 32(1):22-8 2. Garrett et al. THE INFLUENCE OF CONTRACTION TYPE AND ACCELERATION ON EXPLOSIVE MUSCLE-FIBRE PERFORMANCE

Tillin, N.A.1, Pain, M.T.G.2, Folland, J.P.2

1: University of Roehampton (London, UK), 2: Loughborough University (Leicestershire, UK)

Introduction We recently showed that the ability to explosively increase joint torque from rest was greater in concentric than isometric or eccentric contractions (Tillin et al., 2012). It is unclear whether this ability is further delineated by contractile velocity. It is also unclear whether these joint-effects reflect muscle-fibre performance, or are due to muscle-tendon interactions. This study aimed to assess the influence of contraction type and acceleration on explosive muscle-fibre performance. **Methods** 17 males performed explosive voluntary knee extensions on an isovelocity dynamometer in four conditions: eccentric fast (ECCFAST) and slow (ECCSLOW), and concentric fast (CONFAST) and slow (CONSLOW). In all conditions the knee accelerated from a stationary angle of 89° (CON) or 156° (ECC), and participants were instructed to push as 'fast and hard' as possible at the start of this acceleration. In ECCSLOW and CONSLOW the knee accelerated at $500^\circ.s^{-2}$ for 450 ms, peaking at $225^\circ.s^{-1}$. In ECCFAST and CONFAST the knee accelerated at $2000^\circ.s^{-2}$ for 225 ms, peaking at $450^\circ.s^{-1}$. Measured torque was corrected for acceleration and gravity, and entered into a Hill-type muscle model with series-elastic-component (Pain & Forrester, 2009) to determine muscle-fibre forces, lengths, and velocities for each of the quadriceps muscles. Force at 25-ms intervals up to 150 ms from force onset was normalised to maximal voluntary force (MVf) at the same fibre-length and velocity (see below), averaged across the quadriceps muscles, and compared across the four conditions. Participants performed sustained maximal voluntary contractions at different isovelocities. Measured torques were converted to MVFs using the muscle model above, and entered into a 9-parameter model (Tillin et al., 2012) defining the fibre MVf-length-velocity relationship. **Results** The proportion of MVf achieved at each time point during CONFAST was on average $40\% > CONSLOW$, $153\% > ECCFAST$, and $229\% > ECCSLOW$ ($P < 0.01$). The proportion of MVf achieved at each time point in CONSLOW was on average $82\% > ECCFAST$ and $136\% > ECCSLOW$ ($P < 0.01$). The proportion of MVf achieved in ECCFAST and ECCSLOW was similar during the first 100 ms, but greater in ECCFAST after 125 ms ($P < 0.01$). The proportion of MVf achieved within 150 ms was 100% in CONFAST, $80 \pm 10\%$ in CONSLOW, $57 \pm 19\%$ in ECCFAST, and $40 \pm 13\%$ in ECCSLOW. **Discussion** The ability to utilise the available MVf in explosive contractions performed from rest is greatest in CONFAST, followed by CONSLOW, ECCFAST and ECCSLOW. These results are indicative of muscle-fibre behaviour and not due to muscle-tendon interactions. **References** Pain MTG, Forrester SE. (2009). *J Biomech*, 42, 1598-1603. EFFECTS OF STATIC STRETCHING ON FLEXIBILITY AND MUSCLE HARDNESS ASSESSED BY ULTRASOUND ELASTOGRAPHY

Inami, T.1, Ozawa, M.2, Mushika, Y.2, Mizuno, T.2,3, Shimizu, T.2, Lau, W.Y.1, Nosaka, K.1

1: Edith Cowan University (Australia), 2: Chukyo University (Japan), 3: JSPS

Introduction Muscle-tendon unit (MTU) stiffness is a key factor affecting flexibility, and is decreased after static stretching (SS) (1). Ultrasound real-time tissue elastography (RTE) is a relatively new technique to assess muscle stiffness or hardness, and has been used in recent studies in which SS effects were examined. For example, Akagi et al. (2) reported that gastrocnemius muscle hardness decreased 12% immediately after SS. However, no previous study has reported the time course of changes in muscle hardness after SS, and the relationship between muscle hardness and flexibility. These were investigated by the present study. **Methods** Twenty healthy men (19-25

y) received 5-min SS to their left plantar flexors using an isokinetic dynamometer generated 90% of maximal passive torque that each participant could tolerate [3]. MTU stiffness and maximal range of motion of the ankle joint (ROM) were assessed before, immediately, 15 and 30 min after SS. Ultrasound images with a reference material (acoustic coupler) were recorded from the probe placed at proximal 30% of gastrocnemius muscle at the same time points, by setting the ankle joint angle at 0° (neutral position) followed by 30° plantar-flexion (no passive torque). Based on the ratio between the acoustic coupler and the region of interest (18 mm x 30 mm) set in the muscle, strain ratio (SR) was calculated; showing the smaller the SR, the harder the muscle. Results MTU stiffness decreased immediately (16%) and 15 min (11%), and ROM increased immediately (28%), 15 min (17%) and 30 min (13%) after SS ($P < 0.01$). SR increased from the baseline (0°: 0.61 ± 0.12 , 30°: 1.27 ± 0.18) at immediately (0.71 ± 0.13 , 1.43 ± 0.18) and 15 min (0.68 ± 0.13 , 1.39 ± 0.2) after SS ($P < 0.01$). SR was not correlated with any of the flexibility parameters before SS, but the magnitude of the increase in SR from pre- to post-SS was correlated ($P < 0.01$) with the magnitude of the decrease in MTU stiffness ($r = -0.79$) and the increase in ROM ($r = 0.75$). Discussion The results showed that muscles became 9-16% softer after SS for 15 min, and the subjects who showed greater increases in SR after SS (the muscle became softer) had greater increases in flexibility. However, the time course and the magnitude of changes in SR did not appear to be associated with those in ROM. It seems that the increases in SR after SS correspond to the decreases in MTU stiffness, which is probably due to changes in intramuscular connective tissue properties [4]. References 1) Morse et al. SEX RELATED DIFFERENCES IN MOTOR UNIT RECRUITMENT AND DISCHARGE RATES; IMPLICATIONS FOR STEADINESS.

Larocque, K., Lizu, A., Neubauer, N., Harwood, B.J., Jakobi, J.M.

University of British Columbia Okanagan

The ability to maintain a steady force decreases with age and is less in women compared with men. This reduction in ability to produce steady forces is associated with absolute strength which is a consequence of motor unit activity. However, when strength is equal between young and old adults force steadiness is similar. No study has determined the effect of motor unit activity on force steadiness in men and women matched for strength. Six men (23 ± 2 y) and 6 women (22 ± 2 y) matched for strength (194 ± 25 N and 189 ± 16 N, respectively) participated. Voluntary activation, measured with twitch interpolation, was similar between men ($98 \pm 2\%$) and women ($99 \pm 2\%$). Motor unit activity was recorded via intramuscular fine wire electrodes in the short and long heads of the biceps brachii and surface EMG was recorded from the biceps brachii, brachioradialis and triceps brachii. Elbow flexor force steadiness, expressed as the coefficient of variation of force (CV), was evaluated over a 5-s ramp and 7.5-s steady state isometric elbow flexion contraction for target forces of 2.5, 5, 10, 15 and 25% of maximal voluntary force (MVC). Steadiness significantly improved as the target force level increased (2.5%MVC, $CV = 3.0 \pm 1.0\%$; 25%MVC, $CV = 0.6 \pm 0.2\%$); and did not differ between men and women. There were approximately 150 motor unit trains recorded across the five target force levels. Average motor unit recruitment thresholds were higher in women compared with men and this difference was greatest when the ramp was for a 25% MVC target ($p = 0.002$). Higher motor unit recruitment thresholds were accompanied by higher MU discharge rates during the ramp phase of the contractions. At 2.5% for the ramp conditions, discharge rates were ~0.5Hz higher in women, while at 25% they were ~2.5Hz higher. During the steady state contractions, motor unit discharge rates remained higher in women compared with men ($p < 0.05$). At 2.5% the motor unit discharge rates in women were ~14Hz, while in men they were 13Hz. At 25% MVC the discharge rates increased to 19Hz in women and 16Hz in men. Although preliminary, higher MU recruitment thresholds and MU discharge rates in women compared with men, during the ramp and steady state contractions, indicate that in addition to strength, MU activity may be a primary factor contributing to sex-related difference in force steadiness.

DEVELOPMENTAL DIFFERENCE BETWEEN HAND AND FOOT GRIP STRENGTHS FROM CHILDREN TO COLLEGE STUDENTS

Fukuoka, R., Morita, N.2, Kurihara, T.3, Otsuka, M.3, Okuda, T.2, Nakajima, T.4, Ishizawa, N.2, Nakamichi, R.2, Shide, S.2, Kambayashi, I.2, Shinkaiya, H.2, Yamauchi, J.5,6

Grad. Sch. Education, Hokkaido Univ. Education, 1: Hokkaido Univ. Education, 2: Ritsumeikan Univ., 3: Hokkaido Instit. Tech., 4: Tokyo Metropolitan Univ., 5: FfSS, JAPAN, 6

[Introduction] Foot grip strength which is exerted by toe flexor muscles is associated with physical performances (Goldmann JP, et al., 2013). On the other hand, hand grip strength is one of the simplest measures of muscle strength, and is considered to be a proper predictor of systemic muscle strength (Wind AE, et al., 2010). However, no studies were investigated the associations with both grip strengths. In addition, it has not been demonstrated whether both grip strengths show similar developmental trend from children to young adult. The purpose of this study was to investigate the growth curve of the grip strength of the toe flexors as compared with the hand grip. [Methods] Total 652 healthy males and females were volunteered to participate: 3rd grade (8 yrs.) to 2nd year junior high school (13 yrs., equal to 8th grade in US style school grade) children (boys, $N = 269$; girls, $N = 273$) and college-aged students (19 to 21 yrs.; male, $N = 71$; female, $N = 39$). The maximal isometric toe flexor strength (TFS) and hand grip strength (HGS) were measured using a toe flexor dynamometer (Takei Scientific Instruments Co., Ltd, #T.K.K.3362) and a hand dynamometer (Takei Scientific Instruments Co., Ltd, #T.K.K.5401), respectively. [Results] TFS was significantly correlated with HGS in both genders (male, $r = 0.822$, $p < 0.001$; female, $r = 0.669$, $p < 0.001$). Development curves of HGS showed linear increase from 3rd grade children to college-aged students in both genders. However, TFS development curves reached to a plateau of approximately 13 yrs. in both genders. HGS, but not TFS, increases were associated with height and body mass. [Conclusion] Our results demonstrated that the toe flexor strength has different growing process from the hand grip strength. Lithuania), 7; UON, (Nottingham, United Kingdom) Introduction Peak muscle power (PP) can be increased by strength training. However, it is not clear to what extent this increase is attributable to an increase in fibre cross sectional area (FCSA) and/or peak power per kilogram muscle (PP*kg⁻¹). To answer this question and to test the effect of different types of strength training, we compared contractile properties of single muscle fibres from bodybuilders (BB) with those from wrestlers (W) and controls (C). Method Fibres were collected from the vastus lateralis of 9 male BB (29.4±5.5y), 9 W (24.4±2.8y) and 11 C (24.0±3.5y). Contractile properties were determined using maximal isotonic and isometric contractions [1]. Fibre type was determined with SDS-PAGE. Data were analysed with a 2-way ANOVA (group × fibre type). In case of a significant main effect, a Bonferroni post-hoc test was performed. Results PP, PP*kg⁻¹, maximal shortening velocity (Vmax) and the rate of force redevelopment (kTR) were lower in type I than in type IIA, IIA/IIX, and IIX fibres (p<0.01). The FCSA of type I fibres was lower than IIA and IIA/IIX fibres (p<0.01). Vmax, curvature of the force velocity curve (a/P0) and kTR did not differ between groups. The FCSA of BB was larger than that of C (46%) and W (78%) (p<0.01). Fibres from C had a lower PP than those of BB (22%; p=0.04) and W (32%; p<0.01), irrespective of fibre type. PP*kg⁻¹ showed a trend over groups (p=0.08), where PP*kg⁻¹ of BB fibres was a lower than that of fibres from C (40%) and W (50%). Fibres of W had a higher specific tension (P0/CSA) than those of C (20%; p=0.02), and C fibres in turn had a higher P0/CSA than BB fibres (30%; p=0.01). Discussion PP is higher in BB and W than in C fibres, while FCSA was only moderately larger in W fibres. The increase of PP of W is therefore largely attributable to an increase in PP*kg⁻¹. This larger PP*kg⁻¹ in W is due to a larger P0/CSA in W, while it is lower in BB compared to C. Since cross-bridge kinetics seems unaffected, we hypothesize that this difference is due to a differences in myofibrillar density and/or the number of cycling cross-bridges. References 1. SKELTAL MUSCLES' CONTRACTILE PROPERTIES: ESTIMATED FROM TORQUE AND TENSIO MYOGRPHIC TWITCH RESPONSE

Koren, K.1, Šimunič, B.1, Rejc, E.2,3, Lazzer, S.2, Pišot, R.1

1: University of Primorska, Science and Research Centre (Slovenia), 2: University of Udine (Italy), 3: University of Louisville (USA)

Introduction Even force or torque twitch response (Hill, 1953; Close, 1972; Hamada et al., 2000) is the gold criterion for assessing the contractile properties of skeletal muscle, the tensiomyography (TMG) was confirmed as a reliable mechanomyographic-based method designed for assessing muscle composition (Šimunič et al., 2011) that is closely related to contractile properties. In this work we compared contractile properties estimated from torque and TMG twitch response in vivo setting. Methods Both twitch responses were measured in 19 healthy males (aged 46.1 ± 17.8 years). Vastus lateralis was contracted using maximal bipolar single electrical impulse. Torque response was measured distally while TMG response directly on the skin above the muscle belly. Knee angle was set at 60° flexion. The electrical stimulus procedure was constituted of a sequence of pulses, divided by 10 s break, from threshold to highest stimulation, in steps of 5 mA. From both twitch responses the same protocol for contractile parameters was used: peak twitch amplitude (Am), delay time (Td) between electrical impulse and 1% of achieved Am, contraction time (Tc) between 1% and 99% of achieved Am, sustain time (Ts) when response was higher than 50% Am, and half relaxation time (Tr) from 99% to 50% of Am. Results After normalizing Am, an exponential trend described relation between both response peaks, with higher increase in TMG at lower amplitude of electrical stimulation. Estimated from maximal twitch response, Td and Tc were shorter when calculating from TMG while Tr when calculated from torque. There was no inter-method correlation between Td and Tc, while positive inter-method correlation was found in Ts and Tr. Discussion We could conclude that there are few similarities in contractile properties estimated from both methods. It seems that TMG response is less affected from viscoelastic properties of muscle itself and surrounding tissue when measured in vivo. Future research should be focused on explaining mechanisms that affect differences between horizontal and longitudinal direction of twitch response and seek for valid applications of TMG. RELATIONSHIPS AMONG THE MUSCLE STRENGTH PROPERTIES AS ASSESSED THROUGH SST AND ACMC TESTS

Suzovic, D., Prebeg, G., Cuk, I., Stojiljkovic, S., Mitic, D., Jaric, S.

Faculty of Sport And Physical Education

Introduction Relationships among various properties of muscle strength observed from different muscles and strength tests still remain questionable (Bellumori et al., 2011; Bozic et al., 2012). The present study explored the relationships among the maximum forces (F) and the rates of force development (RFD) separately observed through the standard strength test (SST) and the test of alternating consecutive maximum contractions (ACMCs; Bozic et al., 2011,2012) applied on different muscles. Methods Physically active subjects of both genders (N=58; age 21-55 yr; BMI < 30) performed isometric SST and ACMC on the flexor and extensor muscles acting in the knee and elbow joint using a standard Kin-Com isokinetic dynamometer. Results Obtained results revealed that the corresponding F were higher in SST than ACMC, while it was opposite for RFD, particularly regarding the knee flexors. The self-selected ACMC frequency was similar across the genders, joints and muscles (1.15 ± 0.22 Hz; data averaged across the subjects and muscles). All relationships among various F and RFD values were positive and significant (median r = 0.56; range 0.37 to 0.95; all p < 0.01). However, the most important finding was that the principle component analysis neither discerned between the SST and ACMC data nor between their F and RFD values, but only between different muscles. Discussion The findings suggest that recording both F and RFD in routine strength testing procedures could be redundant since they could assess the same strength property of the tested muscle (Bellumori et al., 2011; Bozic et al., 2012), while ACMC may be a feasible alternative to SST since it assesses the same strength properties from two antagonist muscles through a single trial through relatively low and transient forces. However, the data also question the generalization of strength properties of single muscle group to the entire muscular system that has been routinely applied in literature. Acknowledgments This study was supported by grants from National Institutes of Health (R21AR06065) and Serbian Research Council (#175037). References Bellumori M, Jaric S, Knight CA. ANATOMICAL AND NEUROMUSCULAR MECHANISMS INFLUENCING INTER-INDIVIDUAL VARIABILITY IN MAXIMUM KNEE EXTENSOR TORQUE

Trezise, J., Collier, N., Blazevich, A.J.

Edith Cowan University

Introduction Although muscle strength is a key determinant of functional performance, the relative importance of the anatomical and neuromuscular factors underpinning strength expression is not yet clear. This lack of understanding ensures that individually-optimised exercise training plans and targeted interventions cannot be developed. This study examined the relative influence of anatomical and neuromuscular factors on maximal isometric, concentric and eccentric knee extensor torque. Normative data were also established to aid the identification of potential factors to target (i.e. weaknesses) in individuals. **Methods** Muscle cross-sectional area (CSA), fascicle length and angle from the proximal, middle and distal regions of the four quadriceps components; agonist (EMG:Mwave) and antagonist (EMG amplitude) muscle activation, percent voluntary activation (%VA; interpolated twitch technique); maximum isometric and slow speed concentric and eccentric (60°/s), unpotentiated and potentiated twitch torques; and patella tendon moment arm distance were measured in 54 healthy men (athletes and untrained; aged 18-40 y). Person's correlation coefficient was used to assess between variable relationships. Linear regression models were used to quantify the variance explained by combinations of predictor variables using an information-theoretic approach for model selection based on Akaike's Information Criterion (AICc). **Results** The best-fit linear regression models strongly predicted maximum torque in each contraction mode ($R^2 = 0.70, 0.64$ and 0.62 and AICc weight = $0.51, 0.19$ and 0.34 for isometric, concentric and eccentric torque, respectively). Proximal CSA was more strongly correlated with torque than mid-muscle CSA ($r = 0.74$ and 0.67 , respectively) and was included in all best-fit models along with proximal or mid-muscle VL fascicle angle. EMG:M and %VA were included in the isometric and eccentric, and moment arm distance in the concentric, best-fit models. **Discussion** The best-fit models explain up to 70% of the variance in maximal torque. While muscle size, activation and fascicle angle appeared to have the greatest influence on torque production, proximal CSA was more strongly associated with torque production than mid-muscle CSA, and may thus be a more important measurement. Fascicle angle and antagonist activation were consistently included in the best-fit models for all contraction modes, even though they were only weakly correlated with maximum torque in isolation. These data emphasise the need to examine interactions between variables when assessing their influence on maximum joint torque, rather than assessing correlations in isolation. The models, and normative data developed, can be used to aid the design of individualised training programs.

TENSIOMYOGRAPHIC ASSESSMENT OF SKELETAL MUSCLE CONTRACTION TIME AND FIBRE TYPE COMPOSITION IN 9 TO 14 YEAR OLD CHILDREN

Šimunič, B.1, Završnik, J.2, Koren, K.1, Degens, H.3, Volmut, T.1, Pišot, R.1

University of Primorska

Introduction The fibre type composition of skeletal muscle has a strong impact on the contractile properties of the muscle. The fibre type composition is traditionally assessed on muscle biopsies. This is, however, an invasive procedure, which limits its use in particular in children. Previously we have a close correlation between the contraction time (T_c) determined with non-invasive tensiomyography (TMG) and the proportion of myosin heavy chain 1 (MHC-I) in the vastus lateralis of adults (Šimunič et al., 2011). **Methods** Hundred and seven children (53 boys) participated throughout a 5-year longitudinal study. Initial age of these 107 children was 9.1 ± 0.5 years. Six follow-up measurements took place at approximately yearly intervals. The children were recruited from twelve randomly selected primary schools in three of the most populated regions of Slovenia. All children and their parents were fully informed about the procedures and parents gave their written consent for their children to participate in the study. In every child maximal TMG twitch responses to determine T_c were obtained from four muscles: vastus lateralis (VL), biceps femoris (BF), biceps brachii (BB), and erector spinae (ES). **Results** All children had a normal growth pattern. T_c was lowest in the ES, with that of the VL and BB in between and the highest in the BF. A three-way ANOVA revealed significant age ($P < .01$), muscle ($P < .01$), muscle x gender ($P < .01$), age x muscle ($P < .01$), and significant age x muscle x gender effects ($P < .01$) on T_c . Such interactions are difficult to interpret and therefore we analysed each muscle separately. After calculating MHC-I from T_c as described previously (Šimunič et al., 2011) for the VL muscle we found a significant age ($P < 0.01$) and age x gender interaction on the MHC-I ($P = 0.04$). Post-hoc analyses revealed a 11% MHC-I decrease between the age of 9.1 and 9.9 years, and a higher proportion of MHC-I in boys than girls after the age of 12 years. **Discussion** There is only one other longitudinal study that determined changes in the muscle VL fibre type composition between 16 and 27 years of age in muscle biopsies (Glenmark et al., 1992). Our estimated MHC-I data are in agreement with Glenmark et al. (1992) who found that at age of 16 years boys have a higher proportion of MHC-I than girls. However, at the age of 27 years they found the opposite. Our study is unique in that it is 1) the first large sample 5-year longitudinal study 2) that studied young children and 3) analysed T_c – a non-invasive indicator of muscle fibre type composition. **References** Glenmark, B., Hedberg, G., & Jansson, E. (1992). *Acta Physiol Scand*, 146(2), 251-259. Šimunič, B., Degens, H., Rittweger, J., Narici, M., Mekjavić, I. B., & Pišot, R. (2011). *Med Sci Sports Exer*, 43(9), 1619-1625.

CAN THE ACSM'S CLASSIFICATION FOR EXERCISE INTENSITIES BE APPLIED IN HEMATOLOGICAL CANCER PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION?

Kuehl, R., Scharhag Rosenberger, F., Schommer, K., Ulrich, C.M., Wiskemann, J.

National Center for Tumor Diseases (NCT), Heidelberg, Germany

Introduction: The ACSM's guidelines for endurance training prescription were developed for healthy adults, but are also recommended for cancer patients. However, it has yet to be investigated if intensive anti-cancer therapy impacts the relationship between oxygen uptake reserve (VO2R), heart rate reserve (HRR), maximal oxygen uptake (VO2max), and maximal heart rate (HRmax). Therefore, the validity

of the ACSM classification of exercise intensities was examined in hematological cancer patients prior to and post allogeneic stem cell transplantation (allo-HSCT). Methods: Data from an ongoing randomized controlled exercise intervention trial (PETRA-Study, www.clinicaltrials.gov: NCT01374399) were analyzed at two measurement time points. Prior to allo-HSCT $n=106$ patients (age 52 ± 11 yrs, 73 male/33 female, BMI 26 ± 4 kg/m²) and 180 days after $n=49$ patients (age 53 ± 11 yrs, 36m/13f, BMI 25 ± 4 kg/m², 55% exercise and 45% control group) were included. Patients performed maximal stepwise incremental cycling tests with gas exchange measurement. Individual linear regression equations between %VO₂R (reference) and %HRR, %VO₂max, and %HRmax were calculated at the end of each exercise stage. The one sample t-test was used to compare observed data with ACSM's mean value data. Regression models were applied for further analysis. Results: Prior to allo-HSCT, there were significant differences regarding %HRR, %HRmax, and %VO₂max between patients and ACSM's guidelines. %HRR observed values were significantly lower, and %HRR and %VO₂max values significantly higher ($p<0.05$). However, 180 days after allo-HSCT there was no difference to ACSM's values for %HRR. %HRmax and %VO₂max still differed significantly ($p<0.05$). Beta-blocker intake had no effect on calculated percentages, and 180 days after allo-HSCT there was no influence of group assignment on calculated percentages. Discussion: %HRR, %HRmax and %VO₂max may not be appropriate parameters for training prescription during intensive anti-cancer treatment according to ACSM. However, 180 days after allo-HSCT the ACSM recommendations concerning %HRR can be used. Further research is required to develop adequate methods of intensity prescription in hematological cancer patients.

CORRELATION BETWEEN LEISURE-TIME EXERCISE AND QUALITY OF LIFE IN BREAST CANCER SURVIVORS

Casla, S., López Tarruella, S., Jerez, Y., Sampedro, J., Barakat, R.

INEF (Universidad Politécnica de Madrid)

Background Although physical activity has demonstrated to increase survival and quality of life (QoL) in breast cancer survivors (BCS), an important reduction in leisure-time exercise levels (LTEL) after diagnosis exist. Anti-cancer treatments side effects are related to an important reduction in BCS' QoL. The aim of this study was to investigate if a supervised group-based exercise program improves QoL, increasing LTEL in BCS. Methods This project was designed as a randomized controlled trial with an intervention and a control group in early stage breast cancer patients, who recently finished the anti-cancer treatment (from 1 month to 3 years). The intervention consisted of 24 classes of aerobic and resistance exercise focused on increasing physical and psychological parameters related to QoL. Intensity of intervention increased gradually. Aerobic exercises intensity was controlled by a heart rate monitor and resistance exercises intensity was controlled by repetitions of each exercise. QoL, LTEL, fatigue related cancer (FRC), depression, upper-body limbs (ULMS) and legs maximal strength (LMS) and physical capacity, were assessed at baseline and after intervention. U-Mann Withney and Spearman correlation and two factors ANOVA test were used to compare LTEL depending on QoL changes and intervention or control group. Results Partial results are set forth below. Thirty-two women with 48.97 ± 7.4 years completed this study. ANOVA analysis showed a significant improvement in LTEL ($F=6.53$; $p=0.017$) and almost in QoL ($F=0.142$; $p=0.71$) comparing groups. However, who increase QoL, presented a significant rise of LTEL comparing intervention and control group ($p=0.009$; $CI95\% 5.812-36.855$). A significant correlation was observed between changes produced in QoL and LTEL ($r=0.37$; $p=0.048$). In psychological variables, significant reduction between groups was observed in FRC ($z=-2.16$; $p=0.031$) and in depression score ($z=-2.12$; $p=0.034$). In physical variables a significant improves between groups were found in ULMS ($z=-3.61$; $p=0.001$) and LMS ($z=-2.07$; $p=0.005$) but not in physical capacity ($z=-1.29$; $p=0.20$). Discussion These results suggest that BCS who improve LTEL get to increase their QoL, presenting a correlation between QoL changes and LTEL. This integrated intervention may produce changes in life style of BCS using the teachable moment to improve their QoL. Previous reviews (Mishra et al., 2012) have shown exercise improves QoL but, in our knowledge, no studies had correlated this two parameters. These partial data have to be reinforced by final data of the study due to this small sample is not conclusive. Reference Mishra, S. I., Scherer, R. W., Geigle, P. M., Berlanstein, D. R., Topaloglu, O., Gotay, C. C., & Snyder, C. (2012). Cochrane Database Syst Rev, 8.

ATTITUDES AND PERCEPTIONS ABOUT PHYSICAL ACTIVITY IN WOMEN SURVIVORS OF BREAST CANCER

Cruz, L., Tolentino, G.1, Battaglini, C.2, De Sousa, A.F.M.1, Damasceno, A.K.M.1, Matos, M.S.1, Oliveira, R.J.1

Universidade de Brasília (Brasil), University of North Carolina (USA)

Introduction The physical exercise (PE) is an excellent strategy to optimize the quality of life of cancer clients. However, a sedentary lifestyle is a constant among this population. In this sense, the study aimed to assess the beliefs and attitudes related to the practice of physical activity in women surviving breast cancer (BC) Methods The study sample ($n = 22$) were in follow-up phase of the BC, with no metastasis, comorbidities or severe sequelae of treatment and went under cardiopulmonary exercise testing. The sample was divided into 2 groups: a group of women survivors of breast cancer (BC $n = 11$) and women with cancer and controlled hypertension (BCHAS $n = 11$). The International Physical Activity Questionnaire-IPAQ (short version) was used and a survey of knowledge and attitudes towards physical activity was designed for this study. Results According to the IPAQ Questionnaire, about 36 % of the BC group and 63 % of BCHAS group were inactive or insufficiently active. Most women in the BC group (90%) never received indication for physical exercise, and, yet, 40% of these received some contraindications to practice exercises. When there was a contraindication, this was done by medical (45.5%) and physiotherapists (18.2%). In BCHAS group this percentage was lower for the indication (66.7%), probably due to comorbidity, and 40 % of these were contraindicated by health professionals, of what 36.4% were physicians, 27.3% physiotherapists and 18.2% nurses. In a general way, 90.9 % of women would like to do some exercise, and the choice of exercise would be walking (40.9%), followed by hydrogymnastics (1.8%), gymnastics (2.7%), dance (18.2%) and resistance training (4.5%). In addition, a volunteer said that the practice of physical exercise could negatively affect her health. Discussion The volunteers in the study, although not having any reason to restriction of participation in physical exercises and still indicate desire to accomplish them, had contradictory beliefs and received no indication of physical exercise for health professionals involved in their treatment. And the low-impact activities that did not involve overhead on the upper limbs would be preferred. There is evidence that cancer survivors 'prefer' to receive counseling on PE at some point during their experience with the disease, revealing the need for specialized professional accompaniment in motivating and encouraging the practice of PE (Jones and Courneya, 2002). References Jones, L. W. and K. S. Courneya (2002) Exercise counseling and programming preferences of cancer survivors. Cancer Pract 10, 208-15.

NEUROMUSCULAR DYSFUNCTIONS IN PATIENTS WITH CHRONIC GROIN PAIN – SYSTEMATIC REVIEW

Kloskowska, P., Barton, C., Small, C., Morrissey, D.1

Queen Mary University of London

AIM: Long-standing adductor related groin pain (LSARGP) is a common entity among rotation sports disciplines such as football, rugby and hockey. Previous reviews have shown that structured rehabilitation has proven efficacy for these patients but there is little detail on which exercise approaches are most beneficial. We aimed to define the associated muscular activation changes in symptomatic patients needed to guide optimal exercise prescription in order to guide development of more specific rehabilitation approaches. **METHODS:** Four databases were searched for case control, prospective and retrospective studies investigating muscle features in groin pain patients. 5669 returns were screened for inclusion and exclusion criteria with reference lists and citing articles being examined. Study quality was evaluated by two independent reviewers using a modified Downs and Black quality index. The level of evidence was established using the Van Tulder criteria. Meta-analysis was performed where possible following data requests to corresponding authors. **RESULTS:** Eight studies were identified, with 7 ranked high quality and 1 ranked moderate quality (mean=12.125, SD=1.25) in modified Downs&Black Quality Index (maximum score 16). There is conflicting evidence suggesting decreased adductor muscle strength in symptomatic participants when measured with a bilateral squeeze test. No differences were found adductor muscle flexibility. Marked decreases in transversus abdominis muscle activation onset and resting thickness were found in 2 high quality studies, which constitutes a limited evidence level. There was also limited evidence indicating decreased gluteus medius to adductor longus muscle activation ratio. **CONCLUSION:** Muscle strength and activation are altered in people with LSARGP compared to controls, with these alterations especially being evident in the coronal plane and affecting both the adductors and abductors of the hip, and also the abdominal musculature. Altered adductor muscle range of movement is not a therapeutic target. This review has shown that there are characteristic patterns of altered muscle function in people with LSARGP, which will be of relevance to clinicians planning treatment for such patients.

STANCE STABILITY CONTROL IN GIRLS WITH IDIOPATHIC SCOLIOSIS

Machač, S.1, Duspivová, J.1, Kasal, P.2, Bočková, A.1, Štěpánek, L.2, Fiala, P.2

1: ISL (Prague, Czech Republic) 2: CTU FBME (Prague, Czech Republic)

Introduction: Idiopathic scoliosis (IS) is a three-dimensional spinal deformity with high prevalence especially in girls (ratio 8:1). Its pathogenesis and postural consequences remain poorly understood, which limits the use of really specific therapeutic interventions. (de Sèze, Cugy, 2012) This study is supposed to contribute to the discussion by new static posturography findings. **Methods:** Nine girls with severe idiopathic scoliosis (age 14.7 ± 2.3 years, Cobb angle $21.6 \pm 5.8^\circ$) and 32 healthy controls (15.4 ± 2.2 years) were included. A repeated measures design by means of tetra-ataxiometry was performed. The test was recorded two times for 30s in 8 positions of stance challenging to a varying extent for the visual, vestibular, proprioceptive and central nervous system. (Kohen-Raz, 1991) Two main kinds of variables were monitored – spectral power of 8 frequency ranges of probands' sway (within 0-5 Hz) and weight distribution on 4 independent footplates, i.e. 2 for toe-part and 2 for heels. Multiple Wilcoxon rank-sum tests were used also for comparison of absolute differences of feet load (i) on left and right side and (ii) diagonally left tiptoe-right heel (and vice versa). Cronbach's alpha as test-retest reliability was calculated. **Results:** The highest frequency power difference was found within 0.25-0.5 Hz especially in position with neck bent front (higher up to +64%). All the component frequency powers are significantly higher than in controls, $p < 0.008$. In comparison of weight distribution a strong level of significance was not achieved, $p > 0.10$. Cronbach's alpha for the two times-measured data was estimated to be 0.74 in controls and 0.88 in cases, both $p < 0.05$. **Discussion:** Higher oscillations in all component frequencies indicated low stability in girls with IS. Higher sway within 0.25-0.5 Hz could be a reflection of a peripheral vestibular dysfunction (Taguchi, 1978), which was in contradiction with relatively good result in the position with limited feet proprioception and close eyes. Therefore a dysfunction at a brain-stem level and/or changed sensory processing could be the reason. The load seemed to be similarly side-to-side and diagonally distributed on both feet like in controls during all stressful positions – nevertheless, it is just a quantitative measure which does not deal with the laterality within one sole and quality of the foothold. **Conclusion:** This study supports the findings that IS is associated with changed function at CNS level and indicates that not only biomechanical, but also specific neurophysiological principles should be applied in its therapy. **References:** de Sèze M, Cugy E (2012). *Ann Phys Rehabil Med*, 55(2), 128-38 Kohen-Raz R (1991). *Percept Mot Skills*, 73(2), 635-56 Taguchi K (1978). *Agessologie*, 19-B, 69-70 **Contact:** Stanislav Macháč MSc, Institut sportovního lékařství a.s, Ověnecká 380/9, 170 00, Praha 7, Czech Republic; e-mail: machac.s@seznam.cz

MOTOR SKILL ABILITIES, BACK POSTURE AND BACK PAIN IN ADOLESCENT

Imhof, K., Zahner, L., Moser, F., Faude, O.

University of Basel

Introduction The prevalence of low back pain in adolescents is estimated to be more than 50% (Skofter, 2007). Physical activity is often reported as a risk factor of back pain (Heneweer et al., 2009). This study aimed at analysing motor skill abilities, back posture and back pain in adolescent. **Methods** 113 adolescents (51 girls) aged 12-16 years (age 13.9 (SD 0.9), weight 53.3kg (SD 9.8), height 163.3cm (SD 8.1)) were examined. Body mass index (BMI), percent body fat and motor skill abilities were assessed. Motor skill tests included jumping sideways (number of jumps in a side-to-side jumping test), balancing backwards (number of steps on a balance beam), 20m sprint (time in seconds) and a shuttle run (number of paliers; 1palier=1minute). The Matthiass arm-raising test, a clinical test to detect posture changes, and measures of spinal mobility were applied. The prevalence of back pain was assessed with a questionnaire. The reference ranges of back posture changes and the range of motion of the spine were obtained by calculating the means of the sample stratified by gender and taking one standard deviation either side of the mean. We compared the groups above and below one SD of the mean with the group in between as reference group. **Results** In boys we found a lower performance in jumping sideways ($p=0.04$, $\Delta=17\%$) and in sprinting ($p=0.001$, $\Delta=16\%$) in the group with increased as compared normal inclination of the pelvis and a lower performance in balancing backwards ($p=0.01$, $\Delta=31\%$) in the group with decreased inclination of the pelvis. The group with compensatory movements (decreased inclination of the back in the Matthiass test) performed worse in jumping sideways (both gender: $p=0.03$, $\Delta=11\%$). While in girls the BMI was higher ($p=0.03$; $\Delta=21\%$), the boys showed a lower performance in balancing backwards ($p=0.03$, $\Delta=23\%$) and in sprinting ($p=0.01$, $\Delta=13\%$) in the group with a lower range of motion of the lumbar spine. The groups with a lower range of motion in inclination of the whole spine showed a lower performance in balancing backwards in both gender (girls $p=0.03$, $\Delta=21\%$; boys $p=0.02$, $\Delta=24\%$) and in jumping sideways in boys ($p=0.006$, $\Delta=16\%$). There were no significant group differences concerning the frequency of back pain ($p>0.2$). **Discussion** Our results suggest that adolescents with greater or lower mobility of the spine showed worse performance in motor skill

abilities as compared to an average reference group. However, spine mobility was not related to back pain. Thus, we conclude that improved motor skill abilities may have a preventive influence on spine posture and may contribute to improved back health during adolescence. MEASURED PEAK HEART RATE VERSUS TWO COMMON PREDICTION FORMULAS – A COMPARISON IN CANCER PATIENTS.

Hetlelid, K.J., Berntsen, S., Igelström, H., Nordin, K.

University of Agder

Introduction Peak heart rate (HRpeak) is the highest heart rate measured during an exercise test and is broadly used when prescribing exercise intensity. However, when prescribing exercise intensity for older individuals or patient groups, the use of a prediction formula based on the patients age is much more common. The aim of the present study was to compare peak heart rate measurements during a graded maximal treadmill test to exhaustion and two of the most common prediction formulas, amongst cancer patients undergoing treatment. **Methods** Twenty-two patients diagnosed with either breast or prostate cancer (42-79 years old, male/female: 5/17) participated in this study. Heart rate (HR) (Polar s610, Polar Electro KY, Kempele, Finland) was recorded and respiratory exchange ratio (RER) and oxygen uptake (VO2) measured during a graded walk/run test to exhaustion (Vmax, Carefusion, San Diego, USA). The subjects started walking with a speed of 4 km/h with an inclination of 3%. The inclination increased with 1% each minute until reaching 12%, from which the speed increased 1 km/h per minute until exhaustion. The test ended when the participants could no longer keep up with the treadmill or they had reached his or her maximal subjective effort, while reaching a RER ≥ 1.0 . **Results** Paired sample t-test showed a significant difference between the measured HRpeak and predicted maximal heart rate (HRmax) from using the 220-age formula (8.3 (0.02, 16.62) mean and 95% confidence intervals, beats/min), ($p=0.049$). There was no significant difference between the measured HRpeak and the predicted HRmax using 208-0.7age formula (2.6 (-5.61, 10.88), ($p=0.51$)). RER measured at termination of test was 1.11 (1.07, 1.15). **Discussion** The 220-age formula was significantly different from measured HRpeak and is not a reliable estimate of maximal heart rate. Although the formula 208-0.7age did not significantly differ from the measured HRpeak and the mean difference was small when looking at group data, the large individual variations show the importance of measuring HRpeak. Prescribing exercise intensity based on predicted maximal heart rate should be avoided, even in cancer patients undergoing treatment.

COMPARISON OF WALKING PROGRAM ON LAND AND IN WATER AND SIMPLE ADVICE IN PATIENT WITH LOW BACK PAIN

Asadi, K., Sokhanguee, Y., Esbati, N., Zameni, L., Abaszade, H.

1;Islamic Azad University, Sari branch, (Sari,Iran) 2;Social welfare and rehabilitation university(Tehran,Iran) 3; ministry of education, Babolsar (Babolsar,Iran)

Introduction Low back pain (LBP) is a common condition which poses significant problems to health service. The life-time incidence of LBP is 80% (Haugard et al.,2007). Chronic LBP is a major health problem with enormous economic and social costs (Maher et al., 2004). The aim of this study was to compare the effect of a 6-week walking program with simple advice on land and in water on pain and spinal flexibility in subjects with chronic low-back pain (CLBP). **Method** This was a randomized controlled study. 32 subjects (females) with CLBP, who consented, were randomly assigned to receive walking program on land (17 females) or in water (15 females) if they satisfied the selection criteria. The intervention consisted of a 6-week walking program on land and in water, 3 session a week, per session about 1 hour, plus advice session with a physiotherapist based on the content of the Back Book. Both of the groups were matched for time on intervention and attention. **Outcome measures:** Pain-related outcomes were assessed by the Visual Analog Scale (VAS) and by modified Schober test, which was assessed using strip meter at pre and post intervention. Data were analyzed using independent t-test. **Results** There was a significant reduction in VAS scores in the walking program in water group compared to the walking program on land group ($p\geq 0.05$). Spinal flexibility measures improved significantly in both groups but there was not significant different between two group ($p\geq 0.05$). **Conclusions** Although LBP is a wide-spread and disabling condition, there is a lack of evidence-based medicine with respect to its treatment and rehabilitation. There is a general consensus in the literature supporting the need for active exercise therapy in the treatment of LBP. Unfortunately, there is little agreement on which exercise regimens that are most effective (Lewis et al., 2008). This research findings shows that, 6-week walking program in water reduced pain-related disability in patients with CLBP better than a walking program on land; however, no such significant difference emerged for spine flexibility between walking program in water and on land. **References** Haugard A, Persson A. MO-PM44 TT Strength & Power

EXPONENTIAL FUNCTION MODELING OF ALPINE SKIER EXPLOSIVE POWER ENDURANCE TESTS

Hoshino, H., Tsunoda, K., Sasaki, T., Maune, J.F., Takeda, H.

Hokusei gakuen University

NTRODUCTION:Alpine skiers utilize various fitness factors: anaerobic and aerobic capacity, isometric leg extension, core strength, reactive strength, balance ability, agility other than explosive strength power, and speed endurance capability (Raschner, C 2013). In this study we utilized an explosive power endurance test which was fit with an exponential function to generate a time constant which is useful for predicting performance. **METHOD:**The subjects were 15 male alpine skiers. Each subject performed squat jumps (i.e., from the squat

position to the fully extended jump position) every two seconds over a two minute span with a barbell on their shoulder with 0, 20, 40, and 60% body weight randomly selected for each trial; a force plate (Ex-jumper. DKH Co. Ltd. JAPAN) was used to measure the force of each jump, while jump height was calculated based on jump or flight time. RESULTS: As expected the max jump height varied significantly from the average jump height. For this reason we did more stringent analysis of the jump height time courses. An exponential function of high correlation ($p < 0.05$) was obtained with jump height as a function of time. There were significant variations of the time constants among the 15 subjects for all weight loads. Thus, the derived time constants could provide a useful classification value. DISCUSSION: The time constant based model equation had high correlation for each load value ($r > 0.9$ for all). Previous studies have relied on average jump heights which did not result in an efficacious model and moreover are problematic just to measure. Max jump height is easy to accurately measure and combined with the exponential time constant produces a very robust model. CONCLUSION: The most original findings are that max jump height, not average height, and exponential time constant functions are quite useful for estimating explosive power endurance capacity. The current model is still being adjusted in hope of obtaining even higher fidelity as are the experimental conditions. REFERENCES: Raschner, C.; L. COMPARATIVE JUMPING PERFORMANCE PROFILE IN PROFESSIONAL TEAM SPORT ATHLETES

Peña, J.I, Moreno, D.2, Buscá, B.3, Coma, J.I, Cook, M.4

1: University of Vic (Barcelona, Spain), 2: Club Joventut de Badalona (Barcelona, Spain), 3: Ramon Llull University (Barcelona, Spain), 4: University of Alberta (Edmonton, Canada)

Introduction Jump height is a widely studied variable among team sports due to its strong relationship with physical performance. Jump expressions differ in every discipline and they are often focus of revision by the experts. Our aim is to compare three team sports presenting several goal and overall jumping load differences, but with similar specific demands. Methods Forty-six male first division professional Spanish players (age 26.1 ± 4.8 years; height 194.0 ± 7.3 cm; body mass 91.9 ± 9.0 kg) from three different sports took part in our study (basketball, $n=18$; handball, $n=15$; volleyball, $n=13$). Vertical jumps were measured using a contact mat, consisting on a switch mat connected to a digital timer (accuracy: ± 0.001 s). The assessed jumps were the squat jump (SJ), countermovement jump (CMJ) and countermovement jump with arm swing (CMJas). All subjects performed two jumps of each type, with a 10 seconds resting period between them. Results Volleyball players showed better average performances in all the assessed jumps (SJ: 42.0 ± 6.0 ; CMJ: 46.8 ± 4.1 ; CMJas: 58.5 ± 4.5) than basketball players (SJ: 40.2 ± 6.2 ; CMJ: 42.1 ± 6.0 ; CMJas: 50.1 ± 7.4) and handball players (SJ: 40.8 ± 1.7 ; CMJ: 41.9 ± 3.2 ; CMJas: 48.7 ± 4.3). Nevertheless, volleyball players only showed statistically significant better performances in the CMJ ($p < 0.05$) and CMJas jumps ($p < 0.001$). We found no significant differences between basketball and handball players' performances in any type of jump. Discussion Differences between jump performances among the athletes of the three sports have been found. Volleyball players displayed significant higher levels than basketball and handball players in CMJ and CMJas jumps, while handball showed higher non-significant performances in SJ when compared to basketball. These levels appear to be a consequence of the great similarities of the tested jumps with the movements of volleyball blocking actions and the high demand that volleyball has for this action, with the largest number of jumps per player and match displayed (Fontani et al., 2000) when compared to basketball and handball (Póvoas et al., 2012). Squat jump performances were similar in the three sports, due to common requirements of muscular strength and power in all disciplines (Fleck, 1983). References 1. Fleck, S.J. (1983). EFFECT OF CONDITIONING HOPS ON JUMP AND SPRINT PERFORMANCE IN INTERNATIONAL TOP ATHLETES

Kümmel, J.I, Bergmann, J.I, Prieske, O.2, Granacher, U.2, Gruber, M.I

1: SPL (University of Konstanz, Germany), 2: HSF (University of Potsdam, Germany)

Background: It has been shown that a conditioning activity consisting of repetitive hops has the potential to induce postactivation potentiation in triceps surae muscles which was correlated to higher rebound jump height in subsequent drop jumps (DJ) in recreationally active individuals (Bergmann et al., 2013). In the present study, we tested the hypothesis that repetitive conditioning hops affect reactive jump and sprint performance in international top athletes. Methods: Five international top athletes (3m/2w) participated in this study. All subjects were highly trained in stretch-shortening cycle conditioning activities. Athletes' jumping and sprint performances were assessed under two conditions in a counterbalanced randomized order. The control condition (CON) comprised 8 DJs and three trials of 30 m sprints. In the intervention condition (HOP), participants executed the same set of tests with an additional 10 repetitive conditioning hops 10 s prior to each single DJ and sprint trial. During the DJs, ground reaction forces (GRF) were recorded using a force plate in order to determine athletes' DJ height, maximal power, and contact time (CT). During sprints, step length and CT over the first 10 m, as well as total sprint time were recorded using an opto-electric measurement system. Results: Compared to the CON condition, the HOP condition resulted in a mean increase in DJ height of 11% (range: 2-7 cm) and an 11% (range: -3-13 Watt/kg) increase in maximal power. CT and GRF did not show consistent changes from CON to HOP (range: CT -17-25 ms; GRF -5-5 N/kg). Total sprint time, step length and CT during the first 10 m of the sprints varied by less than 1% and did not change consistently among our five subjects. Discussion: The present study revealed that repetitive hops used as a conditioning activity can induce gains in DJ performance in highly trained athletes. These results are in line with previous findings regarding recreationally active subjects (Bergmann et al., 2013). However, we could not detect any transfer effects to sprint performance which may indicate that the performance gains are highly task-specific regarding the type of conditioning activity. The small sample size is a limitation of this study which is why these findings have to be interpreted with care. Nevertheless, since we were able to assess elite athletes, the present results appear to be of importance for coaches, athletes and researchers. References: Bergmann J, Kramer A, Gruber M (2013). OPTIMAL FORCE-VELOCITY PROFILES IN ELITE ATHLETES

Giroux, C.1,2, Guilhem, G.1, Chollet, D.2, Rabita, G.1

1.French National Institute of Sport (INSEP), Research Department, Laboratory SEP, Paris, France. 2.CETAPS UPRES EA 3832, Faculty of Sports Sciences, University of Rouen, France

Introduction Velocity, strength and power are determinant factors of performance in many activities. Protocols using loaded squat jump have been designed to evaluate those capabilities and calibrate precisely training programs. Estimating the optimal ratio between velocity and force production is also a main concern in explosive oriented tasks (Vandewalle et al. 1987). Recent methods have been proposed to determine the optimal force-velocity profile in ballistic movements (Samozino et al. 2008, 2012). Thus, the purpose of this study was to compare the actual force-velocity relationship of elite athletes to their optimal force-velocity profile. **Methods** A cohort of 100 cycling, fencing, rowing, taekwondo and track and field elite athletes (48 females, 52 males), including Olympic medalists, participated in this study. Lower limb force-velocity profiles were evaluated for each athlete. They performed squat jumps with 0, 10, 20 30, 40, 50 and 60% of the maximal external load they were able to lift. Theoretical, maximal power (P_{max}), force (F_{max}) and velocity (V_{max}) were determined from the individual force-velocity relationships. Optimal profiles were assessed by calculating the optimal force (F_{opt}) and optimal velocity (V_{opt}). Student paired t-tests were performed to compare V_{max} and F_{max} with V_{opt} and F_{opt} , respectively. One-way ANOVAs were performed to compare the difference between measured and optimal profile in the considered activities. **Results** We observed significant differences between V_{max} , V_{opt} and F_{max} , F_{opt} ($p < 0.05$). ANOVA revealed an effect of activity on the difference between maximal and optimal force ($p < 0.01$) and velocity values ($p < 0.01$). Fencers, track and field and taekwondo athletes presented more optimized profile than rowers and cyclists ($p < 0.05$). **Discussion** As all the measured profiles were different from the optimal ones, it seems that even in elite athletes muscular profiles are not optimized. These results must be nuanced by the fact that squat jump might not be the more suitable method to evaluate the specific demand of each activity. Indeed specific protocols (e.g., cycling tests for cyclists) could have shown different findings. Moreover, the level of optimization of the profile depends on the activity, suggesting that further investigations are needed to determine if the optimization of force-velocity profile could effectively enhance performance in explosive activities. **References** Samozino P, Rejc E, Di Prampero PE, Belli A, Morin JB (2012). *Med Sci Sports Exerc* 44 (2):313-22. EFFECT OF INTERMITTENT JUDO TEST ON UPPER LIMBS STRENGTH PERFORMANCE

Monteiro, L.1, Massuça, L.1, García García, J.M.2, Calvo Rico, B.2, Carratalá, V.3, Proença, J.1

Universidade Lusófona de Humanidades e Tecnologias, Lisbon

Introduction Judo is a sport characterized by brief bouts of high intensity, intermittent exercise that requires neuromuscular performance (Bonitch-Góngora et al., 2012). These repeated high intensity match after match cause major episodes of fatigue in the judoka. There is a gap in studies concerning the maintenance of intra-fighting strength and its relationship with other variables specifically required in a judo contest. This study aims to determine the effect of fatigue on arm extensor muscles upon power, velocity, strength and rate force development (RFD) output levels, throughout a simulate contest in judo athletes. **Methods** Sixty-three male judo athletes of five national teams participated in this study, and were classified in two performance groups (top-elite, $n=30$; elite, $n=33$). All participants performed an intermittent judo test - the COPTEST (García-García et al., 2007), a 5 minutes duration test, with 9 Nage-komis, 9 Uchi-komis, 9 Jujigatame and 4 repetitions of Bench-press (BP) with the power-load ($\sim 50\%1RM$) in each minute (T1 to T5). BP load was the previous calculated power-loadings of the arm extensor muscles, and 4 measures were collected: force; power; velocity; and RFD. Power-load was tested on a free-weights BP exercise, and an Isocontrol - Dynamic 5.1 Software was used to collect data. Standard statistical methods, one-way ANOVA, and the repeated measures analysis of variance were used. **Results** Significant differences were observed between: (1) performance groups in power, strength and RFD (top-elite athletes were powerful, stronger and have more explosive strength of arms; all, $p < .001$); (2) evaluations (T1 to T5) in strength, power, velocity, and RFD. Moreover, the effect of fatigue on power, strength, velocity, and RFD (all, $p = NS$) is independent of the performance group. **Discussion** In accordance, the maximization of the power development capacity must be a key component of judo training programs. Nevertheless, during the contest, the observed slight reduction in power and velocity (in both, top-elite and elite groups) must be investigated (i.e., changes in the contractile apparatus vs reduced muscle activation).

COUNTER MOVEMENT JUMP PERFORMANCE IN 12-14 YEARS OLD BOYS AND GIRLS; THE INFLUENCE OF DIFFERENT SPORT EVENTS.

Petridis, L.

University of Debrecen

Introduction: Counter movement jump (CMJ) has been used to evaluate neuromuscular performance in many athletes. The type of sport event and the training background seems to influence CMJ performance in adult athletes. The aim of this study was to measure counter movement jump height in 12-14 years old boys and girls on a 3-year follow-up study based on different sport events. **Methods:** A total of 75 young athletes participated in the study (boys=44; girls=31) representing three different sport events (boys= basketball, handball, soccer; girls=basketball, handball, track & field). Data were obtained within a period of three years, one measurement per year; the subjects were 12 years old at the first year and 14 years old at the last year of the measurements. The height of the CMJ was recorded and peak power values were calculated. **Results:** Boys' performance increased significantly between consecutive years (12-13 yrs: 15.6%; 13-14 yrs: 9.5%), while girls' performance didn't show any significant change. At 13 and 14 years age groups differences between boys and girls were significant. Estimated peak power changed significantly in both genders between consecutive years (boys: 12 yrs 2586 ± 648 ; 13 yrs 3254 ± 727 ; 14 yrs 3777 ± 788 and girls: 12 yrs 2796 ± 597 ; 13 yrs 3074 ± 464 ; 14 yrs 3263 ± 365 w). Based on their sport events boys basketball players showed significantly higher performance in CMJ but there were no differences in estimated peak power. The differences in CMJ were present from the younger age group through the oldest age group, however all groups had a similar improvement rate. In girls there were no differences between the three different sport events at any age group. **Discussion:** The improvement in CMJ performance and estimated peak power was well recorded for boys, but not for girls. The latter had no improvement in the CMJ, however peak power had a significant improvement within the 3 year period of the study. The lesser increase in muscle mass that girls experience in this age period, with the increase in total body mass, perhaps indicate a higher need for muscular development and for neuromuscular training. The examined sport events seem not to influence improvement rate in CMJ, nor in estimated peak power at this age period.

RELATIONSHIPS AMONG SPRINT VELOCITIES, VERTICAL GROUND REACTION FORCE, AND ISOKINETIC KNEE STRENGTH VARIABLES

Kale, M., Kirkaya, İ.

Anadolu University

INTRODUCTION: Sprinters should minimize braking ground reaction force and maximize propulsive ground reaction force to reach maximum velocity (Weyand et al. 2000). Stronger athletes can do much better sprint performances because there is a linear relationship between force and sprint. Furthermore, ground reaction force is a determinant of sprint (Nesser et al. 2008). Muscular strength is generally accepted to be a crucial factor affecting athletic achievement. Especially explosive muscle strength has an important part in sprint performance as well as human limb movements controlled by joint torques. The purpose of this study was to investigate of relationships among sprint velocities, vertical ground reaction force, and isokinetic knee strength variables. **METHODS:** Voluntary 19 athletes were participated to the study [age= 20.9±2.3year, training age= 91.3±48.2month, body height= 173.1±6.5cm, body weight= 64.7±8.4kg]. Subjects participated four different sprint tests (10m, 20m, 30m, and 40m) for vertical forces on a non-motorized treadmill (Woodway Force 3.0, USA). Isokinetic knee flexion and extension torques were tested at the angular velocities of 60, 180, and 300o.s-1 with an isokinetic dynamometer (HUMAC, USA). Each angular velocity test consists of 3 submaximal efforts for a warm up and 5 maximal efforts. Pearson correlation coefficients (r) were calculated to establish the relationships among sprint parameters, ground reaction force and isokinetic knee flexion and extension torques. Probability level was ≤0.05. **RESULTS:** The highest correlation was found between the vertical force during 20m sprint and isokinetic knee extension flexion torques at the angular velocities of 60, 180, and 300o.sn-1 (r=0.772; 0.826; 0.829, ≤ 0.01, respectively). **DISCUSSION:** Morin (2010) explained that average vertical force, 723±59N in 6s sprint, is close to the body weight (726±54N). Average body weight was 635±82N and vertical force was 935±42N in 30m sprint in this study. This showed that athletes applied more force to the ground to accelerate. There were highest significance relationship between vertical force during 20m sprint and isokinetic knee extension flexion torques at angular velocities of 60, 180, and 300o.sn-1. The results of this study showed the least applied force to the ground, the most torque of the knee extension-flexion. In conclusion, the sprint performance was affected negatively with vertical component of ground reaction force. **REFERENCES:** Morin BJ. Samozino P. Bonnefoy R. Edouard P. Belli A. CHARACTERISTICS OF A SPECIALIZED TEST IN JUMPING ENDURANCE WITH VOLLEYBALL PLAYERS

Yordanov, P., Groshev, O., Bachev, V.

National Sport Academy

The aim of the experiment carried out was to establish the information validity and reliability of a specialized test created by the authors to study jumping endurance with elite volleyball players and to make normative tables for qualitative evaluation of the data received by the test. **Methodology:** The content of the test includes 3 separate maximal take-offs, 60 maximal uninterrupted multiple jumps, 3 separate maximal take-offs. The height of the separate take-offs and multiple jumps is measured by means of a computerized system "Jumpro-2", and pulse frequency dynamics is registered at the same time. The test offered leads to specific speed-strength loading with maximal intensity, which presents a serious challenge for the glycolytic reserve of the human body and for the compensation abilities of the cardio-respiratory system in order to restore the glycogen and myoglobin in the loaded muscles. The test was experimented with 15 volleyball players from the National Junior Volleyball Team of Bulgaria. It was carried out twice in a short time span of 15 minutes (test-retest method), so that its reliability could be determined. Results and discussion: The coefficients of Pircen's simple linear correlation (r) between the heights of the separate take-offs were calculated in the two attempts. The acquired data give reasons to state that the test has a high significance value. Only in the second separate take-off, the correlation is significant. It is big and very big in the others. This is a proof that the test is very reliable. Table 1 Statistical reliability of the test „3 – 60 – 3 + HR” used with the National junior volleyball team players of Bulgaria (n=15; r ≥ 0.483) Take-offs 1 2 3 10 20 30 40 50 60 64 65 66 rt 0.75 0.60 0.86 0.94 0.92 0.88 0.97 0.93 0.95 0.80 0.72 0.74 On the basis of the acquired results, normative evaluation tables have been created. The application of the tables helps to determine jumping endurance of elite volleyball players individually and in comparison with others.

CRITICAL POWER TESTING IN THE FIELD

Karsten, B., Jobson, S., Hopker, J., Beedie, C.

1: UoG (London, UK), 2: UoW (Winchester, UK), 3: UoK (Kent, UK), Aberystwyth University (UK)

Introduction Critical power (CP) provides an objective, valid, reliable, accurate and sensitive testing variable. CP is usually determined in the laboratory. However, due to its cumbersome testing method, it has not become a regularly assessed performance marker. The aim of these experiments was to develop a practicable field CP testing protocol. **Methods** Participants in experiments I and II were competitive road cyclists (Experiment I: 14 cyclists [mean ± SD: age 40 ± 6 yrs; max 3.8 ± 0.5 L•min⁻¹; MAP 311 ± 32.5 W]; Experiment II: 11 cyclists [age 32 ± 8 yrs, MAP 351 ± 37 W, max 3.9 ± 0.4 L•min⁻¹]). Experiment I compared laboratory determined CP values with CP values determined on an outdoor tarmac track, using a 24 hr recovery between time-to-exhaustion trials (TTE). Experiment II compared laboratory determined CP values with CP values determined on the road, using a 30 min recovery between TTE trials (Bishop & Jenkins, 1995). CP values were calculated using the power-1/time model. Agreement between laboratory and track/road CP values was assessed using limits of agreement (LoA). Linear regression was used to estimate the error associated with predicting track/road CP values. **Results** Experiment I: Laboratory CP (235 ± 24 W) and track CP (236 ± 29 W) values were highly correlated (r = 0.97; P < 0.05). Mean difference between laboratory and track values for CP was 2 ± 8 W (95 % CI, -2.3-25.4; [LOA], -14 -17 W). The predication error associated with laboratory and track determined CP was 2.5%. Experiment II: Laboratory CP (279 ± 33W) and field CP (275 ± 35W) was highly correlated (r = 0.93; P < 0.05). Mean difference between laboratory and field values for CP was 2 +/- 13 W (95% CI, -11.2-7.7; [LOA], -26-29 W). The predication error associated with laboratory and road determined CP was 1.7%. **Discussion** Both environments provided high levels of agreement and low prediction errors between CP values. Gonzales-Haro (González-Haro et al., 2007) accepted their incremental track field test as being valid with reported LoA of 130 W to -24 W and a random error of 77.1 W (13.9%). Results are furthermore supported by those of Quod et al. (2010) who found similar laboratory and road race CP values. We suggest that CP can be more practically determined using a

30 min inter-TTE trial recovery period when compared to the conventional 24 hr method. Moreover the experimental protocols can be considered to be acceptable when testing track and road CP. AGE-RELATED DIFFERENCE IN SHOCK ATTENUATING ABILITY OF CHILDREN

Kuno Mizumura, M., Komuro, Y., Yoshida, M., Yoshida, Y.

Ochanomizu University

Introduction The majority of children's injuries are associated with activities that involve jumping and landing. However, shock attenuating ability in children has not been fully elucidated in different age groups. So the purpose of this study was to investigate shock attenuating ability of children in different age group during drop landing. **Methods** Ninety-eight Japanese elementary school children in grade 5th and 6th whose mean age was 11 (+/- SD 0.56) years and ninety-two Japanese preschool children whose mean age was 6 (+/- 0.30) participated. Participants were required to step off a box 30 cm in height and land on a force platform (kistler, Switzerland) three times after 5 minutes practice. They also performed physical fitness battery test for children proposed by Ministry of Education, Culture, Sports, Science and Technology of Japan. **Results** Peak vertical component of ground reaction force (PGRF) for elementary school children was 4.8(+/-1.1)BW for boys and 5.1(+/-1.1)BW for girls, while PGRF for preschool children was 6.2(+/-1.4)BW for boys and 6.2(+/-1.4)BW for girls. Elementary school children showed significant smaller PGRF during drop landing compared with those for pre-school children for both boys and girls. No significant correlation was obtained between PGRF and any physical fitness measures and anthropometric variables. **Discussion** In this study, preschool children showed significant greater peak ground reaction force during drop landing compared to senior children. There are only few studies determined shock attenuating ability for children. Hewett et al (2006) have reported that male middle school and high school athletes had shown the decrease of maximum landing force in males as they matured whereas females did not change between pubertal stages. For adults, previous studies demonstrated that female showed significant larger vertical ground reaction force compared to males (Pappas et al., 2007, Kernozek et al, 2005). From the results of this study, it is indicated that shock attenuating ability in children would improve with age, although there was no gender difference which was reported for adults. In addition, the level of shock attenuation ability was not associated with developmental changes in both anthropometric measures and physical fitness levels. Therefore, shock attenuation ability of children would be independent from physical fitness level. **References** Pappas E., Hagins M, Sheikhzadeh A, Nordin M, Rose DC. (2007) 17(4):263-8. EFFECTS OF THREE DIFFERENT PRELIMINARY MOVEMENT PATTERNS BEFORE JUMPING IN THE JUMP PERFORMANCE

Shin, J.M., Lee, B.K.

Sangmyung University

Introduction Drop height and preactivation before a main jump can play an important role in enhancing jumping height in jump performance. A drop jump and a double jump have different features in respect of the preactivation before a jump when compared to a counter movement jump. Therefore, the aim of this study is to investigate the effects three different preliminary jumps before a main jump have on jump performance. **Methods** Seven infrared cameras and a force platform were used to analyze the jump tasks of 10 male college students. The participants were subjected to jumping randomly on the force platform with a counter movement jump, a 15cm drop jump, and a double jump. Vertical ground reaction force (VGRF), center of mass (CoM) of total body, and angle and angular velocity of the ankle, knee and hip joints were analyzed in the three different jump patterns, respectively. Repeated-measures ANOVA was conducted to compare the three groups ($p=.05$). This research was based on the raw data from Shin (2014). **Results** With regard to the vertical component of the center of mass (CoM), there were no significant differences in the peak height, the range of motion and the positive peak velocity except the negative peak velocity among preliminary jump patterns ($p>.05$). In the vertical reaction force, the peak value of the counter movement jump was greater than the corresponding value of the drop and double jump ($p<.05$). Both of the peak value of angle and angular velocity of thigh for a drop jump significantly increased ($p<.05$), but there were no significant differences of the peak value of the same variables ($p>.05$). **Discussion and Conclusion** The peak of reaction force and negative velocity of CoM during downward showed significant difference among three different preliminary jump patterns, but these were not necessary to increase the height and positive velocity of CoM during upward in jump performance. Peak angle and angular velocity of the thigh during jump increased, but this could not influence the result of the jump performance. The results indicated that jumping height in the jumping performance did not increase, although the different preliminary movements such as the 15cm drop jump and the double jump were performed before jumping. **References** Kallio J., Linnamo V., Komi P. COMPARISON BETWEEN FIRST AND SECOND LANDING FOR DIFFERENT VERTICAL DROP JUMP TASKS. IMPLICATION IN INJURY RISK PREVENTION

Cordonnier, C.

Université de Liège

Introduction First landing of vertical drop jumps (DJ) is usually used to screen injury risk and deficiencies in neuro-muscular control. Insufficient hip and knee flexion have been identified as mechanical factors contributing to injury risk in ACL lesion (Pollard et al., 2010). The

second landing has largely been ignored in previous study and could provide new interesting informations. Indeed, second landing may be more closely related to a majority of non-contact ACL injuries (Powell et al., 2000). Methods Five sedentary men (age = 23 ±1) without lesion history of the lower limbs performed bipodal DJ from 2 initial heights: 20 and 40 cm. The kinematic and the kinetic of the subjects were recorded using a 3D motion capture system and 2 force plates. The best performance from 3 trials was retained for analysis. We assessed hip and knee angles in the sagittal plane at initial contact (IC) as well as the peak force for the first and second landings. Results For DJ20, the second landing exhibits a statistically significant decrease flexion angle at IC for the dominant (D) and non-dominant (ND) legs: D (22°±6° vs 32°±8°), ND (22°±5° vs 34°±9°). Peak forces are not significantly different for both landings: (D=1692N, ND=1363N) (D=2022N, ND 1749N). For DJ40, the second landing shows a statistically significant decrease of the knee flexion: D (20° vs 32°), ND (18° vs 29°) and of the hip flexion: D (161° vs 153°), ND (161° vs 154°). Peak force is the same at first (D=1605N, ND=1512N) and second landing (D=1641N, ND=2142N). No significant differences of fall height (39 vs 40 cm), peak force or hip and knee angulation were found when comparing the second landing of DJ20 and DJ40. Discussion Previous investigations focusing on the first landing have identified insufficient hip and knee flexion as mechanical factors contributing to ACL injury (Pollard et al., 2010). For DJ20 and DJ40, subjects present a riskier posture during their second landing as they have a more erected position while the force peak remains similar. Moreover, DJ20 has been shown to be less demanding than DJ40 during the first landing. As both drop jumps leads to similar peak forces or hip and knee angulations for second landing, we would recommend to favor DJ20. These preliminary results tends to demonstrate that the second landing of a 20 cm drop jump could be more relevant to assess the risk of injury than using the values obtained from a first landing Reference Chappell JD, Limpivasti O (2008). EFFECTS OF ACUTE STATIC STRETCHING ON MECHANO-MORPHOLOGICAL PARAMETERS AND JUMP PERFORMANCE

Stafilidis, S., Tilp, M.

Institut of Sport Science

Introduction Static muscle stretching is an essential part of daily sport activity. However, its effect on muscle performance is disputed. It has been suggested that static stretching impairs muscle strength (Fowles et al. 2000) and jumping tasks (Behm & Kibele 2007). Since average stretching duration in sports is less than 20s (Simenz et al. 2005) its negative impact is questioned (Kay & Blazevich 2012). Therefore, the aim of our study was to examine the effect of short duration 15-60s acute static stretch on various mechano-morphological parameters and jump performance. We hypothesized that acute low duration static stretch has no negative effect on the mechanical and morphological parameters of the lower extremities as well as the muscular performance. Methods Eleven students (8 male, 3 female) underwent a static stretching program for major muscle groups of the lower extremities for 15 and 60s on two consecutive days in randomized order. The same participants also acted as control group (CG) on a separate occasion. The maximal isometric torque (MVC) of the right knee was measured with a dynamometer and counter movement jumps were executed on a force platform to assess muscle performance. Furthermore, the tendon and aponeurosis elongation of the Vastus Lateralis (VL) were measured by use of ultrasonography and stiffness and strain were calculated to assess mechano-morphological changes. Repeated Anova was used for all pre-post/group analyses. Results There were no significant differences in the MVC (242.2±46.8-249.0±50.2; 236.0±62.5-236.1±68.8, 234.8±47.4-232.3±51.3Nm; 15,60s, and CG pre-post/group respectively) and the jumping performance between and within groups. Additionally, no significant differences were found in the tendon and aponeurosis elongation (2.22±0.50-2.69±0.89; 2.38±0.40-2.42±0.81; 2.35±0.56-2.37±0.49cm, pre-post/group respectively) as well as the strain, and stiffness. Discussion The results indicate that the short duration of static stretch (<60s) is not sufficient a) to induce alteration in the force capability of a major muscle group (quadriceps femoris) and b) to alter the elastic behavior of the tendon and aponeurosis of the VL. The absence of mechano-morphological alterations might also explain c) the lack of differences in the stretch-shortening jumping task. Therefore, we conclude that the acute static stretching (<60s) immediately before sports practice does not impair overall muscular performance. References Fowles JR, Sale DG, MacDougall JD. (2000). ESTIMATES OF LEG STIFFNESS AND JOINT STIFFNESS DURING LOW-LOAD PLYOMETRICS.

Grisbrook, T.L., Cui, L., Travers, M.J., Debenham, J., Allison, G.T.

School of Physiotherapy and Exercise Science, Curtin University

Introduction: Hopping is frequently used to assess leg stiffness; although upright hopping is not always practical in populations where lower-limb function is impaired. We have developed a Sledge Jumping System (SJS) that allows individuals to mimic hopping in a low-load manner (Gibson et al 2013). A field based measurement of leg stiffness, that uses contact and flight time modelling has been validated in upright hopping, however this method has not been validated to allow for changes in gravity associated with hopping on an inclined SJS. This study aimed to determine if this formulae was valid in the context of SJS stiffness estimates. Further this study aimed to ascertain which individual joint spring was the main correlate to limb stiffness in low-load hopping. Methods: Participants were required to hop on SJS inclined at 20°, at a wide range of frequencies. 3D motion analysis and force plate signals were utilised to analyse hopping kinematics and kinetics. Estimates of leg stiffness were calculated using the spring-mass model utilising two different methodologies. The reference method developed by Cavagna et al (1988) was compared to the field method developed by Dalleau et al (2004). Ankle and knee joint stiffness, were calculated using the methods described by Farley and Morgenroth (1999). Results: The contact and flight time method of estimating stiffness was strongly correlated to the traditional spring-mass modelling of stiffness, during hopping on the SJS (r²=0.95). Further we found that ankle stiffness is the major determinant of leg stiffness during sledge hopping (r²= 0.85). Discussion: Lower limb stiffness, with a particular focus around ankle joint modulation, can be determined on an inclined SJS using the field method of estimating stiffness. This is particularly relevant for low-load hopping, given that individuals with injuries or neurological disorders may not be able to hop upright, but would be able to maintain a low amplitude hopping strategy of submaximal loading for a period of time on the SJS. This may provide a good framework to determine optimal rehabilitation strategies where rehabilitation incorporates stiffness modulation and in individuals where only low-load plyometric activities are possible. VALIDITY OF TRI-AXIAL ACCELEROMETRY FOR MONITORING BACK SQUAT REPETITION QUALITY

Nicholson, G., Thomas, L., Bissas, A.

Leeds Metropolitan University

Introduction Whilst high-speed motion analysis systems represent the preferred method of assessing barbell kinematics during resistance exercise, it is now possible to attach an accelerometer to the barbell to gain immediate feedback. Although some studies support the validity of accelerometers, others have found below-standard accuracy and reliability compared to laboratory-based measures (McCurdy et al. 2011). Thus the purpose of this study was to examine the validity of two tri-axial accelerometers for measuring the mechanical characteristics of the back squat exercise. **Methods** Ten trained males (22.2 ± 3.4 years) completed a single testing session involving a standardised warm-up and 4 single repetitions of the back squat (80% training maximum). A force platform (FP, 1000 Hz) and Qualysis motion capture system (QL, 250 Hz) were used to examine the mechanical characteristics of the repetitions as well as a Kistler (A1, 1000 Hz) and Myotest Pro (A2, 250 Hz) accelerometer mounted on the barbell. The FP, QL and A1 systems were telemetrically synchronised, this allowed peak vertical power (PP), velocity (PV), force (PF) and acceleration (PA) to be compared. Three methods of assessing the agreement between the systems were then used after the data were assessed for heteroscedasticity: 95% Limits of Agreement (LOA), Coefficient of Variation (CV) & Intraclass Correlation Coefficient [(3,1) consistency]. **Results** Comparisons between the barbell and FP measures were characterised by high levels of systematic bias, random error and poor ICC's for all of the variables analysed. The comparison between FP and A2 for PV was particularly indicative of the overall trend with a bias of 8.9%, a random error of 67.9% and an ICC of 0.69. Although a poor level of agreement was also observed between the barbell measures for PP and PA, A1 and QL showed a better level of agreement for PV when examined using the systematic bias (5.25%) and random error (0.87%) but not when interpreted using the ICC. A2 overestimated PF by 1.8%, PP by 8.9% and PV by 10.4% when compared to QL. **Discussion** Whilst the lack of agreement between the accelerometer and FP measures most likely reflects the difference between barbell and full-body kinematics, A1 and A2 did not display adequate agreement with a laboratory measure of barbell kinematics for the majority of variables analysed. Based on the fact that the acceleration-time curves followed a similar pattern, there may be some scope for coaches to gain some valuable information from accelerometry. However, from a research perspective the present findings question the accuracy of tri-axial accelerometry for examining barbell kinematics during the back squat exercise. **References** McCurdy, K. et al. BILATERAL SQUAT ASYMMETRY IN SURFING ATHLETES

Lundgren, L.1,2, Secomb, J.1,2, Tran, T.T.1,2, Farley, O.1,2, Nimphius, S.1, Newton, R.U.1, Sheppard, J.M.1,2

1: ECU, 2: Surfing Australia HPC

Introduction Surfing athletes (SA) have an asymmetrical stance while surfing, which may cause these athletes to prefer an asymmetrical posture. Previous studies have found about 6% imbalance on average regarding ground reaction force (GRF) among college athletes (Flanagan and Salem, 2007; Newton et al., 2006), and that bilateral squat asymmetry can be corrected (McGough et al., 2010). This study investigated bilateral asymmetry for SA and compared between left and right side, front and rear side and between groups of athletes, such as divisions and training status. **Methods** Athletes ($n=26$) from four division based groups, i.e., male and female professional seniors ($n=8$ and 3, age: 24.5 ± 3.2 and 25.8 ± 6.6 y respectively) and juniors ($n=8$ and 7, age: 16.0 ± 1.3 and 15.8 ± 0.7 y) performed bilateral squats with their stance split between two force plates (Fitness Technology, Adelaide) recording at 600 Hz. The athletes performed 10, first without any external load (BW) and secondly with an external load (EL) corresponding to 25% of their BW. From the average force of the left and right side a symmetry index (SI) was calculated (McGough et al., 2010). Comparison between SA who strength trained regularly ($n=11$) versus inconsistently ($n=15$) was performed using independent t-test. Bilateral asymmetry between feet was analysed using paired t-test. **Results** The average SI for all SA was $6.8 \pm 4.4\%$ and $8.2 \pm 5.8\%$ for the BW and EL squat respectively. There was no significant preference for the front or rear stance leg ($p=0.19$), or the left or right ($p=0.14$). Of all SA, 9 athletes had a SI $>5\%$ to the rear leg, 6 had a SI $>5\%$ to the front leg, and 11 SA were within 5%. The group of female junior surfers ($n=7$) had a larger average SI than that of the other groups averaging $10.5 \pm 4.2\%$ and $10.9 \pm 5.7\%$ for the BW and EL conditions ($p \leq 0.01$). Of these, 5 preferred their back foot and 2 their front foot. Those who had been strength training regularly during the past six months had a lower SI ($3.5 \pm 2.7\%$) compared to the other athletes ($9.4 \pm 4.5\%$, $p \leq 0.001$). **Discussion** The result of this study suggests that there are bilateral asymmetries in the squat movement for most SA, similarly to that identified in previous research, however larger for the group of female juniors. The asymmetry seems to be minimized in those performing regular lower body strength training exercises. The hypothesis that most surfing athletes would prefer their rear stance leg more than the front turned out to be unconfirmed in this study. **References** Flanagan SP, Salem GJ (2007). *Str Cond Res* 21(4), 1220-1226. DOES A SINGLE LEG SQUAT TEST PROVIDE AN INSIGHT INTO NEUROMUSCULAR CONTROL DURING MORE DYNAMIC SPORTING MOVEMENTS?

Marshall, B.1,2, Franklyn Miller, A.1,3, Moran, K.2, Falvey, E.1,3

1: Sports Surgery Clinic (Dublin, Ireland), 2: Insight (Dublin, Ireland), 3: CHESM (Melbourne, Australia)

Introduction The single leg squat (SLS) is a common functional test used in the assessment of neuromuscular control (Chmielewski 2007). While some authors suggest that the SLS may be useful in screening for injury risk or in the assessment of rehabilitation following injury (Chmielewski et al. 2007), others have questioned its validity and the lack of evidence based research supporting its use (Aikens et al. 2013). The aim of this study is to examine the relationships between 3D kinematic measures in a single leg squat and those same measures in a single leg drop landing, single leg hurdle hop and cutting manoeuvre. **Methods** 40 field sports players diagnosed with chronic athletic groin pain were recruited. 8 Vicon Bonita cameras and 2 AMTI force plates were used to collect 3D data at 200Hz. Testing was carried out in the order of SLS, drop landing, hurdle hop and cut. Trials on the symptomatic side, or on a randomised side for individuals with central lower abdominal pain, were selected for further analysis. Hip, knee and pelvis range of motion, in the three anatomical planes, were examined as measures of neuromuscular control. Pearson product moment correlations were calculated between a given measure in the SLS and the equivalent measure in each of the other movement tests. A significance level of $p < 0.01$ was adopted. **Results** Of the 27 range-of-motion comparisons made, there were no significant correlations between the SLS and either the hurdle hop or running cut, and only two between the SLS and the drop landing (knee frontal [$r = 0.61$] and transverse [$r = 0.62$] range of motion). **Discussion** The SLS does not appear to provide a meaningful insight into pelvis and hip control during more dynamic sporting actions such as

landing, hopping or cutting. This finding is of particular relevance to the assessment of athletic groin pain as abnormal pelvis and hip neuromuscular control during dynamic sporting activities like cutting are considered to be associated with the development of this injury (Falvey et al. 2009). The use of a SLS in clinical practise to assess sport specific abnormal hip and pelvis biomechanics is thus not supported. Additional findings do suggest that a SLS may provide an insight into neuromuscular control at the knee while performing a single leg landing. A NOVEL APPROACH TO BIOMECHANICAL ANALYSIS OF THE KNEE DURING SQUATTING

Djordjevic, S.1, Modic, Z.1, Gerbec Cucek, M.1, Stancin, S.2, Sodnik, J.2, Tomazic, S.2, Berdajs, M.1

1:TMG-BMC d.o.o.Ljubljana,Slovenia,2:University of Ljubljana,Faculty of Electrical Engineering (Ljubljana, Slovenia)

Introduction Mechanical properties of the Muscle-tendon complex (MTC) are an important element in studying human performance. A primary aim in training and rehabilitation is gaining balanced and simultaneous muscle and tendon adaptation. Comprehensive and robust data on MTC behavior in different early conditioning phases can be used to improve training efficiency and prevent non-contact injuries. The MC sensor (Sensmotion PT2 device,TMG-BMC,Slovenia) [1] is a wearable ($m < 1.5$ g) biosensor that measures muscle and tendon tension/force. Using MC sensor in our research, we focus on force transmission from the quadriceps muscles and tendon to the patellar tendon (PT) and ensuing reaction force transmitted to the tibia. We measured the vastus medialis (VM) and lateralis (VL), quadriceps (QT) and patellar tendon (PT) in squatting. Methods Ten international level athletes-five male and five female (age 20-31) were measured during squatting using Smith machine. Tension forces of VM, VL, QT and PT were measured with the MC sensor with 1 kHz sampling rate. Athletes' movements were captured with Qualisys MCS consisting of 8 Oqus 3+ cameras, resolution of 1.3 million pixels and 0.5 kHz sampling rate. Ten passive markers were placed on the head, neck, shoulder, elbow, hips, thigh, knee, ankle, foot and weights enabling calculation of the KA and torques (KT) [2]. Muscle and tendon tension forces were compared to KT and KA. Results A linear relation between PT tension and KA (in the range from 20° to 80°) and between PT tension and KT was found. On the other hand, a nonlinear but very significant relation between QT and KA was found. Simultaneous tensions in VM and VL are also in linear relation to KA and KT. Discussion A necessary condition for training optimization is frequent monitoring of MTC loading dynamic during training. Squatting is one of the most popular exercises for developing strength of the quadriceps muscles. Understanding how force is transmitted from VL and VM over QT to patella and PT could be useful for training and for medical rehabilitation optimization. Our preliminary results using the MC sensor show that each person has a unique pattern of the knee MTC loading. There is a tendency of KA specific nonlinearity on QT. Additional protocols are necessary for a more detailed understanding of the MTC tension dynamics especially for understanding different behavior of tendons during squatting. THE INFLUENCE OF CHAIN-LOADED RESISTANCE ON SUBSEQUENT 1-RM FREE-WEIGHT SQUAT PERFORMANCE

Mina, M.A.1, Blazeovich, A.J.2, Giakas, G.3, Kay, A.D.4

1: UoD (Derby, UK), 2: ECU (Perth, WA), 3: UoT (Thessaly, Greece), 4: UoN (Northampton, UK)

Introduction Varying the load during a back squat exercise using chains in combination with free-weight resistance (FWR) will manipulate the loading characteristics of the lift. Consequently, this may alter neuromuscular demand and induce post-activation potentiation (PAP). Preconditioning the muscle using near-maximal or maximal voluntary contractions can increase force production and improve subsequent strength performance, however the influence of chain-loaded resistance (CLR) on subsequent free-weight squat performance has not been examined. Thus, the aim of the present study was to determine the effects of a chain-loaded resistance warm-up routine on subsequent free-weight squat performance. Methods Sixteen recreationally active men (age = 26.0 ± 7.8 y, height = 1.7 ± 0.2 m, mass = 82.6 ± 12.7 kg) experienced in squatting (>3 y) volunteered for the study after giving written informed consent; ethical approval was granted from the University of Northampton. On two separate occasions the subjects performed either a FWR (control) or CLR (experimental) warm-up consisting of two sets of three repetitions of squat lifts at 85% 1-RM (35% of the load generated from CLR). After a 5-min rest, the subjects performed a free-weight resistance 1-RM squat; when successful a 5% load was added until subjects failed to complete the 1-RM. During the 1-RM, 3D motion analysis recorded knee joint kinematics, whilst vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF) and semitendinosus (ST) electromyograms (EMG) were recorded simultaneously. Repeated measures MANOVA's were used to examine EMG and kinematic differences between conditions; significance was accepted at $p < 0.05$. Results A significant increase in 1-RM (6.2%; $p < 0.01$) and mean eccentric VM EMG (32%; $p < 0.05$) was found following the CLR condition compared to the FWR control condition. However, no difference in peak and mean eccentric (8-10%; $p > 0.05$) and concentric knee angular velocities (11-23%; $p > 0.05$), or knee flexion angle (0.3%; $p > 0.05$) occurred. No subjects increased 1-RM after the FWR condition, however 10 of 16 subjects (63%) increased 1-RM by $\sim 10\%$ after the CLR condition. Discussion Performing a CLR warm-up significantly enhanced subsequent free-weight 1-RM squat performance without changes in knee flexion angle. Thus, a real increase in 1-RM was achieved as the subjects clearly squatted to the same depth and did not compromise the mechanics of the lift. No change in knee extensor EMG activity was observed despite the increased load, which may indicate that the hip extensors were responsible for the greater muscle force production. Regardless, a greater 1-RM load was lifted following the CLR warm up, which may enhance the training stimulus. Contact m.mina@derby.ac.uk

Introduction Magnesium (Mg²⁺) elicits significant enzymatic involvement and physiological regulation in particular to energy metabolism, vascular tone and blood pressure. However, the Mg²⁺ exercise performance relationship in addition to Mg²⁺ application within health and blood pressure, is equivocal and inconclusive, with some previous research questioning the supplemental efficacy of Mg²⁺ on aerobic and cardiovascular performance enhancements. The purpose of this study was to determine the influence of supplemental Mg²⁺ on aerobic and cardiovascular performance responses with a further evaluation into the novel aspect of supplemental Mg²⁺ from an acute (A) and chronic (Chr) loading strategy. **Methods** A total of 20 healthy, trained normotensive males and females were recruited and randomly allocated to one of two groups; 1) A, and 2) Chr. Supplemental Mg²⁺-citrate (elemental 300mg/d) was administered for 1 week or 4 weeks for A and Chr treatment groups, respectively. Subjects engaged in a 2 consecutive day multiple test/re-test protocol, for analysis of 40km cycle time-trial performance and cardiovascular responses at rest, during and post exercise and effect on 24 hour recovery. **Results** Significance was shown specifically within the A Mg²⁺ loading strategy for 40km cycle time-trial performance ($P=0.047$), but not 24 hour recovery. Acute SBP, DBP and Total Peripheral Resistance (TPR) responses showed a greater significant reduction compared to Chr loading during 40km cycle TT performance, despite variability, and no 24 hour recovery enhancement in both A or Chr groups. Post 40km cycle TT DBP and TPR responses were variable but showed a greater significant reductive trend in relation to A Mg²⁺ loading; however, post 24 hour recovery data showed significant reductions solely for TPR in both the A and Chr loading strategies. **Discussion** This investigation showed an A Mg²⁺ induced reduction in 40km TT by more than 2 minutes compared to baseline and 18 seconds when compared to placebo, thus supporting the effectiveness of A supplemental Mg²⁺ for an enhanced performance time, but not for recovery in relation to A and Chr loading. Current findings therefore corroborate with Mg²⁺ augmented performance research (Lukaski Nielsen, 2002), and ineffective performance recovery research (Terblanche et al., 1992). The lack of consistency associated to blood pressure reductions during and post exercise questions the understanding whereby Mg²⁺ intake is highlighted to have a negative association with SBP (Kim & Choi, 2013). However, a greater significant A Mg²⁺-induced reduction of TPR, adds controversy but supports potential Mg²⁺ vasodilatory and antagonistic actions (Geiger & Wanner, 2012). **Conclusion** The current study highlights that A Mg²⁺ supplementation induces favourable performance and vascular enhancements, but not to 24 hour recovery. These improvements noted for A Mg²⁺ loading were not observed consistently within the Chr loading strategy, suggesting a time dependent regulatory effect; thus highlighting Mg²⁺ supplementation duration to be a confounding factor.

CHANGES IN EXPRESSION OF ZN TRANSPORTERS AND IN SUPEROXIDE DISMUTASE ACTIVITY IN ZN-SUPPLEMENTED HIGH PERFORMANCE HANDBALL PLAYERS

Molina López, J.I, Florea, D.I.1,3, Hogstrand, C.3, Molina, J.M.2, Chiroso, L.J.2, Quintero, B.1, Planells, E.1

Introduction Zn had been described as an important mineral in sport population. Zn as antioxidant in exercise is a recognised property that may contribute to protect against free radicals and the effect on sport performance. Zn is a metal that requires transporters, called ZIP family ZnT to develop different functions into the cell. 24 transporters are involved mediating transport of Zn: ZnT family transporting within the cell, which modulate their intracellular concentration, and ZIP family, carrying out the Zn from the organelles, causing an increase in the Zn intracellular. They contribute to maintain Zn homeostasis. Gene expression may provide information or characterization and understanding of physiological and metabolic regulatory pathways of the responses to exercise. **Methods** 14 professional handball players >18y, with intense training and nutrition education for 2 months, supplemented with 50%RDAs for Zn. Zn was measured by flame atomic absorption spectrometry (FAAS) in wet-mineralised erythrocyte samples. Zn intake (%RDAs) was recorded by 72 h-recall and processed with Nutriber® software. SOD activity was determined by an enzymatic-colorimetric method in blood cells. Blood was drawn in PAXgene™ Blood RNA Tubes. Relative expression was calculated by measuring two genes for gene ΔCp calibrator, using three housekeeping genes as standard (GAPDH, UBC and YWHAZ). **Results** 33% of subjects presented low Zn intake at the beginning of the study. Zn intake was significantly increased ($p<0.05$) following supplementation being no influenced by nutritional education. Zn plasma levels showed significant differences after supplementation ($p<0.05$). There were no differences in Zn blood cells levels and SOD activity. Analysis of Zn transporters showed a significant increase in genes ZIP3($p<0.01$), ZIP5($p<0.01$), ZIP13($p<0.01$) and ZIP14($p<0.001$) expression, after supplementation. At baseline, there were correlations between dietary Zn and ZIP13($r=0.62, p<0.05$) and ZIP14 transporters ($r=0.69, p<0.05$). Similarly, the values in plasma were correlated with ZIP11($r=0.82, p<0.01$). A correlation was found between the levels of Zn in blood cells with ZnT7($r=0.61, p<0.05$) at supplemented final point. **Discussion** ZIP3, ZIP5, ZIP13 and ZIP14 transporters increased the expression after intervention with Zn, possibly due of the tendency to overexpression in poor condition, and could indicate that we have not yet achieved the optimum levels of demand for this mineral. Zn intake and values in blood cells correlated with ZIP11, ZIP13, ZIP14 transporters at baseline, suggesting that poor intake or low values of Zn in blood cells are associated with high-expression values, while at higher Zn intake and Zn in blood cells, is lower expression. This confirms the possible role of these transporters as biomarkers of Zn status in humans. Elite athletes should be monitored by a clinical-nutritional follow up to avoid deficiencies that alter antioxidant status in critical situations, so supplementation may be necessary to optimize athletic performance.

VITAMIN AND MINERAL SUPPLEMENT INTAKE REPORTED BY DUTCH ATHLETES

Ceelen, I.1, Wardenaar, F.1, Mensink, M.2, Witkamp, R.2

1: HAN University of Applied Sciences (Nijmegen, NL), 2: Wageningen University (Wageningen, NL)

Introduction Many athletes use dietary supplements as part of their training or during competition to improve general health, performance or recovery. Use of vitamin and mineral supplements up to 84% has been reported for athletes (1). However, uncertainty exists in estimating actual use due to varying compliance. Prevalence and reason for supplement use among competitive athletes is not known in the Netherlands. Therefore the purpose was to determine the prevalence of vitamin and mineral supplement intake, their motivation for intake and frequency of use in Dutch athletes. **Methods** In total 145 (87 males, 58 females) Dutch competitive athletes with an elite or talent status completed a Web-based questionnaire to determine sports nutrition and supplement intake. In February 2013 until June 2013 respondents were asked to fill out if they had ever used supplements, and if they had used supplements during the last 4 weeks. In addition, questions regarding reason for intake, and frequency of intake per week and day were included. Prevalence of supplement intake is presented as percentage of total respondents. Reason of intake is presented as percentage of those respondents who reported supplements use. **Results** 114 (79%) athletes reported use of vitamin and mineral supplements at least once in their life, of which multivitamins (61%), vitamin C (39%), vitamin D (30%), iron (30%) and magnesium (17%) were the most commonly used preparations. Current intake of these supplements was 44%, 26%, 21%, 17%, and 10%, respectively. Besides, only 40% up to 55% of the athletes took these supplements every day, 18% of the athletes used multivitamins less than once week, for vitamin C this was almost 30%. 84% up to 93% of the athletes used these supplements once a day, and the remaining group two or three times a day. Most important reasons given for using vitamin supplements were to prevent deficiencies (25-52%), to support general health (20-35%), and to improve their immune system (16-39%). Iron supplements were mainly used to prevent iron deficiencies (65%). Main reasons given for using magnesium were to prevent muscle cramps (42%), and to improve recovery (21%). **In conclusion**, vitamin and mineral supplement use is very common in Dutch athletes, showing an overall prevalence of almost 80%. However, current intake was lower, up to 44% for multivitamins and even less for others. Considering that products are often not to be taken daily, compliance of vitamin and mineral supplements needs to be continuously monitored as part of nutrition counseling. **References** 1. Maughan, R., Depiesse, F., & Geyer, H. (2007). The use of dietary supplements by athletes. *Journal of Sport Sciences*, 103-113.

MIMICKING EXERCISE TRAINING, GINSENOSE Rg3 IMPROVES CARDIAC MITOCHONDRIAL POPULATION QUALITY

Sun, M.

Shanghai Research Institute of Sports Science

Introduction More recent work has demonstrated aerobic exercise could ameliorate cardiovascular dysfunction and enhance longevity, possibly through improving mitochondrial quality control (Campos et al., 2012). Ginsenoside Rg3, one of the active ingredients in Panax ginseng, is well known in herbal medicine as a tonic and restorative agent (Tang et al., 2008). However, the molecular mechanism underlying the beneficial effects of Rg3 has been elusive. In the present study, we compared the effects of Rg3 administration with aerobic exercise on mitochondrial adaptation in cardiac muscle tissue of Sprague-Dawley (SD) rats. **Methods** 8-week-old male SD rats were randomly divided into 3 groups of 12 rats each: 1) sedentary control, 2) Rg3-treated and 3) aerobic exercise trained. The Rg3 group received Rg3 (5mg/kg/d) by gavage for 8 weeks. Mitochondrial internal structure was observed under transmission electron microscope. Measurement of protein levels of microtubule-associated protein light chain 3 (LC3), mitofusin1/2, peroxisome proliferator-activated receptor-γ coactivator 1α (PGC-1α), nuclear factor-E2-related factor 2 (Nrf2), mitochondrial manganese superoxide dismutase (MnSOD) and catalase was performed with immunoblotting. **Results** Both aerobic exercise training and Rg3 supplementation enhanced PGC-1α and Nrf2 protein levels in cardiac muscle. The activation of PGC-1α led to increased mRNA levels of mitochondrial transcription factor A (Tfam) and nuclear related factor 1 (Nrf1), these changes were accompanied by increases in mitochondrial DNA copy number and complex protein levels, while activation of Nrf2 increased levels of phase II detoxifying enzymes, including nicotinamide adenine dinucleotide phosphate:quinone oxidoreductase 1 (NQO1), MnSOD and catalase. Aerobic exercise also enhanced mitochondrial autophagy pathway activity, including increased conversion of LC3-I to LC3-II and greater expression of beclin1 and autophagy-related protein 7 (ATG7), these effects of aerobic exercise are comparable to that of Rg3. **Discussion** In this study, we characterized the effects of aerobic exercise on cardiac mitochondrial activities by primarily assessing dynamics, biogenesis and autophagy. Rg3 is an ergogenic aid that improves mitochondrial antioxidant capacity and regulates mitochondria dynamic remodeling; these effects mimic improved cardiac adaptations to exercise by training. It may be specifically useful to people who cannot exercise because of physical limitations. Nevertheless, even though Rg3 alone matches some the benefits of traditional exercise, it cannot act as a substitute for exercise. **References** Campos JC, Queliconi BB, Dourado PM. et al., (2012). *PLoS One*, 7, e52764. THE EFFECTS OF BOVINE COLOSTRUM SUPPLEMENTATION ON IN VIVO CELL-MEDIATED IMMUNE RESPONSE FOLLOWING PROLONGED EXERCISE

Jones, A.W.1, Thatcher, R.1, Davison, G.2

1: AU (Aberystwyth UK), 2: UoK (Chatham, UK)

Introduction Prolonged exercise significantly reduces both the induction and elicitation of in vivo cell-mediated immune responses (Harper-Smith et al., 2011). The aim of this study was to investigate the effects of bovine colostrum (COL) supplementation on the in vivo cell-mediated responses to Diphenylcyclopropenone (DPCP) following prolonged exercise. **Methods** In a double-blind design, 28 male participants were randomly assigned to either a COL (20 g a day) (n=14) or placebo (PLA) (isoenergetic/isomacronutrient supplement) (n=14) group for 87 days following stratification for age and aerobic fitness only. Exactly 28 days into supplementation, participants took part in 2 h of running at 60% of maximum oxygen uptake. Within 20 min of exercise completion, all participants were sensitised to DPCP using a single patch applied to the mid-lower back for 48 h. Following the induction of immune-specific memory (sensitisation), participants reported to the laboratory 28 days later for a dose series of DPCP patches to be applied in a randomly allocated order to the volar aspect of their right upper arm for 6 h. Participants returned to the laboratory 24 h and 48 h following the application of patches for skin responses (oedema) to be measured (to the nearest 0.1 mm) at each DPCP patch site using modified skinfold calipers. **Results** There was no difference in total oedema responses (sum of all skinfold sites) between COL and PLA (p > 0.05). In accordance with Harper-Smith et al. (2011), analysis of the dose response curves allowed for the minimum dose (threshold) for a positive response in each group to be determined (i.e. sensitivity). The minimum dose for PLA was 2.0 and 2.1 fold greater than COL at 24 h and 48 h respectively (i.e. greater sensitivity in COL). There was a greater response in COL at 24 h for the lowest DPCP dose (p < 0.05), but not at 48 h or with other doses at either

timepoint ($p > 0.05$). Discussion There was no apparent effect of COL supplementation on the magnitude of cutaneous immune responses (summed skinfold responses) at recall (4 weeks following initial sensitisation to DPCP). The study does, however, suggest that COL enhances sensitivity of the recall of antigen-specific memory. This may support previous evidence from our laboratory where COL has been shown to act as a nutritional countermeasure to prolonged exercise and decrease susceptibility to illness (Davison and Diment, 2010; Jones et al., 2013). IRON STATUS AND HEPCIDIN RESPONSE TO A SEVEN DAY TRAINING PERIOD OF RUNNING OR CYCLING

Sim, M.1,2, Dawson, B.1, Landers, G.1, Tjalsma, H.3, Swinkels, D.3, Trinder, D.1, Peeling, P.1

1: UWA (Perth, Australia), 2: WAIS (Perth, Australia), 3: RU (Nijmegen, Netherlands),

Introduction: Exercise stimulates the production of the iron regulatory hormone hepcidin, causing peak levels 3 h post-exercise (Peeling et al., 2009). Such events may decrease iron absorption and recycling (Nemeth et al., 2004). However, non-weight-bearing exercise (cycling) was previously shown to reduce hemolysis (Telford et al., 2003) and interleukin-6 levels (Nieman et al., 1998) in comparison to weight-bearing activity (running). To date, most studies have examined the acute post-exercise hepcidin response using weight-bearing exercise. Additionally, the impact of cumulative exercise sessions on hepcidin production remains unknown. This investigation compared the impact of an extended period of running vs. cycling on hepcidin levels and iron status. Methods: Ten active males performed two separate training blocks, performing either running (RTB) or cycling (CTB). Each block comprised 5 training sessions (Day [D] 1, 2, 4, 5, 6), performed over 7 days and matched for exercise intensity. Basal venous blood was obtained on D1, and on Recovery Days 3 (R3) and 7 (R7) to assess iron status, while basal and 3 h post-exercise urinary hepcidin levels were measured on exercise D1, D2 and D6, as well as R3 and R7 (basal levels only) for each training mode. Results: In RTB, basal urinary hepcidin levels were significantly elevated ($p < 0.05$) at D2, R3 and R7 as compared to D1. 3 h post-exercise urinary hepcidin levels on D1 were also significantly higher in RTB compared to CTB ($p < 0.05$). In CTB, large effect sizes suggested basal hepcidin levels were higher at R7 ($d = 1.26$) compared to D1. Iron parameters were not significantly different at D1 compared to R3 and R7 during both training modes. Conclusion: Basal hepcidin levels may increase over an extended training program, especially if weight-bearing exercise is undertaken. In comparison, the reduced hemolysis typically associated with cycling may require more training sessions, or sessions of extended duration, before any changes in basal hepcidin levels appear. Chronically elevated hepcidin levels may help explain the high incidence of iron deficiency in athletes. References Nemeth E, Tuttle MS, Powelson J, Vaughn MB, Donovan A, Ward DM, Ganz T, Kaplan J. HYPOVITAMINOSIS D IN YOUNG ATHLETES FROM THE MIDDLE EAST AND SEASONAL VARIATIONS

Nikolovski, Z., Cardinale, M., Varamenti, E., Elzain Elgingo, M., Douglas, A.R., Cable, T.N.

ASPIRE Academy

Introduction The most important source of Vitamin D is skin synthesis upon exposure to ultraviolet B radiation (UVB) and to a lesser extent, food. UVB rays are most intense in zones extending between latitudes 23.5°N and 23.5°S to the equator (the tropics) and vitamin D synthesis is possible all year long. The cut-off to define vitamin D deficiency has been a matter of debate during the past decade; some consider levels >75 nmol/L to define sufficiency (Dawson-Hughes et al., 2005) while others consider 50 nmol/L an adequate cut-off level (Lips, 2007). The aim of this study was to assess Vitamin D levels in young athletes of Qatar in 3 different periods of their training and competition season. Methods 52 elite male youth athletes (age 12 to 18) were assessed for Vitamin D status as a part of their routine medical screenings in September, January and May. After an overnight fast, a blood sample was drawn from the antecubital vein in BD serum vacutainer tubes (BD Diagnostics, Plymouth, UK). Samples were spun to separate serum and stored at -80°C until assayed. Serum Vitamin D level was determined using 25-OH Vitamin D ELISA kit (Euroimmun, Luebeck, Germany). Anthropometric measures were performed for the determination of peak height velocity (PHV; Mirwald et al., 2002). Results Mean PHV of the subjects was 14.1 ± 0.8 years. Serum levels of Vitamin D were consistently lower than the 50nmol/L cutoff suggested in the literature in each period (42.3 ± 10.8 nmol/L; 44.2 ± 10.0 nmol/L; 47.8 ± 11.9 nmol/L). Vitamin D concentration in May was significantly higher than September ($P < 0.05$). The percentage of athletes with Vitamin D levels below the 50nmol/L cutoff improved from September to May (82% below threshold in September as compared to 58% in May). Maturation status was shown to affect Vitamin D metabolism with prePHV ($n=30$) presenting lower Vit D levels than postPHV ($n=22$) athletes (prePHV 39.6 ± 9.6 nmol/L; postPHV 45.8 ± 11.6 nmol/L; $P < 0.05$). Discussion Our data show that young athletes from the Middle-East region present Vitamin D deficiency. However, since a statistical improvement was observed in May, it seems that more outdoor training sessions and activities during the months from January to May, have a positive impact on Vitamin D levels. Furthermore, our data suggest an influence of growth and maturation on Vitamin D metabolism. Future studies are necessary to ascertain the physiological implications for hypovitaminosis D in growing athletes. References Dawson-Hughes, B. et al. NORWEGIAN FOOTBALL ACADEMY PLAYERS – ASSESSING PERSONAL SKILLS AS A RESULT OF SELF-ORGANISED TRAINING

Sæther, S.A., Aspvik, N.P.

Norwegian University of Science and Technology

Introduction Football academies main function is to develop future elite players. According to the theory of deliberate practise (Ericsson et. Al 1993), there should be a direct connection between an athlete's performance level and the amount of performed deliberate practise. The selected players get however advantages in their development process which increases the chance of becoming an elite performer, because of the high-level coaches and training facilities (Ashworth & Heyndels 2007). However, even among talented players there are differences between the players' both actually and self-assessed skill level. These differences could be a result of player background, training load and content, and coach feedback. The main aim of this study was to divide the players into two groups based on their assessment of their own skills (talented and very talented), and see in which degree the players differed to factors such as player background, training load and content, and coach feedback. **Methods** The Norwegian academy players (n=119) representing 2 soccer academies (top-level clubs from premier league and league two) answered a questionnaire regarding their assessment of their own skills as opposed to the other players in their club. They were also answering questions regarding their load and content of their self-organised training, the degree of praise from their coaches, the number of matches played last season and when they started to play organised football. **Results** Results showed that the very talented players, played more matches and got more praise from their coaches. Furthermore, these players both trained more on their own but also focused more on technical skills in their self-organised training, compared to the talented players, who assessed their skills to be on average or less. **Discussion** These results indicate that there could be a connection between the effort/investment the players put in to their training and their performance level. Even so, this might however also reflect the well-known classical issue "what comes first – the hen or the egg"? It could be that the players, who get the most attention and feedback from the coaches, also invest more time and effort because of the confirmation of acknowledged skills. Would this indicate a self-fulfilling prophecy, for the most skilled players in these academies? **References** Ashworth, J. & Heyndels, B. CONTENT AND PEDAGOGICAL FRAMEWORKS CONCEPTUALISING THE COACH AS EDUCATOR

Culpan, I., Bennett, B.

University of Canterbury

A number of scholars have argued that sport coaching and coach education, is still, "ill-defined and under-theorised" (Jones, 2006. p. 3.) Conceptual frameworks that outline coaching content and suggestive pedagogies that address the complexities of the coaching environment are practically non-existent (Jones, 2006; Gilbert & Trudel, 2004). Coach education scholars report that the majority of coaching programmes are limited and confined to largely coach-centred and coach controlled instructional techniques. (Galvan, Fyall, & Culpan, 2012). The absence of coherent coaching frameworks results in little regard for individual athlete learning needs, little cognisance given to individual meaning making in sport and little attention given to the range of pedagogical strategies available in order to maximise learning. Such a restrictive approach implies that the coach's role is one of instructing, conveying, and/or modelling a set of (physical) skills for enhanced performance. This understanding foregoes recognition of the complex educative responsibilities that a coach has within the coaching environment. In this presentation it is argued coaching is a complex, multifaceted, socially significant, interactive reciprocating, and engaging education process. This conceptualisation requires sophisticated processes between the coach as educator, and the athlete as learner, both operating within specific and pressured environments. Specifically, the purpose of this oral presentation will: * Draw on research and present arguments for the coach's role as educator; * Identify the 'traditional' barrier(s) that prevent a coach fulfilling his/her role as an educator; * Suggest content related and pedagogical oriented frameworks to reinforce and facilitate the coach operating as an educator. DOES A STRONG ATHLETIC IDENTITY NEED TO BE EXCLUSIVE? THE CASE OF ELITE AUSTRALIAN FOOTBALL PLAYERS

Saunders, J., Pink, M., Stynes, J.

Australian Catholic University

Introduction Career transition literature has expressed a concern that demands placed upon professional athletes to train and compete can lead to an exclusive focus on the athletic role. Athletic identity (AI) (Brewer et al., 2001) has been used to measure the strength of identification with the athletic role. Although a strong AI has been shown to be beneficial for effort and performance there is also a concern that this may render sportspeople more vulnerable to burnout, poor vocational development, and problems upon transition to retirement. The present study investigated professional AFL players' athletic identity as part of a larger enquiry into measuring the impact of players' involvement in off-field activities upon their well-being and performance. **Methods** 430 professional Australian Rules football (AFL) players (M = 22.93 years, SD = 3.35) were recruited. Players completed the Athletic Identity Measurement Scale-7 (AIMS-7; Brewer et al., 2001), and the Self-description Questionnaire-III (SDQ-III, Marsh et al., 1984). A descriptive correlational approach was used to examine the relationship of AI to players' sense of efficacy in and beliefs about the importance of twelve intellectual, social, physical, and moral

life domains building on the work of Fraser (2012) with an elite group of Australian amateur and professional athletes from various sports. Results. The players ranked having good interactions with their parents and being an honest/reliable/trustworthy person as both the most accurate descriptions of themselves and the most important characteristics to have. Emotional stability and the possession of good relationships with members of the same sex were seen as the next most important characteristics. Verbal ability was rated as more important than both physical ability and general academic ability. Unsurprisingly, they ranked their own physical ability highly. The athletic identities of this group were similar in profile to those reported for US college level athletes (Brewer et al., 2001). Discussion Strength of AI was most highly correlated with sense of efficacy in sports and physical activities, being an honest reliable /trustworthy person, being an emotionally stable person and having good verbal skills. As there were no negative associations with any domain but rather strength of AI showed at least weak associations with feelings of importance for other life domains, our findings suggest that it is not just possible but likely for athletes to maintain a multidimensional self-concept in association with the development of a strong Athletic Identity. Sporting organisations seeking to facilitate and support the general development of their athletes need therefore not be concerned that development in a broader range of personal domains will compromise the maintenance of a strong athletic identity References Brewer, B, Cornelius, A. (2001). *Academic Athletic J*, 15(2), 103-113. Fraser, L. (2012). Doctoral Thesis, Uni Stnrm Queensland Marsh, H. W., O'Neill, R. (1984). *J Educational Measurement*, 21(2), 153-174.

THE VIDEO ANALYSIS AS TEACHING TOOL IN ARCHERY YOUTH

Napolitano, S., Tursi, D.

University of Naples

Introduction The aim is to evaluate the effects of motor imagery practice in training. The motor imagery is a cognitive process of mental simulation of actions in absence of movement. There are two methods to improve skills learning through motor imagery: in first person and In third person. The biological basis on which the motor imagery theory is founded, is formed by: mirror neurons. The archery is a typically closed skill sport. It is a 'closed skill' sport characterized by repetition, as precise as possible, of a movement already known automated. Method It is an experimental approach and it consists of two steps. Both groups were video taped in the execution of sport skills and evaluated, through a check list made by archery indicators: positioning phase, traction and aim, release and follow through in 4 level of descriptors by technicians every four months. A sample of archery team of children (9-11 years old) splitting in control and experimental groups, after a pre-assessment, performed by technicians, about technical skills through an evaluation grid prepared 'ad hoc' on technical fundamentals taken into the study to form two homogeneous groups (Experimental group n = 10, control group n = 10). Experimental group using modelling video performed by a athletes of National Italian Archery Team could lead to significant changes in technical skills. The results are based on the neuro-scientific assumption on the activity of mirror neurons that allow you to use the same nervous substrate for actions performed or observed, or thought. Result Data recruit at starting, ongoing and final training program and their analysis, evaluation and comparison by control group show percentage of 9% better outcomes. particularly, at final training shows a minimum improvement 3.2% than ongoing phase that gives a maximum improvement 9.6%, while a substantial balance in the control group with a medium improvement of 3.2% in every phase of training program. Conclusion In this study two basic aspects of the performance are examined: the motor execution and the motor imagine. Both share the same neuro-motor mechanism: the motor imagery. Using video analysis by modelling approach as a tool in teaching method has the maximum improvement in first part of training program according to motor control theory of Motor Imagery. Starting phase should be played by video modelling teaching method to learn sport skills in qualitative aspects and then should be played according good sport practice in didactics Reference: 1. F. ONE PERSPECTIVE OF GOLF IN PORTUGAL

Brito, A.P., Ferreira, D., Oliveira, J.2, Fernandes, B.2

(1) CESPU-Portugal ;(2) ISMAI-Portugal

Being a coach is an emergent profession. Coach is much more than just a simple training sessions and competitions guide. He's the anchor for all the sportive preparation and much more than a simple training or competition guide. The successful coach is, in fact, a public figure. Intervention of the coach has a very important role on the individual performance, when considering the promoted influence on the development of the athletes' performances not just on the learning sphere but also on the skill evolution. Must find himself fully prepared with a vast specific knowledge of the discipline, as well as all of the components that characterize the inherent development of the age group of the players. This study intend to observe Golf in Portugal, the training methodologies and through the use of the scientific method, to identify elements of practical usage. Not being our objective the generalization, adopted a descriptive investigation so that we could study, understand and explain a current situation of the object of investigation. Adopted the method of participative observation through an interview/survey and whose direct interaction allowed opening the free area, reducing the unknown area and the blind area of the interviewee. Having that way chosen a qualitative investigation for analysis of our corpus, which we considered thorough, representative, homogeneous and pertinent, obtained the categorization – significant, thorough, exclusive, objective and pertinent items for analysis. Being that the semantic unit of the analysis was prior defined, skipped the definition of 6 formal analysis units that emerge from the interviews performed, subdivided in 43 contextual units. Sample was constituted by 4 individuals, being 2 of them School Sports Coaches(AF and JM) and 2 Golf professionals(GP–Vale Pisão Golf(S) and Quinta do Fojo Golf(T)). Data gathering was developed with the semi-structured interviews as a base for work, which led us to the following conclusions: physical condition of golf player is considered as a success factor; golf coach must have a profound knowledge of the discipline; must attend frequent educative actions so that he can enrich his resume and be up to date with motivational methodologies and in that way his athletes can be part of an effective training of discipline; non-existence of any psychological education on this context; shallowness of education provided by Portuguese Golf Federation; GP guide with their methodologies and training planning in their clubs according with results they are obtaining from athletes; time dedicated to practice is sparse, when compared with needs that golf demand; and in a School Sports level, the dedicated time is considered insufficient, as well as material and infrastructures; importance given to physical and psychological component in clubs presents itself in a higher level than those of School Sports; proliferation of golf is desirable, but for that to happen, clubs must change their objectives in a way that this discipline can evolve on the population.

COACHES' PERCEPTIONS OF THE BENEFITS OF USING PERFORMANCE SPEED TO DETERMINE TRAINING ZONES FOR SURF LIFESAVING COMPETITION

Reddan, G.

Griffith University

Introduction The aim of this study was to determine coaches' perceptions of the use of performance speed for the calculation of training zones for surf lifesaving competition. Performance speed here is defined as the average speed an athlete can maintain during a time trial or actual event (Sharkey & Gaskill, 2006). Times and distances can be converted to average speed, allowing simple calculation of interval and training speeds. Another alternative to assess performance speed involves the use of GPS monitors to calculate actual speed during testing. **Methods** Three coaches at a surf lifesaving club on the Gold Coast, Australia utilized performance speed in the application of training zones for athletes involved in board, ski and boat competitions over a two-year period. Time trials were conducted on a monthly basis to determine performance speed on "out-and-back" river courses in order to negate the effect of currents and tides. GPS monitors were attached to all craft to determine average performance speed over these distances. Training was divided into four zones - easy (EZ), no-training (NZ), performance (PZ) and maximal training (MZ). The following percentages of performance speed were used in calculating the speeds for each zone (Sharkey & Gaskill, 2006): EZ (20-30% below performance speed); NZ (2-20% below performance speed); PZ (1-5% above performance speed); and MZ (maximal speed for 5-20 seconds). A semi-structured interview was utilised to gather information related to the coaches' perceptions of the effectiveness of this approach to training. **Results** The mean improvement in time trials over a two-year period was 9.8%. Coaches indicated that athletes displayed a positive attitude to training using this approach. In comparison to other methods of training, the coaches suggested that this approach was simple for athletes to understand. Coaches enjoyed the increased ability to control the intensity of training, using mainly the EZ and PZ zones, which resulted in positive improvements for all athletes and no injuries were recorded. Coaches also appreciated that outputs in training were measurable, which assisted athlete understanding of the relevance of training to their competition goals. **Discussion** Many coaches of endurance sports face practical challenges and/or uncertainties when using training zones to determine appropriate intensities and volumes for their athletes. The simplicity and specificity of this approach proved appealing to coaches and athletes as they could see the relevance of the training zones to training, recovery and competition, and were motivated by observing regular improvement in time-trial performances. **References** Sharkey & Gaskill (2006). *Sport Physiology for Coaches*. IMPROVING TACTICAL COACHING ABILITIES IN SOCCER

Cordes, O.

University of Augsburg

Introduction/ Problem All efforts in sports games aim to improve the players' performance. But it's the coaches who are the first to be dismissed if the results are not as expected. Nevertheless, methods to improve the performance of the coach have hardly been processed and documented so far. The aim of this paper is to accompany, in the sense of a formative evaluation, the coaches in their work and to uncover and solve methodologically problems in the assessment of game scenes. **Method** By means of an observation system (Cordes, 2013) the games of a second division team were observed and documented over the duration of a Bundesliga season (34 game days). Thus the tactics shown in the game could be analyzed and documented. In a second step the perspective of the coach was determined with an interview in order to find out about deviations between the coach's subjective viewpoint and the objective data. **Results** The empirical results of the study show significant differences between the subjective opinion of coach and the objectively collected data. Especially when it comes to combination play, the coach has often problems to evaluate what he has seen. To explain these deviations depend on different factors must be considered. But the outcome of a game for example, usually influences the perception of the game quite considerably. The deviations found are fed back to the coach, so that a new training process can be initiated. This feedback can be supported by video clips, too. In doing so, the presented method and the results obtained (Cordes et al., 2012) offer the coaching staff a chance to improve his/her rating capacity and well as the development of a long-term strategy and optimize his/her expertise in this context. **Discussion** Methodically, the combination of quantitative and qualitative methods for investigating the performance evaluation of the coach has been proven rewarding (Cordes, 2013). The study showed that there are significant deviations between the coach's subjective point of view and objective performance data. A significant performance improvement in this area is to be expected, if - on the basis of conceptual rules (Cordes, 2013) - a coach-the-coach is carried out and controlled by scientific methods. **Literature:** Cordes, O. ACUTE EXERCISE AND FITNESS MODULATE COGNITIVE FUNCTION IMPROVEMENT IN OLDER ADULTS

Chu, C., Wang, C., Yang, K., Chang, Y.

National Taiwan Sport University

Introduction This study investigated the effects of acute exercise on two types of cognitive function as assessed by the Stroop Test and the modulatory role of fitness on the relationship between acute exercise and cognitive function. **Methods** Forty-six healthy older adults were recruited and categorized into higher or lower fitness groups based upon their fitness level assessed by the YMCA cycle ergometry proto-

col. The participants were administered the Stroop Test after 30 min of aerobic exercise with moderate intensity and after a reading control condition; a counterbalanced order was implemented. Results Results indicated that shorter response times and an increased accuracy rate in both Stroop Test conditions were observed following the cessation of exercise. In addition, superior beneficial effects of acute exercise were detected in older adults with higher fitness levels relative to adults with lower fitness levels. Discussion These findings suggest that acute exercise leads to general improvements in multiple cognitive functions and specific improvements in executive function. In addition, older adults with higher fitness received more beneficial effects resulting from acute exercise, implying the need to exercise on a regular basis. Contact cchu042@yahoo.com

FREQUENT EXERCISE BEHAVIOR DOES NOT RETARD THE ACTUAL ACADEMIC ACHIEVEMENT

Nakajima, T., Yamatsu, K., Sagawa, M., Morita, N.

Hokkaido University of Science

Introduction. In the past, there had been a common misconception that frequent exercises lead the decline of academic ability due to reduction of studying. Recently, several reports have explained the positive relationships between academic ability and exercise (Hillman et al., 2008). However, most of which have been focused on the relationship between test scores rather than total academic performance in school. It is also necessary to consider the influence of other sources such as household income, parents' educational background, and lifestyle which is thought to be involved in academic performance. The purpose of this study is to reveal the influences of exercise behaviors on the school grades as the actual academic achievement in consideration of other factors in Japanese junior high school students. Methods. Participants were 278 male students (body mass index [BMI]: 19.3+/-3.2) and 240 female students (BMI: 19.0+/-2.8) of 1st grade (7th grade in USA style) in public junior high schools in Japan. All students and their parent completed the questionnaires about the exercise behavior, household income, and life style including home learning habits. BMI and academic performance (school grades) were received from school records. The sum total of the 5 subjects grades (Japanese, social studies, math, science, and English) were used as the academic achievement score. Results. Using ANCOVA that controlled for several covariates (household income, mother's educational background, home learning frequency, amount time of TV watching, amount time of Videogame/Cell-phone using), high frequent exercisers (5-7 days/week, mean grade: 17.8+/-4.0) and medium frequent exercises (2-4days/week, mean grade: 18.3+/-5.3) had significantly higher school grades than less exercisers (0-1 days/week, mean grade: 15.4+/-3.7, $p < 0.05$) in male students. On the other hand, in female students, high frequent exercisers (19.6+/-3.2) and less frequent exercisers (18.3+/-4.0) had significantly higher school grades than medium frequent exercisers (16.8+/-4.2, $p < 0.05$). Conclusions: These results suggest that high frequent exercises do not retard the school grades as the actual academic achievement. Furthermore, the tendency of positive influences of exercise on school achievements has been revealed prominently among male students. ANALYSE OF CLINICAL EXERCISE PROGRAMS IN THE TREATMENT OF CLINICAL DEPRESSION: RANDOMIZED CONTROLLED TRIALS

Carneiro, L.1, Fonseca, A.4, Vieira Coelho, M.3, Mota, M.2, Vasconcelos Raposo, J.2

1:CIDESD (Portugal), 2:UTAD (Vila Real, Portugal), 3: FMUP (University of Porto, Porto Portugal), 4: CIFI2D, FADEUP (University of Porto, Porto Portugal)

Introduction Several exercise randomized controlled trials (RCTs) have been proposed as a viable treatment for depression. However, there are conflicting data and some research has shown that exercise, as a treatment, is not effective for depression. The aim of the present study was to evaluate the reported impact of exercise frequency, intensity, session duration, type of exercise, intervention duration, in the success of therapeutic interventions in depression. Methods A systematic review was undertaken on RCTs research reports published in peer-reviewed journals between 2010 and 2013. The databases searched were: Pubmed, Cinahl, Medline, Psycinfo and Psycarticles. Results A total of seven papers were reviewed and five of them reported a significant contribution (71. 43%) effect in the treatment of depression. Results showed that the majority of the interventions were based on aerobic training protocols. The therapeutic programs were based on 30 to 45 min. sessions, and were implemented three times a week, throughout 10 to 12 weeks. In regard to exercise intensity results remains unclear. Discussion / Conclusion Chalder et al. (2012) in a one trial study, based on the non-observation of positive effects of exercise in clinically depressed subjects, reported some methodological inconsistencies. In fact the majority of studies published do not report the protocols used, namely describing both the physical exercise intensity and dosage applied. Methodological flaws might explain the inconsistency in the reported results found in the literature. Recently published studies, with better research designs, suggest that physical exercise tends to improve the patient's response to treatment. In future studies, RCTs should be more specific describing the structure of the exercise program and the exercise volume and intensity (dosage). As a complement to drug based therapeutics to improve mental health, exercise treatment research reports should provide specific recommendations for patients and clinical practitioners. EFFECTS ON MOOD AND SLEEP QUALITY OF THE ELDERLY IN THE DIGITAL ORIENTAL QIGONG EXERCISES INTERVENTION

Cheng, C.M.1, Huang, S.T.2, Hung, C.C.3, Lau, K.O.4, Ting, W.C.5

1: KUAS (Kaohsiung, Taiwan), 2: LYIT (Yilan, Taiwan), 3: AAROC (Chungli, Taiwan),

Introduction According to the investigation of sleep medicine association, one out of five people experience long-term insomnia. Many studies suggest that oriental qigong exercises can stabilize mood and improve sleep quality. The aim was to investigate and collect Shiang Kung and Kang-In Dance (ESK), Ping-Shuai Gong(EXP), and Wai Tan Kung(EXW) audio-visual teaching materials, and set up the web-based motor learning of movement skill assisting platform for middle-aged and elderly people, in the hope of stabilizing mood and improving sleep quality, thus improving the quality of life. Methods 187 subjects were divided into experimental group (93/EX, including ESK, EXP, and EXW group) and control group (94/CO). Three questionnaires and scales were used as assessments tools for the first year. In the second year, digital audio-visual technologies of oriental qigong exercises were implemented to help support the assessment of

the questionnaires. The SPSS17.0 was given to analyze with an independent t-test, repeat single-factor analysis of covariance and paired sample t-test and comparison of the differences and LSD conducted post hoc comparisons, the significance level was set at $\alpha = .05$. Results The results reveal a scale subscale score: 1) Profile of Mood State Scale, POMS: interference and confusion dimension showed CO>EX, self-esteem and vitality dimension revealed EX>CO ; 2) Pittsburgh Sleep Quality Index, PSQI score demonstrated CO>EX; 3) Insomnia Severity Index, ISI score indicated CO>EX ($p<.05$). Discussion Oriental qigong exercises have the impact of reducing the emotional interference into and confusion of the middle aged and the elderly caused by the external environment, while enhancing self-esteem and inherent vitality, lessening insomnia severity (Cheng et al, 2014 ; Cheng and Chen, 2012)). It is recommended that oriental qigong exercises should be embedded in the health care plan as lifelong health care reference. References Cheng CM, Ting WC, Hung CC, Huang CH, Huang ST (2014). IS PERIPHERAL VISUAL PERCEPTION VULNERABLE TO STRENUOUS EXERCISE?

Ando, S., Komiya, T., Kagimoto, T., Kokubu, M., Sudo, M., Kiyonaga, A., Tanaka, H., Higaki, Y.

Fukuoka University

Introduction Visual field is composed of central and peripheral visual fields, and visual resolution decreases towards the periphery of the visual field. We have recently proposed that peripheral visual perception may be impaired during strenuous exercise [Ando et al. 2013]. However, it remains to be elucidated whether some other brain areas (i.e. motor cortex), in addition to areas associated with visual processing, are also affected by strenuous exercise. The purpose of this study was to investigate whether peripheral visual perception is primarily affected by strenuous exercise. **Methods** Eight participants performed visual reaction time (RT) tasks at rest and during exercise on two separate days (central and peripheral conditions). In the central condition, visual stimulus was randomly presented at 2° and 5° to the right or left of the midpoint between the eyes. In the peripheral condition, visual stimulus was presented at 30° and 50° to the right or left. Exercise intensity corresponded to 50% and 75% peak oxygen uptake. The participants responded to the onset of visual stimuli by releasing the button. We measured electromyogram from the forearm, and visual RT was divided into premotor time and motor time based on the onset of the electromyogram [Ando et al. 2009]. **Results** Premotor time to peripheral visual stimulus increased during exercise at 75% peak oxygen uptake ($P < 0.05$). However, premotor time to central visual stimulus was not altered during exercise. Motor time was not affected during exercise in both conditions. **Discussion** In both central and peripheral conditions, the participants responded to the visual stimulus in the same manner. Nevertheless, the increase in premotor time was exclusively observed in the peripheral condition. Hence, the present results may suggest that peripheral visual perception is vulnerable to strenuous exercise as compared with central visual perception, which is in line with the proposal that peripheral visual perception may be impaired during strenuous exercise. Teleologically, this finding may imply that humans focus on central vision at the expense of peripheral vision under life-threatening conditions. **References** Ando S (2013) Peripheral visual perception during exercise: why we cannot see. *Exerc Sport Sci Rev*, 41, 87-92. VISUAL SEARCH, EXERCISE AND PHYSICAL FITNESS LEVEL

Llorens, F., Sanabria, D., Huertas, F., James, R., Bennett, S.

Universidad Católica de Valencia

Introduction Some studies have demonstrated that the abrupt onset of an object in the visual field captures over attention, indexed by eye movements (e.g., Theeuwes et al., 1998). The question addressed here was whether acute intense exercise would modulate attentional capture. **Method and Design** Fourteen undergraduate students (23-31 years old; $M = 26 \pm 2$ years old), from the Faculty of Physical Education and Sport (Liverpool John Moore University, UK) participated in this study. Movement of the left eye was recorded using an EyeLink 1000 with a desktop-mounted camera (250-Hz temporal resolution and 0.2° spatial resolution). Participants completed a visual search task at rest: 1) without a previous effort (non-exercise condition); or 2) after an acute bout of intense aerobic exercise (post-exercise condition). The visual search task consisted of the presentation of six circles, one of which contained a landolt C. Participants had to determine which of the circles contained the landolt C and then respond regarding its orientation (i.e., normal or reverse). Crucially, on half of the trials, an additional circle (object present condition) was added to the display at the same time the landolt C appeared. Manual reaction times (RTs) and the latency of the first goal-directed saccade toward the target were calculated and submitted to separate Exercise (post-exercise, non-exercise) by Object (present, absent) within-participants ANOVA. **Results** Manual RT were slower in the object present condition than in the object absent condition. For saccade latency, there was a significant interaction between Exercise and Object. Crucially, the main effect of Object was significant only in the non-exercise condition. **Discussion** The results of this study replicate Theeuwes et al.'s (1998) finding that the appearance of a novel object interferes with the planning and execution of a goal-directed eye movement to the target. In the non-exercise condition, we found longer saccade latencies toward the target and slower RTs to identify the target, presumably by the appearance of an unexpected novel object capturing overt spatial attention. We suggest that the results of the post-exercise condition were the consequence of the reduced metabolic resources after the intense effort. This would have made the brain (e.g., superior colliculus and parietal cortex) less prone to respond to irrelevant stimuli, in order to focus attention on the primary task goal of identifying the target. **References** Theeuwes, J., Kramer, A. F., Hahn, S., & Irwin, D. E. (1998). Our eyes do not always go where we want them to go: Capture of the Eyes by New Objects. *Psychological Science*, 9(5), 379-385. Contact: flm@ugr.es

SWIMMING AND INTELLIGENCE: A STUDY BETWEEN SWIMMERS AND SEDENTARY PEOPLE.

García, O., Bekendam, N., Díaz, G., Burgos, S.

Universidad Europea de Madrid

Introduction Some studies reflect that the practice of sports is has associated to the development of cognitive abilities, not only physical abilities. (García & Burgos, 2012; Ellemberg & St. Louis-Deschênes, 2010). The aim of this study is to analyse individual differences in intelligence between different groups of swimmers and sedentary people. **Method** We applied the following tests in order to obtain a measure of intelligence: DAT-SR (Bennett et al. 1997), and PMA-R (Thurstone & Thurstone, 1938). We also have a measure of spatial ability

PMA-E (Thurstone & Thurstone, 1938). Sample The sample was formed by 236 Sedentary People, 14 University swimmers, 123 amateurs' swimmers (clubs swimmers) and 6 elite swimmers (low to high performance) Results We found significant differences in intelligence among the four groups. In general intelligence, the clubs swimmers are the group that shows higher scores in DAT-R (43.91), followed by university swimmers (43), elite swimmers (39.40) and sedentary (33.02). In PMA- R, the clubs swimmers shown the higher score (22.65), followed by high performance swimmers (21.80), university swimmer (17.79) and sedentary people (17.79) In spatial ability, PMA- E, elite swimmers shown the higher score (31.20), followed by clubs swimmers (29.25), university swimmers (23.85) and sedentary people (15.58). Discussion Our data give support to the idea that physical activity influences the improvement of cognitive abilities. Physical exercise requires a complex, controlled and adaptive cognitive effort and that physical activity can determine the impact on cognitive processes (García & Burgos, 2012). High performance swimmers, clubs swimmer and university swimmer, have been those who have obtained the highest scores in cognition. It should be relevant in order to clarify the total set of variables involved in sport performance References Bennett, G. K., Seashore, H. G. & Wesman, A. G. (1997). DAT. Test de Aptitudes Diferenciales. Madrid: Publicaciones de Psicología Aplicada. Ellemberg, D., & St-Louis-Deschênes, M. (2010). ASYMMETRIES IN RATE OF FORCE DEVELOPMENT FOLLOWING ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Mirkov, D.M.1, Knezevic, O.M.1,2, Nedeljkovic, A.1, Kadija, M.3, Jaric, S.1,4

1: UB-FSPE (Belgrade, Serbia); 2: UB-IMI (Belgrade, Serbia); 3: UB-SM (Belgrade, Serbia); 4: BMS-GPB (Newark, Delaware, USA)

Introduction The aim was to compare bilateral difference (BLD) and hamstring-to-quadriceps (HQ) ratios calculated from the maximum force (Fmax) with those calculated from the rate of force development (RFD) in athletes after ACL reconstruction (ACLR), and in the healthy subjects (Control group). We hypothesized that ACLR would have larger asymmetries in strength ratios than Control group, as well as that those asymmetries in RFD would be larger than those in Fmax. **Methods** Fifteen athletes with ACL reconstruction (4.0 ± 0.1 months postoperatively) and 15 controls were included in the study. RFD derived at 50, 100, 150 and 200 ms from the contraction onset and Fmax were used to calculate BLD for quadriceps and hamstring muscles. HQ ratios of the involved and uninvolved (in ACLR), and dominant and nondominant leg (in Control group) were also assessed. Results Prominent BLD in both Fmax and RFD variables were observed in quadriceps, but neither in hamstring muscles of ACLR group, nor in both muscles of the Control group. The highest HQ ratios were obtained from the involved leg, while no differences were found among uninvolved, dominant and nondominant leg. RFD recorded at 150 and 200ms from contraction onset yielded highest BLD and HQ ratios. **Discussion** Marked asymmetries in RFD obtained in ACLR suggest that in addition to Fmax, the assessment of the RFD may provide another valid outcome regarding the recovery of ACLR. Therefore, in addition to the routinely tested Fmax, RFD should also be included in the assessment of athletes rehabilitating after ACL reconstruction. **References** 1. A PILOT STUDY FOR THE PREVENTION OF LOWER LIMBS INJURIES IN YOUTH FEMALE BASKETBALL PLAYERS

Benis, R., Vignardi, S., La Torre, A., Bonato, M., Pugliese, L.

Università degli Studi di Milano

Introduction Female basketball players, compared to male athletes, are characterized by an increased risk of lower limbs injuries. For this reason, aim of this pilot study was to investigate the effects the Italian Basketball Injuries Prevention Program (IBIPP) especially designed for female athletes **Methods** Forty-five young, female, regional level basketball players (16±2 y-o; 52.9±11.4 kg; 160±1 cm; 20.1±3.1 kg/m²), were enrolled in a 16-wks protocol consisting of 3 session/week of 2 hours. All subjects were divided in two groups: 23 in the "IBIPP Group" and 22 in a "control" group. The IBIPP program consisted of 25 min active mobility, strength and agility exercises whereas the control group did the normal training routine. Subjects were tested at baseline (BL) and week 16 (W16) by Y excursion balance test, Counter Movement Jump (CMJ) and one legged CMJ (Optojump, Microgate, Bolzano, Italy). Adherence at the training program was registered and the estimation of injuries was calculated according to the study of Knowles et al., 2006. Differences over time were assessed with paired T-test and differences between groups with unpaired t-test. Results were expressed as mean ±SD. Significant differences were found p<0.05. **Results** All participants completed the 16-weeks program with a mean adherence of 90%. No significant differences were found at BL in the two groups. At W16, experimental group showed significant improvements in CMJ (ES 0.8) one-legged CMJ right leg (ES 0.8) CMJ left leg (ES 0.6) and Y excursion balance test for right leg (ES 0.5) and for left leg (ES 0.5). Regarding the control group we didn't find any significant differences at W16 compared to BL. There isn't significant difference between groups with unpaired t-test in CMJ one-legged CMJ and Y excursion balance test. For the other parameters non-significant differences were detected. Significant reductions of injuries rate was detected only in the experimental group with 4 injuries on 890 games and 1781 hours of activity, with incidence rate of 2.3 per 1000 hours exposure (SE 0,0011) with a possibility of 0,05 to 4,45 on 1000 hours to incurring in a injury. On the other hand, the control group had 10 injuries on 1036 games and 2072 of activity with an incidence rate of 4,83 per 1000 hours exposure (SE 0,0015) with a possibility of 1,84 to 7,82 on 1000 hour to incurring in an injury. **Discussion** The IBIPP program, through a neuromuscular, resistance and mobility training, has shown to reduce the incidence of injuries in young female basketball players. **References** Knowles et al. *Journal of Athletic Training* 2006;41(2):207-215 Contact roberto.benis@unimi.it

STRENGTH RATIOS OF SPECIFIC MUSCLE GROUPS IN MALE ELITE ATHLETES WITH DIFFERENT TRAINING BACK- GROUNDS

Pelzer, T., Ullrich, B., Felder, H., Raab, J., Stening, J., Fröhlich, M.

Olympic Training and Testing Center Bad Kreuznach

Introduction Agonist-antagonist strength ratios for the shoulder internal and external rotators, the knee extensors and flexors as well as the trunk extensors and flexors are frequently used to assess muscle performance, the risk for injuries, and to guide rehabilitation in athletic populations (Ayala et al., 2012; Zanca et al., 2011). However, few studies present agonist-antagonist strength ratios for different muscle groups measured in healthy male elite athletes with specific training backgrounds. **Methods** According to their physical activity a total of 112 male German elite and junior-elite athletes with top-national and international performance level were divided up into 7 sport-specific groups: Wrestlers (n = 12), badminton players (n = 31), pool swimmers (n = 11), Olympic triathletes (n = 10), handball players (n = 30), junior tennis players (n = 9), and junior slalom canoeists (n = 9). Data were collected in 2012-2013 at the annual central performance testing's when athletes aimed for peak physical performance. Isokinetic concentric (60°/s) and isometric MVC testing's near optimal joint configuration were performed for the shoulder internal and external rotators, and the knee extensors and flexors using a Biodex-dynamometer. Isometric MVC of the trunk extensors and flexors were measured at a trunk muscle device (DIERS, myoline professional, Germany). **Results** According to physical activity, isometric and isokinetic concentric HAM/QF ratios varied from 0.60 ± 0.12 to 0.70 ± 0.11 and from 0.55 ± 0.07 to 0.70 ± 0.10 , respectively. Isometric and isokinetic concentric shoulder ARO/IRO ratios varied from 0.43 ± 0.05 to 0.47 ± 0.12 and up 0.42 ± 0.13 to 0.47 ± 0.10 across disciplines, respectively. Finally, isometric trunk flexion/trunk extension ratios varied from 0.40 ± 0.10 in wrestlers to 0.61 ± 0.08 in triathletes. The 95% confidence intervals for all agonist-antagonist strength ratios were also calculated for each athletic group. **Discussion** This work presents average strength ratios for knee joint muscles, shoulder rotators, and trunk muscle groups in male elite athletes with specific training backgrounds. With few exceptions, these strength ratios showed only small variation among the analyzed athletic groups and were quite similar to literature values of non-athletic healthy subjects. **References** Ayala, F., De Ste Croix, M., Sainz de Baranda, P., Santonja, F. ACUTE EFFECT OF KINESIO-TAPING ON 6-S MAXIMAL CYCLING SPRINTS IN HEALTHY ACTIVE PEOPLE: A PILOT STUDY

Trecroci, A., Formenti, D., Esposito, F., Alberti, G.

University of Milan

INTRODUCTION Sprint performance is closely linked to muscle power, which is a key element for many physical activities, especially cycling. Based on the relationship between cutaneous afferent stimulation and motor unit firing rate, underlying neurofacilitation mechanisms have been hypothesized (Macgregor et al., 2005). In this context, Kinesio-taping (KT) could improve power performance by the interaction with motor control. According to the latter outlines, the aim of this study was to investigate the acute effect of KT on sprint cycling performance. **METHODS** Five healthy male subjects participated to the study (23.0 ± 1.5 yrs, 71.8 ± 7.6 kg, 1.8 ± 0.1 m, 22.0 ± 1.5 kg/m²). Two taping conditions were tested on each participant: KT dominant leg (KT1) and KT both legs (KT2) compared to untaped (nKT). KT was applied over vastus medialis and vastus lateralis muscles. Participants performed three single 6-s sprint on a cycle ergometer, interspersed by 180-s of rest. The sprint bout with the highest peak power (PP) value was considered in the analysis for each condition. Mean power output (MP) and total 6-s-work (TW) were also assessed. **RESULTS** Muscle power and total work values during a 6-s sprint increased by approximately 5% in KT2 compared to nKT. However, the ANOVA for repeated measures pointed out that differences in PP were not statistically significant (nKT 12.77 ± 1.35 vs. KT1 12.78 ± 0.97 vs. KT2 13.27 ± 1.19 W/kg; $p > 0.05$) as well as for MP (nKT 11.65 ± 1.31 vs. KT1 11.8 ± 0.91 vs. KT2 12.25 ± 0.88 W/kg; $p > 0.05$) and for TW (nKT 70.70 ± 7.01 vs. KT1 70.51 ± 4.78 vs. KT2 74.17 ± 5.10 J/kg; $p > 0.05$). **DISCUSSION** In terms of PP, MP and TW values normalized for body mass, KT did not influence sprint cycling performance. To our knowledge, this preliminary study is the only that investigated the acute effect of KT on cycling power performance. Anyhow, other authors confirmed that KT did not significantly change lower limb function on strength (Fu et al., 2008) and power movements such as jumps (de Almeida et al., 2013). In conclusion, statistical results do not seem to support the use of KT applied on the anterior thigh to significantly enhance a 6-s single sprint performance, even though higher values of muscle power were generated in KT2 condition. Further research is needed in order to improve the understanding of KT method and its effectiveness in the power disciplines. **REFERENCES** de Almeida C.A. et al. CORRELATION OF CONVENTIONAL AND FUNCTIONAL KNEE STRENGTH RATIOS IN ELITE SOCCER PLAYERS

Pinto, R.1, Ruas, C.V.1, Pinto, M.D.1, Brown, L.E.2

1. UFRGS (Porto Alegre, Brazil), 2. CSUF (Fullerton, USA)

Introduction Isokinetic hamstrings to quadriceps (H:Q) conventional ratio (CR) and functional ratio (FR) are frequently used to assess muscle imbalances and to screen for potential risks of knee injuries in sports. The CR has functional limitations compared to the FR, because it considers only the H:Q concentric (CON) strength relationship and does not evaluate the H eccentric (ECC) strength necessary to decelerate Q CON actions, included in FR calculations (Coombs, 1998). However, CR is an easier assessment compared to FR because it does not include an ECC strength test, which requires greater test coordination and may lead to significant muscle damage in athletes (Cheung, 2012). Thus, the aim of this study was to investigate the correlation between knee CR and FR in Brazilian elite soccer players and create an equation to predict FR using CR to evaluate knee functionality, thus avoiding operational difficulties related to ECC testing. **Methods** One hundred and four elite soccer players (25.24 ± 5.3 yrs) performed maximal dominant knee isokinetic CON and ECC strength tests at $60^\circ \cdot s^{-1}$ through 90° of range of motion on a CYBEX NORM. The Pearson correlation (r) was used to evaluate the relationship between CR and FR. A linear regression model was employed to identify adjustments for comparisons between variables and to create an equation to estimate FR from CR. All analyses were performed with SPSS 18.0 (α level 0.05). **Results** The correlation coefficient between knee CR and FR values was 0.546 ($p < 0.01$). The linear regression results demonstrated that an equation using CR explained 29.8% of the variance observed in FR ($F = 47.048$; $p < 0.001$). This suggested the use of a regression equation adjustment [$Y_i = (\beta_0 + \beta_1 \times X_i) + \varepsilon_i$] to estimate FR from β constant and β_{CR} values. The equation at $60^\circ \cdot s^{-1}$ was indicated as followed: $FR = [0,397 + (0,653 \times CR) + 0,014]$ **Discussion** The CR and FR are important knee assessment tools, but have limitations regarding test operational difficulties and reproduction to sports functionality, respectively. Our study showed a moderate to strong correlation between ratios. Based on this, we recommend that knee screening assessments should use values of both ratios to determine knee imbalances conclusions (Aagaard et al., 1998). This positive correlation also suggests that the equation presented here can predict FR by only assessing CR in elite soccer players. This would avoid

ECC test issues, diminish post-test muscle damage and lead to a simpler and more accessible assessment tool to calculate both ratios values. ANKLE KINESIO® TAPING DOES NOT IMPROVE POSTURAL CONTROL IN ASYMPTOMATIC SUBJECTS.

Booghs, C., Brasseur, T., Kinet, J., Duchateau, J., Baudry, S.

Université Libre de Bruxelles

Introduction Kinesiotape (KT) is assumed to increase the somesthetic information flux and to influence the activity of muscles surrounding joints (Konishi, 2012). These characteristics may therefore improve balance although the effects of KT on postural control remain largely unknown (Bicici et al., 2012). The present study investigated the acute effects of KT application on postural stability and associated leg muscle activity. Methods 11 adults (age 21.9 ± 2.8 yrs) performed unperturbed unipodal upright standing with eyes closed on a force platform (30-s duration) and the Y Excursion Balance Test (YEBT) in 3 counterbalanced conditions: with KT, with classical elastic contention (EC) placed with similar parameters as the KT, and with no contention (NC). Surface electromyography (EMG) was recorded for tibialis anterior, gastrocnemius medialis, soleus and fibularis longus during the two balance tests. Centre of pressure (CoP) parameters, scores in YEBT and EMG activity were compared across conditions. Results No statistical difference was observed between the three conditions on total CoP path length ($p > 0.05$). Similar results were obtained for CoP velocity and sway area. The averaged YEBT scores across directions, normalized to lower limb length were not modified by the contention conditions (0.8432 ± 0.06511 %, 0.8484 ± 0.07145 %, 0.8375 ± 0.05672 % for NC, KT and EC respectively; $p > 0.05$). The EMG activity did not differ across conditions for both tests ($p > 0.05$). Discussion These results show that KT applied around ankle joint does not influence postural stability and the associated muscle activity in asymptomatic young subjects. These results do not support the use of KT as a prophylactic method to improve postural control but do not exclude possible effects on individuals suffering of ankle instability. IMPORTANCE OF QUANTITATIVE RETURN-TO-FIELD CRITERIA

Schwartz, C., Cordonnier, C., Lehance, C., Delvaux, F., Forthomme, B., Denoël, V., Brûls, O., Croisier, J.L.

University of Liege

Introduction After an injury, rehabilitation programs aim at retrieving pain and limiting the risk of new injuries by restoring optimal physical shape (muscle balance, proprioception and neuromuscular control) and therefore allowing an efficient return to competition. However various factors may lead to a premature return to the field such as key competitions or the absence of available tests for quantitative measurements. Athletes and their staff may also have the idea that the return to "normal" training will lead to a gradual reduction of the remaining imbalances. Our goal aims at illustrating on a specific example that without a specific rehabilitation program imbalances do not disappear. Methods This study concerns a high level professional skier, who had sustained a ACL surgical reconstruction on one knee after a ski injury. When she was authorized by the medical staff to return to training and competition (t0), she performed several tests to quantify analytical and functional parameters including an isokinetic test (quadriceps and hamstring muscle groups), maximal height during a unipodal squat jump and maximal distance covered for a triple crossover hop test. Two months later (t1), the same tests were conducted. During these two months she followed her general training program, which focused on ski practice, and participated to competitions. Results The results are expressed as the difference of performance between both legs. The isokinetic deficit on the injured knee reached 20% at t0 and 25% at t1 for the quadriceps peak torque. The unipodal squat jump leads to differences of 24% and 25% at t0 and t1 respectively. We observed a distance difference of 23% at t0 and 22% at t1 for the hop test. Discussion Just before returning to normal training, we were able to identify large imbalances between both legs for isokinetic and functional performances. The injured leg was at least 20% weaker than the healthy side. These results show that even if the athlete was authorized to return to field by the medical staff, she had not yet fully recovered from her injury. Two month of training focusing on skiing skills did not reduce the imbalances. All parameters still showed lingering deficits higher than 20%. These results show that one should not expect a non specific training program to reduce significantly imbalance after injury. The persistence of these differences could be a potential source for further injury (Kvist, 2004). This case study emphasized the need of quantitative return-to-field criteria that could be used by the medical staffs. We hypothesize that such criteria would limit early return to training and reduce injury risks. Reference Kvist J (2004). *Sports Med*, 34, 269-280.

NEUROMUSCULAR CONTROL AND ADAPTATIVE MECHANISMS AFTER ANTERIOR CRUCIATE LIGAMENT RUPTURE: A CASE REPORT

Melloni, M., Gonçalves, E., Nunes, K., Guerra Júnior, G.

Universidade Estadual de Campinas

Background The anterior cruciate ligament (ACL) is one of the most injured ligament in the sports practice. Thus, its treatment gets special attention. Due to presumable joint instability after injury, the surgical treatment has been frequently recommended for athletes. Objective The purpose of this study was to identify the mechanisms responsible for normal knee function and stability of an athlete who underwent to a conservative treatment after ACL injury and investigate why patient did not present any complaint even during the intensive rotational exercises. Methods We investigated a military student who was 17 years at the time of the injury. The ligament rupture at the right knee was diagnosed by clinical findings and magnetic resonance imaging. After diagnosis the patient underwent to conservative rehabilitation for 4 month. When the 4 month rehabilitation period had finished a Lysholm questionnaire was filled in by patient. KT1000® arthrometer was used to detect ACL injury and isokinetic dynamometer was used to assess the muscle strength. To the assessment of lower limb functional performance and neuromuscular control the "Hop Test" was performed. Results After treatment period had finished, KT1000® confirmed ACL rupture in the right knee. It was measured 15 mm of anterior translation in the right knee while the left knee had an anterior translation of 10 mm. However, the Lysholm questionnaire demonstrated that the athlete did not have any complaint or restriction related to the right knee (score =100). In the isokinetic exam at 60 deg/s the limb without injury demonstrated 10% extensor deficit and 16% flexor deficit. At 180 deg/seg we could observe an extensor deficit of 5% and a 14% flexor deficit, both in the uninjured knee. At the Hop Test it could be observed a normal performance for the injured limb. Comparing the performance of both lower limbs, the injured side demonstrated to achieve 91% of the performance demonstrated by uninjured one. Conclusion Although the ACL rupture had been confirmed at the right knee, the patient developed adaptive strength and neuromuscular control mechanisms which allowed him the full practice of sports and military activities. It was possible after intensive rehabilitation program. Consequently it suggests that surgical or

conservative treatment option may be also based on dynamic and functional analysis, not only on static evaluation and static measurements.

AGE IS JUST A NUMBER; MATURITY IN MOVEMENT IS A CHOICE

O'Brien, W., Belton, S., McGrane, B., Issartel, J.

University College Cork

Age is just a Number; Maturity in Movement is a Choice Introduction: In recent years, there has been a compelling argument to suggest that fundamental movement skill (FMS) proficiency is positively associated with childhood physical activity and fitness levels (Belton et al., 2014; O'Brien et al., 2013). Considering children have the developmental potential to master most FMS by 6 years of age, there has been a noticeable absence in the literature documenting "actual FMS age equivalence" amongst youth. This study is the first of its kind to systematically investigate 12 to 14 year olds FMS age equivalence using a globally accepted measurement tool. Methods: One hundred and fifty four participants (12.88 ± 0.44 yrs) were assessed during their typical 80 minute physical education (PE) lesson using the Test of Gross Motor Development-2 (TGMD-2) (Ulrich, 2000). To ensure that adolescent performance was constant over time across twelve selected FMS, the research team conducted a 48 hour time sampling test-retest reliability measurement amongst a sample of 35 participants aged 12-14 years. The coefficients reached 0.87 which shows that the scores across all skills were stable over time. Two way ANOVA's explored the impact of gender and schools on FMS proficiency. Results: There was a significant gender difference in locomotor subtest score ($p < 0.0005$), with males possessing significantly higher skill proficiency. Accounting for actual age equivalence using the norm-referenced, standardized TGMD-2, results indicated that participants were performing the range of skills at a developmental capacity of $7.35 (\pm 1.1)$ years. Discussion: Results of this study highlight that gender differences in locomotor skill proficiency exist. Yet, overall gross motor skill proficiency amongst Irish youth is far below their expected level of age equivalence. School based programmes with developmentally appropriate FMS experiences delivered by physical education specialists (Belton et al., 2014; O'Brien et al., 2013) can significantly improve FMS proficiency in youth. EFFECTS OF ANXIETY ON THE PERCEPTION OF ACTION CAPABILITIES: TOWARDS A SENSORIMOTOR INTEGRATION PERSPECTIVE

Daviaux, Y.1, Cremoux, S.1, Tallet, J.2, Amarantini, D.3, Cornu, C.1, Deschamps, T.1

University of Nantes

1: Lab « Motricité, Interactions, Performance » (EA 4334), University of Nantes (France), 2 and 3: Lab PRISSMH-LAPMA (EA 4651) and Lab ICHN (UMR 825) (Toulouse, France) Introduction Accurate perception of our own action capabilities is an essential prerequisite for sport performance (Fajen et al. 2008). But changes in emotional states were found to alter estimating opportunities for action. Investigating brain dynamics allows better understanding of underlying sensorimotor integration, but no study has addressed the link between the impairment in perceived action capabilities and the sensorimotor integrative processes at the cortical level. Thus we examined the impact of anxiety levels on participants' perceived action capabilities, while recording electroencephalographic (EEG) activity. Methods Fourteen volunteers verbally reported whether they feel to catch a glass with their dominant right hand. The glass was presented at various distances during 300 ms in a specific box (Oliveira et al. 2012). EEG data were simultaneously recorded using a Biosemi ActiveTwo system of 64 scalp electrodes placed according to the 10-20 system, at a 1024 Hz sampling rate. The ratio between perceived and actual catching performances was compared within an intra-volunteers design in control CTL vs. anxiety ANX conditions. Breathing restriction was used to induce anxiety levels, rated in a 0-100 scale. Cortical activity in the 4-8 Hz band were computed over medial central premotor (FCz electrode), contro- and ipsi-lateral sensorimotor cortex (C3 and C4 electrodes) and compared in an ANOVA with two repeated measures: perceived as catchable or not (CATCH vs. NON-CATCH) and anxiety (CTL vs. ANX). Results The anxiety levels were higher in ANX (70.0 ± 11.6) than in CTL (10.7 ± 7.1) ($p < 0.001$). Considering a baseline error of overestimation, the participants underestimated their action capabilities in ANX (1.3 ± 0.5) as compared with CTL (1.4 ± 0.5) ($p < 0.05$). The ANOVA revealed a main effect of ANX with greater synchronization in the 4-8 Hz band under FCz (+39%) and C3 (+34.6%) ($p < 0.05$) during the glass presentation in the ANX condition. No difference between CATCH and NON-CATCH condition was found. Discussion Changes in cortical activity over the premotor cortex and the contralateral to the right hand sensorimotor cortex could reflect an adaptation of sensorimotor network to changes in perception of action capabilities in anxiety condition. The results address the relationships between the sensorimotor cortical network and the network involved in the perception of action capabilities. References Fajen BR, Riley MA, Turvey MT (2008). EFFECT OF PRACTICE SOCCER JUGGLING WITH DIFFERENT SIZED BALLS UPON PERFORMANCE AND TRANSFER TO BALL RECEPTION.

Råstad, O.

Nord Trøndelag university College

Introduction Usually in practice, coaches use training methods that achieve high levels of performance during acquisition, but falter during later transfer test to similar sport skills (Vickers et al, 1999) To investigate which variables that enhance transfer performance, often blocked (easy) or randomly (difficult) practice is used (Porter & Saemi, 2010). However, only few studies have altered the difficulty of practice by manipulating the size of the equipment to investigate transfer effects (Tillaar & Marques, 2013). In addition, there is a lack of research examining transfer between sports skills (O'Keefe et al, 2007). Thus, the aim of this study was to compare if practice with different ball sizes would have a positive effect in a soccer juggling performance, and if this practice has a positive transfer on a ball reception task. **Methods** Twenty-two adolescent soccer players (age 16.6 ± 0.93 yr.) juggled a soccer ball as many times as possible within 30 seconds using only dominant foot. In addition the control of an approaching ball inside a restricted area was tested. After the pretest the subjects were randomly divided in two equally sized groups. In the training period of 6 weeks four times per week, one group (Small ball-group) practiced juggling with a smaller ball then the test ball, while the other group practiced juggling with a bigger ball. (Bigger ball group) No training consisting of ball reception was practiced during the training period. **Results** The ball juggling performance increased significantly for both practice groups ($F=16.7$, $p=0.001$) with no difference between groups ($p=0.68$). In addition, no transfer was found to ball reception ($p \geq 0.22$) in none of the measured parameters (time and distance covered to control ball). **Discussion** The findings in ball juggling performance supports the view that if the practice task is resemble to each other, the increased workload is a more important factor than the size of the equipment (Tillaar & Marques, 2013). Thereby it follows the variability of practice hypothesis as opposed by Schmidt (1975). Furthermore, the finding that improvement in ball juggling performance had no positive transfer effect to ball reception supports the specificity of learning principle (Tremblay & Proteau, 2001) This could be due to the different movement and perception elements between juggling and ball reception. **References** O'Keefe SL, Harrison AJ, Smyth PJ (2007). *Phys Educ Sport Ped*, 12(2), 89-1021. ARE ADOLESCENTS AS GOOD AS THEY THINK? DISCREPANCY BETWEEN PERCEIVED MOTOR COMPETENCE AND FUNDAMENTAL MOVEMENT SKILLS PROFICIENCY.

McGrane, B., Belton, S., Powell, D., O'Brien, W., Issartel, J.

Dublin City University

Introduction: The purpose of this study was to investigate the fundamental movement skill (FMS) proficiency levels and perceived motor competency of Irish adolescent youth. FMS are considered the basic units of movements which are deemed capable of mastery by six years of age and allow for the development of more complex sport specific skills (Kirk & Rhodes, 2011). Both FMS proficiency and perceived motor competency are seen as important contributors of future participation in sport and physical activities (Goodway & Rudisill, 1997). **Methods:** 570 adolescents, aged 12-13 years old, were tested. The Test of Gross Motor Development 2 was used to assess 6 locomotor skills and 6 object control object control skills. Three further skills including balance were assessed as they were deemed relevant to the Irish sporting culture. These were videoed and later analysed. Perceived motor competency was assessed via questionnaire where children stated on a scale of 1 (not confident) to 10 (very confident) how confident they were at carrying out specific skills. **Results:** Overall participants performed below expected levels of FMS proficiency. Object control skills were performed better than locomotor skills, ($p < 0.0005$). Males performed better at locomotor skills than females, ($p < 0.0005$). The mean perceived motor competency was 7.23 ($SD=2.75$) with a positive correlation between perceived motor competency and FMS proficiency ($r=.299$, $p < .01$). FMS scores were categorised into 3 groups (low, medium and high FMS proficiency). The perceived motor competency for these groups differed significantly (Range: 5.63 – 7.89). The low group presented a negative correlation between FMS proficiency and their perceived motor competency ($r=-.285$, $p < .01$) while the high group had the opposite effect (i.e. positive correlation $r=.231$, $p < .01$). **Discussion:** Even if children are developmentally able to master most FMS by the age of six, results from this study revealed that participants scored below the expected threshold levels which will prevent them in the development of sport specific skills. Perceived motor competency can have a major influence on children's motor skill proficiencies. Children that perceive themselves to possess low competence will be less likely to persist with the skill or activity. If a child is unable to estimate their motor competence which is the case with the low FMS proficiency group, then they consequently over or under estimate their motor abilities. This leads to unrealistic expectations resulting in either failure or loss of motivation. Goodway, J.D. and Rudisill, M.E. (1997). Perceived Physical Competence and Actual Motor Skill Competence of African American Preschool Children. *Adapted Physical Activity Quarterly*, 14, 314-326. Kirk, M.A. and Rhodes, R.E. (2011). SHORT TIME EFFECTS OF TASK VARIATIONS ON CLUB HEAD KINEMATICS IN GOLF PUTTING

Schmidt, M.1, Hennig, M.1, Jensen, U.2, Eskofier, B.2, Jaitner, T.1

1: TU Dortmund University, 2: Friedrich-Alexander-University Erlangen-Nuremberg

Introduction Based on system dynamics the differential learning approach proposes the implementation of multiple task variations during skill acquisition for superior motor learning performance. Parameters as well as structural variations are included randomly without repeating a single task, and even movement errors are considered as essential noise (Schöllhorn, 2000). Evidence has been given that this leads to superior motor learning than traditional approaches that focus on task repetitions and error correction and even to at least equal performance than lower level of structural variations (Savelsbergh et al. 2010, Schmidt et al. 2013, e.g.). To define an appropriate range of variation most studies align on recommendations of Schöllhorn (2000) that are derived mostly from theoretical considerations and practical experience. However, little is known how these variations affect the movement processing. Therefore, this study aims to analyze short time adaptations of different task variations in a simple golf putting task in order to develop a more biomechanically founded framework for the optimal range of variation in motor learning. **Methods** 12 novices practice the golf putt in three blocks, each assigned to one category of task variations according to Schöllhorn (2000). These categories contain (1) variation of initial and/or final conditions, (2) change of movement range, and (3) changing of a movements time course with respect to relative and absolute duration

and rhythm. All subjects perform ten trials within each block, and additionally 5 trials in normal conditions at the beginning and the end of each block. The sequence of the tasks and the blocks are randomized between all subjects. Club head kinematics of each trial are captured with an instrumented golf putter capable of collecting 3-D gyroscope and 3-D accelerometer data (Jensen et al., 2011). Kinematic data of every trial are analyzed separately. Pattern recognition methods including distance measures and cluster analysis are applied to classify the task variations. Results and Discussion It is expected that intra-individual as well as inter-individual clusters of movement pattern can be identified that can be assigned to specific task variations. Hence, this should allow firstly quantifying the effect of different task variations on the individual, and secondly to classify the task variations based on the changes of movement kinematics that are caused by these tasks. PERFORMANCE AND COMPLEXITY IN BALANCE TASK DEPENDING ON SPORT SKILL LEVEL AND AGE.

Moreno, F., Urbán, T., Hernández, H., Caballero, C., García, J.A., Sanz, D.

Miguel Hernandez University of Elche

Introduction Complexity has been related with the capacity of the system to generate adaptive responses to stressors (Barbado et al., 2012) but there is controversy about complexity results. Some studies have tried to analyze the interactions of neuromuscular components by analyzing the complexity of COP (Manor et al., 2010). The aim of this study is to contrast the hypothesis about the relationship between complexity and performance in a balance task in a wide sample in which there are different sports, skill levels and ages. Methods 120 tennis players and 131 handball players were divided into groups according to their skill level (expert and novel) and age (10-12 y., 14-16 y. and +18 y.). They were asked to stand still (60s) on an unstable surface. COP excursion was collected from a force platform. Balance performance was assessed by standard deviation (SD) and mean velocity of antero-posterior (AP) and medio-lateral (ML) axis, and by bivariate variable error (BVE) and mean velocity of magnitude (VMeanM). Dynamics of COP displacement was measured through Fuzzy Entropy (FE), Permutation Entropy (PE) and Detrended Fluctuation Analysis (DFA). Multivariate analysis was used to analyse the differences between ages and experience level. Results The higher skilled handball players showed less SD of AP axis and less BVE in 10-12 and 14-16 year old groups, but these differences do not follow the same trend in the +18 group. Tennis players showed significant differences in the dispersion of COP according to the age. The younger tennis players exhibited higher dispersion values. There were significant differences between groups in the COP velocity. The older players showed less values of COP velocity. Regarding dynamics of COP, the expert handball players showed higher FE values in the ML axis, and lower PE and DFA values in the AP axis. In tennis only expert players between 14 and 16 years old showed significant lower PE values than novel players in the AP axis. Discussion Expert players have been better in a balance task than novel players but the differences have been higher in younger ages. The older participants showed fewer differences between both skill levels. In this sense, the sport performance level can indicate better coordination ability only in younger ages. The differences in COP dynamics according to the axis, would reveal different emergent strategies due to the adjustments made in the different axis to control balance tasks (Caballero et al, 2013). OBSERVATIONAL ASSESSMENT OF FUNDAMENTAL MOVEMENT SKILL PROFICIENCY IN PRESCHOOL CHILDREN

Sasaki, R., Ishizawa, J.

Keio University

Introduction: The concern over declining fundamental movement skill (FMS) competency in young children has grown in recent years. Early childhood is a sensitive period for the development of FMS. In fact, the mastery of several of these skills during this stage is a prerequisite for daily functioning and participation in later physical or sport-specific activities. Although quantitative methods have been developed for assessing movement development in children, it is also important to qualitatively evaluate such skills in developing children (Hardy et al. 2010, Cliff et al. 2012). In this study, we investigated children's proficiency in FMS from a qualitative perspective via an observational assessment. Furthermore, validation of observational criteria was discussed. Methods: Participants were 144 preschool children from 4 to 6 years of age. In this study, 5 categories of FMS (25-m run, zigzag run, horizontal jump, overarm throwing, and ball bouncing) were measured as quantitative indicators of competency. Then, all of their movements were videotaped simultaneously, and evaluated qualitatively based on observational assessment criteria of "whole-body movement image" and "several movement components". We also investigated developmental changes in these aspects of FMS proficiency. To evaluate the validity of our observational criteria, the relationship between qualitative and quantitative measures was analyzed. Statistical analysis was performed with SPSS ver.19. Results: Participants were categorized by age and sex for appropriate comparisons. Quantitative measurement values of all FMS showed that these abilities were more advanced in older children. Mastery prevalence rates were compared across categorized groups for qualitative evaluations of FMS, which confirmed that older preschoolers had greater FMS proficiency based on our observational criteria of whole-body movement image, but few movement components. There was a significant relationship between whole-body movement image and quantitative data on each movement ($p < 0.05$). Discussion: These results suggest that FMS generally improves during the preschool years, as evaluated by observational assessment as well as quantitative measurements. However, some movement components were not yet evident in the preschool stage (e.g., trunk rotation in overarm throws, takeoff angle in horizontal jumps). Results also indicated that observational data can be valid assessment tools for FMS assessment in preschool children (Hardy et al. 2010). An observational assessment seems to be a useful method for preschool teachers to evaluate children's movements during structured activities and free play. References: Hardy L.L., et al. 14:00 - 15:00**Mini-Orals****MO-PM47 Sport Injuries****SELF-CARE IN RUGBY PLAYERS**

Martínez Rueda, R., Dallos Santander, D.

UNIVERSIDAD MANUELA BELTRAN

Introduction: Rugby is a sport with high growth and development in recent years in Colombia, where it is practiced in amateur category (FCR, 2013). Its highly physical demanding and injury risk require self-care and other strategies to promote the welfare and proper performance of athletes both individually and collectively. The aim of this study is to identify the determinants of self-care in Rugby players in Bogota. **Methods:** A qualitative study was performed, through semi-structured interviews to six Rugby players and a physiotherapist in Bogota inquiring about their self-care knowledge and its determinants in sport practice (Orem, 2001). **Results:** Self-care is recognized and basically related to sports injury prevention and better performance. Knowledge of self-care practices is variable and in general players feel they more need education about. Most of the practices prevalent in athletes are inconsistent with existing knowledge. Adherence to medical or rehabilitative treatment is quite low, partly because of the ignorance about the sport that is still in the local medical field. Most of the players return to the field before discharge. As determinants of self-care, it was found that the shortage of resources associated with the practice of amateur sport, hinders the development of promotion and prevention strategies in sport. The culture also determines self-care practices. Group dynamics and the desire to play, makes despite knowledge assumed practices recognized as risk. The development of sport in recent years, which is also, associated with a more trained human resources results in a better adherence to healthier practices and behaviors, from being a practice dominated by empiricism become increasingly systematized. **Discussion:** The findings of this study contrast with the evidence that the sport promotes healthier behaviors (Batista, Soares, 2013). However, these seem to be part of the development of a relatively new and rapidly evolving of Rugby in Colombia. The social determinants of self-care and cultural factors are evidenced in this sport, where behaviors in which the interest in the game is above the own personal welfare. 1. TYPES OF INJURY OF ELITE FOOTBALL PLAYERS OF THE ANATOMICAL LOCALIZATION

Gümüş, M.1, Akalın, T.C.1, Göktepe, M.2, Gökdemir, K.3, Çıplak, M.E.1, Emektar, B.1

1Bülent Ecevit University (Zonguldak,Turkey), 2Ağrı İbrahim Çeçen Üniversitesi (Ağrı,Turkey), 3Gazi Üniversitesi (Ankara,Turkey)

Introduction In football which is one of the most popular branches of sport and which has become a huge industry with globalization, it is known that injury instances of elite players are quite high. It is also known that the injury risk in professional football is 1000 times higher than industrial work areas accepted as highly risky, besides it was reported that elite male footballers are facing 65-95% performance-restricting injuries within a season at least once. It is observed that injuries in football are 85% in low extremities. 15-20% of these injuries are in soft tissues, 53% in hips, 42% knee flexor and 52% are in knee extensor. When all these are taken into account, the type of injury and anatomic localization and both the prevention of the injuries and their treatment are of great importance. This study aims to analyze several factors that play role in the injury process of elite footballers and to determine the anatomic localization of types of injuries. **Method** The participants of the study are 130 professional male footballers playing in Professional Leagues of Turkish Football Federation with a mean age of 20-29 (25.4±3.1) with 12.67±3.72 years of experience in football. The necessary permissions were taken from team authorities prior to the study and the medical departments of the teams were cooperated. The logs and reports recorded within the last year in formal matches and trainings were investigated. The data obtained was analyzed with SPSS for Windows 16.0 statistical software and the means, standard deviations ± and percentiles (%) were placed in tables. **Findings** It was found out that the 50 players participating our study underwent 43 injuries in sum and 4 of them were goalkeepers (9.3%), 10 of them were defence players (23.3%), 16 of them were midfield players (37.2%), and 13 of them were forward position players (30.2%). When the injuries are analysed in terms of anatomical positions, out of these 43 injuries, it was observed that 3 (7%) were in head and neck parts, 13 (30.2%) were in high extremity part and 27 (62.8%) were in lower extremity part. When the injury frequencies were analyzed according to the players' positions, it was observed that goalkeepers got injured 4 (9.3%) times, defence players got injured 10 (23.3%) times, midfield players got injured 16 (37.2%) times and forward players got injured 13 (30.2%) times. **Discussion** The findings obtained are supporting the data in the literature. Great majority of footballers underwent injuries due to a number of reasons. Players in midfield and forward positions are facing more injuries. In terms of anatomical positions, more injuries were observed in lower extremity part and in feet, ankles and around knees. The most frequently observed types of injuries are muscle abduction, torn muscles and sprain.

FITNESS AND SAFETY IN HORSE RIDING

Adriaenssens, L., Kemler, H.J., Goossens, H.

VeiligheidNL

Introduction In the Netherlands, horse riding is a rather popular sport, especially among females aged 15-30. On average, 350,000 Dutch men and women participate in horse riding each year.¹ The number of injuries in horse riding is relatively low compared to other sport modalities in the Netherlands. However, the severity of these injuries is often tremendous.² Annually, 11,000 horse riders are treated at an Emergency Department (ED). Fifteen percent of these horse riders (N=1600) were hospitalized after treatment at an ED. Also, medical costs of horse riding injuries are high (1500 per injury).² Fitness and safety are important topics for injury prevention in horse riding, however, a covering intervention programme to improve fitness and safety is lacking. The aim of this study was to access the requirements and develop a covering programme to enhance fitness and safety in horse riding. **Methods** Horse riders aged 16 and older

(N=559) were questioned online to access their opinion of fitness and safety in horse riding and their needs for injury prevention. Riding school owners and instructors (N=31) were first questioned by phone. After the individual interviews, focus group interviews took place. Results Both the horse riders (73%) and the riding school owners/instructors (89%) mentioned that there was already a lot of attention for safety in horse riding. However, the need for information about and attention to fitness in horse riding is huge. According to only 31% of the horse riders and 32% of the riding school owners/instructors, there is enough attention to fitness in horse riding. For horse riders, the focus must be on the improvement of their physical fitness (horse riding is definitely a sport and not just some leisure activity), riding skills and abilities and knowledge about behaviour of horses. Riding school owners and instructors benefit by information and inspiration regarding fitness in horse riding, i.e. a balance and skill training programme. Discussion Based on the results of this study, a new intervention programme to prevent horse riding injuries was developed, consisting of a training for instructors. Instructors who attend this training receive a manual, a complete example lesson, and instruction cards with exercises to train the fitness and riding skills and abilities of horse riders. In March 2014 the kick off of this intervention programme will take place. In April 2014 first training sessions for instructors will begin. In 2014-2015 the effectiveness and applicability of this programme will be studied. References: 1. VeiligheidNL. Cijfersfactsheet paardrijdblessures. TOE FLEXOR STRENGTH AND FOOT ARCH HEIGHT IN CHILDREN

Morita, N.1, Yamauchi, J.2,3,4, Kurihara, T.5, Fukuoka, R.6, Otsuka, M.5, Okuda, T.1, Ishizawa, N.1, Nakajima, T.7, Nakamichi, R.1, Matsuno, S.6, Kamiie, S.6, Shide, S.1, Kambayashi, I.1

Hokkaido Univ. Education, 1: Tokyo Metropolitan Univ., 2: FIFSS, 3: Khon Kaen Univ., THAILAND, 4: Ritsumeikan Univ., 5: Grad. Sch. Education, HUE, 6: Hokkaido Instit. Tech., 7

Introduction. It has been discussed whether the foot arch height is responsible for motor skills and physical performance in children (1) or not (2,3). In addition, no studies have investigated the muscle strength of the foot and the role of foot muscle strength for physical performance in children. Thus, the aim of this study was to investigate the arch height and muscle strength of the foot and the relationships between these indices and physical performances involving the lower limbs in children. Methods. A total of 308 elementary school children (3rd grade, N = 157, age = 8.6 ± 0.5 yr; 5th grade, N = 143, age = 10.6 ± 0.5 yr) participated. The maximal isometric toe flexor strength (TFS) in the standing position was measured using a toe flexor dynamometer. Foot arch height was assessed as the distance between the navicular tuberosity of the foot and the floor in the standing position, and the foot arch index (FAI) was defined as foot arch height divided by foot length. For physical performance involving the lower limbs, double-legged jump, repeated side-step, 50-m sprint, and rebound jump performance were measured. Results. There were no significant correlations between TFS and FAI, and between rTFS (TFS / body weight) and FAI in both age groups. rTFS was significantly correlated with standing long jump in both age groups. No significant correlations among FAI and physical performances were found, except for repeated side-step in 3rd grade girls and the 50-m sprint in 5th grade girls. After multiple regression analyses, only TFS was significantly correlated with all physical performances in both age groups. Conclusion. This study suggests that TFS would play a role in enhancing the level of physical performance involving the lower limbs in children. These results suggest that foot function should be evaluated in terms of the muscle strength of the foot and the height of the foot arch.

THE INFLUENCE OF HEAD AND IMPACT SURFACE CONDITION ON DYNAMIC RESPONSE OF THE HEAD

Winegarden, A., Taylor, K., Hoshizaki, T.B.

University of Ottawa

Introduction: There are challenges associated with controlling the interface between the headform and helmet when undertaking impact testing. A nylon stocking is typically used to cover the headform in order to reduce friction between the helmet and the head(1). The purpose of this study was to analyze different head surface conditions on peak angular acceleration (PAA) and peak linear accelerations (PLA). Methods: A helmeted 50th percentile Hybrid III headform fitted with a 3-2-2-2 accelerometer array was impacted at 5 m/s using a pneumatic linear impactor. Testing was completed with commercially available hockey and football helmets. Each helmet was impacted at three locations following the uOTP9 Front Positive Elevation 15° (FPE), Front Boss Positive Azimuth 45° (FBPA), High Side Center of Gravity (HSCG) for hockey and Side Center of Gravity (SCG) for football. Four head surface conditions were tested; bare headform, nylon cover, wig (to simulate hair) and oil filled bladders (to simulate skin). Hockey helmet results: It should be noted that there was an increase in PLA for the bladder condition at FPE and both bladders and wig condition at FBPA when compared to the bare headform. Noticeable changes in PAA occur at HSCG where the wig obtained the highest PAA. However no statistically significant differences were observed between the headform conditions for PLA and PAA. Football helmet results: At FPE, PAA was significantly lower for the wig condition (2411 rad/s²) and bladder condition (2497 rad/s²) when compared to the bare headform condition (3234 rad/s²). PLA was significantly greater for the wig condition (56 m/s²) when compared to the bladder condition (43m/s²); at FBPA the PAA for the nylon condition (3631rad/s²) was significantly lower than the bare headform condition (3234 rad/s²) and; at SCG the PAA was significantly lower for the wig condition (3346 rad/s²) when compared to the bare headform condition (3666 rad/s²). The bare headform condition had consistently higher PAA than the other three conditions; the differences were most notable at the FPE location. Conclusion: The head impact surface conditions used in this study did not result in significant differences for peak linear or peak angular acceleration for hockey helmet testing. However when testing football helmets the wig and bare headform, results were significantly different when compared to the nylon covered headform. These differences for head surface conditions were also dependent on impact location. This study demonstrates that head surface condition influences PAA and PLA in unique ways dependant on impact location and helmet type. (1)Pellman,E, Viano,D, Tucker,A, Casson,I & Waecherle,J (2003). 14:00 - 15:00**Mini-Orals****MO-PM48 SM Exercise Responses****THE EFFECTS OF ENDURANCE TRAINING ON MRNA LEVELS OF KIF1B MOTOR PROTEIN IN SENSORY AND MOTOR NEURONS OF RATS WITH DIABETIC NEUROPATHY**

Rahmati, M., Gharakhanlou, R., Movahedin, M., Mowla, S.J.

lorestan University

Introduction Previous research has demonstrated diabetic-induced axonal transport deficits. Kinesin motor proteins have been shown to transport various cargos along highly polarized neurons. However, whether kinesins are involved in diabetes, as well as the chronic effects of exercise on these motor proteins are not elucidated, yet. Therefore, the aim of present study was to investigate KIF1B mRNA in sensory and motor neurons of wistar male rats with diabetic neuropathy following endurance training. **Methods** Experiments were performed on Twelve 300 to 320-g male Wistar rats. The rats randomly assigned in 3 groups (N=4): diabetic trained (DT), diabetic control (DC) and healthy control (HC). For inducing diabetes, intraperitoneal injection of STZ solution (45 mg/Kg) method was used. Two weeks after STZ injection, diabetic neuropathy was demonstrated with mechanical allodynia and thermal hyperalgesia tests, after which moderate endurance training protocol was performed for 6 weeks. 24 hours after final training session, the rats were dissected and L4-L6 sensory and motor neurons of spinal cord tissue were removed. Also KIF1B gene expression was performed with Real time- PCR methods. **Results** After training period, blood glucose concentration was significantly lower in DT compared with DC group ($p<0/05$). Diabetes increased the KIF1B mRNA in both sensory and motor neurons of diabetic rats ($P<0/05$). Moreover, exercise training modulated the KIF1B mRNA levels in sensory and motor neurons of diabetic trained rats ($P<0/05$). **Discussion** The present study demonstrates that the STZ-induced diabetic rats are accompanied by changed KIF1B mRNA levels in spinal cord sensory and motor neurons, and chronic endurance exercise training can modify these changes which may contribute to the mechanisms of decreased hyperglycemia in diabetes. Accumulated evidence shows that hyperglycemia appears to be an important factor for neurodegeneration in diabetes (Sharma et al. 2010) which has been associated with reduced axonal transport rates in STZ-induced diabetic rodents (Hellweg et al. 1994). Neurodegenerative diseases are associated with mutations/dysfunctions in molecular motor proteins (Millecamps and Julien, 2013; Morfini et al., 2009). This study suggested a potential role for KIF1B as a novel treatment of diabetes. Finally, it can be concluded that neuronal machinery system at transcriptional levels might be affected in diabetic state and exercise can modify it. **References** Hellweg R, Raivich G, Hartung H-D, Hock C, Kreutzberg GW. EFFECTS OF COMBINED AEROBIC AND RESISTANCE CIRCUIT TRAINING ON PANCREATIC B CELL FUNCTION, BODY COMPOSITION AND PHYSICAL FUNCTION IN COMMUNITY-DWELLING HEALTHY ELDERLY

Hou, M.T., Chio, P.L., Chen, J.J.

Physical Therapy and Assistive Technology, National Yang-Ming University, Taipei, Taiwan

Introduction: Healthy aging and disease prevention is an important issue of the aging problem. Many diseases prevalence such as Type 2 diabetes increased with age. Type 2 diabetes is a hyperglycemia condition which is result from the insulin resistance and pancreatic beta cell dysfunction. In older adults, physical inactivity and sarcopenia obesity also plays a role for the development of Type 2 diabetes. Exercise, either aerobic or resistance exercise have been proven that can reduce the insulin resistance. Combined two exercises have a better effect than one alone. Aerobic, especially moderate intensity exercise, have been showed that have the effect to improve the function of the beta cell. While aerobic exercise have been showed that the effect on the beta cell function, the effect of combined aerobic and resistance circuit training on the beta cell function are less well studied. **Methods:** Subjects (Age \geq 60) will be recruited from the Taipei Community. Dependent on the subjects' intentions, they will assess to the combined aerobic and resistance circuit training group (CTG) or control group(CG). CTG will perform training twice per week. The exercise program is about 50 minutes which contains the hydraulic resistance training and aerobic exercise. Bioimpedance analysis will be used to investigate the muscle mass and muscle strength is measured with handheld dynamometer for grip strength and isometric dynamometer for knee extension. The physical fitness will be investigated by using the Senior fitness Test items. Beta cell function is measured by using the Homa- β equation and HbA1C is also measured to monitor blood sugar control situation. All tests will be done at baseline and 3 months later. **Results:** Compared with the CG, the CTG maintain the muscle mass and muscle percentage while the CG decrease after 3 months. HbA1C is also maintained. Physical function such as muscle endurance ($p<0.01$), dynamic balance ($p<0.05$) and aerobic endurance ($p<0.01$) are increased in the CTG. Fasting insulin increases in CTG($p<0.01$). **Conclusions:** 12w combined aerobic and resistance circuit training have the effect on: (1) Improve the beta cell function (increase insulin secretion) (2) Stabilize the HbA1C (blood glucose) (3) Maintain the muscle mass and muscle % (4) Improve the muscle endurance, dynamic balance and aerobic endurance.

EXERCISE AMELIORATES CARDIAC DYSFUNCTION CAUSED BY LACTATIONAL DEHP EXPOSURE IN YOUNG ADULT RATS

Huang, H.M., Yang, S.H., Wang, D.C.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction Exercise is an effective treatment on preventing cardiovascular diseases by inducing heat shock protein 70 (HSP70) expression in cardiomyocytes (Lollo et al., 2013). Di-(2-ethylhexyl)-phthalate (DEHP), an endocrine disruptor, has been found to exert toxic effects by interfering calcium homeostasis in cardiomyocytes (Gillum et al., 2009). Because the induction of HSP70 provides beneficial effects on modulation of ionic channels and calcium homeostasis in cardiomyocytes (Chang et al., 2013), therefore, an attempt is made in this study to reveal whether exercise can ameliorate the cardiac dysfunction caused by lactational DEHP exposure in young adult male rats. **Meth-**

od Rat dams were fed with vehicle or DEHP (10mg/kg per day) during lactation. After weaning, the male offspring were divided into 4 groups: control (C), DEHP (D), exercised control (Cx), and exercised DEHP (Dx). Exercised rats were trained on treadmill every day from 3-weeks of age for 5 weeks. At the age of 8 weeks, animals were subjected to electrocardiogram (ECG) recording. Then the animals were sacrificed and their hearts were weighted, followed by biochemical examination for HSP70, sarcoplasmic reticulum Ca²⁺ ATPase 2A (Serca2A), and sodium-calcium exchanger 1 (NCX1). Result The heart mass-to-body weight ratio was increased in DEHP-treated rats, indicating cardiac hypertrophy occurred in these rats, which was confirmed by ECG analysis in prolonged QT interval and increased QTc value. The expression of HSP70, Serca2a, and NCX1 were significantly decreased in the left ventricles of DEHP-exposed rats. Exercise provided beneficial effects on cardiac function by shortening QT interval and reducing QTc value in the Dx group. The expression of HSP70, Serca2a, and NCX1 were increased significantly in the Dx group after the 5-week aerobic exercise. Discussion Increased QTc value is associated with cardiac hypertrophy and may lead to sudden death (Panikkath et al., 2013). Lactational DEHP-treated rats showed increased incidence of cardiac hypertrophy and reduced levels of ionic channels associated in calcium homeostasis. Aerobic exercise in the early life increases the expression of HSP70, Serca2a, and NCX1 in the hearts, providing beneficial effects on cardiac protection in the DEHP-exposed rats, even in later life. AEROBIC EXERCISE AMELIORATES MUSCULAR DYSFUNCTION IN RATS EXPOSED TO DEHP DURING LACTATIONAL PERIOD

Yi Shiuian, S., Dai Ying, L., Dean Chuan, W.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction Di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, is regarded as an endocrine disruptor to exert adverse effects on the myogenic differentiation (Chen et al., 2013). Exercise has been proposed as a strategy for ameliorating a range of muscular disorders by strengthening strength and increasing resistance to fatigue (Alexanderson et al., 2014). In this study, we conducted an experiment regarding the effects of aerobic exercise on muscle endurance in young adult male rats receiving postnatal DEHP exposure. Methods Rat dams were fed with vehicle or DEHP (10mg/kg) during lactation. After weaning, the male offspring were divided into 4 groups: control (C), DEHP (D), exercised control (Cx), and exercised DEHP (Dx). Exercised rats were trained on treadmill every day from 3-weeks of age for 5 weeks. At the age of 8 weeks, animals were sacrificed and their gastrocnemius muscles were isolated for measuring the muscle mass. The isometric contractions of gastrocnemius muscles were measured to determine the fatigue index, which was calculated as the maximal twitch divided to the time to minimal twitch. The muscles were then subjected to immunohistochemistry to determine the proportion of type I and type II fibers in the gastrocnemius. Results Lactational DEHP exposure decreased the gastrocnemius mass-to-body weight ratio (Gas/BW ratio) in the D group at the age of 8 weeks. Exercise reserved the Gas/BW ratio in the Dx group. Data from isometric contraction revealed that increased fatigue index was observed in the D group, indicating poor fatigue resistance ability in the D group. Exercise demonstrated an improvement in fatigue resistance in the Dx group. Immunohistochemical study revealed a reduced proportion of type I fibers in the gastrocnemius muscle of D group, while exercise increased the proportion of type I fibers in the gastrocnemius muscle of Dx group. Discussion During development, the increased mass and content of type I fibers in the gastrocnemius muscle leads to the gain of muscle strength and fatigue resistance, which indicates the maturation of skeletal muscles. The reduced Gas/BW ratio and decreased type I fibers proportion in the gastrocnemius muscles of lactational DEHP-exposed rats suggests an adverse effects of DEHP on the development of skeletal muscles. Aerobic exercise trained on early life may ameliorate a range of DEHP-induced adverse effects later in life. The result of this study is no longer confined to toxicity, muscle physiology and sport sciences but may help to provide potential therapeutic targets in clinical application. AEROBIC EXERCISE IMPROVES THE IMPAIRED MOTOR COORDINATION IN LACTATIONAL DEHP-EXPOSED RATS

Kuan Chung, W., Shu Chieh, Y., Dean Chuan, W.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction In addition to the benefits on cardiovascular system, exercise has beneficial effects on central nervous system. Studies indicated that aerobic exercise improve learning and memory, and reduce the risk of neurodegenerative diseases. Cerebellum, an important role in motor coordination and motor skill learning, is also benefited by exercise (Kim et al., 2013). Di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer usually applied in polyvinyl chloride manufacture, is regarded as an endocrine disruptor. It has been reported that perinatal treatment of DEHP leads to the functional impairment in the hippocampus (Smith et al., 2011). However, there is no study focusing on the effect of DEHP exposure in cerebellar function. The purpose of this study is to reveal the effect of exercise on cerebellar dysfunction in the lactational DEHP-exposed rats. Method Rat dams were fed with vehicle or DEHP (10mg/kg per day) during lactation. After weaning, the male offspring were divided into 4 groups: control (C), DEHP (D), exercised control (Cx), and exercised DEHP (Dx). Exercised rats were trained on treadmill every day from 3-weeks of age for 5 weeks. At the age of 8 weeks, animals were subjected to rotarod test and runway training for assessment of motor coordination and motor skill learning, respectively. Result The motor skill learning was not affected by lactational DEHP exposure. The rotarod performance was impaired in D group, indicating the impairment of motor coordination in these rats. Gait analysis of foot prints showed that decreased stride length and increased distance between feet were observed in D group. Exercise restored the motor coordination of rotarod test and normalized the gait analysis of foot prints in the Dx group. Discussion According to the result, although lactational DEHP exposure has no significant effect on motor skill learning, the motor coordination was impaired in DEHP-exposed rats. Exercise in early life restores the motor coordination and motor control in lactational DEHP-exposed rats, providing beneficial effects on protection of cerebellar function in later life. AEROBIC EXERCISE PROVIDES ANXIOLYTIC EFFECTS IN LACTATIONAL DEHP-EXPOSED FEMALE YOUNG ADULT RATS

Yue Cih, J., Ming Lu, L., Dean Chuan, W.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction Exercise provides beneficial effects on mental health through regulations of hypothalamus-pituitary-adrenal cortex axis (Liu et al., 2012). Di-(2-ethylhexyl)-phthalate (DEHP), a plasticizer leached from polyvinyl chloride devices, acting as an endocrine disruptor. Evidence shows that lactational DEHP exposure may induce anxiety-related behavior in male rats (Carbone et al., 2013). However, this gender-specific adverse effect of DEHP is dependent upon the route and dose of DEHP treatment. The purpose of this study was to evaluate whether exercise can ameliorate the impaired stress response in female rats which were exposed to DEHP during their lactational period. **Methods** Lactational rat dams were fed with vehicle or DEHP (10 mg/kg per day) for twenty days till weaning. The weaned offspring was subjected to four groups: control (C), trained control (Cx), DEHP (D), and trained DEHP (Dx). Exercised rats were trained on treadmill every day from 3-weeks of age for 5 weeks. At the age of 8 weeks, female offspring rats were assessed by open field test and elevated plus maze for measuring locomotor activity and anxiety-related behavior, respectively. Thirty minutes after behavioral assessment, blood was collected from aorta and levels of plasma adrenocortical tropic hormone (ACTH) and corticosterone were analyzed by enzyme-linked immunosorbent assay (ELISA). **Result** Either lactational DEHP exposure or exercise has no significant effects on locomotor activity in female offspring rats. Lactational DEHP exposure reduced the time and number of open arm entries in the elevated plus maze, which indicated the induction of anxiety-related behavior in the D group. Exercise provided anxiolytic effect by increasing the time and number of open arm entries in the Dx group. The results from ELISA revealed an increased ACTH level in D group, while exercise decreased the ACTH level in Dx group when compared to D group. The corticosterone levels were decreased in D, Cx, and Dx group. **Discussion** Abnormal activation of the HPA axis during the early development stage leads to persistent changes in stress responsive circuits, which contributes to later behavioral alterations in the adults. The increased ACTH level and reduced corticosterone level in DEHP-treated female rats after challenged by mild stressor such as elevated plus maze, indicates the dysregulation of HPA axis in these rats. Exercise provides beneficial effects on the regulation of HPA axis and provides anxiolytic effects in DEHP-exposed female rats. **Reference** Liu W, Xu Y, Lu J, et al. MICROCIRCULATORY ANALYSIS BEFORE AND AFTER EXERCISE UNDER HEAT CONDITION IN HUMAN

Natsui, H., Kato, C.

Japan Women's College of Physical Education

Introduction It is thought that for understanding of exercise under heat condition, the analysis of microcirculatory hemodynamics is important. In this study, we intended to evaluate the microcirculatory hemodynamics before and after exercise under heat condition, using intra-vital microscope system. **Methods** 8 young female athletes (age: 21.9 years, height: 161.7 cm, weight: 57.9 kg) exercised under heat condition (temperature: 30.9 degree, humidity: 58.6 percent). They exercised 60-90 minutes using ergometer. Skin and tympani temperature were measured during exercise until 30 minutes after exercise. Microcirculatory hemodynamics on the nail fold were observed with intra-vital microscope system and video camera system, and recorded on digital video disc (DVD). Erythrocyte velocity was measured by distance of moving erythrocytes on TV screen and time with frame-by-frame playback analysis of DVD. All data were compared with before exercise and 30 minutes after exercise. **Results** Skin temperature on just after exercise was increased 4.0 degree compared with before exercise, and recovered on 30 minutes after exercise. Tympani temperature was kept about 36.4-37.5 degree during exercise and 30 minute after exercise. Capillary vessel diameter of nail fold was dilated 8.9 percent compared with pre-exercise, erythrocyte velocity was increased 5.0 percent and blood flow rate was also increased 25.1 percent. **Discussion and Conclusion** Exercise induce heat production, and it is very important to excess these heat from skin surface. To excess these heat production, skin circulation must increase by occlusion of arterio-venous shunt (AV shunt). In this study, skin microcirculation was still increase until 30 minute after exercise, it is thought that AV shunt still occlude.

RELATIONS BETWEEN HEART RATE VARIABILITY AND TRAINING

Schäfer, D.1, Leimgruber, F.1, Gjerdalen, G.F.2,3, Solberg, E.E.4, Trachsel, L.1, Saner, H.1, Wilhelm, M.1

Hospital, Aker, Oslo, NOR **3**Bjorknes College, Oslo, NOR **4**Diakonhjemmet Hospital, Oslo, NOR **Introduction** There is increasing interest in monitoring training with heart rate variability (HRV). The aim of our study was to assess relations between HRV and training in elite cross-country skiers. **Methods** A 14-week study in female (n=6) and male (n=9) elite cross-country skiers was performed during summer training. They were members of either the national, junior national or a regional team. HRV was assessed with a training computer Polar RS800CX (Polar Electro Oy, Kempele, FIN). Measurements were taken in the morning after a day with low-intensity training. Segments of 4 minutes were recorded in supine position and after an orthostatic load with controlled breathing and analyzed with frequency domain spectral analysis. Analysis were performed using high frequency power in normalized units (HF n.u.) from supine and standing position and calculated for the absolute (delta HF n.u.) and percental HF n.u. change (%delta HF n.u.) between the two positions and the percental change of the sympathovagal balance (%delta LF/HF). Training intensity and duration were recorded daily and training load, standard deviation of training loads (SD training), monotony, training strain and mean duration and mean intensity were calculated for each week using the method of Foster et al. (2001). Mean values from all HRV measurements and mean training from the last 7 days before measurement were calculated for each subject. **Results** No correlations between HRV and training were found when analyzing male and female athletes together. For male athletes, a large positive correlation was found between mean training duration and HF n.u. in supine position (R=0.736; p=0.024). For female athletes, a very large correlation was shown between SD training and %delta LF/HF (R=-0.921; p=0.026) and large correlations between mean intensity and HF n.u. standing (R=-0.886; p=0.019) and %delta HF n.u. (R=-0.886; p=0.019), mean duration and %delta LF/HF (R=-0.831; p=0.081) and monotony and delta HF n.u. (R=0.701; p=0.121). **Conclusion** For a similar amount of training, the relations between HRV parameters and training were different between sexes. We suggest that male athletes may benefit from a higher HF n.u. with increasing training duration and that a high mean intensity, monotony and low SD training may decrease some markers of parasympathetic activity in female athletes. We conclude that

gender differences should be taken into consideration when monitoring training using HRV. References Foster C, Florhaug JA, Franklin J, et al. A new approach to monitoring exercise training. *J Strength Cond Res.* 2001; 15: 109-15. Contact: daniela.schaefer@insel.ch

CARDIAC AND VASCULAR AUTONOMIC MODULATION BY DIFFERENT SET CONFIGURATIONS OF RESISTANCE EXERCISE

Mayo, X., Iglesias Soler, E., Dopico Calvo, X.

University of A Coruña

Introduction: Markers of cardiac and vascular autonomic modulation have been shown to be independent predictors of increased cardiac risks. Resistance exercise is accompanied by an increased of sympathetic modulation of the heart in protocols with different intensity and volume. Nevertheless, the effect of set configuration has been less studied both in heart rate (HR) and blood pressure (BP) variability. This study analyzes the effect of set configuration on high-frequency of HR (HF-HR) and low-frequency of systolic BP (LF-SBP), as indicators of vagal cardiac and sympathetic vasomotor activity, respectively. **Methods:** Eleven healthy college-aged students (23.81 ± 2.48 yr; 1.74 ± 0.08 m; 66.38 ± 9.75 kg) with experience in resistance training were evaluated in 3 set configuration and a control session (CS) for leg press. 10 repetitions maximum (RM) was determined twice for leg press. In a counterbalanced design, subjects realized at maximal velocity a) 5 sets of 8 repetitions with 3 mins of rest between sets (8S). b) 10 sets of 4 repetitions with 1:20 mins of rest between sets (4S) and c) 40 sets of 1 repetition with 18 sec between each repetition (1S). All protocols had the same load, volume, and total rest. HR was recorded beat-to-beat by electrocardiogram and SBP was obtained beat-to-beat by photoplethysmography (Task Force Monitor). Autoregressive spectral analyses were used to obtain HF-HR and LF-SBP. Data were obtained in a semirecumbent position before and after each session during 40 min in epochs of 5 (T1-T8). Data were log transformed to achieve normality. 2-way repeated measures ANOVA (Session x Time) was used for all criterion variables ($p \leq 0.05$). **Results:** No differences were observed at baseline values. For HF-HR, a significant interaction ($p=0.006$) between Session x Time was observed: HF-HR was higher in CS compared with 8S for the first 7 times (T1-T7), higher compared with 1S at T4, T6 and T7 and higher compared with 4S at T5. At T5, higher values were observed for 1S and 4S compared with 8S. Significant decrement respect to baseline was only observed in 8S. No differences were observed for LF-SBP. **Discussion:** HF-HR was affected by the set configuration, suggesting that less demanding protocols may cause less parasympathetic withdrawal (De Souza et al., 2013). In addition, no differences were observed for LF-SBP, indicating differences in cardiac and vascular autonomic changes. **References:** De Souza, J. C., Tibana, R. A., Vieira, D. C., De Sousa, N. EFFECT OF ATROPINE ON THE FIRST PHASE DYNAMICS OF CARDIOVASCULAR RESPONSES TO LIGHT EXERCISE IN HUMANS

Bringard, A., Porcelluzzi, A.M., Adami, A., Tam, E., Moia, C., Ferretti, G.

University of Geneva

Introduction Cardiac output (CO) and heart rate (HR) are under the control of both vagal and sympathetic components of the autonomic nervous system. Hence, the adjustments of CO and HR at light exercise onset are influenced by both components of the autonomic nervous system. Our hypothesis is that vagal withdrawal fully explained the rapid increase (phase I) of HR, and thus partly explained the phase I of CO. To test this hypothesis, we investigated the dynamics of cardiovascular responses to light exercise in subjects with full vagal blockade. **Methods** 8 young healthy subjects (Age 24.0 ± 3.7 years) performed rest to light exercise transitions, with and without vagal blockade with atropine (Jose and Taylor, 1969). Atropine was slowly infused intravenously over a 30 min period up to a vagolytic cumulative dose of 0.04 mg/kg. In each condition, 3 repetitions of the same exercise (50W) were performed. Blood pressure and HR were recorded beat-by-beat (Portapres). Stroke volume (SV) was determined by Modelflow from pulse pressure profiles. CO was obtained as HR times SV. HR and CO were fitted using bi-exponential models (Barstow and Molé, 1987; Lador et al, 2006). The time constant (τ_1) and the amplitude (A1) of the first exponential with and without (control condition) atropine were compared using ANOVA for repeated measures. **Results** In control, phase I was present in all subjects. The τ_1 value was 3.1 ± 2.0 s for HR and 3.2 ± 1.2 s for CO. A1 was 20.2 ± 7.5 for HR and 2.5 ± 0.9 l.min⁻¹ for CO. With atropine, phase I for HR was absent (A1 = 0 bpm) in 5 out of 8 subjects. A1 was 3.2 ± 4.6 bpm. τ_1 was 4.4 ± 4.1 s (3 subjects). Concerning CO, phase I was found in all subjects. A1 was 1.7 ± 0.9 l.min⁻¹ and τ_1 was 2.6 ± 1.5 s. For HR, A1 was significantly lower with atropine than in control. No significant differences were found between atropine and control for CO. **Discussion** These results are in agreement with the hypothesis that at exercise onset the phase I increase in HR is a consequence of sudden withdrawal of vagal activity. In fact, when this was suppressed by atropine administration, A1 was greatly reduced, even fully suppressed in 5 subjects. In contrast, this was not the case for CO. We suggest that the maintenance of phase I characteristics under vagal blockade for CO is a consequence of the sudden increase in stroke volume due to the Frank-Starling mechanism. **References** Barstow TJ, Molé PA. *J Appl Physiol*, 63, 2253–2261, 1987. THE Q'-V'O₂ DIAGRAM: AN ANALYTICAL INTERPRETATION OF OXYGEN TRANSPORT IN ARTERIAL BLOOD DURING EXERCISE IN HUMANS

Fagoni, N., Adami, A., Ferretti, G.

University of Brescia

Introduction The linear relationship between cardiac output (Q') and oxygen uptake (V'O₂) is classically considered invariant (Cerretelli and di Prampero, 1987). However, it is shifted as a function of changes in arterial oxygen concentration (CaO₂). Since $Q' = (V'O_2 + Q'vO_2) / CaO_2$, Q'vO₂ being oxygen flow in mixed venous blood, then the linear relation between Q' and V'O₂ has slope = 1/CaO₂ and x-axis intercept = -Q'vO₂ (Q'-V'O₂ diagram). A family of CaO₂ isopleths converges on the x-axis at x = -Q'vO₂. Q'vO₂ is a constant whose value depends respectively on arterial oxygen saturation (SaO₂) and on the activation state of the autonomic nervous system (Anchisi et al, 2001; Ferretti et al, 2005). The aim of this paper is to propose and discuss this new analytical interpretation of the Q' versus V'O₂ relationship, using data from different sources in the literature, in three different conditions: moderate exercise below the ventilatory threshold, rest, and hypoxia. **Analysis of literature data** During moderate exercise in normoxia equation validation shows Q'vO₂ = 1.35 L/min and CaO₂ = 203 ml/L. CaO₂ being invariant at exercise, values lie around a given CaO₂ isopleth. **Resting data** are below exercise data: thus, resting Q'vO₂ is decreased. In hypoxia, apparent Q'vO₂ = 1.12 L/min and CaO₂ = 148.6 ml/L. However, we operate on the steep portion of the oxygen equilibrium curve: the reduction in pulmonary capillary transit time associated with the increase in Q' during exercise may have evident effects on SaO₂ which turns out lower the higher is Q'. Consequently, the SaO₂ diminishes with increasing the workload. Thus the calculated regression line in hypoxia would not coincide with a CaO₂ isopleth (which dropped with increasing the exercise intensity), and represents the displacement of the Q' versus V'O₂ relationship across progressively decreasing CaO₂ isopleths. **Conclusion** The Q'-V'O₂ diagram allows a general theoretical analysis of the interplay of oxygen transport variables as a function of exercise intensity and CaO₂; it expands applicability of the historical Q'-V'O₂ relationship to include CaO₂ variations due to conditions, such as exercise, in which the cardiovascular system is under sympathetic control, and vagal activation is suppressed; it opens new pathways for understanding underlying mechanisms; it allows computation of Q' from CaO₂ and V'O₂ measurements, when Q' cannot be measured. **References** Anchisi S, Moia C, Ferretti G (2001). *Pflugers Arch.* 442, 443-450 Cerretelli P, di Prampero PE (1987). A CORRELATION BETWEEN BRADYCARDIA DURING COLD FACE TEST AND HEART RATE RECOVERY IMMEDIATELY AFTER EXERCISE

Konishi, M.1, Kim, H.K.2, Ando, K.2, Tabata, H.2, Nishimaki, M.2, Xiang, M.2, Sakamoto, S.1

1: Waseda University (Japan), 2: Waseda University (Japan)

Introduction Heart rate recovery immediately after exercise is considered to be a function of the reactivation of the parasympathetic nervous system. The parasympathetic activity plays key roles in our health, and a delayed decrease in the heart rate immediately after exercise is a powerful predictor of overall mortality (Cole et al., 1999). However, it is hard to apply heart rate recovery to epidemiological studies because the measurement of heart rate recovery need physical load to participants by a maximal exercise test. In contrast, cold face test is a non-invasive and easy challenge maneuver of the autonomic nervous system used to assess vagal activity (Stemper et al., 2002). Therefore, we investigated a correlation between bradycardia during the cold face test and heart rate recovery immediately after exercise. **Methods** Eight males participated in this study (age: 25.6 ± 1.8 years, body mass index: 22.9 ± 2.1 kg/m²). The cold face test was performed in all participants in the sitting position with face immersion in cold water (3-5 degree) and apnea for 40 seconds before a graded exercise test. R-R intervals were recorded before and during the cold face test to determine maximal bradycardia and the latency of maximal bradycardia. Heart rate recovery was determined by the graded exercise test on a treadmill. After achieving peak exercise, all participants spent three minutes in the sitting position. The value for the recovery of heart rate was defined as the reduction in the heart rate from the rate at peak exercise to the rate one, two and three minutes after the cessation of exercise. **Results** The cold face test induced a significant decrease in heart rate (P < 0.01). The mean value of maximal R-R interval during the cold face test was 1541.1 ± 92.2 ms, and the latency of maximal bradycardia was 24.8 ± 3.2 sec. The average of peak oxygen uptake for the participants was 47.3 ± 1.2 ml/kg/min, and heart rate at the peak exercise was 195.1 ± 3.7 beats/min. Heart rate recovery at 1, 2 and 3 min after peak exercise were 26.1 ± 2.2, 53.9 ± 2.6, 68.0 ± 2.9 beats/min, respectively. The latency of maximal bradycardia correlated well with the heart rate recovery, especially two minutes after peak exercise (1 min: R = -0.629, P = 0.095; 2 min: R = -0.968, P = 0.000; 3 min: R = -0.904, P = 0.002). **Discussion** The present study suggests that bradycardia during the cold face test are associated with heart rate recovery immediately after exercise. **References** Cole CR, Blackstone EH, Pashkow FJ, Snader CE, Lauer MS. (1999). *N Engl J Med*, 341, 1351-1357. Stemper B, Hilz MJ, Rauhut U, Neundörfer B. (2002). *Clin Auton Res*, 12, 78-83.

THE DYNAMICAL INTERRELATIONS OF ECG DURING PHYSICAL LOAD

Berskiene, K.1, Vainoras, A.1, Jurkonis, V.1, Sveistiene, R.1, Lukoseviciute, K.2, Navickas, Z.1

1: Lithuanian University of Health Sciences (Lithuania), 2: Kaunas University of Technology (Lithuania)

Introduction Advanced nonlinear methods of measuring interactions of the cardiac parameters, derived from the mathematics of complex dynamics and fractal geometry have provided new insights into the abnormalities of cardiac behavior in various conditions (Sharma V, 2006). Two or more digital time series (in our case – ECG signals) contain information about the research object, and using certain mathematical methods this information can be expressed in the form of mathematical relationships. Our recent findings and research results of other scientists clearly indicate that these complex fluctuations exhibit interesting structures that were not previously anticipated. More importantly, these fluctuations may also contain useful information about the emerging complexity of the systems. Thus, the research aim of this paper was to create new algorithm for the analysis of individual dynamical interrelations of ECG data during rest, physical load and the rest periods. **Methods** It was created and tested new algorithm, based on two or three signals cointegration to matrixes sequences, for the analysis of signals and their parameters dynamical interrelations, changes of their mutual relations. Complexity measure, reflecting the degree of coupling between variables, was expressed as the value of discriminant. If the value of discriminant decreases and is close to zero – the interaction between two synchronous numerical time series (ECG signals) increases, but the complexity of the system decreases. **Results and discussion** The algorithm for calculations of dynamical interrelations was also tested on healthy persons at different conditions – during different physical load. It was estimated, that new signal processing algorithm gives new quality information about heart activity properties during physical load and recovery, comparing with usual methods. The values of dy-

dynamic interrelations were significant higher ($p < 0.05$) in well trained healthy persons. The results showed that a short and quick reciprocity of the signals could be observed using matrix analysis (Bikulciene L, 2013). Newly created algorithm allows to investigate the individual dynamical interrelations during each cardiocycle. Sharma, V. ELECTROMYOGRAPHY OF THE ARCH SHOT STAGES

Buchatskaya, I., Pukhov, A., Gorodnichev, R.

Velikiye Luki State Academy of Physical Education and Sports

Introduction Only single works are known to treat certain particulars of the forearm muscles' electric activity with archers making a shot [1]. The kinematics shot structure was previously split by us into cycle phases and the most important one, the phase of "after-strengthening" was studied electromyographically as one of the most relevant. That is why the goal of the present research is to study specifics of the muscle electric activity at other technically important archery phases. **Methods** 14 archers of 16-22 years of age and of different mastery level took part in the experiment. 30 shots from the distance of 18 meters were required of each. The shot electromyographic factors were registered with the help of a 16-channel "MegaWin ME 6000" (Finland, 2008) electromyograph, kinematics was analyzed by a "Qualisys" 3D video-analysis system (Sweden, 2010) **Results** It is discovered that the highest electric activity at the "expansion" phase was shown by the anterior fascicles of the left arm deltoid muscle (m.deltoides anterior), posterior fascicles of the right arm deltoid muscle (m.deltoides posterior), by upper and lower left and right fascicles of the trapezius muscle (musculus trapezius), right hand radial flexor muscle (m.flexor carpi radialis) and by the left hand ulnar extensor muscle (m.extensor carpi ulnaris). A statistically relevant amplitude increase of the mentioned muscles in the phase when the arrow leaves the clicker (the phase of "after-strengthening") was also recorded. The highest activity was recorded in the front region of the anterior left and the posterior right part of the deltoid muscle, the right hand radial flexor, the lower left and right fascicles of the trapezius muscle. Evidently, those muscles are the ones that play a "leading part" at the "after-strengthening" phase. At the "shot final" phase, a statistically relevant amplitude increase of the left hand radial flexor muscle, upper left and right fascicles of the trapezius muscle activity as compared with such at the "expansion" and "after-strengthening" phases point to it that it is the activity of these muscles that provides the shot finality. **Conclusion** Thus, the most active muscles to provide the technically important stages in archery were singled out. **Bibliography** 1. Ertran H. Does fatigue change muscular activation strategies in recurve archery. 16th Annual Congress of the European College of Sport Science. Book of abstracts. 2011, p. 457.

ALTERATIONS IN MITOCHONDRIAL STRUCTURE AND FUNCTION IN RAT MYOCARDIUM IN CHRONIC HEART FAILURE

Wüst, R.C.I., de Vries, H.J., Niessen, H.W.M., Stienen, G.J.M.

VU University Medical Center Amsterdam

Background: In chronic heart failure (CHF), alterations occur in cardiac metabolism, mitochondrial enzyme content and activities. However, little is understood about the causes of alterations in mitochondrial respiration in CHF. **Material and Methods:** Monocrotaline injection (60 mg.kg⁻¹) was used to induce right ventricular CHF (n=9) and compared to saline (CON; n=6). After 23±1 days hearts were excised after isoflurane anaesthesia and oxygen consumption (JO₂) of saponin-permeabilised right ventricular tissue was measured by high-resolution respirometry (Oroboros). Maximal ADP-stimulated JO₂ was assessed using malate/glutamate/pyruvate (complex I), succinate (combined complex I and II), FCCP (maximal electron transfer system (ETS) function) and rotenone (complex II inhibition). Mitochondrial volume density and ultrastructure were assessed by electron microscopy. ETS protein content was determined by Western immunoblotting (MS604, Mitosciences). **Results:** Maximal complex I-stimulated JO₂ was ~6 times higher in CON than in CHF: 16±10 vs. 99±27 pmol O₂.mg⁻¹.s⁻¹ ($P < 0.001$). Maximal mitochondrial oxidative phosphorylation, by complex I and II respiration, was ~2.5 times higher in CON vs. CHF (87±41 vs. 227±28 pmol O₂.mg⁻¹.s⁻¹). The lower flux control ratio in CHF (0.42±0.13) vs. 0.22±0.15 (CON), $P < 0.001$ suggests complex I dysfunction. ETS protein content (complex I/IV in CHF: 90.6% of CON) and mitochondrial density (21.1±1.2 vs. 20.8±1.0%) were not different in CON and CHF, but mitochondria in CHF showed disturbed ultrastructure and alignment along the myofibrils. **Conclusion:** These results suggest that mitochondrial respiration is more severely affected in CHF than predicted from mitochondrial ETS protein content or density. Mitochondrial complex I dysfunction, and other factors such as ultrastructural alterations and mitochondrial super-complex destabilisation (Congliati et al, Cell 2013), are likely contributing to a bio-energetic limitation in CHF. Supported by CVON-ARENA

CONCURRENT EXERCISE TRAINING REDUCES INFLAMMATION BIOMARKERS ASSOCIATED WITH RISK CARDIOVASCULAR IN HIV-INFECTED INDIVIDUALS

Alves, G.1,2, Adriano, C.1, Tietbohl, D.1, Sprinz, E.2, Umpierre, D.1,2

1: LAFIEX (Brazil), 2: Clinical Hospital of Porto Alegre - Porto Alegre (Brazil)

Introduction Fibrinogen and highly-sensitive C-reactive protein (hs-CRP) has been associated with cardiovascular risk in HIV-infected individuals. Chronic infection with HIV and highly active combination antiretroviral therapy (HAART) induces inflammation (Appay and Sauce, 2008; Coll et al., 2007). However reductions of inflammatory markers by performing physical exercise suggest that exercise training may have anti-inflammatory effects (Perk et al, 2012). Our objective was to evaluate the effects of concurrent exercise training on fibrinogen and hs-CRP in HIV-infected individuals. **Methods** Twenty HIV-infected therapy-naïve patients twenty one HIV-infected starting HAART and twenty three HIV-infected patients on HAART were randomly assigned to supervised concurrent exercise training three times a week or control group for fourteen week. The control group received only recommendations on quality of life and adherence to treatment weekly. Before and after intervention, fibrinogen, hs-CRP, peak oxygen uptake, body composition, CD4, viral load, glucose and lipid profile were measured. **Results** Fibrinogen decreased significantly after supervised concurrent exercise training at the HIV-infected therapy-naïve patients from 402.4±63.1 to 296.5±34.1mg/dl-1 ($p < 0.05$) and HIV-infected patients on HAART from 351.0±308.0 to 284.5±217.0 mg/dl-1 ($p < 0.05$) but not significant changes in fibrinogen in control group after fourteen week. Body weight, body fat, and waist-to-hip ratio decreased significantly in concurrent exercise training group. There were no significant changes in immunologic variables in either group. Likewise, plasma triglycerides, total cholesterol, glucose and HDL cholesterol levels did not change significantly in either group. The hs-CRP decreased significantly in HIV-infected therapy-naïve patients from 7.5±3.9 to 2.7±1.3 mg/dl-1 ($p < 0.05$) after supervised concurrent exercise training. **Discussion** The HIV-infection is associated with endothelial dysfunction, hypercoagulability, vascular damage, and inflammation with hs-CRP elevation. In these instances, these effects are independent of HAART (Troll, 2010). The main finding of

the present study is that the inflammation biomarker reduces significantly in HIV-infected therapy-naïve patients submitted to concurrent exercise training. Our findings indicate that regular exercise are crucial for reduce cardiovascular risk in HIV-infected individuals. Appay V, Sauce D. (2008) J Pathol, 214(2):231–41. HEART RATE RECOVERY IN ELITE SWIMMERS

Ganzevles, S.P.M., de Haan, A., Beek, P.J., Truijens, M.J.

VU University Amsterdam & Institute for Biomedical Research into Human Movement and Health, Manchester Metropolitan University & School of Sport and Education, Brunel University

Introduction: Heart Rate Recovery (HRR) might be used to monitor training status in athletes[1] and thus be of help to optimize individual training programs. In this study we examined the predictive value of HRR for the velocity-heart rate relation during standardized training in competitive swimmers. We hypothesized that faster HRR predicts lower heart rate (HR) while swimming at a certain velocity compared to slower HRR. **Methods:** Nine competitive swimmers (7 female and 2 men, age 21 (SD 3.4)) participated. First, the swimmers performed a 5x250 incremental step-test to identify training zones. The step-test was followed by three separate sessions consisting of a 300m front-crawl warm-up and a 10x100m front-crawl training protocol. Individual swimming velocities were standardized based on the step-test. For the 300m, velocity was related to 75% Heart Rate Reserve (%HRres) and for the 10x100m to 85%HRres. Sessions were separated by at least 5 days. During each session HR and lap time were measured. HRR in the first 60 seconds (HRR60) after exercise was calculated as the difference between mean HR in the last 15 seconds of the 300m (HREnd) and the mean HR between 45 and 60 seconds after the 300m. Furthermore, average HR from the 10x100m was calculated (HRtraining). R2 was calculated for the relation between HRR60 and HRtraining and between HREnd and HRtraining with a significance level of 0.05. **Results:** No significant relation was found between HRR60 and HRtraining (R2 = 0.10, p>0.05). In addition, a significant relation was found for HREnd and HRtraining (R2 = 0.63, p<0.001). **Discussion:** Contrary to our hypothesis HRR had no predictive value with regard to the velocity-heart rate relation during training. This finding stands in contrast with the literature (mainly on running and cycling) and raises questions about the usability of HRR in competitive swimming. HREnd during standardized warm-up might be a better predictor of the velocity-heart rate relation. It is suggested that the relative importance of the efficiency of the swimming motion for performance might be part of the explanation of this discrepancy with HRR literature[1]. To control for the effect of efficiency, it is recommended to add biomechanical constraints (e.g. stroke count) to the test protocol for future research. **Reference:** [1] Daanen HA et al. (2012). THE EFFECTS OF GRAVITY ACCELERATION ON AUTONOMIC CONTROL IN RESTING HUMANS

Fontollet, T.1, Barthélémy, J.C.2, Bonjour, J.1, Linnarsson, D.3, Pichot, V.2, Ferretti, G.1,4

University of Geneva, Switzerland (1) ; Université Jean Monnet, Saint-Etienne, France (2); Karolinska Institute, Stockholm, Sweden (3); University of Brescia, Italy (4)

Introduction : The effects of ag on the activity of the autonomic nervous system (ANS) were not systematically investigated. Yet studies of the cardiovascular responses to hyper gravity suggest an increased activity of the sympathetic system. Our hypothesis is that ag changes the sympatho-vagal balance at rest. Our aim was to determine the effects of ag on spontaneous heart rate variability (HRV) and baroreflex sensitivity (BRS). **Method :** Eleven healthy subjects (age 26.6 ± 6.1) were studied in the human centrifuge of Karolinska Institute, Stockholm, Sweden, at four ag levels (1, 1.5, 2 and 2.5 G) during 5-min sessions at rest. We evaluated spontaneous variability of R-R interval (RR), and of systolic, diastolic and mean blood pressure (SAP, DAP, MAP, respectively), by means of the sequence method, using the BRSanalysis software. **Results :** At 2.5 G, with respect to the value observed at 1 G: 1) for HRV cross-spectral analysis (CSA), the total power (Ptot), the low-frequency component (LF) and the high frequency component (HF) were significantly lower, while the LF/HF ratio was significantly higher; 2) for SAP CSA, Ptot, LF and HF were significantly higher, but the LF/HF ratio did not change; 3) for DAP CSA, Ptot and LF were significantly higher, while HF and the LF/HF ratio were unchanged; 4) BRS was significantly lower. **Conclusions:** The decrease in RR LF power shows that the concept of sympatho-vagal balance does not hold when ag is increased. The increase in both SAP and DAP LF powers is coherent with the concept that LF has some links with the peripheral sympathetic activity. Reduction of the RR LF power would suggest that RR variability is dissociated from arterial pressure control and peripheral sympathetic activity. The lower BRS is consistent with these conclusions. The effects of ag on ANS activity are similar to those observed during exercise.

EFFECT OF TAI CHI ON POSTURAL STABILITY AMONG ELDERLY MEN WITH DIZZINESS

Maciaszek, J., Osiński, W.

University School of Physical Education in Poznan

Introduction Dizziness is relatively common, especially in the elderly but only a few studies on this subject are available. It is a common problem in patients visiting primary health care centres (Perez-Jara et al. 2012, Uneri, Polat 2008). Dizziness associated with altered balance, is a frequent complaint in elderly subjects. Research has been inconclusive with respect to possible aetiology. As many as 1/5 of people over 60 years of age may expect to experience dizziness or vertigo in the period of one year to an extent that medical attendance is needed. In some studies of exercise programs a reduction in dizziness and improvement in balance have been reported. **Methods** The purpose of this study was to assess the effect of Tai Chi training on postural stability in different trials among elderly men with dizziness. Subjects were 40 men (aged 60 to 80 years) who reported a history of dizziness. The participants were randomised to either the exercise group (n=20) and control group (n=20). The exercise group participated in an 18-week Tai Chi training, 45 minutes twice a week. Postural

stability was studied in two ways: "8 foot up and go test" and using a Computer Posturographic System PE 90 (Maciaszek et al. 2007). The ability to perform specific tasks (maximal deflections in four directions) was measured on posturographic platform. Results The results before and after training in the experimental and control groups was confirmed statistically in "8 foot up to and go test" (differences between groups in pre-post training - $H=8.21$; $p=0.003$), and in three posturographic parameters: forward deflection (differences between groups in pre-post training - $H=3.70$; $p=0.050$), backward deflection (differences between groups in pre-post training - $H=5.04$; $p=0.024$) and maximum sway area (differences between groups in pre-post training - $H=8.86$; $p=0.002$). Conclusions. The 18-week period of Tai Chi training, with a frequency of twice a week for 45 minutes, is beneficial for postural stability, which is important from the point of view of reduction of fall risk factors among elderly men with dizziness. EFFECT OF INTERMITTENT LOW INTENSITY AND HIGH SPEED POWER TRAINING ON THE RISK OF FALLS AND FRACTURES IN JAPANESE POSTMENOPAUSAL WOMEN

Hamaguchi, K., Kurihara, T., Iemitsu, M., Sato, K., Otsuka, K., Hamaoka, T., Sanada, K.

Ritsumeikan

INTRODUCTION: Previous studies has been established that low intensity and high speed power training (LIHS-PT) has a favorable impact on regional strength (Tschoop et al. 2011) and bone mineral density (BMD) in postmenopausal women (Stengel et al. 2005). However, it is still unclear that the effect of intermittent LIHS-PT on the risk of falls and fractures in Japanese postmenopausal women. PURPOSE: The aim of the study was to investigate the effect of intermittent LIHS-PT on the risk of falls and fractures in Japanese postmenopausal women. METHODS: Sixteen postmenopausal women were participated in this study, and the subjects were divided into 3 groups: training with sarcopenia (Training S, n=5), training without sarcopenia (Training N, n=6) and control without sarcopenia (Control N, n=5) groups. All subjects performed intermittent LIHS-PT during 6-week, which included squat, front lunge, side lunge, calf raise and toe raise. The exercises were consisted eight sets of three repetitions (rapid concentric/slow eccentric) with 15 sec interval between each set. Participants trained twice per week using weighted vests as a load. Total and regional lean soft tissue mass and BMD were measured by Dual-energy X-ray absorptiometry (DXA). Reference values for sarcopenia (skeletal muscle index, SMI; appendicular muscle mass/height², kg/m²) was defined by our previous study in Japanese adults (Sanada et al. 2010). Serum HDL-cholesterol, triglyceride and plasma glucose levels were measured in all subjects. RESULTS: The SMI in the Training S group was significantly increased by 6-week training ($P<0.05$), but not in the Control N and Training N groups. Additionally, the pelvis BMD in the Training S group was significantly increased by the training ($P<0.05$). However, no effects were seen in the Control N and Training N groups. CONCLUSION: Intermittent LIHS-PT increased muscle mass and pelvis BMD in Japanese postmenopausal women with sarcopenia. These findings suggest that intermittent LIHS-PT may be effective in reducing the risk of falls and fractures in Japanese postmenopausal women with sarcopenia. DIFFERENCES IN THE CARDIOMETABOLIC RISK PROFILE OF OBESE VS. SARCOPENIC OBESE WOMEN SUBJECTED TO A MIXED WEIGHT-REDUCING PROGRAM

Garnier, S.1, Barbat Artigas, S.2, Joffroy, S.1, Riesco, E.3, Sanguinol, F.4, Aubertin Leheudre, M.2, Mauriège, P.1

1: Université Paul Sabatier (Toulouse, France), 2: UQAM, (Montréal, Canada), 3: CSSS-IUGS, (Sherbrooke, Canada), 4: Clinique du Château de Vernhes, (Bondigoux, France)

Introduction Although the impact of sarcopenia on the subjects' cardiometabolic risk profile has been largely investigated, no study has examined yet the influence of a short and mixed weight-reducing program in this major health variable of sedentary and moderately obese women. Objective: To compare the effects of a 3-week weight loss program combining caloric restriction (1400 ± 200 kcal/day) and aerobic exercise (90 min./day, 6 days/week) on anthropometric variables, body composition and fasting lipid-lipoprotein profile of 146 patients whose fat mass was above 40 %, once differences in lean body mass index (LBMI) are taken into account. Research design and methods: Tertiles of LBMI (i.e., lower than 17.87 kg/m², between 17.87 to 18.94 kg/m², and greater than 18.94 kg/m²) were considered to perform our statistical analyses. Variables of interest were compared between the 50 women showing the lowest LBMI (sarcopenic obese) vs. the 50 women characterized by the highest LBMI (obese). Results: At baseline, sarcopenic obese women were older, and had lower body weight, BMI, fat mass and fat-free mass as well as reduced waist girth, compared to obese women ($p < 0.05$). Fasting lipid-lipoprotein profile was comparable in both groups. After correction for age differences, body weight and thus BMI, as well as fat-free mass were less reduced in sarcopenic obese than in obese patients in response to the weight loss intervention ($p < 0.05$). However, decreases in fat mass and waist girth ($p < 0.05$) did not differ between groups. Also, reductions in fasting serum triglycerides, cholesterol (CHOL) and LDL-CHOL levels ($p < 0.05$) were not significantly different between sarcopenic obese and obese women. Conclusion: The cardiometabolic risk profile was significantly improved in response to this weight reducing program, irrespective of patients' lean body mass index. Finally, this short and mixed weight loss intervention seems to be safe regarding the less decrease in fat-free mass of sarcopenic obese women. Contact : Sophie.garnier@wanadoo.fr

EFFECTS OF WALKING GROUPS ON OLDER ADULTS' AEROBIC ENDURANCE, LOWER BODY STRENGTH, WALKING AND SEDENTARY TIME: DIFFERENCES BETWEEN AN INDOOR AND AN OUTDOOR INTERVENTION.

Carrapatoso, S., Colaço, P., Santos, M.P., Carvalho, J.

Faculty of Sports, University of Porto

Active lifestyles and particularly walking may be influenced by environmental and societal factors as well as by interventions. Despite of the strong evidence of the walking benefits on older adults' functionality, the relation of the indoor and outdoor walking interventions and functional fitness has not been studied specifically in older adults. Our objective was to investigate the effects of a walking intervention on older adults' physical fitness and physical activity, detecting the differences between an indoor and an outdoor participation. A sample

(n=45) of 2 walking groups (indoor, n=23; mean age=66.19±1.32 & outdoor, n=22; mean age=66.07±1.06) were recruited to participate in this study. Regular walking exercise sessions were conducted (3 times per week) with the participants during 10 months and a pre and post evaluation of physical activity and functional fitness was applied. Aerobic Endurance and Lower Body Strength were measured by Rikli & Jones Senior Fitness Test (6 Minutes Walking and 30 Seconds Chair Stand) and Physical Activity was measured through the International Physical Activity Questionnaire. We've calculated the variances of measures and t tests were computed using SPSS. The indoor walking group had a positive effect on Chair Stand test (p=0.00) and no significant effect on the other variables. The outdoor walking group had a significant positive effect on Chair Stand test (p=0.05), 6 Minutes walking test (p=0.01) and walking time per week (p=0.04) and no significant effect was observed on sedentary time. Compared with walking exercise indoors, walking exercise outdoors seems to result in greater benefits on aerobic endurance. One possible explanation is that outdoor walking is more likely to induce higher intensities of walking, probably related with the different inclined planes used. Older adults who were enrolled in the outdoor walking program also accumulated significantly more minutes of walking per week. Core external factors, including perceptions of the environment, access, and social interaction could be noted as fundamental reasons for this result. Indoor walking group participants, showed greater improvements on Lower Body Strength suggesting that this type of intervention could be important to older adults with impairment since they may not be able or willing to access outdoor activity locations (Kerr et al., 2012). This study suggests that outdoor walking interventions promote greater benefits on physical activity and aerobic resistance, which may result in greater health benefits. However the indoor walking interventions seem to be a favorable option to improve functionality of older adults with impairment. Kerr J, Sallis J, Saelens B, Cain K, Conway T, Frank L, King A. (2012). *Int J Behav Nutr Phys Act*, 9, 89. Granted by FCT/FCOMP-01-0124--FEDER 014697/PTDC/DES/11807/2009 and PEst-OE/SAU/UI0617/2011

PEDOMETERS AFFECT PHYSICAL FITNESS CHANGES DURING A FALL-PREVENTION PROGRAM IN OLDER JAPANESE ADULTS.

Jindo, T.1, Tsunoda, K.2, Kitano, N.1,3, Soma, Y.1, Tsuji, T.1,3, Abe, T.1, Okura, T.1

1: University of Tsukuba, 2: Meiji Yasuda Life Foundation of Health and Welfare, 3: Research Fellow of the Japan Society for the Promotion of Science

Introduction Since pedometers are often used as motivational tools to increase physical activity, providing a pedometer during an exercise program may encourage participants to maintain or even increase their daily activity. The purpose of this study was to examine the effect on physical fitness of wearing a pedometer during an exercise program. **Methods** The subjects of this study were 105 community-dwelling older adults (mean age: 70.5 ± 4.3 years) in Kasama City, rural Japan. They participated in a fall-prevention program once a week for 11 weeks performing an exercise called Square-Stepping Exercise (SSE) (Shigematsu et al., 2008). We placed subjects into two groups: SSE with pedometer (male = 7, female = 41) and SSE without pedometer (male = 11, female = 46). To ascertain the physical fitness benefits induced by the exercise program, we measured 7 physical performance tests before and after the intervention: grip strength, one leg stand, sit and reach, 5-time sit-to-stand, timed-up-and-go, 5-m habitual walk and choice-stepping reaction time. We used a 2 way analysis of variance to confirm the interaction between the different programs. **Results** During the exercise program, mean pedometer step count was 6,348±2,406 (range 2,075-11,701) steps per day. After adjusting for baseline differences, we found a significant group-by-time interaction on timed-up-and-go (P < 0.01) and 5-m habitual walk (P = 0.02); participants in the SSE with pedometer group improved their performance more than those in the SSE without pedometer group. **Discussion** Bravata et al., (2007) reported a significant association between pedometer use and increased physical activity. In our study, the pedometer may have encouraged the participants to maintain or increase their daily activity. This study suggests that providing a pedometer during an exercise program can improve mobility compared to an exercise program that does not incorporate a pedometer. **References** Shigematsu R, Okura T, Nakagaichi M, Tanaka K, Sakai T, Kitazumi S, Rantanen T. FACILITATORS AND BARRIERS TO CONTINUING GROUP EXERCISE ACTIVITIES IN OLDER JAPANESE ADULTS

Sato, A.1, Jindo, T.1, Tsunoda, K.2, Saghaazadeh, M.1, Kitano, N.1,3, Soma, Y.1, Yoon, J.1, Abe, T.1, Okura, T.1

1: University of Tsukuba, 2: Meiji Yasuda Life Foundation of Health and Welfare, 3: Research Fellow of the Japan Society for the Promotion of Science

Introduction The various health benefits of exercise training disappear once we stop exercising. Shigematsu et al. (2011) reported on why subjects of a Square-Stepping Exercise (SSE) intervention program for older adults continued SSE after ending the official intervention. However, it is unclear whether older adults will enthusiastically take part in SSE group activities managed by volunteers after participating in an SSE program supervised by a trainer. The purpose of this study was to determine the facilitators and barriers to participating in SSE group activities after finishing an official SSE program. **Methods** We held a three months SSE program that was supervised by a trainer and held once a week for 11 weeks in Kasama City, rural Japan, and allowed participants to continue SSE after the intervention by participating in SSE group activities. There were 49 community-dwelling older adults (mean age: 72.0 ± 5.1 years) who took part in the official SSE program. We examined facilitators and barriers to continued participation using multiple-choice questions: 1. "Do you want to join SSE group activities in the future?" and 2. "Why or why not?" Subjects could choose multiple reasons as facilitators or barriers. **Results** There were 39 subjects who wanted to continue SSE by joining group activities, 7 subjects were undecided and 3 subjects did not want to join. According to frequency of the reasons chosen, the facilitators for continued participation were: "I like SSE" (32 votes), "To preserve and improve my present state of health" (30 votes), and "To make new friends" (27 votes). Meanwhile, frequently reported barriers to participating in SSE group activities were "Disease and pain" (3 votes), "Lack of time" (3 votes), "Not good at exercise" (2 votes) and "Dislike being part of a group" (2 votes). **Discussion** About 80% of subjects in this study wanted to join SSE group activities. The most important facilitator for participating in group activities is the expectation of reaping a benefits, in particular, preserving and improving their health and social contact. This study shows that important barriers to joining group activities and continuing SSE were health problems and lack of time. We should consider tackling those items as we try to improve physical fitness in older adults. **References** Shigematsu R, Nakanishi R, Saitoh M, Okura T, Nakagaichi M, Nakata Y, Sakai T, Nakamura Y, Kurimoto M, Tanaka K. EFFECTS OF SQUARE-STEPPING EXERCISE ON PHYSICAL FUNCTION IN OLDER WOMEN WITH AND WITHOUT COGNITIVE DECLINE.

Abe, T., Jindo, T., Sato, A., Soma, Y., Yoon, J., Kitano, N., Okura, T.

University of Tsukuba

Introduction To gain the most benefit from an exercise intervention, cognitive function of the individual should be considered. Andrade et al. (2013) suggested that older adults with cognitive decline had difficulty understanding the task during exercise which may prevent them from successfully engaging in exercise. We developed a novel exercise for maintaining and enhancing physical function called "Square-Stepping Exercise" (SSE) (Shigematsu et al., 2008). SSE allows the task to be varied to match the appropriate difficulty level for each person. Although we investigated cognitive function, the particular purpose of this study was to reveal the effects of SSE on physical function in older women with and without cognitive decline. **Methods** We used the 5-cognitive function test (5-cog test) to measure cognitive function in 81 older Japanese women. After determining which women were in cognitive decline (CD), we age-matched them (69.8 ± 3.7 years) with women who were not in cognitive decline (NCD), eliminating women who did not match with a woman in the other group ($n = 24$ each group). The NCD and CD groups completed a 3-month, once weekly exercise intervention that included 15 min warm up, 40 min SSE, 20 min upper and lower limb exercise and 15 min cool down. Grip strength, one-leg balance with eyes open, sit and reach, standing time from a long sitting position, 5-time sit-to-stand, timed up-and-go (TUG), 5-m habitual walk and peg-moving task were used as measures of physical function. We used a two-way repeated-measures analysis of variance. **Results** There was no significant Group \times Time interaction on any measurement. We observed significant time effects in sit and reach, TUG, 5-m habitual walk and peg-moving task. Both groups improved significantly ($P < 0.05$) in TUG. Sit and reach improved significantly only in the NCD group, and 5-m habitual walk improved significantly only in the CD group. **Discussion** Regardless of the level of cognitive function, SSE was considered beneficial for older women in this study. Uemura et al. (2013) suggested that exercise intervention improved physical function in older adults with cognitive decline. Although the exercise program in our study was different from the Uemura et al. study, both the NCD group and the CD group improved in physical function with SSE. Since SSE can be adapted to provide the appropriate level of difficulty for each person, SSE enables older adults with and without cognitive decline to be involved in an exercise intervention at the same time. **References** Andrade LP, Gobbi LT et al. "WALK MORE ACTIVE" - WALKING INTERVENTION FOR OLDER ADULTS: RATIONALE AND DESIGN

Bento, T.1,3, Ramalho, F.1,4, Santos Rocha, R.1,4, Carnide, F.2,4

CIDESD / Escola Superior de Desporto de Rio Maior - Polytechnic Institute of Santarém

Background Physical activity interventions have been targeting older age groups because of the large number of sedentary people and the health consequences associated to inactivity. Walking has been widely advised and prescribed in community based interventions as a way to improve and increase physical activity levels, and proved to be successful in these ages. The "Walk More Active" project aims to provide opportunities for older people to engage in physical activity and examine the effects of a walking intervention program in physical and functional health, as well as in the prevention of falls and walking efficiency. **Methods/Design** Participants, 65 years or older, are being recruited randomly in the community, and engaged in the program. The program consists of a 36-weeks graduated walking community-based program, targeting people of 65-80 years of age, performed three times a week, with one supervised session weekly. Participants assessment will be performed on Health, Functional Fitness and Physical Activity variables, at baseline, and after 12, 24 and 36 weeks of intervention. A fall and health questionnaire; three items from the "Senior Fitness Test" by Rikli and Jones ("8 Foot Up and Go", "chair stand test" and the "2 minute step in place test"); four items from the Fulleton Advanced Balance Scale ("Step Up and Over a 6" Bench", "Tandem Walk", "Standing on One Leg" and "Standing on Foam with Eyes Closed"), the Calf Raise (CR) and Calf Stretch (CS) tests (in validation process) and the Yale Physical Activity Survey will be administered. Walking efficiency will be measured using a barometric platform (Novel Emed-X system, Germany). **Discussion** The "Walk More Active" project will provide insights on the adequateness and efficacy of such an intervention program in increasing physical activity in the community, in preventing the risk of falls but, in an innovative way, in increasing efficiency of the walking program in older people. Project funded by QREN-INALENTEJO 2007-2013 (ALENT-07-0262-FEDER-001883) and ESDRM-IPS. **References** Ogilvie, D.; Foster, C., Charles E Foster; Rothnie, H.; Cavill, N.; Hamilton, V. AEROBIC EXERCISE FOR IMPROVING MUSCULAR STRENGTH AND FUNCTIONAL PHENOTYPES IN OLDER ADULTS: A SYSTEMATIC REVIEW

Jones, T.W., Trenell, M.I., Gorman, G.S.

Newcastle University

Introduction The age related decline in skeletal muscle mass and strength is a consistent symptom of aging. Known as sarcopenia this decline is associated with increased risk of physical disability and quality of life. Presently little is known about the efficacy and safety of aerobic exercise for improving muscle and functional phenotypes in sarcopenic adults. **Aims:** To perform a systematic review to determine the effects of aerobic exercise on muscular strength and physical functioning in older adults. **Methods** SPORTdiscus, MEDLINE and SCOPUS databases were searched with no language restrictions applied. Pre-set inclusion criteria for trials were as follows: 1. randomised controlled trial; 2. involved at least one intervention that consisted of aerobic exercise alone; 3. examined at least one marker of strength; 4. all participants were ≥ 60 years old. **Results** Nineteen studies met our inclusion criteria and employed a variety of exercise modalities involving 1082 males and females with a mean age of 69.5 ± 4.9 years. The length of training interventions ranged from 12 – 26 weeks with most participants exercising 3 times per week for 20 – 60 min at intensities of 50 – 80% heart rate reserve. Fifteen adverse events were reported yet only three considered serious. **Discussion** Review of the literature would suggest that performing aerobic exercise on 3 days per week for a minimum of 12 weeks may be an effective means of improving muscular strength and physical functionality in older adults. There is also evidence to suggest that aerobic exercise may be an effective means of increasing muscle mass and quality of life indices in older men and women, the former attribute not previously ascribed to this exercise modality. This suggestion is supported by the findings of various studies included in this review (Antunes et al., 2005, Bocalini et al., 2008, Gault et al., 2012). Aerobic exercise would therefore appear to be an appropriate intervention for many older people to improve muscular strength and some simple physical tasks, particularly in individuals unable to tolerate resistance type training. The long term effects of aerobic exercise in older individuals

are yet to be fully elucidated as only three studies provided any follow up analysis. References Antunes, H. K. M., Stella, S. G., Santos, R. F., Bueno, O. F. A. and Mello, M. T. d. THE EFFECT OF A LIFESTYLE INTERVENTION PROGRAM ON PHYSICAL ACTIVITY LEVEL AND STEP COUNTS IN OLDER LATINA WOMEN

Sebastiao, E., Chodzko Zajko, W., Schwingel, A.

University of Illinois

Introduction Older Latinas are particularly vulnerable for unhealthy lifestyle behaviors and the resultant chronic diseases. Physical activity (PA), along with other different behaviors, is an important component of health. The Federal Government of the United States recommends that every adult should accumulate at least 150 minutes per week of moderate to vigorous PA for health benefits (DHHS, 2008). In addition to minutes of PA, the number of steps accumulated in a day has also been used as a measure of activity status. This study examined the effect of a lifestyle intervention program on PA levels and step counts in older Mexican women living in a predominantly Hispanic neighborhood in Chicago, United States. **Methods** A total of 18 older Mexican women (64 ± 9 years) recruited for the Grandmothers in Action Program (GAP) had their PA and step counts assessed pre- and post- 6 months intervention. Participants wore for 4 to 7 consecutive days an accelerometer (Actigraph GT3X plus) at the hip. GAP is a culturally sensitive program that consist of educational workshops on PA, nutrition and stress management. Accelerometer data were processed using ActiLife 6.0 employing the Freedson adult cut points (Freedson et al., 1998). The following variables were then examined: light, lifestyle, moderate to vigorous intensity physical activity (MVPA), and step counts per day. Paired t-test adopting $p \leq 0.05$, was used to test the effectiveness of the intervention in the selected variables. **Results** Participants, significantly increased MVPA after the intervention (pre= 229.52 ± 116.5 min/wk vs post= 294.2 ± 195.9 ; $t(17) = 2.11$, $p \leq 0.05$). However, no changes were observed in time spent in light (pre= 371.0 ± 128.7 min/wk vs post= 365.3 ± 128.9 min/wk), and lifestyle (pre= 338.1 ± 114.9 min/wk vs post= 337.7 ± 136.4 min/wk) intensity activities. On average, step counts per day increased by 873 steps (5933 ± 2372.80 vs 6807 ± 3808.05 ; $p = NS$). **Discussion** Despite most of the participants being active in the baseline, the findings suggest that the lifestyle intervention program, including PA, was effective in significantly increasing MVPA of the participants. As noted by other studies (Greaves et al., 2011), lifestyle intervention programs are an effective means to change behavior and should be considered when promoting PA among older adults. **References** DHHS. IMPACT OF HIGH INTENSITY INTERVAL TRAINING AND / OR SELENIUM SUPPLEMENTATION ON OXIDATIVE STRESS AND ANTIOXIDANT STATUS IN ACTIVE FEMALES.

Keane, K.1, Dolan, E.2, Burgess, K.2, Howatson, G.1, Bermano, G.2

Northumbria University

INTRODUCTION: Cells continuously produce free radicals (FR) and reactive oxygen and nitrogen species (RONS), as part of metabolic processes, which are then neutralized by antioxidant defence systems. An imbalance between FR/RONS and antioxidants is referred to as oxidative stress. Evidence suggests that increased oxidative stress is involved in the pathogenesis of various disorders including cardiovascular and neurodegenerative diseases, diabetes and several types of cancer (Campbell et al. 2010). Furthermore, exercise is thought to elicit transient increase in oxidative stress. Several strategies have been proposed in an attempt to attenuate the effect of post-exercise oxidative stress. Selenium (Se), as an essential component of the Glutathione peroxidase (GPX) enzymes family, has the ability to neutralize FR/RONS and increase cellular protection against stress. Moreover, regular training appears to increase antioxidant capacity, thus decreasing oxidative stress response. The present study explored the influence of Se supplementation and High Intensity Interval Training (HIIT) in minimizing oxidative stress and increasing antioxidant capacity. **METHOD:** Twenty-two healthy females, who participated in intermittent sports, were recruited and, in a randomised manner, equally allocated to either a Se only group (250 ug sodium selenite/day) or a Se + HIIT group (250 ug sodium selenite/day + 2 sessions HIIT/week) for 3 weeks. Measures of fitness, malondialdehyde (MDA) levels and total antioxidant capacity (TAC) in plasma, and GPX activity in plasma and red blood cells were assessed before and after an initial and final bout of HIIT. **RESULTS:** No statistically significant changes were identified for any of the measured markers, although a number of trends were noted. Following intervention, MDA levels in response to a single bout of HIIT were decreased by 9% in the Se + HIIT group and by 12% in the Se only group. GPX activity in plasma increased by 15% in the Se group and decreased in the Se + HIIT group by 2% pre to post intervention, whilst GPX activity in RBC increased in both groups by 6% and 2% respectively. TAC increased by 40% in the Se + HIIT group and 66% in the Se only group. Furthermore, there was an improvement in a number of fitness components in the Se + HIIT group post intervention, namely speed and maximal aerobic capacity. **CONCLUSION:** This is the first study to examine the impact of HIIT and/or Se supplementation on oxidative stress and antioxidant capacity in active females. Whilst there were no significant differences observed, there were some promising trends highlighting a potential benefit of Se (and possibly HIIT) in reducing oxidative stress and increasing antioxidant status post high intensity interval exercise in females engaged in intermittent sports. **REFERENCES:** CAMPBELL, P. CHARACTERIZATION OF THE PHYSIOLOGIC CHANGES IN AN INDOOR CYCLING PROGRAM – RAW POWER IN MOTION ®

Cerca, L.1,2, Raposo, F.1,2, Melo, X.1, Almeida, J.P.1, Santa Clara, H.1

1: CIPER, FMH-UL (Lisbon, Portugal), 2: FEFD-ULHT (Lisbon, Portugal),

Introduction: Raw Power in Motion (RPM) is a cycling program well spread in the Fitness world. It's implemented over 80 countries and it's a fitness trend represent by 100.000 instructors. The purpose of this study was to analyze the effects of one RPM session. It's a 50 minutes cycling format with nine tracks, between 4 and 6 min each. This study can be characterized as a descriptive research of RPM session for the following physiological parameters: oxygen uptake (VO₂), heart rate (HR), energy expenditure (EE) metabolic equivalent (MET) and resting quotient (RQ). **Methods:** Nine trained males (age: 35±10 yrs, BMI: 26.2±2.6 kg/m²) underwent a maximum cycle protocol (MONARK 824 E Ergomedic) with an incremental workload adjustment and a constant pedal stroke (70 rpm) in order to determine HR_{max} (polar T71) and VO_{2max} (K4b2 Cosmed, Rome, Italy). Using the same equipment their oxygen consumption (VO₂) was continuously measured during a 50 minutes RPM session. The dependent variables were expressed by the mean and SD. Repeated measures were used to compare the different tracks (p<0.05). **Results:** Maximal values were HR_{max} 174±10bpm and VO_{2max}: 53±11 ml/kg/min, during the RPM protocol there was a significant increase on the different physiological parameters. The average intensity was 32.84 ± 8.39 mL/kg/min VO_{2max}, with an HR average of 145.08 ± 15.38 beats/min, which represent an average intensity of 80.8% HR_{max}. Tracks 3 and 7 were identified as the two higher intensity peaks, track 3 (75.8 VO_{2max}) and track 7 (75.7 VO_{2max}), being the lowest value obtained in the track 5 (66 VO_{2max}). The EE was really high, with an average of 12.92 ± 3.12 Kcal/min, representing an EE average of 585 ± 141 Kcal/session. The MET average during the RPM session was 9.29 ± 2.17. As regards, the QR data, it was recorded over 0.90. **Discussion:** The present study confirms a high or very high correlation between VO₂ and EE during the nine RPM tracks with the duration of 50 minutes. As regards, the MET average we could assume that fits into the cycling kind of exercise, according to the activities index. It seems that a RPM session offers a high intensity interval training with a high EE and a high carbohydrate metabolism. **References:** Faria, E. et al (2005) The science of cycling – Physiology and Training – Part1. THE DIFFERENCES IN THE EMG AMPLITUDE PARAMETERS DESCRIBING PELVIC FLOOR MUSCLES EXERCISE TECHNIQUE AFTER 6-WEEKS TRAINING PROGRAMME AMONG FUTURE EXERCISE PROFESSIONALS – A RANDOMIZED CONTROLLED TRIAL

Szumilewicz, A.

Gdansk University of Physical Education and Sport

Introduction: The pelvic floor muscles (PFM) require regular exercise to maintain their function. However, they are commonly overlooked in exercise programmes. An important task is to prepare professionals to conduct physical activity classes, where PFM exercises are a regular feature, to prevent and cope with urinary incontinence (UI) (Bø, 2004). To meet this challenge first they should learn to perform a proper exercise technique for this muscle group. The aim of the research was to get knowledge about the PFM exercise technique among future exercise professionals. The research question was whether there are any statistically significant differences in the EMG amplitude parameters describing their PFM exercise technique after 6-weeks training programme. **Material and method** It was a randomized controlled trial conducted among 100 nulliparous future exercise professionals with a mean age of 22,7 years (SD=2,5), randomly allocated into three groups. Groups 1 (n=35) and 2 (n=34) differed in the intervention method, group 3 (n=31) was the control group. All subjects were assessed for pelvic floor muscle activation by Noraxon EMG & Sensors System, using vaginal probes. Groups 1 and 2 received 6-week PFMT programme prepared to exercise at home supported with verbal instructions. Only group 1 was treated with one biofeedback session. The PFM EMG evaluation was repeated after 6 weeks. The technique of PFM exercises was determined through the EMG activity level of pelvic floor in relation to the EMG activity level of synergistic muscles in particular exercises. Proper technique was defined as the ability to contract PFM keeping synergistic muscles relaxed. **Results** Future exercise professionals exhibited difficulty with the correct technique of the PFM exercises in the first EMG PFM evaluation. The technique performed during the second evaluation was improved in both intervention groups and also slightly in the control group, but the results in biofeedback group were significantly better. **Discussion** Exercise professionals should be educated how to perform PFM exercises. This is particularly important because UI is prevalent among this professional group (Bø et al., 2011). While in recent years researchers have devoted a lot of attention to PFM training for pregnant or incontinent women, there is a lack of reports on the issue of PFM exercises performed by exercise professionals. **References:** Bø K, Bratland-Sanda S, Sundgot-Borgen J (2011). THE EFFECT OF RPM DURATION ON THE EXCESS POST-EXERCISE OXYGEN CONSUMPTION. COMPARISON BETWEEN SHORT SESSION VS. COMPLETE SESSION

Raposo, F.1,2, Cerca, L.1,2, Melo, X.1, Almeida, J.P.1, Santa Clara, H.1

1: CIPER, FMH-UL (Lisbon, Portugal), 2: FEFD-ULHT (Lisbon, Portugal)

Introduction: The magnitude of excess post-exercise consumption (EPOC) after aerobic exercise clearly depends on both the duration and intensity of exercise and the conflicting results that surround EPOC may be resolved if differences in these parameters are considered. As the absence of a sustained EPOC after exercise seems to be a consistent finding in low exercise intensity modalities, the purpose of this study was to analyze the effect of a complete (CSRPM - with 50 minutes) and a short (SSRPM – with 35 minutes) high intensity indoor cycling class [Raw Power in Motion (RPM™)] on: 1) energy expenditure; and 2) the magnitude of EPOC during the first hour after exercise. **Methods:** Nine trained males (age: 35±10 yrs, BMI: 26.2±2.6 kg/m², HR_{max}: 174±10bpm, VO_{2max}: 53±11 ml/kg/min), had their oxygen consumption (VO₂) continuously measured using a portable gas analyzer on the two randomized conditions (CSRPM and SSRPM), both performed at maximum voluntary capacity on non-consecutive days. VO₂ was also measured for 30 min prior to each exercise condition and for 1h after exercise. Dependent T-test and Wilcoxon Matched-Pairs Test were used, to analyze differences between sessions, for parametric and non-parametric data, respectively. Repeated Measures of General Linear Model and Pairwise Comparisons were used to analyze dependent variables evolution during the post-exercise period. **Results:** No differences were found between conditions for rest

VO₂ (4.20 ± 0.69 mL/kg/min (SSRPM) and 4.83 ± 1.48 mL/kg/min (CSRPM), $p=0.314$) and mean EPOC 2.78 ± 1.38 mL/kg/min (SSRPM) and 2.78 ± 0.81 mL/kg/min (CSRPM), $p=0.998$. However, in the first 5 minutes after exercise VO₂ and fat metabolism were higher in CSRPM (0.863 ± 0.163 L/min and 538.1 ± 127.4 g/day) compared to SSRPM (0.667 ± 0.281 L/min and 349.4 ± 155.7 g/day) ($p<0.05$). Discussion: The magnitude of EPOC after high intensity aerobic exercise apparently does not depend on the duration of exercise. However, exercise duration may be associated with a higher post-exercise energetic metabolism immediately after exercise. No differences were found in any dependent variables (VO₂, HR, Respiratory Quotient, Ventilation and Energy Expenditure), during the one hour recovery period. The only differences occurred within the first 5 minutes of recovery, relative to oxygen consumption and absolute fat metabolism, which were significantly higher after CSRPM. These results are according to literature, which indicates that short high intensity exercise, seems mainly affect the fast component of EPOC (Bahr, 1992). References: Bahr, R. (1992) Acta Physiologica Scandinavica 144 suppl.(605): 1-70 Contact: santaclara@fmh.ulisboa.pt raposo.frederico@gmail.com

EFFECTS OF 8-WEEK FITNESS-BOOT CAMP TRAINING ON BODY COMPOSITION IN UNTRAINED WOMEN: A CONTROLLED TRIAL

Mierau, J., Brandt, J., Mierau, A., Strueder, H.K.

German Sport University Cologne

Introduction Fitness-boot camp (FBC) training is a specific form of high intensity interval training which has grown in popularity over the years. Commercial operators claim that it is particularly efficient to improve fitness, and to induce positive effects on body composition. However, this has not been studied yet. Therefore, the aim of this study was to compare the effects of 8-week FBC and training in a traditional fitness center (FC) on body weight, body fat and three girths in untrained women. **Methods** 37 untrained women participated in the study. They enrolled in either a FBC training group ($n=21$; 33 ± 6.9 yrs.; 169 ± 6.6 cm; 68 ± 9.7 kg, BMI 23.9 ± 4.1) or a FC training group ($n=16$; 33.7 ± 8.7 yrs.; 165.4 ± 6.2 cm; 65.4 ± 10.7 kg, BMI 23.9 ± 3.4). Both groups exercised 2x60 min per week for 8 weeks. Outdoor FBC consisted out of a warm up (10min), movement games (5min), strength circuit training (40min), and a cool down (5min). The strength circuit was completed three times. It included pulls, push-ups, plyometrics, squats, as well as core stability and strength workouts for the whole body. Each exercise lasted 40-60s with an inter-exercise interval of 10-20s and 2min rest after circuit. The control group trained in a traditional fitness center. A typical training session started with aerobic endurance exercise on a treadmill or a crosstrainer (10-30min) and this was followed by machine-aided muscle hypertrophy training (30-50min). Body weight, body fat, as well as hip, waist and abdominal girth were measured before (PRE) and after (POST) 8 weeks of training. Repeated measurement analysis of variance (ANOVA) with the factors GROUP and TIME was calculated for each dependent variable. Significant main effects and interactions were further analyzed using the Fisher's LSD post hoc tests. **Results** Groups did not significantly differ at baseline for any of the dependent variables. The ANOVA yielded no significant effects for body weight. However, there was a significant GROUP x TIME interaction for all girth measurements, as well as for body fat. Post hoc analyses revealed that girths and body fat significantly decreased from PRE to POST in the FBC group (all $p<0.001$) while there were no changes in the FC group. **Discussion** The results of the present study show that 8 weeks of FBC is sufficient to obtain a reduction in body fat as well as hip, waist and abdominal girth in untrained women. Moreover, FBC training was more effective compared to FC training with regard to body fat and girths. Possible mechanisms underlying the FBC-induced effects on body composition may include increased exercise fat oxidation, excess post exercise oxygen consumption and decreased postexercise appetite (Boutcher, 2011). It is concluded that FBC can be recommended as a time efficient way to induce positive changes in body composition. **References** Boutcher, SH (2011). J Obes;2011:1-10. THE INFLUENCE OF A SIX WEEK EXERCISE INTERVENTION ON THE PULMONARY OXYGEN UPTAKE KINETICS IN PRE-PUBERTAL OBESE AND NORMAL WEIGHT CHILDREN

McNarry, M., Lambrick, D., Westrupp, N., Faulkner, J.

Swansea University

The pulmonary oxygen uptake (VO₂) response is deleteriously influenced by obesity in pre-pubertal children, as evidenced by a slower phase II response relative to their normal-weight counterparts. No studies to date have investigated the ability of an exercise intervention to ameliorate this negative effect. Therefore, the purpose of the present study was to investigate the influence of a six week, high-intensity games orientated intervention on the VO₂ kinetic response of pre-pubertal normal-weight and obese children during moderate and heavy intensity exercise. Twenty-nine NW children (9.2 ± 0.8 y, 16.9 ± 1.6 kg•m², 17 boys) and twenty-six OB children (9.3 ± 0.9 y, 23.5 ± 3.6 kg•m², 13 boys) completed a graded-exercise test to volitional exhaustion and two submaximal constant work rate treadmill tests at moderate (90% gas exchange threshold) and heavy (40% of the difference between the gas exchange threshold and peak VO₂) exercise intensities pre and post the intervention. The twice weekly exercise intervention involved repeated bouts of 6-minutes of high-intensity exercise followed by 2 minutes of recovery. This intervention closely reflected the highly sporadic nature of children's play patterns which are characterised by bursts of high-intensity, intermittent exercise. Following the intervention, during heavy intensity exercise OB children demonstrated a significantly faster phase II τ (Pre: 30 ± 8 cf. Post: 24 ± 7 s) and reduced phase II amplitude (Pre: 1.51 ± 0.30 cf. Post: 1.34 ± 0.27 l•min⁻¹) whilst the magnitude of the VO₂ slow component was not effected (Pre: 3 ± 5 cf. Post: 2 ± 4 % end-exercise amplitude). No influence of the intervention was evident during moderate intensity exercise in OB children. Furthermore, the intervention did not influence the dynamic VO₂ response, irrespective of exercise intensity, in the normal weight children. These findings demonstrate that although the deleterious physiological effects of obesity are present in pre-pubertal children, positive improvements may be elicited following regular participation in high-intensity exercise. These adaptations would be expected to reduce metabolic perturbation and fatigue development in the transition from a lower to a higher metabolic rate, and may therefore improve exercise tolerance. Furthermore, if sustained, they may directly translate to a reduced O₂ cost of daily activities and thereby potentially enhance functional capacity and quality of life.

THE EFFECT OF WEARING A CUSTOM-MADE MOUTHPIECE ON BMX PERFORMANCE

Smit, A.

*NOC*NSF/ISLP*

INTRODUCTION In BMX racing the start is very important. A good timing on the start signal and a high peak power output are important for a good start [1]. Recent studies suggest that wearing a custom-made mouthpiece which properly aligns and relaxes the jaw can improve anaerobic power output on a Wingate test in trained and highly trained athletes [2] and auditory and visual reaction time [3] in untrained subjects, although another recent study using a commercial mouthpiece did not find an effect on strength and power in rec-

reationally trained men [4]. The purpose of this study was to determine if wearing a custom-made mouthpiece could instantly improve the start time in World Class BMX riders. METHODS Five World Class BMX riders (3 men and 2 women) volunteered to participate in this study (age 22.2 ± 2.7 years old). A cross-over design with repeated measures was used. All measurements were executed in one session of 2.5 hours, with a custom-made mouthpiece randomly assigned. Each rider recorded seven correct trials with and without the mouthpiece. The time on the first downhill section of the track was measured. Times were averaged per rider for each condition. Magnitude-based inferences were used to determine probabilities of practical significance [5]. Effects were deemed unclear if the confidence interval overlapped the thresholds for both benefit and harm, and only effects greater than 75% likelihood were considered substantial. The smallest worthwhile change in performance was set at 0.5%. RESULTS The mean time \pm SD for the trials with the mouthpiece was 2.72 ± 0.11 s and without the mouthpiece 2.73 ± 0.10 s. The results showed a marginal effect for the mouthpiece for the average time over the seven trials. A 0.3% change in the mean (90% confidence limits: -0.2 to 0.8) was found, making it unlikely that the mouthpiece had a positive effect on the performance. DISCUSSION No indication that wearing a custom-made mouthpiece has at least a small effect on BMX start performance in World Class BMX riders was found. A possible explanation for finding only a marginal effect is that in World Class athletes, the margin for improvement is so small, that interventions that have a large effect in untrained or trained persons, are likely to have a small effect in well trained and possibly a marginal effect in elite and World Class athletes. It can be concluded that wearing a custom-made mouthpiece has a marginal effect on BMX start performance in World Class BMX riders. REFERENCES 1 Zabala et al. (2009). MO-SH18 Physical Activity & Age

THE EFFECT OF SPORT ON QUALITY OF LIFE IN PARENTS WHO HAVE DISABLED CHILDREN

Karakas, G., Yaman, Ç.

Sakarya University

Introduction In previous studies there was found to be positive relationship between physical capacity and quality of life. Thus, the physical capacity is important for a healthy and quality of life. On the other hand, problems of individuals have disabled children effect the quality of life in families in a negative way. Recreative power of sport play a big role for the troubleshooting of these negativities. In this respect, in this research it was aimed to examine the quality of life in parents who have disabled children. Methods In this study, 164 parents (132 Mothers, 32 Fathers) who have disabled children participated in voluntary in this study. A Family Information Form, which was prepared by the researcher, was used to reach the demographic informations of parents. With the aim of measuring the quality of life in parents, World Health Organization Quality of Life-Bref Form (WHOQOL-BREF), which was adopted to Turkish by Eser et al. (1999) and for measuring the level of physical activity of parents, International Physical Activity Questionnaire-Short Form (IPAQ), which was adopted to Turkish by Öztürk (2005) were used in the study. After the descriptive statistical processes had been applied in the analysis of datas, an Independant T-Test was used. Results As a result, the fact that the quality of life parents who have disabled children and doing sport (61 parents) was found to be at a higher level of those who have disabled children but not doing sport (103 parents). In addition to this doing sport was detected to increase the quality of life parents who have a disabled children. Quality of life in parents with disabled children who do sport was found to be higher than the parents with disabled children who do not sport in terms of psychological field, social field, environmental field, environmental TR (Turkey) field and MET (Metabolic Equivalent) vaules ($p < 0.05$). Just, physical field subdimension of the scale were not found significant differences between the two groups ($p > 0.05$). Discussion With this result, sport has importance on the quality of life in parents who have disabled children. There is a difference between the parents with disabled children who do sport and the parents with disabled children who do sport in terms of quality of life. It is possible to say that doing sport increase the quality of life. Altun et al. (2011) has also pointed that participation to sport effect the quality of life in a positive way. LEISURE AND INFANCY IN BRAZIL - BOLIVIA BORDER

Loro, A., Pimentel, G.G.A.

Universidade Federal da Fronteira Sul / Universidade Estadual de Maringá

Introduction During the civilizing process the society has reached one of its greatest stages. However, it is still perceptible the reinvigoration of homo ludens, expressed by playful emotion, allowing contemporary human being to experience the pleasure of strain in free time, in activity that is their free choice and with social consent, by routinization of informal spaces. Methods The present qualitative study, with sociocultural approach, was developed in the city of Corumbá, located on the border of Brazil and Bolivia. The work included interviews conducted with thirty descendants of Bolivian children, who were students in Brazilians schools. The questions attempted to identify aspects of children's play culture frontier in leisure time. Results The participants' narratives demonstrate the popular games experiences, like games of chase, sung wheels and soccer; It became evident they have incorporated characteristics of Brazilian culture, ethnic conflicts emerge during interaction with their peers; it is perceptible the representation of social roles (imitation), usually associated with the parents' profession, in the enjoyment of practices. Discussion The mechanisms of restriction and control present in organized societies restrict the human relationships and the possibility of leisure, reducing the field of action with regard to spontaneous arousal. The civilizing process has reduced the serious excitations, threatening, adding the compensatory function of excitement- play, pleasurable excitement, whose enjoyment is conscious and socially accepted. However, many of these characteristics are present in infancy, especially in

the border region, because of its permissivity. References Elias N., Dunning E. (1992). *The Quest for Excitement*. Lisbon: Difel. Huizinga J. (1990). *Homo Ludens*. Sao Paulo: Perspectiva. Turner F. REPRODUCTION OF INACTIVITY AMONG HUNGARIAN YOUTH BETWEEN 2000-2012

Perenyi, S.

University of Debrecen

Introduction A series of structural and funding changes has been implemented as sport became a strategic area in governmental policy in 2010. The amendments in the 2004 sports law and the approval of a new financial support scheme by the European Commission allowed these changes (Perényi, 2013), which on the micro levels of sport resulted in a 30% growth in sport participation in five team sports (Bardóczy, 2012). The purpose of this analysis is to reveal whether this growth can also be tracked on the macro levels of sport participation related to Hungarian youth. It is also the goal to describe the recent trends of sport participation of youth in Hungary along the socio-demographic and other sport related variables. **Methods** This study used four cross-sectional sets of data from the years 2000, 2004, 2008 and 2012. Stratified random sampling was used to obtain an accurate representation of the Hungarian youth population (N=8000) between the ages of 15-29, which created a base for statistical analysis applying binary logistic regression analysis to sport participation variable, and used gender, age, main activity, size of residency and social economic status as a control. **Results** The results showed that the growth on the micro levels of sports cannot be tracked on the nationwide representative samples, as the rates showed a decline from 38% to 35% between 2008 and 2012; and approached the rates of those twelve years ago (33%). Data showed that being a man; having younger ages, being a student, and higher on economic status enhances the probability of becoming a member of the sport participant group. The level of urbanisation, however, seems to give more opportunities to those living on the municipality centre level. Results also demonstrated that the power of different socio-democratic variables on sport participation switching by the year of measurement, but economic status gained increasing influence over the years. **Conclusion** Sport participation in Hungary continues to be one of the biggest challenges for the societal and economic subsystem of sport; it seems that growth on the micro level is delayed to be recorded on national samples. Sport became a strategic area in 2010, the new amendments of the 2004 sports law reshaped the structure and the funding of sports. Whether these changes, however, would bring the long-awaited democratization of sports and the societal integration into sports in Hungary; and would initiate a process in which sport participation rates would increase shall continue to be measured also in the future. THE IMPACT OF STRUCTURAL CONDITIONS IN COMMUNES ON PHYSICAL ACTIVITY AND SPORTS BEHAVIOUR OF ADOLESCENTS AND YOUNG ADULTS IN SWITZERLAND

Klostermann, C., Hayoz, C., Schlesinger, T., Nagel, S.

Institut of Sport Science

Introduction The physical activity of the Swiss population differs considerably depending on the linguistic region. German speakers are more often physically active than people living in the French- or Italian-speaking part of Switzerland (Stamm & Lamprecht, 2008). This study analyses how differing structural conditions in communes (e.g. sport facilities, significance of the municipal promotion of sport) across different linguistic regions of Switzerland correlate with physical activity and sports participation for adolescents and young adults. **Methodological approach** Based on the theory of social action (Coleman, 1990), it is assumed that individual behaviour is not only determined by individual but also by structural and socio-cultural factors in which a person is socially embedded. In two case studies, multi-level data was gathered analysing possible influences of structural factors on sports behaviour. Using an online survey, 15 to 25 year old inhabitants (N = 205) living in a German- and French-speaking commune were questioned about their sports participation in and outside of their commune, as well as their perception of sport-related structural characteristics in their commune. To collect information about communes' sport facilities, the sport providers (N = 23) were interviewed. Sport-related characteristics of the communes were also collected through two interviews with representatives of the municipal administration. **Results and discussion** Physical activity is significantly higher ($\chi^2(1, N = 183) = 4.78, p < .05$) and sport participation is significantly lower in the French speaking commune ($\chi^2(1, N = 205) = 3.84, p < .05$). Adolescents and young adults in the French speaking commune ($M = 3.15, SD = 1.23$) are less satisfied with the opportunities to be physically active in the environment than their counterparts living in the German speaking commune ($p < .001$, Mann-Whitney U – test). These first findings show the impact of structural conditions in communes on physical activity and sport participation of adolescents and young people. However, it must be noted that this study is explorative and further communes would need to be examined in order to generalize the results. MALMÖ YOUTH SPORT STUDY – GENDER POSITIONS IN SCHOOL SPORT

Larneby, M.

Malmö University

Introduction In Sweden, sport is a popular activity but the numbers of participants have been declining since a few years back. In addition, even though almost all children are members of (at least) one sports club many drop out during the teenage period (girls younger than boys). This is perceived as a worry due to the vital state sports policy objective of high activity levels (Norberg 2013). However, many upper secondary schools in Sweden have in recent years specialized in physical activity and sports. The objective is often twofold: to promote an active lifestyle and/or foster elite athletes (Peterson & Norberg 2008). Malmö Youth Sport Study is an interdisciplinary research project with the main objective to study factors that are likely to influence adolescents to continue doing sports. The target group is a cohort of pupils attending a school with an explicit sport profile, who are admitted for skills in their specific sport. The purpose of my PhD-thesis is to study these adolescents' experiences of and expectations on sport from a gender perspective. Questions like why and when gender is becoming important to young athletes, and how they negotiate gender positions in sport, will be considered. **Methods and theoretical framework** A qualitative methodological approach with interviews and observations is used. An ethnographic approach is emphasized. Of importance is to take part of the adolescents' everyday life to be able to get hold of their voices, attitudes, conscious and unconscious ways of displaying, constructing and negotiating gender in sport. The theoretical framework is influenced by a construc-

tivist approach, specifically the concepts of gender as a social institution (Lorber 1994) and inclusive masculinity (Anderson 2009). Considerations While the study is in its initial stage, no tentative results will be presented. There are many aspects to consider pertaining to the specific context of an explicit sport profile in school curricula. The daily, often gender integrated, training at school is added to the adolescents' ordinary, mainly gender segregated, leisure training. How do they talk about and perform gender in (their) sport in school? Based on traditional notions of how men's and women's sport are valued differently regarding performance and status, how do these adolescents reflect upon and (re)construct gender? IMMEDIATE EFFECTS OF BREAKING UP SEDENTARY BEHAVIOUR

Engeroff, T., Füzeki, E., Vogt, L., Banzer, W.

Goethe University Frankfurt

Introduction A growing body of observational data suggests that sedentary behavior (SB), such as prolonged sitting, negatively affects cardiometabolic health. Breaking up SB has been shown to be beneficially associated with cardiometabolic markers in observational studies. Findings of experimental studies on the acute effects of breaks in SB on cardiometabolic markers are, however, equivocal. Further, little is known about the effect of a single bout of exercise prior to SB. The purpose of this examination was to compare the effects of a single bout of exercise prior to and regular activity breaks within SB on cardiometabolic markers. **Methods** Eighteen healthy female subjects ($25.6 \text{ years} \pm 2.6$, BMI $21.5 \text{ kg/m}^2 \pm 2.0$, VO_2max $41.9 \text{ ml/min/kg} \pm 4.8$) participated in 3 repeated (2 exercise, 1 control) 4-hour sitting trials (1 week in between) including one meal in each trial. During the 2 exercise trials subjects cycled on a standardized ergometer (70% VO_2max) continuously for 30min prior to (PRE); or in 5 bouts of 6min interrupting during (INT) 4 hours prolonged sitting. A non-exercise trial (4h continuous sitting) was used as control condition (CTRL). Sequences of experimental trials were delivered in a balanced order. Triglyceride, insulin and glucose readings were taken before and 6 times during all 3 trials, area under the curve (AUC) was calculated for each parameter. Maximal oxygen uptake via spirometry (VO_2max) and anthropometric data were obtained one week before the experimental study. Energy intake and VO_2max were used as covariates. ANCOVA was applied for statistical analysis. **Results** AUC of insulin readings differed significantly ($p=.04$) between trials. Adding food consumption as cofactor increased explained variation of insulin readings ($p=.001$). Post hoc analysis of Insulin AUC showed differences from INT to CTRL ($p<.01$) and PRE to CTRL ($p<.05$). Maximum insulin values revealed a tendency ($p=.078$) toward lower values in INT compared to PRE. No significant differences were obtained for triglycerides and glucose. **Discussion** Overall PA either in a single bout before or multiple bouts during sedentary behavior influenced total serum insulin level as an indicator of energy metabolism modulated by the total amount of calorie intake. The tendency to lower maximum insulin values during multiple bout interrupting PA trial (INT) points to a more balanced insulin level compared to the continuously prior PA trial (PRE). Further studies are needed to confirm and specify preliminary evidence concerning metabolic changes. Contact Engeroff@sport.uni-frankfurt.de

ASSESSMENT OF MATURITY IN YOUTH SPORTS USING DXA-DERIVED HAND SCANS

Romann, M., Fuchslocher, J.

Swiss Federal Institute of Sport Magglingen

Introduction Individuals in the same annual age category can differ by as much as five years in skeletal age (SA) (Malina et al., 2004). Therefore, modern models of talent identification and development try to include maturation characteristics of young athletes in the selection process. SA is said to be the most accurate indicator for assessing biological maturity (Malina, et al., 2004). Dual-energy X-ray absorptiometry (DXA) derived hand-wrist scans have been suggested as an approach to adjust for factors related to growth and maturity (Gordon et al., 2008). Evaluating SA via hand-wrist radiographs using DXA produces a 10-fold lower effective dose ($0.1 \mu\text{Sv}$) than using X-ray ($1 \mu\text{Sv}$) (Gordon, et al., 2008). The aim of the present study was to validate DXA as a technique for assessing SA and classifying the maturity of under 15 (U-15) soccer players. **Methods** Paired X-ray and DXA scans of the left hand of 63 Swiss U-15 elite soccer players were performed, and SA assessments were then compared between the two techniques. SA was assessed by comparing the maturity indicators on each participant's X-ray or DXA scan to the reference pictures of the TW3 RUS method (Tanner et al., 2001). SA and maturity assessments were performed twice by two blinded raters. Maturity status classifications were based on SA-CA according to Malina, et al. (2004). Intra- and interrater reliability were analysed using intraclass correlation coefficients (ICC) with a 95% confidence interval (CI). For the method comparison Bland-Altman plots and kappa (κ) statistics were used. **Results** The intrarater reliabilities of both raters were excellent; both had ICCs of 0.98 using X-ray and ICCs of 0.97 and 0.95 using DXA. The interrater reliabilities of both raters were also excellent, with an ICC of 0.93 using X-ray and an ICC of 0.95 using DXA. Bland-Altman plots showed that SA assessments of the two raters differed by 0.2 and -0.1 years between X-ray and DXA. 14 players were classified as early, 39 as normal and 10 as late using the data of X-Ray. 11 players were classified as early, 38 as normal and 14 as late using the data of DXA. Concordance between assessments showed (κ) = 0.77. **Discussion** The Bland-Altman plots and ICCs between X-ray and DXA showed good agreement between maturity classifications in a youth sport setting. Therefore DXA can be used to classify the maturity of U-15 soccer players. The major advantage of the DXA technique compared with the classical X-ray technique is a 10-fold lower exposure to radiation. **References:** Gordon, et al. (2008). EFFECT OF TOURNIQUET CHARACTERISTICS ON THIGH MUSCLES BLOOD FLOW RESTRICTION

Grapar Zargi, T., Vauhnik, R., Jelenc, J., Ipavec, M., Kacin, A.1

University of Ljubljana, Faculty of Health Sciences

Introduction Blood flow restricted resistance exercise (BFRRE) is commonly used to gain muscle mass and strength. The most efficient technique of blood-flow restriction for muscle conditioning has not been identified as yet. During rest, width of the tourniquet (Loenneke et al., 2012) and limb circumference (Tuncali et al., 2006) has been shown to substantially influence pressure distribution to the tissues. Thus the aim of this study was to further optimize tourniquet characteristics for restriction of limb muscles blood flow. **Methods** Newly designed double-compartment contoured tourniquet (IMT, 14 cm wide) and single-compartment straight surgical tourniquet (ST, 10 cm wide) were tested on 17 healthy volunteers (27.3 ± 5.2 yrs., 9 female, 8 male) during rest. Thigh circumference and skinfold were determined for each leg. Efficiency of tourniquets was compared bilaterally on proximal thighs at four occlusion pressures (OP = 120, 160, 200 and 240 mmHg). Changes in hemoglobin kinetics in v. lateralis muscle (near-infrared spectroscopy), cardiovascular responses (ECG and ABP) and pain perception (visual analogue scale, VAS) were analyzed. Results Lean thigh circumference did not differ between legs ($L = 57.3 \pm 3.7$ cm, $R = 57.1 \pm 3.8$ cm). VAS scores did not differ between tested tourniquets, but did significantly increase ($p = 0.03$) at OP 200 mmHg and higher. Difference ($p = 0.009$) in slope of total hemoglobin concentration change ($[tHbs]$) was found between the tourniquets at OP 160 mmHg ($IMT = 0.028 \mu M/s$, $ST = 0.056 \mu M/s$). Mean ABP was significantly increased ($p = 0.02$) at OP 120 mmHg compared to baseline values, whereas change in heart rate was detected. **Discussion** Based on differences in $[tHbs]$, arterial occlusion was induced at $OP \geq 160$ mmHg with IMT, whereas $OP \geq 200$ mmHg was required with ST. Given that higher pressure may cause damage to underlying tissues (Pedowitz et al., 1991) and increases discomfort (Estebe et al., 2000), it is concluded that novel tourniquet design allows for safer and more efficient blood flow restriction at a given tourniquet pressure and discomfort during rest. Whether the same is achieved during BFRRE, needs further investigation. Estebe JP, Le Naoures A, Chemaly L, Ecoffey C. (2000). *Anaesthesia*, 55, 21-6. ACUTE EFFECT OF YOGA TRAINING ON THE ALPHA BRAIN WAVES IN WOMEN WITH PMS

Lin, T.Y., Liang, J.M., Wu, W.L.

Kaohsiung Medical University

Introduction Depressive mood, difficulty in concentrating and anxiety are the common symptoms of the Premenstrual syndrome (PMS). These situations may relate to the lower alpha percentage of the brain wave in women with PMS, because the higher alpha brain waves of electroencephalogram (EEG) research is now known to increasing focus, awareness and states of peace and relaxation. Also yoga exercise has been noted to increase frontal EEG alpha wave activity. In the past study, they examined the frontal alpha asymmetry during a depressive induction condition, but there was no research about the alpha percentage in the static situation (Lin et al., 2013). Therefore, the aim of this study was to analyze the changing of alpha percentage between luteal phase and follicular phase and the effect of yoga training in static condition in women with PMS. **Methods** Three women with PMS performed 50 minutes yoga exercise across a menstrual cycle, then recorded seven minutes of their static EEG with eye-closed, and those records were accessed before the yoga class and within 60 minutes after the class, also those were executed in luteal phase and follicular phase separately. The EEG was recorded from electrodes which attached at seven scalp positions (Fp1, Fp2, Fz, F3, F4, F7, F8) according to the 10-20 system. The analysis of static EEG signals included five minutes data from 60 seconds to 360 seconds, and the alpha brain wave percentage was averaged off-line from these seven scalp positions. Results The repeated-measures ANOVA results of the alpha brain wave percentage showed significant yoga training effect ($p = 0.029$). Then the Mann-Whitney test showed the significant higher alpha percentage after yoga training than before the training in luteal phase ($p = 0.05$). In the situation of after yoga training, the alpha percentage was significantly higher in luteal phase than in follicular phase ($p = 0.05$). **Discussion** The yoga exercise was thought to let people relax and the higher alpha percentage after yoga training may explain the consequent, and it was consistence with the past study (Kamei et al., 2000). In the present study, the higher alpha percentage after training may reflect the acute effect of yoga training for women with PMS. Besides, the higher alpha percentage after training in the luteal phase may explain the acute benefit of yoga exercise for women with PMS was more than in the follicular phase. But the number of subject in our study was not enough. Therefore, more subjects would be involved in the future study. References Kamei T, Toriumi Y, Kimura H, Ohno S, Kumano H, Kimura K. WHAT IS EVIDENCE-BASED ABOUT MYOFASCIAL CHAINS? A SYSTEMATIC REVIEW

Wilke, J., Krause, F., Vogt, L., Banzer, W.

Goethe University Frankfurt

Introduction Fascial tissues are increasingly addressed in the treatment of musculoskeletal disorders. Manual and osteopathic therapists in particular often rely on concepts of myofascial chains. However, to our knowledge, the existence of bodywide continuities forming muscle-fascia lines has not been evaluated systematically. The present review aims to provide evidence for six of the myofascial meridians proposed by Myers (1997) based on anatomical dissection studies. **Methods** A systematic literature research was conducted in MEDLINE (Pubmed), ScienceDirect and Google Scholar (each 1900-2014). Peer-reviewed anatomical dissection studies examining myofascial continuity were considered eligible. Publications in language others than german or english and case studies were excluded. If no study reported fascial continuity for a station of a myofascial meridian, papers on general anatomy of the corresponding region were targeted. The literature research yielded a total of 431 studies. Forty-seven were included. To assess methodic quality, two independent investigators rated each study by means of a validated assessment tool (QUACS). Results There is moderate to good evidence for the existence of three myofascial meridians. These are the superficial backline (plantar fascia, gastrocnemius, hamstrings, erector spinae; based on 15 studies), the back functional line (latissimus dorsi, contralateral gluteus maximus, vastus lateralis; 7 studies) and the front functional line (pectoralis major, contralateral rectus abdominis, adductor magnus; 6 studies). Partial evidence was found for existence of the spiral line (17 studies). No or little confirmation was obtained for the superficial front line (4 studies) and the lateral line (3 studies). **Discussion** As there is good evidence for the existence of three meridians, considering them in therapy seems conceivable. Moreover, some of the lines might exist despite poor or missing evidence because few studies explicitly aimed at identifying myofascial links. Further

study on presence and functional significance of myofascial continuities is warranted. This especially applies to the capability of strain transfer in the course of the meridians.

SHORT-TERM EFFECTS OF ACUPUNCTURE AND STRETCHING ON MYOFASCIAL TRIGGER POINT PAIN OF THE NECK: A DOUBLE-BLIND, PLACEBO-CONTROLLED RCT

Fleckenstein, J., Wilke, J., Vogt, L., Niederer, D., Hübscher, M., Rothmayr, J., Ivkovic, D., Rickert, M., Banzer, W.

Goethe-University Frankfurt/Main

Purpose: This study was done to evaluate the short-term effectiveness of acupuncture and stretching to reduce pain and improve range of motion in patients afflicted with cervical myofascial pain syndrome. **Relevance:** Myofascial pain syndrome is commonly associated with restricted range of motion and pain arising from trigger points. Recent literature indicates that acupuncture is able to alleviate the symptoms. A combination with additional stretching exercises could support therapeutic success. **Methods:** Nineteen patients (male $n = 11$, female $n = 8$, mean age 33 ± 14 years) with myofascial neck pain were included in the double-blind crossover study. In randomized order, they received the following treatments with one week of washout in between: acupuncture and stretching, acupuncture and placebo laser acupuncture. Mechanical pain threshold (MPT), measured by means of a pressure algometer represented the primary outcome. Secondary outcomes consisted in motion-related pain (100mm visual analogue scale, VAS) and cervical mobility. Range of motion (ROM) was recorded with an ultrasonic 3D movement analysis system. Outcomes were assessed immediately prior and 5, 15 and 30 minutes post treatment. **Analysis:** Friedman tests with post hoc bonferroni-holm correction were computed to compare differences between treatments. **Results:** After 5 minutes, both acupuncture as well as acupuncture and stretching increased MPT by 5 respectively 11 percent. However, only acupuncture and stretching was superior to placebo ($p < 0.05$). There were no significant differences between the interventions at 15 and 30 minutes post treatment. VAS did not differ between treatments at any measurement. Five minutes after application of acupuncture plus stretching, ROM was increased significantly more in the sagittal plane and in the transversal plane compared to placebo ($p < 0.05$). **Conclusions:** The combination of acupuncture and stretching could represent a suitable treatment option to improve range of motion and reduce cervical trigger point pain in the short-term. However, further well-designed studies are warranted. **Acknowledgement:** The present study was funded by the German Society for People with Muscular Diseases (DGM).

VALIDATION OF A MODIFIED STEP TEST FOR DETERMINATION OF MAXIMUM OXYGEN UPTAKE

Fisch, M., Czechor, K., Limmer, M.J., Krusche, T., Platen, P.

Ruhr University Bochum

Introduction The step test (ST) is a frequently applied test in performance and functional diagnostics, easy to handle, low in equipment, and especially useful for testing in the field during mountaineering. The aim of this study is to validate a modified Canadian Aerobic Fitness test (mCAFT) on a commercially available stepper for the determination of $\text{VOI}_{2\text{max}}$ **Methods** 22 subjects (9f, 13m, 26.2 ± 3.3 yrs, 176.0 ± 8.5 cm, 72.2 ± 11.9 kg) performed a Bruce protocol on a treadmill (gold standard, GS) for the determination of $\text{VOI}_{2\text{max}}$, and three incremental ST (step frequency 66, 84, 102, 114, 132, 144 bpm, and, after increasing step height by 5cm: 118, 132 bpm, each step 5 min with 1 min rest between stages), with spirometry, heart rate and lactate analysis until exhaustion (two tests with nearly 90° knee angle (ST[90], ST[90r] for test-retest-reliability), and one test with an additional top (+5cm, ST[90+1]) in randomized order). Parameters included $\text{VOI}_{2\text{max}}$, heart rates (HR), blood lactate concentration (La), and maximum step frequency (STfmax). **Results** Both ST resulted in similar values for Hfmax and Lafmax, while $\text{VOI}_{2\text{max}}$ was higher and STfmax was lower in ST[90+1] (192.2 ± 7.9 vs. 191.9 ± 9.3 bpm; 7.8 ± 2.1 vs. 8.5 ± 1.9 mmol/l; 47.4 ± 6.0 vs. 47.1 ± 6.5 ml/min/kg; 142.1 ± 12.8 vs. 130.0 ± 13.5 bpm). Test-Retest reliability was highly significant for $\text{VOI}_{2\text{max}}$, Hfmax, Lafmax, and STfmax (ICC-values: $\text{VOI}_{2\text{max}}$: 0.948, Hfmax: 0.907, Lafmax: 0.826, STfmax: 0.963). ST90 underestimated $\text{VOI}_{2\text{max}}$ compared to GS (47.4 ± 6.0 vs. 54.5 ± 8.3 ml/min/kg, $p < 0.01$), however nearly all subjects remained within the 1sd-range around the mean difference of 7.1 ml/min/kg in the Bland-Altman plot. **Discussion** Concerning the high validity and test-retest-reliability, the modified step test with 90° knee angle might be used for the determination of $\text{VOI}_{2\text{max}}$ under field conditions in the mountains where no other technical equipment is available. **References** Bruce, R. A.; Kusumi, F. & Hosmer, D. (1973). Maximal oxygen intake and nomographic assessment of functional aerobic impairment in cardiovascular disease. American heart journal, 85 (4), 546- 562.

COLD WATER IMMERSION ON RECOVERY FROM EXERCISE-INDUCED MUSCLE DAMAGE

Siqueira, A.F.1, Vieira, A.1, Ferreira Junior, J.B.1,2, Vieira, C.A.1, Rocha Júnior, V.A.1,3, Bezerra, M.S.1, Alves Dias, P.P.M.A.1, Durigan, J.L.Q.1, Bottaro, M.1

1: University of Brasília (Brasília, DF, Brazil), 2: IFTM (Paracatu, MG, Brazil), 3: National Academy of Police (Federal Police, Brasília, DF, Brazil)

Introduction Muscle damage is associated to unaccustomed exercise involving eccentric actions. The symptoms included strength decrease and muscle soreness (Cheung et al., 2003). Cold water immersion (CWI) is been extensively used as therapeutic modality for treating muscle damage in sports (Vieira et al., 2013). However, there are some controversial results regarding the benefit of this practice. Therefore, the potential benefits of CWI treatments remain to be determined. Thus, the aim of this study was to investigate the effects of CWI on symptoms of muscle damage. **Methods** Sixteen untrained men (age 22.3 years, height 174.0 cm, body mass 72.3 kg) completed five sets of 20 drop jumps with 2 min of rest interval between sets. The single drop jump consisted of landing on the floor from a 60 cm box and jump immediately upward maximally. After exercise, participants were randomly assigned to two groups: 1) 20 min CWI at 15°C ($n=8$); or 2) Control ($n=8$). Isometric knee extensors torque (KT) and ratings of perceived soreness (DOMS) were measured at baseline and 24, 48, 72 and 96 hours after exercise. **Results** There was no interaction between intervention and time on KT [$F(2.428,33.995) = 2.387$, $p = .10$]. However, main effect of time on KT was significant different [$F(2.428) = 37.643$, $p < .000$]. The greater KT decrement ($30.0 \pm 12.0\%$) was observed 24 hours and returned to baseline value at 96 hours after exercise for both group. There was no interaction between intervention and time on DOMS [$F(4,56) = .578$, $p = .68$]. However, DOMS presented a significant main effect for time ($F(4) = 35.808$, $p < .000$). DOMS peaked at 48 h (5.8 ± 2.1) and returned to baseline at 96 hours after post exercise for both groups. **Discussion** The therapeutic value of CWI consists of reduced nerve conduction velocity, blood flow and local tissue metabolism. These effects may promote pain relief, reduces edema and secondary injury area. However, the results from the present suggest that CWI at 15°C is an ineffective strategy to prevent or minimize symptoms of muscle damage in untrained men. As reduced tissue temperature is an important effect for the treatment of musculoskeletal injuries or damage (Merrick et al., 2003), further studies still need to investigate the effects of CWI using different water temperatures and different time points of application after exercise. The authors would like to thanks FAPDF-Brazil for the financial support. **References** Cheung K, Hume PA, Maxwell L (2003). Sports Med, 33, 145-164. Vieira A, Oliveira AB, Costa JR, Herrera E,

AEROBIC EXERCISE AMELIORATES THE IMPAIRED MOTOR COORDINATION IN LACTATIONAL SODIUM META-VANADATE-EXPOSED RATS

Wang, D.C., Lin, Y.Y.

Kaohsiung Medical University

Introduction: Early-life exercise can reduce risk of neurodegenerative diseases in later life by induction of brain-derived neurotrophic factor (BDNF). Because the brains of infant baby are more vulnerable to environmental toxic agents, early-life exposure to environmental toxic agents may result in increased risk of neural dysfunction in the adults (Swinny et al., 2005). Postnatal exposure to sodium metavanadate (NaVO₃) can impair the development of cerebellum by reducing the volume of cerebellar white matter in adult animals (Soazo and Garcia, 2007). An attempt is made in the present study to evaluate the effects of exercise on ameliorating the neonatal NaVO₃ exposure-induced neural dysfunction in young adult rats. **Method:** Sprague Dawley female rats were treated with NaVO₃ (3 mg/kg per day, ip.) or vehicle during lactational period. After weaning (postnatal day 22), the male offspring were divided into 4 groups: control (C), NaVO₃ (V), exercised control (Cx), and exercised NaVO₃ (Vx). Exercised animals were trained on treadmill running for 5 weeks. At the age of 8 weeks, animals were subjected to rotarod test and catwalk test for assessment of motor coordination and gait analysis, respectively, followed by ELISA measurement of plasma and cerebellar BDNF contents. **Results:** No significant difference was found in gait analysis among groups. Deficit of motor coordination, as well as reduced plasma and cerebellar BDNF levels were observed in the V group. These results indicated that neonatal NaVO₃ exposure may reduce the release of BDNF, leading to dysfunction of the cerebellum. After the five-week aerobic exercise training program, the performance of motor coordination was improved and plasma BDNF level was increased in the Vx group. **Discussion:** Early-life exercise can enhance capacity to evoke memories and reduced risk of neurodegenerative diseases in later life. This long-term effects of exercise-induced BDNF release can maintain the structure and function of central nervous system, suggesting that exercise may be a useful method to ameliorate the adverse effects caused by insults in early life. Given the findings of this study, it was proposed that aerobic exercise may provide beneficial effects on ameliorating the altered biochemical and neurobehavioral outcomes in lactational NaVO₃-exposed young adult rats.

PRACTICE OF RAMADAN FASTING IN MUSLIM FOOTBALL PLAYERS PARTICIPATING IN OLYMPICS

Farooq, A., Herrera, C.P., Zerguini, Y., Almudahka, F., Chamari, K.

Aspetar-Qatar Orthopaedic and Sports Medicine Hospital

Background: Studies have shown that Ramadan fasting can negatively influence diet, sleep and some performance measures in athletes. The prevalence of Ramadan fasting in a high level competition is not known. Understanding the knowledge and beliefs about Ramadan fasting among athletes is the first step in designing an intervention to maintain performance during competitions. **Methodology:** Muslim footballers from three national teams (A, B and C representing African and Middle-Eastern regions) agreed to participate in the study (n=54, age: 22.7±2.6 y, body mass: 74.8±6.5 kg, height: 180.5±7.1 cm). Athletes completed a structured questionnaire one week before Ramadan and the London 2012 football tournament. The questionnaire included 21 items to assess knowledge, beliefs and intended practice of Ramadan fasting during the tournament. **Results:** The majority of footballers (61%) reported they did not intend to fast throughout the tournament. The remainder (39%) reported they would only fast on training days and not competition days, but the responses varied between teams: 83%, 15% and 0% in Teams A, B and C, respectively. None of the football players intended to fast on game days. More than half believed Ramadan fasting would negatively affect their sleep (57%) as well as their physical (74%) and mental (60%) abilities, but these responses were independent of whether they intended to fast or not. Few football players believed that Ramadan fasting could make them physically (6%) or mentally stronger (11%), but about half believed that it will increase their confidence (54%). The players' decision to fast was associated with the perceived coach's opinion regarding Ramadan fasting (p=0.001). **Conclusion:** There were cross-cultural differences on how Muslim football players planned to observe Ramadan. Despite good knowledge about the influence of Ramadan fasting on sleep and performance some athletes still chose to observe the fast but during training days only.

RELATIVE AGE EFFECTS AND IMPACT ON PERFORMANCE: A STUDY OF SWEDISH U15 DISTRICT SOCCER TEAMS

Söderström, T.1, Brusvik, P.2, Lund, S.3

1: Umeå university, 2: Swedish Football Association, 3: Linneus University

Introduction This study reports empirical data from a project that investigates talent development in the 24 soccer districts in Sweden. The purpose of this study is to examine how birth dates for girls and boys relate to the district teams performance at the elite camp at the age of 15. **Methods** The material that the study is based on is an analysis of data from Sweden's 24 football district between 2001-2011. The study was based on 4517 girls and 4404 boys who attended the elite camp at the age of 15. A compilation of all 24 districts match results against other districts at the elite camp were used as a measure of district performance (30 matches between 2001-2011 were registered for each district). Based on the birth dates of the players a relative age index (RAE index) ranging from 4, january –march to 1, october-december, was constructed for each district during the period 2001-2011. **Results** The results show for both boys and girls that a majority of those who attended the elite camp between 2001 and 2011 were born the first six months. Overall, the results show that for girls are 34% born in the first quarter, 30% in the second quarter, 22% in the third quarter and 14% in the fourth quarter. The 24 districts RAE index varies between 2.6 and 3.0. For the boys, the results show that about 41% were born the first quarter, 30% in the second quarter, 19% in the third quarter and 10% in the fourth quarter. The district RAE-index is higher for boys and varies between 2.8 and 3.3. The analysis

show that there are statistically significant correlations between district RAE index and match results for boys but not for girls. Discussion The study shows, for both girls and boys a marked RAE effects for all Swedish football districts compared to the general population (Peterson, 2011). The relationship with the match result at age 15 are only found among the boys. We can conclude that for the boys, but not for girls, district teams with higher RAE index perform better at the elite camp. The relative age differences that exist between boys and girls may be partially due to the girls' earlier biological and mental maturation processes which contribute to that girls may compete on equal physical conditions at the tryouts for the district teams when they are 14 years of age (cf. Romann & Fuchloser, 2011). This earlier maturation process may also be a reason why the girls' performances do not have any connection with the district RAE. References Peterson, T. (2011). THE PROFILE OF MARATHONERS FROM SÃO PAULO INTERNATIONAL MARATHON

Benetti, M., Sierra, A.P.R., Santos, V.C., Gorrão, R., Cury Boaventura, M.F., Sierra, W.R.T.R., Rocco Junior, A.J., Bastos, F.C. *EEFE-USP, ICB-USP, University Nove de Julho, Cruzeiro do Sul University*

Introduction: Despite the known health benefits of physical activity, relatively few individuals initiate or maintain their involvement in such activity, with the challenge for professionals in this area being to get a larger number of individuals to make physical activity a life habit. Thus, the quest for the practice of outdoor physical activities, such as walking and running street marathons it is becoming more frequent and more significant since they are accessible to the whole population, demand low-cost training and participation, being characterized as a mass physical activity. Thus, the present study aims to assess the profile of the marathon runners from São Paulo International Marathon. Methods 34 male marathoners aged 24 to 51 years old (38.02 ± 6.33) answered a profile questionnaire idealized for the researcher, before the São Paulo International Marathon. Statistical analyses were performed in SPSS 17. The results are presented as the mean \pm standard deviation. Results The marathoners were 38.02 ± 6.33 years, and did 2.35 ± 2.64 previous marathons (minimum 1 and maximum 13 marathons). They run on average 8.81 ± 6.08 years (minimum 2 and maximum 24 years) and the main aims to practice exercise are life quality (32.35%), health (26.47%) and performance (14.7%). From these, 41.17% of the marathoners practice just running, 29.41% cycling, 17.64% gym and 14.7% soccer. The sports consulting attendance just is required for 23.52% of the athletes. The marathoners live in São Paulo (70.59%), ABCD cities (8.82%) and others cities (20.59%) all in São Paulo State. 58.82% were married, 35.29% single and 5.8% separated. The level of schooling was predominantly upper level (64.7%), followed by post-graduated level (17.65%) and high school (17.65%). 76.47% of the athletes perform a medical evaluation periodically. However, 2.94% were diabetic, 2.94% smoke, 14.7% has dyslipidemia and none of them were hypertensive patients. Around 32.35% of the marathoners were injured in the last 12 months. About the parents 67.64% had cardiovascular disease and hypertension how a family history. Discussion Our findings show that the marathoners are older runners, with some training experience but have no sports consulting. However, running street marathons it is becoming more frequent and more accessible to the whole population attracting runners with several goals within the practice of sports since improve the health until performance. Despite, these marathoners have no many modifiable risk factors but the frequency of injuries is higher.

INFLUENCE OF PARENTS ON CHILDREN'S ATTITUDES TOWARD DIFFERENT KINDS OF SPORTS

Celiksoy, S.
Anadolu University

Introduction Socio-economic status and level of income have different impacts on sports activities from the ancient time up to the present (Bayraktar, 2003, s.23). Parents' jobs, family income and level of education designate their status in the society and identify children's attitudes toward different branch of sports. According to the majority opinion, football, wrestling and martial arts are favorite sports of children from lower class, and some sports such as swimming, tennis, golf and skiing are more popular sports of those who have higher income. In other words, socio-economic differences affect individuals' interests in sport (Topkaya, 2004). In this research, the main objective is to try to find out if there is a relation between parents' jobs, level of education, income and children's favorite sports. Method In the sample group there are 200 students chosen randomly from 10 high schools in 2011-2012 teaching year in Eskişehir. % 52 of the students are male and % 48 are female students. There are demographic features of families and 11 favorite sports in the survey. Arithmetic average, frequency and percentage analyzes have been used in evaluation process. Results The most favorite sport is football; %37, swimming is % 27, volleyball is % 11 and other sports are % 25. According to parents' jobs, favorite sports are football and swimming; in accordance with parents' education level, favorite sports are football, swimming and basketball, in accordance with parents' level of income football, swimming and volleyball are the most popular sports. Discussion It may be not a surprise that football is the most favorite sport in all aspects. Because individuals prefer this sport to have a social statue and they would like to be a member of a popular group. Swimming is the second favorite sport as Turkey is surrounded by three seas. RUGBY FOOTBALL: THE BEGININGS IN PORTUGAL AND IN BRAZIL

Alpuim, J.
Instituto Federal de Brasília

Introduction This study tried to understand where and when did Rugby football started to be played, both in Portugal and in Brazil. Methods The method used in this research was a bibliographic revision and personal data from former rugby players that are keeping important proofs of history. There were also interviews on some of those ancient players, to understand and connect the data researched. Results Perhaps the biggest difficulty in the findings of this research was the by-then confusion on what was really Rugby football and the actual Football (association). In fact, Rugby football and Football look-a-like too much, and seem to have developed side-by-side for quite

a while, sharing the same pitches, the same clubs or schools, the same uniforms, even the same players several times. Both came from the same British and/or French elite and/or university backgrounds, and their first matches played in Portugal and Brazil were with or without British company workers. Discussion Besides today Rugby being more developed in Portugal than in Brazil, it's clear that it arrived before in South America (1888 vs 1903), through the same person - Charles Miller - that took both Football and Rugby football first balls, when getting back from England. And it's also notorious that Rugby in Brazil took to their English background and terms, instead of Portugal's French ones. References CARREIRA J (1924). Publicitas, Lisbon. CASTRO J et al (1998). POLISH ATHLETICS AS A EUROPEAN NEIGHBOURHOOD AND PARTNERSHIP INSTRUMENT

Kisiel, J.

Adam Mickiewicz University in Poznań

Any form of sport, both professional and amateur, is more than just a way of boosting one's physical and mental disposition – it is also a factor which unites people from different backgrounds. Nearly 60% of Europeans engage in sports regularly, and there are ca. 700 thousand sports clubs across the EU. Sport is also an important and fast-growing sector of the economy, which is of great importance for economic and employment growth. Sport and physical activity hold an important place in the lives of many Europeans and in the traditions of European societies. In 2011, the European Commission adopted a strategy aimed at supporting sport in Europe. Sport plays an increasingly important role in the European Union, while the Community policies concerning many spheres of life have an impact on the domain of sport. The year 1989 was a great breakthrough in the post-war history of Eastern European Countries. It marked the beginning of democratic transformations in the region and the onset of the decline of Russian hegemony in this part of Europe. The political system change which took place at the time made it possible for Eastern and Central European countries to establish cross-border cooperation and institutionalize it. Sport exchange begins, and not just at the level of national teams but also municipalities, districts and sportsmen themselves. From the moment Poland stepped onto the path of transformations, becoming a member of the European Union was one of the foreign policy priorities. Poland joined the European Union on 1 May 2004 along with other countries. One of the basic challenges faced by the new EU members states, particularly in their cross-border areas, is striving for the cohesion of the EU borderland with its new east and south neighbours. In order to meet this challenge, the European Union launched the European Neighbourhood and Partnership Instrument (ENPI). The sport policy under these programmes is implemented on the basis of a cyclic cooperation structure (the cyclical pattern of organizing competitions, and establishing sport, scientific and social contacts between competitions). In both partnership programmes athletics is the leading discipline when it comes to sport contacts. Athletics enjoys a great level of popularity in the society, millions of people engage in it worldwide, it transcends national borders, unites and activates communities and is a timeless "queen of sports". The publication presents the achievements of Polish athletics as an instrument of neighbourhood and partnership with Poland's adjacent countries. The work discusses the history of development of this cooperation, taking into account particular disciplines and regions, and even the partnership exchange between cities and municipalities. The actions of individual sportsmen are also presented.

PREDICTION OF TEAM PERFORMANCE IN AMERICAN FOOTBALL

Fomin, R.1, Kekolahti, P.2, Huttunen, P.3, Fish, J.4, Nasedkin, V.1

1: Omegawave (Espoo, Finland), 2: Aalto University (Espoo, Finland), 3: Loughborough University (Loughborough, UK), 4: JFC (Atlanta, USA)

Introduction Success in the National Football League (NFL) depends on overall team performance as well as the individual contribution of players. Performance outcomes are determined by a multitude of factors; training load, preparedness and readiness levels. The purpose: to predict performance by analysing all components of the team's preparation. Methods The study examined 22 players of an NFL team for 7 months, during the 2012-13 season. The data set consisted of over 2000 samples with 147 parameters containing anthropometrical, physiological, performance, and training load variables. The physiological readiness of the Central Nervous System (CNS), Cardiovascular System and Energy Supply System were frequently monitored and assessed by Omegawave 4 (Finland). Regression and Principal Component Analysis, Bayesian and Decision Tree modelling were utilised to verify the usability of the data set, by using RapidMiner 5.3 (Germany) and Bayesialab 5.2 (France). Supervised Learning and Augmented Naïve Bayes (ANB) modelling were used to construct predictive models for 3 different performance concepts. 1) A new performance metric, Overall Team Performance (OTP), was constructed to represent performance on a team level. This was achieved by weighting 14 individual performance metrics based on their correlation with Game Success (GS). Normalized OTP values were classified in the following way: 0-0.3 = low, 0.3-0.6 = medium, 0.6-1 = high. 2) Performance was analysed in terms of GS (win) or Failure (loss). 3) Performance was analysed on an individual level where only the following metrics were evaluated: quarterback rating (QBR), sacks, interceptions, rushing yards, and receptions. The predictive models for these performance concepts used 47 parameters as predictors. Model accuracy was confirmed by a Receiver Operating Characteristic (ROC) and Confusion Matrix. Results The ROC for OTP prediction was 86%. The cardiac and metabolic readiness as a part of the model, were the strongest predictors. The ROC for GS prediction was 89% (win = 93%, loss = 72%). The Readiness variables alone were able to predict win (77%), but not loss. Training load was the strongest predictor of GS. Regarding physiological factors, CNS readiness was the strongest predictor, followed by cardiac readiness. Individual performance metrics such as sacks and QBR were accurately predicted by physiological parameters, however the strongest predictors varied amongst performance metrics. Discussion For each of the 3 performance concepts, cardiac and CNS readiness were consistently amongst the strongest predictors. These findings can be used for improved management of a team's preparation process. Contact roman.fomin@omegawave.com

MO-PM53 PH Endurance Exercise

MAXIMAL OXYGEN UPTAKE IS ASSOCIATED WITH RESTING ENDIASTOLIC VOLUME IN PREPUBERTAL CROSS-COUNTRY SKIERS

Hallén, J.1, Landgraff, H.W.1, Sarvari, S.1.2, Aeng, A.1, Ansari, H.2, Edvardsen, T.2

1:Department of Physical Performance, Norwegian School of Sport Sciences, Oslo; 2:Department of Cardiology, Oslo University Hospital, Rikshospitalet, Oslo

Introduction In adults, a high aerobic power (VO₂max) is associated with a high maximal cardiac output. A high cardiac output is achieved by a high stroke volume (SV) which again is achieved by a large left ventricle (LV) end-diastolic volume (EDV) during exercise. If EDV at rest also is associated with VO₂max is not known. Furthermore, if these relationships are true also in children is unknown. This study aimed to investigate if there is an association between resting LV EDV and VO₂max in a group of prepubertal Norwegian cross-country skiers. **Methods** Seventy-four Norwegian children (boys n=46, age 11.9 ± 0.3 and girls n=28, age 11.9 ± 0.2) were recruited from cross-country ski clubs. VO₂max was determined by incremental treadmill running to exhaustion. End-diastolic volume (EDV) and end-systolic volume (ESV) at rest were assessed by 2D echocardiography. Hemoglobin mass (Hbmass) was measured by the optimized CO-breathing method. Results Heights were 151 ± 7 and 154 ± 7 cm and weights were 39.2 ± 4.91 and 41.0 ± 6.0 kg for boys and girls, respectively, with no significant differences between genders. There was a significant correlation between absolute VO₂max (L/min) and LV EDV (ml) (r=0.66; 90%CI 0.53 – 0.76). Relative to body mass the correlation between VO₂max (ml/kg/min) and resting EDV (ml/kg) was also significant (r= 0.53; 0.37 – 0.66). Furthermore, ESV correlated positively to VO₂max both in absolute values (r=0.47; 0.30 – 0.61) and relative to body mass (r=0.37; 0.19 – 0.53). Resting SV (EDV-ESV) correlated with Hbmass, both in absolute values (r=0.72; 0.61 – 0.80) and relative to body mass (r=0.40; 0.22 – 0.55). There was no correlation between resting ejection fraction and VO₂max. **Discussion** The association between resting LV EDV, Hbmass and VO₂max in absolute values is partly determined by body mass. However, the relatively high correlation coefficients indicate a relatively high reliability of the measurements. VO₂max is associated with a high maximal cardiac SV which again is achieved by a large EDV during exercise. The significant correlation found between resting EDV and VO₂max normalized for body mass, indicates that maximal EDV during exercise is associated with resting EDV. Furthermore, the positive association between resting ESV and VO₂max indicates that those with higher VO₂max have a higher cardiac reserve at rest. Contact: Jostein Hallén [jostein.hallen@nih.no]

EFFECT OF MARATHON RACE ON ADHESION MOLECULES AND APOPTOSIS RECEPTORS OF NEUTROPHILS.

Cury-Boaventura, M.F., Santos, V.C., Caçula, K.G., Santos, C.M.M., Sato, F.T., Silva, M.B.B., Oliveira, H.H., Santos, O.G., Sierra, A.P.R., Benetti, M.P., Kiss, M.A., Pithon-Curi, T.C., Gorjão, R.

1Institute of Physical Activity and Sports Sciences, Cruzeiro do Sul University. 2Institute of Biomedical Sciences, 3School of Physical Education and Sport, University of São Paulo. (São Paulo).

Introduction: Prolonged intense exercise such as marathon race is associated with alterations on neutrophils functions. The aim of this study was to investigate the effect of marathon race on expression of surface molecules and DNA fragmentation in neutrophils. **Methods:** Forty marathon runners (body mass: 73.4 ± 1.2 Kg, height: 175 ± 0.9 cm, BMI: 24 ± 0.3 Kg/cm², fat mass: 17.3 ± 0.6%) were evaluated 1 day before, immediately, 24h and 72h after race (São Paulo marathon). Blood samples were collected and neutrophils were isolated. The following parameters were carried out by using flow cytometry (BD Accuri, BD, USA): a) expression of adhesion molecules L-selectin (CD62) and ICAM-1 (CD54), b) expression of apoptosis receptors Fas (CD95) and TNFR (CD120), and c) DNA fragmentation. **Results:** L-selectin expression on neutrophils increased significantly 72h after marathon race compared to before, immediately after and 24 h after race (by 43, 25 and 38%, respectively). The expression of ICAM-1 was elevated immediately after and 24 h after marathon race (by 64% and 69%, respectively) compared to before competition. Marathon race decreased expression of neutrophil apoptosis receptor TNFR-1 immediately after and 24 h after race (by 36% and 78%, respectively). However, Fas receptor expression increased 24 h after race (26%). The DNA fragmentation of neutrophils decreased immediately after race (7.8 ± 0.1% to 4.4 ± 0.07%), and increased 72 h after race (4.4 ± 0.07% to 9.5 ± 0.13%) compared to before race. **Discussion:** Some previous studies suggested that neutrophil activation and infiltration follows exercise-induced muscle injury (Cabrini et al., 2010). We observed an increase in L-selectin and ICAM-1 expression after race indicating adhesion on endothelium and possible migration to muscle injury. Neutrophil death is critical for the optimal expression as well as for efficient resolution of inflammation. The cell surface receptors, TNFR and Fas both trigger apoptosis (Cabrini et al., 2010). The apoptosis receptor TNFR-1 may contribute to decrease in DNA fragmentation after race and Fas receptor to increase 72 h after race. We suggested that the elevation in expression of L-selectin and ICAM-1 may contribute to infiltration follows exercise-induced muscle injury and neutrophils death in recovery period can be important to inflammation resolution. **References** Cabrini M, Nahmod K, Geffner J. (2010) Curr Opin Hematol. Jan;17(1):31-5.

INTAKE, SERUM AND URINE CONCENTRATIONS OF ESSENTIAL TRACE ELEMENTS IN ENDURANCE RUNNERS.

Crespo, C.1, Llerena, F.2, Robles, M.C.1, Iglesias, P.J.1, Grijota, F.J.1, Maynar, M.1

UNIVERSITY OF EXTREMADURA

1: Sport Sciences Faculty. University of Extremadura (Cáceres, Spain) **2:** Medicine Faculty. University of Extremadura (Cáceres, Spain) **Introduction** Essential trace elements are necessary for different functions of the organism. These metals can play important functions in the adaptation to exercise. Some trace elements are part of the composition of vitamin B12 and increases erythropoiesis (Lippi et al., 2005); also, biological effects about mimetics-insulin properties that occur in the majority of intact cell systems (Jakusch et al., 2010). The aim of the present study was to determinate changes occurring in the serum and urinary concentration of essentials trace elements as a result of a period of six month of physical training in endurance runners living in Extremadura (Spain). **Methods** Sixteen Spanish long distance runners, well-trained, were recruited before the start of their training period. Athletes had performed training regularly for the previous

two years and they had a rigorous training average of 120 km per week oriented at high-level competition. All athletes were residing in the same geographical area. Serum and urine of Co, Cu, Mn, Mo, Se, V and Zn samples was analyzed, before and after a training period of six months, with a ICP-MS. Results Serum concentrations of Mn ($p<0.01$), Se ($p<0.01$) and V ($p<0.05$) decrease at the end of the training period. Serum concentrations of Zn ($p<0.01$) in the athletes are high at the end of the training period. Results are presented in $\mu\text{g/L}$, without and with hemocentrification correction. The urine concentrations of Cu ($p<0.01$ and $p<0.01$) were lower after training period; Urinary Co ($p<0.01$ and $p<0.001$) and Zn ($p<0.05$ and n.s) in athletes are higher at the end of the training period. Results are presented in $\mu\text{g/L}$ and $\mu\text{g/g}$ without and with creatinine correction. Discussion All these athletes have a significant increase in metabolism. The body is subjected to increase spending on all substances essential to him as metals. Physical exercise and the consequent increase in the activity of Mn-SOD can induce cardioprotection, and could this be the cause of its decline in serum in our athletes (Bicer et al., 2012; Lee et al., 2012). THE OUTSTANDING RUNNING ECONOMY OF ERITREAN RUNNERS IS NOT A BIOMECHANICALLY BASED PHENOMENON.

OLIVAN, J., SANTOS-CONCEJERO, J., MUNIESA, C.A., TUCKER, R., MONTIL, M., LUCIA, A.

UNIVERSIDAD EUROPEA DE MADRID-MRC/UCT RESEARCH UNIT FOR EXERCISE SCIENCE AND SPORTS MEDICINE, UNIVERSITY OF CAPE TOWN (SOUTH AFRICA).

Introduction: It has been hypothesized that the explanation for the East African running phenomenon may be partially due to an extraordinarily efficient running economy (1). This advantage has been attributed to structural and anthropometric characteristics including smaller calf circumference and optimised gastro-Achilles tendon characteristics (1,2). Since biomechanical variables such as ground contact and swing time, stride length and frequency have been shown to directly influence running economy (3), the aim of this study was to analyse whether improved running economy in Eritrean runners is associated with biomechanical variables of the gait cycle. Methods: Nine elite Eritrean (23.3 ± 4.8 years and 27.7 ± 0.8 min 10-km race time) and eight elite European (28.0 ± 4.2 years and 28.5 ± 0.8 min) runners participated in this study. All runners completed three 6-minutes running stages on a treadmill at different set velocities (17 km/h, 19km/h and 21km/h). During the test, ground contact time, swing time, stride length and stride frequency were recorded using an optical measurement system (Optojump, Microgate, Italy) and VO_2 values were measured to calculate running economy. Results: Eritrean runners had better running economy than the European runners when running at 19 km/h (191.4 ± 10.4 ml/kg/km vs. 205.9 ± 13.3 ml/kg/km, $p=0.026$, $ES=1.21$). There were no differences between groups in the ground contact time, swing time, stride length or stride frequency. Swing time was related to running economy at 21km/h in the Eritrean runners ($r=0.71$, $p=0.033$) but not in their Europeans counterparts. Discussion: This study confirms the previously reported superior running economy of Eritrean athletes in comparison to European runners. However, our data suggest that this superior running economy does not have a biomechanical explanation since the biomechanical variables of the gait cycle did not differ between groups. Further studies are required in order to unravel the factors underlying the outstanding running economy of East African athletes. THE EFFECTS AND DIFFERENCES OF SPRINT INTERVAL TRAINING, ENDURANCE TRAINING AND THE TRAINING TYPES COMBINED ON PHYSIOLOGICAL PARAMETERS AND EXERCISE PERFORMANCE

Hurst, R.A., Kass, L.S.

University of Hertfordshire

Sprint Interval Training (SIT) is a time efficient way in order to elicit similar changes as Endurance Training (ET) on aerobic capacity. Minimal research is currently available combining these training types, in a single training session to obtain potentially greater benefits over the same period of time. The aim of this study was to compare and contrast the effects of SIT, ET and combined training on physiological parameters and exercise performance after an 8 week training programme. Twenty nine participants volunteered to take part in the 8 week matched paired training study (age: 35.1 ± 13.1 years, female:16). All participants undertook a preliminary VO_2max test and baseline measurements recorded. Participants were matched paired into groups based on sex, VO_2peak (ml/kg/min) and resting heart rate (HR), then randomly assigned into a SIT, ET, COMB or control group. Training was undertaken three times per week. SIT group undertook; 5-8 5-second sprints with intervals of 30 seconds, twice, interspaced with 4 minutes rest on a cycle ergometer. ET group cycled for 40-60 minutes over 8 weeks, at 60% of VO_2peak . COMB group undertook combination of the above two protocols based on a pilot study undertaken. The CON group did not undertake any training regime. After 4 and 8 weeks of the training, all participants undertook a VO_2max test and baseline measures were re-recorded. Prior to each VO_2max test, capillary blood samples were taken for the colorimetric assessment of cholesterol. One way ANOVA, K independent samples and Repeated measures ANOVA with Bonferroni correction were used for statistical analysis. The 4 groups were not significantly different at baseline in VO_2max ($p=0.993$) and resting HR ($p=0.790$) after being match paired into groups. There were no significant differences in VO_2max between the training groups after 4 or 8 weeks ($p>0.05$), significant changes were seen within SIT ($p=0.06$), ET ($p=0.029$) and COMB ($p=0.004$). Significant differences were evident in the resting HR between the CON and SIT ($p=0.005$) and between COMB and CON ($p=0.037$). Significance was indicated within the training groups in resting HR; SIT ($p=0.006$), COMB ($p=0.016$), ET ($p=0.036$). Significance was shown in triglycerides after 8 weeks, between CON and SIT ($p=0.048$). In terms of age, significant difference was seen in VO_2max between those aged <35 years and >35 years, after 4 ($p=0.022$) and 8 weeks ($p=0.020$) of training. No significant differences were measured in AT, resting SV, resting Q, resting BP & body fat percentage between the training groups ($p>0.05$), changes within training types were evident ($p<0.05$). Overall the results indicate when ET is substituted partly with SIT, greater beneficial effects are obtained in numerous variables. Furthermore, a lower duration of sprint i.e. 5 seconds, as in this study provided comparable benefits to previous studies that used longer sprint durations. These findings demonstrate that a short time frame or a combined approach to training, can assist with improving health, performance and cardiorespiratory fitness parameters.

SWIMMING PATTERN OF RATS IN THE MAXIMAL LACTATE STEADY STATE TEST BY AN APPARATUS OF TETHERED SWIMMING

dos Reis, I.G.M.1, Beck, W.R.1, de Araujo, G.G.2, Martins, L.E.B.1, Gobatto, C.A.1,2

1: State University Campinas (Sao Paulo, Brazil), 2: Federal University of Alagoas (Alagoas, Brazil)

Introduction Only by observation is possible to realize that rats may behave distinctly in swimming tests and the study of the swimming patterns (SP) is strictly important to reduce the number of animals and to improve the reproducibility and the reliability of physiological measurements. Based in the coefficients of variation (%) of swimming force (SF) signals obtained at tethered swimming, there are 4 SP, which we called continuum (9%), intermittent (52%), overstrain (11%) and dive (75%). The continuum pattern is the expected behavior in a test of performance while the others are unwanted since it could raise the blood lactate levels and anticipating fatigue. We propose to verify if the effort intensity at tethered swimming can modify the SP by affect the coefficient of variation (CV), root mean square (RMS) and amplitude spectrum of the fast Fourier transform (FFT) of the SF and if these SF variables can be used as a tool to identify different physiological intensities. **Methods** We used 12 male Rattus Wistar, with 150 days old at the beginning of the experiment. A tethered swimming apparatus for rats was developed with a load cell and data acquisition system to access the SF directly and to evaluate the aerobic capacity by an adapted maximal lactate steady state (MLSS) 30-min protocol. The tests were preceded by adaptation to the water environment and swimming exercise. All animals were submitted to effort intensities below, at and above MLSS and the SF variables were analyzed by ANOVA One-way, followed by a pair-wise multiple comparison method between efforts when necessary ($p < 0.05$). **Results** The SF were of 13 ± 2 , 15 ± 3 and 18 ± 3 kgf ($\times 10^{-3}$) on concentrations of 2.7 ± 0.5 , 3.6 ± 0.6 and 5.8 ± 0.7 mmol.L⁻¹ for the effort intensities below, at and above MLSS respectively. The CV were of 22 ± 7 , 24 ± 9 and 20 ± 9 % for the effort intensities below, at and above MLSS respectively. The RMS were of 2.2 ± 0.5 , 2.4 ± 0.9 and 2.4 ± 0.9 kgf ($\times 10^{-3}$) for the effort intensities below, at and above MLSS respectively. The CV, RMS of the SF were not significantly different and the FFT amplitude spectrums were visually very alike among the effort intensities. **Discussion** Apparently the SP were not affected by the different effort intensities and the SF variables cannot be used to identify physiological intensities. Probably, the SP are survival and escape strategies and the unwanted patterns could not be totally avoided. Maybe strategies of adaptation to water and swimming exercise could reduce the incidence of unwanted behaviors. Contact: cgobatto@uol.com.br Support: FAPESP- 11/08284-2, 12/20501-1

EFFECTS OF A OF PROLONGED EXERCISE SESSION ON BLOOD-BRAIN BARRIER INJURY OF ATHLETES AND NON-ATHLETES INDIVIDUALS

Uba Chupel, M., Massart, A., Teixeira, A., Filaire, E.

University of Coimbra

Introduction The beneficial effects of exercise on the body health are very well know but elite athletes don't always have healthy parameters of some bodily functions. In that sense, little is known of the effects of regular exercise on brain, in particular on the structure of the blood-brain barrier (BBB). It is still debatable whether exercise is able to promote improvements in BBB function, so the aim of this study was to compare the effect of a of prolonged exercise session on BBB injuries among elite athletes and non-athletes individuals. **Methods** Our study was consisted of 18 subjects divided in 8 professional cyclists ($n = 8$) and 10 nonathletic persons ($n = 10$). All subjects performed an exercise protocol consisted of cycling during 40 minutes at continuous exercise intensity of 70% of VO_{2max} . Blood was collected before and immediately after exercise protocol for analysis of serum S100B (BBB injury marker). **Results** The results showed that there was no significant increase in the mean concentration of S100B after cycling Protocol ($p < 0.05$) in both groups (athletes and non-athletes). **Discussion** Some physiological factors from prolonged exercise practice have already been singled out as possible to raise S100B rates (Schulpis et al., 2007). Activities that involve direct impact on the head are the main causes able to promote damage to the BBB (Otto et al. 2000), however, intrinsic factors present in prolonged exercise such as increased body temperature (Watson et al. 2005) and increased serotonin synthesis (Dietrich et al. 2003), can also contribute to this increase without necessarily promote structural changes and increased permeability of the BBB. There is no evidence that physical exercise can act as inducer of structural adaptations in BBB decreasing their vulnerability to endothelial injury. In this sense, the present study showed that the mean levels of the BBB injury marker (S100B) did not show differences between athletes and non-athletes individuals after performing a prolonged exercise protocol. The present study suggests that it is necessary to increase the intensity or duration of exercise to promote a difference in this marker, and this may will be due to several physiological factors involved during prolonged exercise. **References** Watson P, Shirreffs SM, Maughan RJ. ENERGY SYSTEM CONTRIBUTIONS AND DETERMINANTS OF PERFORMANCE IN CLASSICAL SPRINT CROSS-COUNTRY SKIING

Andersson, E.1, Willis, S.J.1, Holmberg, H.C.1, Ørtenblad, N.1,2

1: SWSRC, Mid Sweden University, Östersund, Sweden, 2: ISSCB, University of Southern Denmark, Odense, Denmark

Introduction Performance in sprint cross-country skiing (XCS) is related to oxygen uptake (VO_2), oxygen deficit (OD), and gross efficiency (GE) (Losnegard et al., 2012). To the best of our knowledge, the relative importance of these factors in classical sprint XCS involving the double poling (DP) and the diagonal stride (DS) techniques have not been examined. Therefore, this study aims to address this. **Methods** Eleven male cross-country skiers were tested on three different days and all tests were performed in the DP and the DS skiing techniques on a treadmill. Test-day one consisted of five sub-maximal stages, to assess GE, followed by an incremental VO_{2max} test. Test-day two consisted of maximal velocity (V_{max}) tests together with two time-trials as a familiarization. Test-day three consisted of four sprint time-trials (TT) over 1300 m including 3 DP sections (1° incline) and 2 DS sections (7° incline) separated by 45 minutes. Data from all four TT were averaged. Treadmill speed and VO_2 were measured continuously during the TT in order to estimate OD. To assess the relative importance of different variables, a Pearson's correlation analysis and a hierarchical multiple regression were performed. **Results** The GE in DP at 22 km/h and in DS at 8.5 km/h were $15.6 \pm 1.2\%$ and $19.8 \pm 0.9\%$, respectively. The VO_{2max} was 65 ± 4 ml/kg/min in the VO_{2max} test and 67 ± 3 ml/kg/min in the TT. DP V_{max} was 33 ± 2 km/h and DS V_{max} was 18 ± 1 km/h. The TT time was 232 ± 10 s (56% DP and

44% DS) and the DP and DS velocities were 27 ± 1 km/h and 14 ± 1 km/h, respectively. Accumulated VO₂ and OD were 201 ± 10 and 58 ± 15 ml/kg, respectively, or $78 \pm 5\%$ and $22 \pm 5\%$ of the total energy demand. The V_{max} in DP and DS was negatively correlated to TT time ($r = -0.79$ and -0.57 , both $P < 0.05$). The multiple regressions demonstrated that the variance in TT time was related to GE by 38%, VO₂ by 34% and OD by 23% ($r^2 = 0.95$, $P < 0.05$). Discussion The relative energy contribution in the present study was similar to previous findings for uphill DS skiing and ski-skating (McGawley and Holmberg, 2014; Losnegard et al., 2012). Although Losnegard et al. (2012) concluded that OD explained 66-75% of the variance in TT time, we found OD to explain only 23% of this variance, with GE and VO₂ together explaining 72%. Furthermore, the largest inter-individual differences were observed for the OD, range: 33-78 ml/kg. Finally, the correlations between V_{max} and TT time highlight the importance of a high speed generation for sprint XCS performance. References Losnegard T, Myklebust H, Hallén J. (2012). ENZYME ACTIVITY AND GENE EXPRESSION OF CREATINE KINASE DURING AND AFTER A TENNIS MATCH: PRELIMINARY RESULTS

Hoppe, M.W., Wehmeier, U.F., Baumgart, C., Hilberg, T., Freiwald, J.

Departement of Movement Science, University of Wuppertal, Germany

Introduction It is known that creatine kinase (CK) activity in the blood increases after repeated eccentric exercises, most likely due to muscle fiber damage and/or alterations in cell membrane permeability (1). However, the changes of CK during exercises have not been investigated. Therefore, we aimed to investigate the changes of CK activity during and after a tennis match involving eccentric activities. We aimed further to question whether changes of the expression of the skeletal muscle CK (CK-MM) encoding gene will allow additional knowledge regarding muscle function. Since it has been shown that also capillary blood can be used for gene expression analysis (2), we used this approach for our analysis. Methods Two male elite tennis players (29 and 26 years; 52.8 and 49.1 ml/min/kg VO₂max) played a tennis match over 2 hours on clay court surface confirming to ITF-rules. Players' heart rate, blood lactate, and RPE were monitored. Capillary blood probes from the ear lobe were sampled at baseline, during, and up to 24 hours after the match. The CK activity was determined using a Reflotron spectrophotometer (Roche Diagnostics, USA). The expression of the CK-MM encoding gene was quantified using a StepOne real time PCR unit (Applied Biosystems) applying a Taqman gene expression assay (Applied Biosystems). The 18S rRNA served as control. Results Comparing to baseline, the CK activity decreased continuously during the match and reached a minimum of -51.9 and -64.6% at 1 hour after the match. Subsequently, the CK activity increased and reached a maximum of +53.1 and +44.3% at 3 and 2 hours after the match. However, the CK-MM mRNA was not detectable in verifiable amounts. Discussion In this study, we have shown that the CK activity decreases profoundly during a tennis match. This finding may be caused by an exercise-induced clearance mechanism (e.g., by the reticuloendothelial system). We have also found that the CK activity increases only mildly after a tennis match suggesting that no muscle fiber damage but rather changes in cell membrane permeability (e.g., by muscle glycogen depletion, intracellular acyl-CoA accumulation or lipid peroxidation of membrane lipids) (1) have been occurred. Our finding that the CK-MM mRNA was not detectable in verifiable amounts supports our assumption that muscle damage, which may have led to mRNA release in the blood, did not occur during the tennis match. MO-BN18 Muscle Fatigue

DOES DECREASED INITIAL MVC FORCE AFFECTS TIME TO TASK FAILURE?

Matkowski, B., Lepers, R., Martin, A.

Université de Bourgogne

Introduction Sustained submaximal isometric contractions induce muscle fatigue, which can be characterized by a transient reduction in maximal voluntary contraction (MVC) force (Gandevia, 2001). It has been shown that time to task failure of submaximal isometric contractions depends on the absolute level of force, i.e. stronger subject have a briefer time to task failure (Hunter & Enoka, 2001). Previous experiments have used various paradigms to study muscle fatigue in young male adults, manipulating for example the joint angle (Place et al., 2005) or the number of limbs involved (Matkowski et al., 2011). However, these paradigms implied to compare different tasks (different angles or different limbs) which could potentially affected the results. The purpose of the present study was to compare the time to task failure of submaximal contractions following fatigue-induced contractions by voluntary activation or neuromuscular electrical stimulation (NMES). It was hypothesized that prior fatigue would reduce the absolute target force produced by the subject, and thus prolong time to task failure. Methods On three separate sessions, subjects performed voluntary contractions at 20% MVC with the knee extensor muscles to failure. One session served as a control (CON) while the other two were preceded by 30 repeated submaximal fatiguing contractions (20% MVC; 6s on x 6s off) induced by NMES (constant intensity) or voluntary effort (VOL; constant level of electromyography). The tasks sustained to failure were performed at 20% of MVC force recorded following the fatigue protocol (NMES or VOL). Results The decrease in MVC force was greater ($P < 0.05$) following NMES (-17.7%) compared to VOL (-12.7%) before time to task failure. Whilst time to task failure was similar ($P = 0.49$) for the three sessions, the decline in MVC after time to task failure was more pronounced following NMES than following VOL ($P = 0.002$). No differences were found on MVC between VOL and CON ($P = 0.08$) or between NMES and CON ($P = 0.19$). Also, no relation was found between MVC and time to task failure. Discussion For a similar level of produced force, NMES induced greater muscle fatigue than VOL contractions. However, the level of fatigue induced by the prior contractions (NMES or VOL) has no effect on time to task failure of a submaximal contraction. These results suggest that the mechanisms responsible for the decrease in MVC are different than those responsible for the time to task failure. References Gandevia SC. (2001). ACUTE EFFECTS OF PAROXETIN ADMINISTRATION ON PARAMETERS OF NEUROMUSCULAR FATIGUE

Knicker, A.J., Buschermöhle, S., Fricke, H., Rojas, S., Strüder, H.K.

German Sport University Cologne

Introduction Paroxetine augments serotonin availability and has been shown to affect fatigue after endurance type of exercise (Strüder et al., 1999). No publication exists to date which demonstrates effects of the serotonergic system on parameters associated with neuromuscular fatigue. This study aimed to investigate acute effects of paroxetine administration on central and peripheral fatigue symptoms. **Methods** 37 healthy male subjects finished a neuromuscular test consisting of maximum voluntary isometric knee extensions in three kneeangle positions with superimposed electrostimulation triplet pulses applied to two quadriceps muscles before and after 50 consecutive eccentric – concentric knee extension contractions on an isokinetic dynamometer at 40°/s. The same procedure was repeated after full recovery but after the intake of a dose of 20mg of a paroxetine drug (n=19) or a placebo (n=18). **Results** The exercise protocol caused severe neuromuscular fatigue effects on both peripheral and central sites. Paroxetine intake showed inconsistent effects on fatigue parameter patterns. No significant differences were identified for absolute and relative (to bodyweight) torque output. However the paroxetine group showed altered central activation patterns either compared to the controlgroup as well as compared to baseline tests. A lower contribution of central fatigue after paroxetine intake to overall torque loss after the fatiguing protocol appeared to be likely. **Conclusion** Altered central contribution to neuromuscular fatigue might be attributed to serotonin availability caused by the administration of the selective serotonin reuptake inhibitor. THE INFLUENCE OF SHORT SLEEP ON RECOVERY FROM LOW-FORCE FATIGUING CONTRACTION

Shioda, K., Suzuki, T., Ishii, T., Kinugasa, R.

Kanagawa University

Introduction Physical fatigue is divided into central and peripheral components. Sleep is crucial for recovery from physical fatigue, but it is unclear that the effects of short sleep on recovery from central or peripheral fatigue resulting from muscle contraction. The interpolated twitch technique is typically used to assess voluntary activation (VA) of skeletal muscles (Merton, 1954). Also, the reduction of VA in maximal voluntary efforts is the clue of central fatigue (Gandevia, 2001). The purpose of this study, therefore, is to investigate the influence of short sleep on recovery from low-force exhausting contraction using interpolated twitch technique. **Methods** Healthy young adults with no history of sleep disorder were recruited. They participated in the 2 experimental conditions in a counter-balanced order: with and without sleep conditions. Subjects performed approximately 30-min sustained isometric elbow flexion at 15% of maximum voluntary contraction (MVC). At last 5 seconds of this sustained contraction, subjects elevated their contraction level to the maximum for assessing VA using interpolated technique. After a 2-hour rest (sleep or no sleep), this sustained contraction was repeated. Polysomnogram including electroencephalogram (ECG), electro-oculogram (EOG), electromyogram (EMG), and heart rate (HR) were recorded during entire time of the sleep. **Results and Discussion** The coefficient of variation of torque exertion during sustained contraction was lower in sleep condition than control condition. Additionally, there were quite differences in MVC and VA immediately after sustained fatiguing contraction between conditions. In conclusion, the present study indicated the possibility that short sleep enhance recovery from low-force fatiguing contraction of elbow flexor muscles. **References** Merton PA. (1954). Voluntary strength and fatigue. *J Physiol*, 123, 553-564. Gandevia SC. (2001). Spinal and supraspinal factors in human muscle fatigue. *Physiol Rev*, 81(4), 1725-1789.

MECHANISMS ASSOCIATED WITH TASK FAILURE DURING ISOMETRIC KNEE EXTENSION EXERCISE AT A FIXED WORK-LOAD

Froyd, C.1,2, Beltrami, F.G.2, Millet, G.Y.3, Noakes, T.D.2

Sogn og Fjordane University College

1: SFUC (Sogndal, Norway), 2: UCT (Cape Town, South Africa), 3: UCalgary (Calgary, Canada) **Introduction** The aim of the study was to compare the level of peripheral fatigue in humans at task failure with or without prior exercise fatigue, and when exercising to task failure at a lower intensity than at the previous trial. **Methods** Ten physically active participants performed isometric knee extension exercise during five trials to task failure at different or the same intensities on two different days. Neuromuscular function - including a 5-s maximal voluntary contraction (MVC) and electrical stimulation - was assessed prior to the trials, after each set of contractions and within 2 s after task failure. **Results** When two maximal trials of similar intensity (60% MVC) were performed in sequence with a recovery period, time to task failure was significantly shorter ($P < 0.001$) and peak evoked force (PF) at task failure was significantly lower ($P < 0.001$) on the second trial. When exercise to task failure at 60% of MVC force (60% MVC) was followed immediately by maximal contractions until task failure at 50% of MVC force (50% MVC) followed by a sustained MVC until force decreased to 15% of MVC force (15% MVC), PF was significantly lower ($P < 0.001$) at task failure at 15% MVC compared to 50% and 60% MVC. After task failure at 15% MVC, substantial recovery ($P < 0.001$) occurred in both MVC force and normalized maximal EMG within 10 s while peripheral PF remained unchanged. **Discussion** Different levels of peripheral fatigue at task failure indicate that peripheral fatigue was not the major determinant of task failure. Substantial recovery in skeletal muscle recruitment without recovery in peripheral fatigue within 10 seconds after exercise indicates that exercise termination is influenced by central factors. It is probable that the brain acts as a regulator by modifying and ultimately limiting the extent of central recruitment to insure safe exercise. Feedback from the periphery may be an important factor in this regulation but it is clearly not the singular controlling mechanism. christian.froyd@hisf.no

THE USE OF COMPRESSION STOCKINGS DO NOT IMPROVE MUSCULAR PERFORMANCE DURING A MARATHON

Del Coso, J.

Camilo José Cela University

Del Coso, J.; Areces F.; Salinero J.J.; Abian-Vicen J.; González-Millán C.; Ruiz-Vicente D.; Lara B.; Soriano, M. Camilo José Cela University. Exercise Physiology Laboratory, Madrid. Spain. **Introduction** Exercise-induced muscle damage (EIMD) has been identified as one of the

main causes for the decreased muscular performance found during endurance competitions. Compression garments apply mechanical pressure to the body and support underlying tissues. The use of this sport clothing might help to reduce muscle vibrations and to prevent EIMD during running competitions. The aim of this study was to investigate the effectiveness of wearing compression stockings to prevent EIMD and to preserve muscle performance during a marathon race. Methods Thirty-four healthy and experienced runners were matched (in pairs) for age, anthropometric data and best race time in marathon and randomly assigned to the control group ($n = 17$; conventional socks) or to the compression stockings group ($n = 17$). One day before the race, a sample of venous blood was obtained and jump height and leg muscle power were measured during a countermovement jump. During the race, running pace was measured at 5-km intervals with a timing-chip. After the completion of race, participants repeated the countermovement jump and a blood sample was withdrawn. The pre-to-post-race changes in jump height and leg muscle power were used to assess muscle fatigue. Serum myoglobin and creatine kinase concentrations were determined as blood markers of EIMD. Besides, participants rated their perception of leg muscle pain at the end of the race and the following day by using a visual-analog scale (1-to-10 point). Results Mean running speed during the race was similar in the control group vs the compression stockings group (3.28 ± 0.37 vs 3.34 ± 0.4 m s⁻¹, respectively). Leg muscle power (-19.6 ± 17.7 vs $-25.2 \pm 18.4\%$) and jump height (-19.0 ± 15.0 vs $-28.8 \pm 23.0\%$) were similarly reduced in both groups after the race. There were no differences in serum myoglobin (568 ± 347 vs 573 ± 271 $\mu\text{g}\cdot\text{mL}^{-1}$) and creatine kinase concentration (390 ± 166 vs 487 ± 227 U $\cdot\text{L}^{-1}$) at the end of the race. Self-reported leg muscle pain at the end of the race was similar between groups (7 ± 2 vs 7 ± 2 points). However, participants in the compression stockings group reported a reduced muscle pain 24-h after the race (6 ± 2 vs 5 ± 2 points; $P < 0.05$). Conclusion The use of compression stockings during a marathon did not improve running pace and it did not prevent the reduction in leg muscle performance produced by the race. Although the compression stockings reduced muscle pain 24-h after the race, this sport clothing did not reduce post-race serum concentrations of markers of EIMD. Thus, wearing compression stocking is an ineffective strategy to increase performance during long-distance running events. Contact: jdelcoso@ucjc.edu

ELECTRICALLY INDUCED TORQUE DECREASE DOES NOT ONLY REFLECT MUSCLE FATIGUE

Papaiordanidou, M., Stevenot, J.D., Mustacchi, V., Vanoncini, M., Martin, A.

Aix-Marseille University, Faculty of Sports Science

It has been shown that high stimulation frequencies result in greater fatigue development during Electrical Stimulation (ES) (Gregory et al, 2007), as expressed by the percent declines of the electrically evoked torque between the beginning and the end of the fatiguing exercise. However, the magnitude of these torque losses does not always reflect the functional impact of the protocol on the subjects' force generating capacity. A greater percent decline of the ES-evoked torque compared to the maximal voluntary contraction (MVC) losses has been shown at post fatigue conditions (Papaiordanidou et al, 2014), suggesting that the former parameter leads to overestimation of fatigue, possibly linked to loss of motor units (UM, Bostock and Bergmans, 1994). In order to examine the potential mechanisms responsible for this difference, the impact of different ES protocols on both the ES and MVC torque was studied. The triceps surae muscle of 8 healthy subjects was fatigued with 4 protocols (30Hz-500 μs , 30Hz-1ms, 100Hz-1ms and 100Hz-500 μs), composed of 60 trains (4s on-6s off), delivered at an intensity evoking 30% of maximal voluntary contraction (MVC). Fatigue was quantified by the ES and MVC torque decreases. The amplitude of the twitch delivered at the intensity and pulse width used in each fatiguing protocol (twitch at Istim) was analyzed. ES torque significantly decreased throughout all protocols. This decrease was higher for the 100-Hz protocols (20% and 60% for the 30-Hz and 100-Hz respectively, $P < 0.001$). Whatever the protocol, similar decreases for MVC torque and the twitch elicited at Istim at post fatigue conditions were observed. The decrease of the twitch at Istim was positively correlated with the ES torque decrease only for the 30-Hz protocols ($r = 0.74$, $P < 0.001$). Results show that the 100-Hz torque declines could not solely be attributed to fatigue of the solicited MU, but included other mechanisms influencing torque output. The repetitive high-frequency electrical activation may have led to an increase in the excitability threshold of active intramuscular axonal branches. Subsequently, MU having an excitability threshold close to the stimulation intensity could have been lost during the elicited contractions, thus contributing to the greater torque decrease (Vagg et al, 1998). Moreover, results show that when fatigue is quantified by the MVC losses, submaximal ES has the same impact on the force generating capacity independently of the stimulation parameters used. Introduction: High intensity dynamic exercise induces muscle fatigue that is associated with reduced ability of the muscle to generate force. Accumulation of the metabolites within the fatigued muscle can also change proprioception, which is expected to have an effect on reflex activity of the muscle to regulate joint stiffness during unexpected postural perturbations. Aim: The purpose of the study was to investigate the reflex activity of knee muscles to rapid valgus/ varus knee perturbations before and after dynamic fatiguing exercise. Method: Fatigue induced to knee muscles using a Kin Com isokinetic dynamometer. Bipolar surface EMG signals were recorded from 12 healthy men with five pairs of electrodes located on the knee extensor muscles (vastus medialis, rectus femoris, and vastus lateralis) and knee flexor muscles (the medial and lateral heads of the hamstring) of the right leg during rapid valgus/ varus perturbations. Results: Maximal voluntary contraction force and time to task failure were significantly reduced after fatiguing exercise with respect to baseline ($P < 0.05$). During the post exercise valgus/ varus perturbations, the average rectified value of the knee extensor muscles was significantly lower than baseline ($P < 0.05$). Moreover, a significant reduction in the level of co contraction between the hamstring and quadriceps muscles was observed during valgus/ varus knee perturbations after fatiguing exercise ($P < 0.05$). Discussion: Fatigue alters reflexive muscular activity and muscle co contraction around knee joint during valgus/varus perturbations. The altered co contraction around the knee may expose structures of the knee joint to abnormal varus/valgus moments during exercise and may contribute to sport-related injuries.

STRATEGIES OF CONTROL AND INHERENT CHARACTERISTICS OF THE INDIVIDUALS IN BALANCE TASKS.

Caballero, C., Barbado, D., Urbán, T., Moreno, F.J.

Miguel Hernández University

Introduction Some studies have revealed that the structure of movement variability changes as task constraints increase or as participants adopt a new strategy of control (Van Order, Kloos & Wallot, 2011). Nevertheless, previous works have suggested that human variability also reveals inherent characteristics of the individual (Riley & Turvey, 2002). Previous works in balance tasks have identified that some variability characteristics of COP remain constant between trials while others change under the same task conditions (Caballero, Barbado, Moreno, 2013). In this study we have manipulated different task constraints in order to know which variability characteristics of COP change according to the motor control requirements and which ones remain constant revealing inherent characteristics of the individual. **Methods** Fourteen volunteers took part in this study (Age 29.5 ± 7.44 years; Height 1.73 ± 0.1 m; Mass 72.07 ± 8.94 Kg). Participants were asked to stand still (70s) on a stable surface and under three unstable situations increasing the difficulty in each situation. Each situation was performed twice, with and without visual feedback. COP excursion was collected from a force platform. Balance performance was assessed by bivariate variable error (BVE) and mean velocity of magnitude (VmeanM). Dynamics of COP displacement and velocity were measured through Fuzzy Entropy (FE), Permutation Entropy (PE) and Detrended Fluctuation Analysis (DFA). Repeated measures ANOVAs were used to analyse the differences between balance difficulty and the effect of visual feedback. **Results** COP excursion, expressed in BVE and VmeanM values, increased according to the difficulty of the unstable situation. Regarding the structure of COP, FE and PE increased when the difficulty increased, both in displacement and velocity signal, although in the second signal to a lesser extent. DFA didn't show changes depending on this constraint. On the other hand, PE, FE and DFA velocity were constant despite the effect of visual feedback, whereas FE increased and DFA decreased with visual feedback in COP displacement. **Discussion** The manipulation of task constraints produces changes both in excursion and structure of COP. However, the structure of COP velocity seems to be less affected by tasks constraints. It could reflect that the COP displacement reflects the strategy of control under different constraints, while the velocity, which indicates the ratio of the position changes, seems to represent inherent characteristics of the individual motor variability. **Reference** Caballero, C., Barbado, D., & Moreno, F. 15:00 - 16:00**Mini-Orals****MO-PM54 Biochemistry****CHRONIC INFLAMMATION AND NEUTROPHIL ACTIVATION AS POSSIBLE CAUSES OF JOINT DISEASES IN BALLET DANCERS**

Hatanaka, E.1, Borges, L.S.1, Bortolon, J.R.1, Santos, V.C.1, de Moura, N.R.1, Dermargos, A.1, Gorjão, R.1, Pithon Curi, T.C.1, Cury Boaventura, M.F.1

Cruzeiro do Sul University

Introduction The search for perfection by aesthetic standards, coupled with the desire for total control of body movements, compels the dancer to exceed the body's natural limitations. We hypothesized that dancing could expose the dancers to chronic inflammation with reactive neutrophils, which may then lead to the onset of joint problems. **Methods** Blood samples were taken from 13 dancers before, immediately after and 18 hours after a ballet class. The group had the following characteristics (mean + SE): age 20.0 ± 0.8 years, body mass 41.4 ± 1.6 kg, height 1.6 ± 0.0 m, body fat 24.0 ± 1.3 %, VO_2 max 36.8 ± 2.9 mL.kg⁻¹.min⁻¹ and sports experience of 7.0 ± 1.5 years. We investigated the effects of a ballet class on the kinetic profiles of CK and LDH activities, cytokines, complement component 3 (C3) and the concentrations of immunoglobulin (Ig), IgA and IgM in ballerinas. We also verified neutrophil death and ROS release. **Results** The ballet class increased the plasma activities of CK-Total (2.0-fold) immediately after class, while the activities of LDH (3.0-fold) was observed to increase 18 hours after the class. Levels of the TNF- α , IL-1 β , IgG and IgA were not affected under the study conditions. The exercise was found to induce neutrophil apoptosis (6.0-fold) 18 hours after the ballet class. Additionally, immediately after the ballet class, the neutrophils from the ballerinas were found to be less responsive to PMA stimulus. **Discussion** Chronic inflammation is characterized by influxes of neutrophils at sites of inflammation and may be the main factor involved in the development of arthritis and other inflammatory joint diseases that have been observed in ballerinas. Immediately after a ballet class, neutrophils from ballerinas were found to be less responsive to stimuli, thereby pointing to a transient immunosuppression. Eighteen hours after the class, signs of muscular lesion, neutrophil necrosis and decreased levels of anti-inflammatory cytokines were observed in the ballerinas, thereby suggesting a persistent inflammatory condition. These findings may represent a tool to design new studies and strategies to protect dancers against microorganism infection as a result of transient immunosuppression immediately following the class and to prevent dancer's performance from declining as a result of chronic inflammation. **References** [1] Walsh NP, Gleeson M, Shephard RJ, Gleeson M, et. al. DESCRIBING THE ANTIOXIDANT DEFENCE AFTER PLAYING A SOCCER MATCH

Gravina, L.1, Bidaurrezaga Letona, I.1, Santos Concejero, J.3, Sesma, J.1, Granados, C.1, Lekue, J.A.2, Gil, S.M.1

SCHOOL OF NURSING

Institutions: 1University of the Basque Country, UPV/EHU (Spain). 2Athletic Club de Bilbao (Spain). 3University of Cape Town (South Africa). **Acknowledgements:** This study was partially supported by a grant from the Consejo Superior de Deportes (20/UPB10/10). **Introduction** Soccer is an intermittent-type sport that lead into muscle damage due to an acute-phase inflammatory response characterized by free radical production (1). These free radicals can be neutralized by a wide range of endogenous antioxidants for the maintenance of redox

status and cellular function (2). Different antioxidant status responses have been shown following a soccer match and during recovery (3) but a complete screening of markers of oxidative stress following a soccer game has not been published yet and is still an issue to determine. Methods Fourteen injury-free, male elite players (age 17.4 ± 0.6 years, weight 70.2 ± 6.2 kg, height 175 ± 0.05 cm) from the Athletic Club of Bilbao participated in this study. Participants competed in SUB-19 division and trained 6 days per week. Blood samples were obtained at rest, immediately after and 36h after the competition game. Serum levels of Total Antioxidant Status (TAS), Reduced Glutathione (GSH), thiobarbituric acid-reactive substances (TBARS) and protein carbonyls were measured, as well as the activity of antioxidant enzymes: Superoxide Dismutase (SOD), Glutathione Peroxidase (GPx) and Catalase (CAT). One way ANOVA for repeated measures and Friedman's ANOVA were used for the statistical analysis. The significance level was set at $p < 0.05$. Results Higher levels of TAS (0.97 ± 0.1 vs 1.19 ± 0.2 mmol/l, $p < 0.01$) and CAT (24.7 ± 18 vs. 51 ± 19 nmol/min/ml, $p < 0.01$) were observed immediately after playing the soccer match. After 36 hours, levels of TAS (0.97 ± 0.1 vs 1.28 ± 0.3 mmol/l, $p < 0.01$), CAT (24.7 ± 18 vs. 46.5 ± 21 nmol/min/ml, $p < 0.01$) and SOD (0.14 ± 0.06 vs. 0.23 ± 0.07 U/ml, $p < 0.01$) were still higher than the rest values. Discussion Only two antioxidant enzymes were found to be altered following a soccer match, such as CAT and SOD. Although CAT uses the same substrate than GPx, CAT is more efficient with lower H_2O_2 concentration. Therefore, the low free radicals produced after playing the match could explain the no significance in other markers of oxidative damage, such as TBARS or protein carbonyls which means that lipid and protein oxidation might not have occurred. Moreover, the increase of blood total antioxidant capacity after 36 hours could prove the beneficial effect of soccer in the maintenance of redox status for protecting cellular function. THE EFFECTS OF IRON SUPPLEMENTATION ON ANTIOXIDANT ACTIVITY FOLLOWING AN ACUTE ECCENTRIC EXERCISE BOUT

Deli, C.K., Paschalis, V., Georgakouli, K., Zalavras, A., Fatouros, I.G., Koutedakis, Y., Jamurtas, A.Z.

University of Thessaly

Introduction Unaccustomed muscle damaging eccentric exercise has been shown to lead in excessive production of reactive oxygen and nitrogen species (RONS). Thus, the typical approach so far, was to provide antioxidants in order to minimize RONS production, yet the debate regarding its effectiveness is still open. Although RONS may facilitate the restoration of the injured muscle, the role of pro-oxidants, such as iron, that could modify redox responses, has not yet been examined. Therefore, the purpose of the present study was to investigate the effect of iron supplementation on antioxidant activity after an acute eccentric exercise bout in adults compared to children. Methods Sixteen male adults (Age: 18 – 50 yrs) and eleven boys (Age: 10 – 12 yrs) participated in the study. In a double blind, randomized, cross over design, participants received either the iron supplement (37mg of elemental iron per day for four weeks) or the placebo. Blood was drawn prior to and at the end of the first supplementation period, that lasted 3 weeks, and 72 hours following an acute bout of eccentric exercise (5 sets x 15 max reps) that caused muscle damage. Blood drawings were repeated at the same time points during the second supplementation cycle. Blood was used to assess reduced glutathione (GSH), catalase (CAT) activity and total antioxidant capacity (TAC). Results Significant time x age interactions came up for CAT and TAC, and main effect of age for CAT, GSH and TAC. Regarding CAT, children had significantly higher values before (244.9 ± 9.76) and 72h (248.27 ± 8.67) ($p < .001$) after eccentric exercise compared to adults (before: 206.03 ± 8.5 , and 72h: 204.35 ± 7.56 , respectively) ($p < .01$). TAC was lower in children compared to adults only at 72h after exercise (children: 0.858 ± 0.21 , adults: 0.934 ± 0.18) ($p < .01$). Children (6.585 ± 0.31) demonstrated higher values of GSH in relation to adults (5.228 ± 0.27) ($p < .01$) irrespective of time or condition. Discussion The main finding of the present study was that age plays a critical role on antioxidant activity. Four weeks of iron supplementation did not significantly alter the antioxidant responses after eccentric exercise in both adults and children. Future research should address higher, therapeutic doses of iron and assess more redox status indices, to clarify the effect of iron supplementation on redox adaptations after muscle damaging exercise. DECREASING MUSCLE INJURY AND INFLAMMATION IN WORLD-CLASS FEMALE WRESTLERS: A LONG-TERM SPORTOMICS STUDY.

Bachini, F., Magalhães Neto, A., Bassini, A., Cameron, L.C.

Federal University of State of Rio de Janeiro

Introduction We have been studying different protocols in field exercise by Sportomics, the use of ‘-omics’ sciences with laboratory analyses (Bassini & Cameron, 2014). Low red blood cells count is a feature in female athletes mainly due to imbalances in nutritional intake and menstrual flow. It is concerning that non-authorized hypohydration is adopted by athletes to lose weight for pre-competition weigh-ins. The aim of this study was to analyze long-term iron profiles, muscle injury and inflammatory biomarkers in world-class female wrestling athletes using a Sportomics follow-up before and after nutritional and training changes intended to improve athletic performance. Methods We monitored seven athletes for 17 months using a Sportomics protocol, evaluating ~ 100 parameters in each test. The athletes prepared for the competition season under similar conditions (diet, training, rest and sleep). The athletes were assessed at T1 (beginning) and T2 (8 months). A nutritional intervention, increasing carbohydrates and protein uptake, as well metabolic-driven changes in training strategies were established after T1. The protocol was then repeated (T2). Three of the athletes were eligible for the world championship and retested at T3 (17 months). Blood collection through venipuncture was performed prior to exercise. Statistical analysis was performed by two-way ANOVA. Results Here we will show experimental data related to hematopoiesis, immune response, muscle and liver injury biomarkers. The intervention promoted a rise in both hematocrit (37.9 ± 1.0 to $42.5 \pm 1.0\%$; $p < 0.05$) and hemoglobin concentration (20.8 ± 1.0 to 22.0 ± 0.3 mmol/L; $p < 0.05$), without significant changes in erythrocytes (4.3 ± 0.1 to $4.6 \pm 0.1 \times 10^{12}/L$; $p = 0.60$). Additionally, no differences were found in either serum iron (13.4 ± 3.2 to 17.2 ± 5.6 $\mu\text{mol/L}$; $p = 0.57$) or transferrin saturation (19.7 ± 1.7 to $25.0 \pm 9.5\%$; $p = 0.40$). There were decreases in the muscle injury biomarkers creatine kinase (417.4 ± 88.1 to 163.6 ± 39.5 U/L) and lactate dehydrogenase (357.0 ± 25.3 to 174.0 ± 3.2 U/L). No changes were found in AST, ALT, γGT , AP, leucocytes, AGP or CRP. Cytokines (IL – 1, – 5, – 6 and TNF) were under detectable limits. Discussion This study describes the use of Sportomics to evaluate and change athletic training, nutrition and metabolic responses to exercise. We demonstrated the effects of the protocol to reduce muscle injury and inflammatory response, combined with an improvement of hematological status. Taken together, these findings could improve the metabolism, trainability and performance of athletes to reach higher levels in competition.

THE EFFECTS OF AN ACUTE AEROBIC EXERCISE BOUT ON BETA ENDORPHIN AND LACTIC ACID IN ALCOHOLIC PATIENTS

Manthou, E.1,2, Georgakouli, K.1,2, Zourbanos, N.1, Georgoulas, P.1, Fatouros, I.G.2,3, Theodorakis, Y.1, Jamurtas, A.Z.1,2
1University of Thessaly (Greece); 2Institute for Research and Technology Thessaly (Greece); 3Democritus University of Thrace (Greece)

Introduction Relapse rates among alcoholic patients are considerably high ranging between 60 and 90% making this one of the most significant problems in alcoholism. Finding ways that could be used as an adjunctive strategy towards attenuation of the relapse is imperative and exercise has been suggested as one. Therefore, the purpose of the present study was to examine the effects of physical exercise on beta endorphin (β -E) levels of individuals participating in alcohol rehabilitation programmes. **Methods** Nine participants with a history of alcohol addiction 10 years or more and 8 healthy controls volunteered to participate in an exercise trial on a cycle ergometer. The intensity of the exercise was low (55-60% of maximum heart rate) and the duration was 30 minutes. Blood was collected prior to and immediately following the exercise session and β -E and lactic acid levels were determined. **Results** Baseline β -E levels were significantly ($p < .001$) lower in alcoholic patients ($1.60 \pm .40$ pmol/L) compared to healthy controls (8.36 ± 4.40 pmol/L) whereas baseline lactic acid levels did not differ ($p = .55$) between the two groups (alcoholics: $1.24 \pm .40$ mM; control: $1.36 \pm .52$ mM). Exercise resulted in significant ($p < .001$) increases in β -E levels in alcoholics (4.73 ± 1.68 pmol/L) whereas there were no significant ($p = .15$) changes in healthy controls (9.16 ± 3.60 pmol/L). Lactic acid levels significantly increased ($p < .001$) following exercise in both groups (alcoholics: $2.81 \pm .51$ mM; control: $3.18 \pm .87$ mM). **Conclusion** The results from the present study indicate that β -E levels are lower in alcoholic patients whereas a bout of low intensity exercise affects the endogenous opioids in alcoholic patients. **Author Note** This research has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program ‘Education and Lifelong Learning’ of the National Strategic Reference Framework (NSRF) ? OXIDATIVE STRESS IN CANCER CACHEXIA : PREVENTIVE EFFECTS OF ANTIOXIDANTS ?

Rebillard, A.

UNIVERSITY RENNES 2 - ENS RENNES

Introduction: Cancer cachexia describes the progressive skeletal muscle wasting and weakness that is associated with many cancers. It impairs quality of life and accounts for >20% of all cancer-related deaths. Recent studies provide evidence that muscle weakness during severe cancer cachexia cannot be entirely due to muscle atrophy, and that muscle phenotype shift also plays a non-negligible role (Murphy, Chee et al. 2012; Roberts, Frye et al. 2013). However, the underlying molecular mechanisms involved in these processes remain unknown. We hypothesize that (1) oxidative stress OS could play an essential role in cancer cachexia and that (2) antioxidant could have preventive effects through regulation of Nuclear Factor of Activated T cell NFAT signaling. **Methods:** Fourty Balb/c mice were divided into four groups: Control (received a subcutaneous injection of PBS), C26 (received a subcutaneous injection of C26 colon cancer cells), C26 + Allopurinol (received a subcutaneous injection of C26 colon cancer cells and a daily supplementation with allopurinol), C26 + Oxy (received a subcutaneous injection of C26 colon cancer cells and a daily supplementation with antioxidant mixture). Tumor, blood and skeletal muscles were removed 20-22 days after cancer cells injection. **Results:** Injection of C26 cells induced weight loss, skeletal muscle atrophy and also reduced grip strength test performance. Whereas muscle wasting was associated with ubiquitin- dependent protein degradation, muscle weakness seemed to involve the phosphorylation of NFATc1 without calcineurin expression alteration and the phosphorylation of JNK which is a redox dependent kinase. C26 tumor-bearing mice exhibited systemic oxidative stress markers (i.e. carbonylated proteins and 4-HNE increases) but not muscular oxidative stress. In this context, supplementation with antioxidants (Allopurinol or Oxy) had deleterious effects since it induced premature death of mice, increased muscle wasting, didn't reverse contractile phenotype switch and didn't reduce systemic oxidative stress markers. **Discussion:** Cachexia induced by colon 26 cells involves systemic oxidative stress. Antioxidant supplementation doesn't induce beneficial effects. However, JNK seems to be a key target in colon cancer dependent-skeletal muscle phenotype shift.

COX4I2 EXPRESSION POST EXERCISE IS MODIFIED BY ANGIOTENSIN CONVERTING ENZYME

van Ginkel, S., Waldron, S., Ruoss, S., Rittweger, J., Vaughan, D., Flueck, M.

MMU Manchester / VU Amsterdam /University Hospital Balgrist

Elevated expression of the oxygen sensitive isoform 2 for subunit 4 of cytochrome c oxidase (COX4I2) in knee extensor muscle post exercise responses specific to exhaustive endurance exercise under hypoxia. This correlates to elevated volume density of subsarcolemma mitochondria with repetition of the exercise stimulus (Desplanches et al 2014). We have been demonstrating that genetic inhibition of the major regulator of vascular tone, Angiotensin converting enzyme (ACE), likewise affects gains in volume density of subsarcolemma mitochondria with endurance training (Vaughan et al 2013). We hypothesised that pharmacological inhibition of ACE blunts the response of COX4I2 transcript to a single bout of bicycle exercise. 14 healthy young male from Greater Manchester performed a single leg exercise test for 25 minutes at constant load ending with a ramp to exhaustion on a bicycle ergometer with their dominant leg in fasted state. Anthropometry, VO₂ and P_{max} during exercise was measured. A needle biopsy was collected from the vastus lateralis muscle of the non-exercising leg prior and from the exercising leg 3 hours post exercise. Eight subjects consumed lisinopril (10 mg/day) in blind fashion for two days before the exercise. Total RNA was isolated from the muscle biopsy and subjected to RT-PCR for COX4I2. Effects were assessed with a repeated ANOVA with Fisher post hoc test with $p < 0.05$ called significant. Anthropometry (age [y]: 23.7 ± 1.4 vs. 30.8 ± 3.0 ; weight [kg]: 72.2 ± 2.9 vs. 76.8 ± 5.0 ; height [cm]: 178 ± 1 vs. 177 ± 1 ; $n=8$ vs. $n=6$) and respiratory measures (P_{max} [Watt] 194 ± 17 vs. 178 ± 10 ; VO₂max [mL/min] 3244 ± 232 vs. 3369 ± 204) did not differ between the two groups. COX4I2 mRNA levels 3 hours post exercise were 3.3-fold increased in the group not receiving ACE inhibitor ($p=0.04$, $n=6$) but not those receiving ACE inhibitor (0.8-fold, $p=0.85$, $n=8$) and there was a trend for an interaction effect between the effect of exercise and intake of ACE inhibitor ($p=0.09$). The data point out an effect of commonly used antihypertensive medication in the treatment of hypertension on the muscle response to exhaustive bicycle type endurance exercise. The absence of a cross over design is a potential limitation. Our findings support a role for angiotensin regulated muscle oxygenation in dictating response of peripheral muscle to endurance exercise. The absence of a cross over design calls for a further study to confirm our findings and expose the functional implication of our observation. **References** Desplanches D, et al. Hypoxia refines plasticity of mitochondrial respiration to repeated muscle work. *Eur J Appl Physiol* 114(2):405-17, 2014 Vaughan D, et al. 15:00 - 16:00**Mini-Orals****MO-PM55 TT Fatigue****AN EVALUATION OF METABOLIC RESPONSES BY TIME CONSTANT VALUE DURING POST EXERCISES USING DIFFERENT LOADS CONDITIONS**

Sasaki, T., Tsunoda, K., Hoshino, H., Takeda, H., Maune, J., Eguchi, H.

Hokusei Gakuen University

Introduction In the study of Sasaki and Tsunoda (2006), the oxygen consumption returns to resting level earlier than the change of HR after exercise. Changes of VO₂ and HR can be described respectively with different exponential curve fitting. Exponential curves that are described by time dependent functions, had shown different time constants after the exercise. Those exponential functions represent different physiological responses in the individual athlete. The purpose of this study is to clarify physiological characteristics of individual athlete by using loads conditions both the Aer-T and the An-T. **Methodology** Five athletes corresponded in this study. They performed fixed speed load exercise of the Aer-T and the An-T on the tread mill. Metabolic responses were recorded into the oxygen analyzer of the Sensor Medics Co.. The incremental load tests were started at 3 km/h and increased by 0.5km/h every minute until exhaustion. After the test, athletes had taken at least 5 min sitting rest for collecting the lactate every 1 minute. The second order differential equation applied to decide the load conditions both the Aer-T and the An-T from an incremental metabolic test data. **Result** In fixed load test of 10 minute, the change of oxygen consumption reached to steady state or turned to decrease on the way from steady state level at the load condition of the Aer-T. The concentration of the blood lactate indicated small value of 6.52 mmol/l at just after the exercise. In the Aer-T condition, time constant values of the exponential fitting are shown shorter than the values of the An-T condition in metabolic changes (oxygen consumption, HR and VE). **Discussion** The blood lactate value after the exercise should affect to some metabolic responses. The higher the blood lactate is, the larger time constant value at the response will be during the post exercise. In individual athlete, different time constant value is shown in each level of exercise intensity of the Aer-T, the An-T and VO₂ max. Therefore, it could be considered that the blood lactate value become indicator of the intensity of the exercise. It is suggested that intensity of the An-T level should be given the important evaluation in the intensity of individual endurance capacity. **Conclusion** 1. The blood lactate after the exercise affect to the decrease of metabolic responses. 2. The higher the blood lactate is, the larger the time constant value of metabolic response at the post exercise will be. 3. Time constant value is different in each level of exercise intensity (the Aer-T, the An-T and VO₂ max.). 4. The intensity of the An-T level can be the index of the important evaluation in the individual endurance capacity. **References** Sasaki, T. and Tsunoda, K. (2006), The estimation of oxygen consumption from heart rate using an exponential equation, *Hokkaido J. Phys. Educ. Hlth, Sport Sci.* 41 :27-35.

MUSCLE ACTIVATION AND KINEMATICS DURING INCREMENTAL IN-LINE SLIDE BOARD SKATING TEST: A PRELIMINARY STUDY

Piucco, T., De Lucas, R.D., Dias, J.A., Dos Santos, S.G.

Federal University of Santa Catarina

Introduction The specificity of laboratory speed skating evaluations remains to be established, since skating treadmills are very expensive and challenging to be used as a routine tool to evaluate athlete fitness. There is only scarce scientific literature about specific physiological and biomechanical demands during speed skating, and most of information comes from observations in similar sports, such as cycling and running. However, evaluations and exercise prescriptions must be movement-specific, such that optimal results can be obtained due to the general physiological and functional muscular load on the body (de Groot et al, 1987). Considering this statement, this preliminary study aims to investigate muscle activation patterns and kinematics during an incremental slide board skating test. **Method** Four in-line skaters (28.2±8.3 years, 69±6.2 kg, 174.2± 8.2m) familiarized with slide board practice, completed an incremental skating protocol on an instrumented slide board (Brazilian Slide Board Test®), controlled by a specific-developed software. Surface electrodes at bipolar configuration were placed at rectus femoris (RF), vastus lateralis (VL), biceps femoris (BF), gluteus maximum (GM), and gastrocnemius lateralis (GL) muscles. The raw EMG signals (sample rate 2000 Hz) were smoothed using a fourth-order band-pass Butterworth filter (20- 500 Hz). The root mean square (RMS) and median frequency (MF) were calculated for each stage. The test was recorded using two 30 Hz-resolution video cameras. 2D analysis (knee and hip, Skill Spector®) and RMS envelope analysis of 10 consecutive strides (% step=contact at the lateral slide board stoppers, right leg) at a rate of 33 push-off/min were performed. **Results** GM and VL presented more activity during the test; some muscles showed an increase in RMS and decrease in MF during the test, suggesting peripheral fatigue. The muscle activation and kinematics pattern during slide board skating are qualitatively similar with those found in literature during treadmill skating (Chang et al. 2009; Gourdeault et al. 2002). The VL and BF showed slightly less activation on slide board, probably due the limited push-off movement. The knee and hip extension duration on slide board were longer, probably due to lack of rotation in the hip. **Discussion** Slide board skating tests seems to be a good choice to evaluate skater's performance and supports training prescription. At the present moment, more data collection is been done to verify correlations among variables obtained from a concurrent treadmill skating test. **Reference** De Groot G, et al. (1987). *J sports Sci*, 5(3), 249–59. Chang R, et al. (2009). *Sports Biomech*, 8(3), 212–22. Goudreault R, et al. (2002). INFLUENCE OF LOAD AND DURATION ON MAXIMAL LACTATE PRODUCTION RATE IN SUPRAMAXIMAL SPRINTS

Niessen, M., Hartmann, U.

University Leipzig - Faculty of Sport Science

Introduction In exercise physiology performance testing the maximum lactate formation rate (VL_{max}) has not been in an adequate focus so far, justified by very rare available studies on the methodology of determining the maximum flow rate of glycolysis. According to Mader et al. (1983) and Heck & Schulz (2002) the VL_{max} cannot be measured directly at the cellular level. Based on system-theoretical approaches and computer simulations they expect the VL_{max} around a load time of ten seconds and therefore indicate estimations by

short supramaximal sprints (SP). Aim of the study is the empirically quantification of the influence of the load time on VLamax. Methods Within the present study ten male competitive track and field athletes (100-400 m sprinters; anthropometrics: 25 ± 3 yrs, 182 ± 6 cm, 81 ± 8 kg) performed various supramaximal SP on separated days on an outdoor track (20-300 m; range of average velocity (vr_{un}): 6.43-9.32 m/s) after an individual, not interfered warm-up (WU: 20 min). Before WU and every SP as well as subsequent SP recovery phase (RP) (1st - 12th min) capillary blood samples were drawn from the hyperemised earlobe to analyse lactate concentration (LA) (EKF Diagnostics, GER). Sprint duration was captured by timing gates (Smartspeed, AUS). VLA was calculated based on the assumptions of Mader (1994) assuming a lactate-free interval of 1 s for short SP (very high power) up to 3 s for longer SP (medium power). Descriptive and group-specific parametric statistics were applied. Results Mean LA results prior and post WU were 1.77 ± 0.93 mmol/l and 3.59 ± 1.45 mmol/l ($p \leq 0.001$). The supramaximal SP lasted between 2.64-40.20 s with highest mean peak vr_{un} of 8.83 ± 0.51 m/s (100 m). LA accumulated with risen SP distance from 5.27 ± 1.36 mmol/l (20 m) to 18.44 ± 3.03 mmol/l (300 m) ($p \leq 0.001$). The delta LA production decreased in relation to increased SP time and distance. Highest VLamax findings of 0.84 ± 0.23 mmol/l/s were calculated after 80-100 m SP or 9-11 s duration. Discussion/Conclusion The calculated VLA results depend upon the exposure time, range from 0.13 to 1.16 mmol/l/s and were somewhat lower than for elite sprinters (Heck & Schulz 2002). Less fast sprinters and more endurance trained athletes achieve overall reduced VLamax values. It is assumed that the VLamax can be measured at a load time of 10 s between 80-100 m SP. In further studies, the reliability and the day-to-day variability of the VLamax as well as the clarification of the extent to distinguish between differently trained athletes or individual physiological characteristics have to be investigated. EFFECTS OF REPEATED SPRINT AND CHANGE-OF-DIRECTIONS ABILITIES ON NEUROMUSCULAR FATIGUE IN BASKET-BALL PLAYERS.

Jorge, J., Tous Fajardo, J., Moras, G.

UIC universitat internacional de Catalunya

INTRODUCTION: In team and racquet sports, a large number of acceleration, braking, sprints and quick changes of direction (COD) are repeated over prolonged time periods with incomplete recovery. Thus, the repeated change of direction ability (RCODA) appears critical for performance in these sports. Moreover, Repeated change directions has been linked to a reduced mechanics parameters (i.e. Fatigue) (Zebis 2010) and higher injury risk (Robineau et al 2012), in intermittent sports. The aim of this study was to analyze how muscle mechanical and contractile properties are modified after performing either a repeated sprint ability (RSA) or a RCODA exercise mode. METHOD: 10 basketball junior elite players, all right leg dominant, were tested in both RSA (2x(10x25 m)) with 25 s of recovery between series and 5 min between blocks and RCoDA tests including four 135° COD every 5 m (2x(10x25 m)) and same recovery as RSA test. Muscle contractile properties were analyzed in the Vastus lateralis (VL) using the maximal muscular displacement (D_m) of tensiomyography (TMG) before, between series, and after tests while maximal mechanical power output was calculated using an incremental load power test (one leg press exercise in a pneumatic ergometer) before and after both field tests. RESULTS: The TMG's D_m showed a significant decrement in the dominant leg after RCODA test with respect to the right leg (11.7% $P < 0.05$). Decrements in maximal mechanical power output were found in both legs after performing both tests ($p < 0.05$) but the a higher decrement in the dominant leg (10.90%) after RCODA test was found compared to the left leg (7.79%) while no differences were found between legs after performing the RSA test (7.57% R; 8.86 L) DISCUSSION: Results showed that RCODA exercise mode caused a greater neuromuscular fatigue (TMG's D_m and maximal power output) in the dominant limb compared to the RSA exercise mode. This could be debt to the greater involvement of the dominant leg while braking and accelerating, which reduces neuromuscular activity potentially leading to impaired functional performance (Thorlund, et al 2008) and a higher injury risk (Robineau et al, 2012). In conclusion, the RSA and RCODA exercise modes showed different acute responses with respect to mechanical and contractile properties of the muscles involved and these differences are accentuated on the dominant limb. THE INFLUENCE OF PHYSICAL CONTACT ON THE EXTERNAL AND INTERNAL DEMANDS DURING SIMULATED RUGBY LEAGUE MATCH PLAY

Twist, C.1, Mullen, T.1, Waldron, M.2, Highton, J.1

1:University of Chester (Chester, UK); 2: University of New England (Armidale, Australia)

Introduction Rugby league is an intermittent sport comprising prolonged periods of high and low intensity activity interspersed with repeated physical contacts. While these physical contacts are extremely demanding, little is known about their influence on the internal and external demands of match play. Accordingly, this study examined the role of physical contact on the movement, physiological, neuromuscular and perceptual responses to a simulated rugby league match. Methods Using a randomized crossover design, 19 male rugby players (20.1 ± 1.3 y; 80.1 ± 8.3 kg; 1.78 ± 0.1 m; $VO_{2max} = 50.2$ ml/kg/min) completed contact (CON) and non-contact (NCON) trials of a rugby league match simulation protocol (RLMSP-i; Waldron et al. 2013) with 7-10 days between trials. The RLMSP-i comprised 2 x 23 min bouts simulating the match demands of rugby league forwards. Movement (5 Hz GPS), heart rate (% maximum), blood lactate concentration [BLa] and RPE were assessed during the RLMSP-i. Countermovement jump (CMJ) flight time (pre, half-time and post) and isokinetic muscle force for knee extensors and flexors (pre and post) were also assessed. Session RPE (sRPE) was measured after each trial. Results Distance (457 ± 12 cf. 440 ± 13 m/min) and high intensity running (111 ± 11 cf. 104 ± 14 m/min) was higher in CON than NCON. While peak speed was higher in NCON (24.0 ± 1.2 km/h) compared to CON (22.7 ± 1.5 km/h), sprint performance decreased more in bout 1 of CON ($\Delta -1.6 \pm 1.5$ km/h) than NCON ($\Delta -0.3 \pm 1.0$ km/h). HR (88 ± 5 cf. $85 \pm 5\%$), RPE (14.3 ± 1.8 cf. 13.7 ± 1.6), sRPE (290 ± 66 cf. 219 ± 43) and [BLa] (3.8 ± 1.8 cf. 2.6 ± 1.3 mmol/l) were higher for CON compared to NCON. Muscle force was reduced from pre-values immediately after the RLMSP-i in both trials for peak torque of the knee extensors (CON: -4%; NCON: -2.6) and flexors (CON: -3.6%; NCON: -6.4%). CMJ remained unchanged for both CON and NCON trials. Discussion Alongside increasing the external and internal demands during a simulated rugby league match, physical contact compromises a player's ability to maintain sprint performance. This is despite lower limb muscle function changes being similar for simulated matches with and without contact. Conditioning should therefore incorporate physical contacts within repeated high intensity running practices to ensure players are prepared for the demands associated with match play. FATIGUE INDEX REPRODUCIBILITY IN ISOKINETIC TESTING

Paulus, J.1, Bosquet, L.2, Gremaux, V.3, Maquet, D.1, Forthomme, B.1, Nowak, N.1, Lehance, C.1, Croisier, J.L.1

1: ULg (Liege, Belgium), 2: UP (Poitiers, France), 3: uB (Dijon, France)

Introduction The isokinetic testing is a reference in muscular performance evaluation. Isokinetic device is mainly used to assess maximal strength using short length protocols. In some cases, such as to evaluate an athlete who mainly uses the lactic anaerobic metabolism, clinicians increase the lengthening of the protocol in order to investigate more specifically the fatigability profile. Bosquet et al. (2010) studied the effect of the lengthening of the protocol on some indicators of fatigue. However a great deal of indices can be provided by the machine and there is no real consensus about the index to be used in clinical applications. The aim of this study was to determine the most reliable index calculated either from peak torque or maximal work parameters. **Methods** 17 moderately active men performed a fatigue protocol on three occasions with one 7-10 days recovery between each session. Isokinetic protocol consisted in 30 reciprocal maximal contractions at the concentric angular velocity of 180°/s. Flexors and extensors peak torque and maximal work were computed for each repetition and subsequently used to calculate 52 different indices (among others best performance, total or partial sum and various index based on a performance normalization quotient). Their reliability has been assessed through interclass correlation coefficient calculated from results of repeated measures ANOVA. Results Indicators computed for the knee extensors were frequently more reliable than those computed for the knee flexors. The most reliable indicators were: - by order, the best performance among 30 repetitions, cumulated value of first 5 repetitions, of first 10 repetitions and of the 30 repetitions for the extensors peak torque and extensors maximal work; - the sum of the 30 repetitions for the flexors peak torque and flexors maximal work. All extensors and almost all flexors index based on a performance normalization quotient showed respectively at best a moderate reliability and a low reliability. **Discussion** Because of excellent reliability for extensors maximal work and high reliability for extensors peak torque and flexors, the sum of 30 repetitions appears to represent the fatigability indicator with best compromise between reliability and specificity. It should be noticed that maximal work is yet more specific to isokinetic fatigability protocol than peak torque for the sum of 30 repetitions. On the basis of our results, almost all isokinetic index based on a performance normalization quotient must be at least used carefully by clinicians due to their low reliability. **References** Bosquet L., Maquet D., Forthomme B., Nowak B., Lehance C., Croisier J.-L. INFLUENCE OF CAFFEINE IN GLUCOSE AND PEAK FORCE LEVELS AFTER ANAEROBIC EXERCISE

Rezende, T.M.1,2, Herédia, M.G.1, Coelho, I.A.1, Ferreira, R.P.1, Lodovichi, S.3, Gonçalves, L.1, Júnior, A.J.S.1

INTRODUCTION Performance in physical exercises can be improved by the use of ergogenic supplements (EP). Caffeine is an EP used to improve performance claimed to help fatigue reduction. However, caffeine effects and its mechanisms in the organism are yet not fully understood. Researchers argue that caffeine could improve protein resynthesis inside the muscle, especially after aerobic exercise (AE) (Pedersen et al., 2008; Santos et al., 2013). Few studies analyzed the effect of caffeine during intense and heavy exercise (>90% VO₂max). The aim of this study was to determine if caffeine supplementation could improve the performance and recovery of volunteers after anaerobic running. **METHODS** Volunteers were running recreationists, male (N=8) of 20.6 ± 1.7 years old. They run in the treadmill at their maximal capacity until they reach exhaustion, in a double blind system, one time after taking a caffeine pill (6 mg/kg) and again after receiving placebo (Pla) an hour before the start of the protocol. Blood was collected for the determination of glucose level and peak force was determined by the measurement of muscle strength of the knee extension (Kendall, 2005) with a handheld dynamometer. These parameters were collected before and immediately after the exercise and at 3, 7, 12 and 30 minutes of the recovery. **RESULTS** Values of glucose level and peak force were compared between the caffeine and Pla individuals, and they differed only at the time of 30 min of the recovery. Mean glucose level in the caffeine group at 30 min was 97.2 ± 8.8 mg/dL and in the Pla was 84.7 ± 8.4 mg/dL (p<0.01, T-test). Peak force (Newton) of the left leg had a mean value in the caffeine group of 263.0 ± 51.6 N whereas in the Pla it was 241.7 ± 37.4 N (p<0.03, T-test). **DISCUSSION** This result indicates that caffeine may play a role in the recovery after an anaerobic exercise. Previous studies show that caffeine have effects on glucoregulatory mechanisms responsible for restoring the glycogen levels (Pederson, 2008) helping in the faster recovery of highly trained individuals. In our study, the volunteers treated with caffeine showed that after 30 min they were able to start a new intense exercise, with 14.8% higher level of glucose level than the non-caffeine individuals. Athletes of high performance could benefit from the use of this EP, increasing their capacity. **REFERENCES** Pedersen DJ, Lessard SJ, Coffey VG. (2008). *J Appl Physiol* 105, 7-13. EFFECTS OF INTERMITTENT NEGATIVE PRESSURE THERAPY OF LOWER-BODY ON RECOVERY AFTER PLYOMETRIC EXERCISE

Sarabon, N., Fonda, B.

University of Primorska

Introduction The use of devices to stimulate the effects of manual lymphatic drainage have first been used to compensate for weightlessness in space (Schneider et al., 2002). Dietmar (2007) later found that application of lower-body negative pressure (LBNP) implemented in regular training of elite athletes provides beneficial effects on the recovery after training. However, to date, no studies published in peer-reviewed periodicals empirically examined the effects of LBNP therapy after the exercise. Therefore, the aim of the present study was to examine the effects of LBNP on pain and performance parameters during a 5-day recovery period after a damaging plyometric exercise. **Methods** Twenty four healthy young female adults were randomly allocated into two groups; experimental (n = 12; 20.1 ± 1.8 years, 166.6 ± 6.1 cm and 59. ± 8.5 kg) and control (n=12; 21.0 ± 2.1 years, 168.5 ± 4.5 cm and 59.9 ± 8.5 kg). Prior to and 1, 24, 48 and 96 hours after the damaging exercise for hamstrings (50 drop jumps and 50 leg curls) participants underwent a series of tests (pain sensation, counter movement jump, maximal isometric torque production, maximally explosive isometric torque production and 10 m sprint). The experimental group was exposed to intermittent LBNP therapy daily for 60 min. **Results** Results showed statistically significant (p < 0.05) interactions for maximal strength, explosive strength, pain sensation and vertical jumps (maximal power and force). No statistically significant interaction was present for jump height and 10 m sprint. **Discussion** This is the first study that empirically examined the effects of LBNP on recovery after damaging exercise. Results indicate that LBNP therapy hastens the recovery by limiting the loss in muscle strength and power. In addition, there was a reduced presence of delayed onset muscle soreness in the group using LBNP therapy. **References** Dietmar, F. A. (2007). CAN THE CALF-RAISE TEST KINEMATICS PREDICT FUNCTIONAL FITNESS IN ELDERLY? - AN ELECTROMYOGRAPHIC APPROACH

Moço, A.1, André, H.1, Ramalho, F.1, Carnide, F.1, Veloso, A.1

1: Faculty of Human Kinetics - Lisbon University (Portugal)

Introduction The Calf-raise (CR) test is a screening tool to assess ankle muscle function whose applicability has not yet been investigated to stratify the elderly in terms of Functional Fitness. To our knowledge, it is not clear if the muscular pattern of the calf muscles follows the kinematic pattern during the CR test, nor if the levels of functionality and physical fitness of the subjects influence them. **Methods** 26 independent elderly participants with different levels of functionality were recruited (ages 73.7 ± 7.1 yrs; 50% women). The tests were administered on two occasions with an interval of three days between them. In the first day, subjects were tested for maximal isometric (ISM) ankle plantar flexion on a Biodex isokinetic dynamometer. In the second day, the CR test was administered. We collected EMG signals at the right soleus (Sol) and medial gastrocnemius (MG) muscles on both occasions with a Delsys Trigno Wireless System (Boston, MA; bandwidth 20-450 Hz). Simultaneously, angular kinematic data from the sagittal plane of the ankle joint were calculated using a 2D video analysis system (APAS, Ariel Dynamics Inc). Signal processing and statistical analysis were conducted in MATLAB (The Mathworks, MA, USA). The amplitude of the EMG signals acquired during the CR tests were low-pass filtered and normalized according to the corresponding values registered during the ISM tests. For each subject, we determined the normalized average delay between the curves of the angular position of the ankle and the EMG envelopes at the Sol and MG during the CR test (nAvD_Sol and nAvD_MG, respectively). The association between the number of repetitions at the CR test and the nAvD_Sol and nAvD_MG variables was assessed with the Pearson correlation coefficient and by linear regression. **Results** The number of repetitions at the CR test (average 37; range 16 - 67) showed a significant and positive linear relationship with nAvD_MG and nAvD_Sol ($r(2)=0.82$, $r(2)=0.83$, $p<0.001$, respectively). The normalized average delay ranged from 6% to 51%. The higher delays correspond to subjects who scored more repetitions at the CR test and translate a shift in the activation of the calf-muscles from the concentric to the eccentric contraction phase, suggesting a stretch-shortening cycle pattern. **Conclusion** The results suggest that the variables nAvD_Sol and nAvD_MG adequately characterize the muscular activation pattern of the calf muscles in the CR test. Its combination with the number of repetitions seems a promising approach to stratify older adults in terms of functional fitness. Contact moco.a.v@gmail.com

CONTROL OF THE CENTRE OF MASS DURING DIFFERENT STAIR DESCENT STRATEGIES IN THE ELDERLY

King, S.L.1, Underdown, T.B.1, Reeves, N.D.2, Baltzopoulos, V.3, Maganaris, C.N.1

1LJMU (Liverpool, UK), 2MMU (Manchester, UK), 3Brunel University (London, UK)

Introduction The elderly are at an increased risk of falls and trips during stair descent due to the increased musculoskeletal demand imposed by this task (Reeves et al. 2008). Reduced functional capacity, muscle recruitment, coordination or strength may limit the ability to adjust the limb to safely control the body in instances of unexpected instability (Buckley et al. 2013). The aim of this study was to determine how the elderly controlled their centre of mass (CoM) during different stair descent strategies. **Methods** Eleven elderly participants descended a four step custom built instrumented staircase at a self-selected speed. Two step configurations were tested: 1) a standard rise height of 170mm using a step over step strategy (STD SoS) and 2) a rise height of 255mm using step over step, (INC SoS), step by step (INC SbS) and side step (INC SS) strategies. The going stayed constant at 280mm. Centre of pressure (CoP) and whole body model accelerations and A/P displacement were captured at 1080Hz and 120Hz respectively. Data were analysed using a repeated measures GLM. Significance was accepted at $p<0.05$. **Results** Significantly reduced CoP-CoM A/P separation during the landing phase was evident in STD SoS compared to INC SoS and INC SbS ($6.1\text{vs}10.6$ and 10.7cm , $p<0.05$). INC SS resulted in significantly greater separation during mid-stance compared to STD SoS, INC SbS, INC SS ($10.4\text{vs}4.3$, -2.2 , -2.5cm , $p<0.01$). During toe off, INC SbS resulted in a larger A/P acceleration compared to STD SoS and INC SoS ($0.8\text{vs}0.7$ and -1.0m/s/s , $p<0.01$) with a reduced CoP-CoM separation compared to INC SoS and INC SS ($2.5\text{vs}10.0$ and 6.2cm , $p<0.02$). **Discussion** The capability of the elderly to control their CoM during stair descent can fluctuate. During the landing phase a greater posterior 'lean' towards the staircase occurs with increased step rise, which could reduce the eccentric muscle action necessary to control lowering of the CoM. This lean was maintained by the SS strategy during mid-stance suggesting that this approach provides a mechanism for a safer single limb support. However, this strategy resulted in a simultaneous rapid CoM acceleration (1m/s/s) and large CoP-CoM separation (10cm) prior to toe off, indicating an unstable and potentially dangerous transition into swing. Whilst the INC SbS strategy also resulted in a large peak acceleration, a smaller CoP-CoM separation (1.2cm) occurred at a slower rate (0.07m/s/s) during this transition. This INC SbS strategy could offer increased CoM control, stability and support during stair descent. **References** Reeves N. et al. (2008). *J Electromyogr Kines*, 18, 218-227. Buckley J. et al. STRENGTH TRAINING FAILED TO IMPROVE GAIT BIOMECHANICS IN HEALTHY OLD ADULTS

Beijersbergen, C.1, Tatarski, R.2, Rider, P.2, DeVita, P.2, Hortobágyi, T.1

1University of Groningen; 2East Carolina University, USA

Introduction: Walking is a key activity of daily living and self-selected walking velocity predicts a variety of clinical conditions in old adults. Numerous interventions, applying resistance, power, balance, and specific locomotor training have demonstrated to improve gait velocity.

ty. However, virtually none of these studies evaluated the biomechanical mechanism of how a newly acquired physical ability enables old adults to walk faster. Objective: To determine if a 12-week-long lower extremity strength training program: 1) improves gait velocity; 2) if increased leg strength modifies joint kinematics and kinetics measured during level walking in old adults, and 3) if these changes occur in a correlated manner. Methods: This is a non-randomized controlled study in healthy subjects ($n = 16$, age over 65) without functional limitations who provided written informed consent. Training was done 3 times / week for training and control groups. Strength training ($n = 8$) was performed at 60-80% 1RM and consisted of supine bilateral leg-press exercises. Stretch (control) training ($n = 8$) consisted of dynamic and static plantarflexor stretching exercises. Before and after training 3D kinematic and ground reaction forces were collected during self-selected and maximal walking velocities. Gait kinematics and kinetics were calculated using inverse dynamics. Leg strength was measured using bilateral 1RM for training group, and plantarflexor strength was measured using single 1RM for control group. Results: Training group improved leg strength 35% from 75 (± 22) kg at pre-test to 101 (± 34) kg at post-test ($p = 0.007$). There was no increase ($p = 0.08$) in control group's strength from pre-test 59 (± 17) kg to post-test 62 (± 16) kg. For training and control groups, respectively, initial gait velocity was 1.43 (± 0.14) m/s and 1.46 (± 0.19) m/s at self-selected pace and 1.90 (± 0.20) m/s and 1.78 (± 0.24) at maximal pace. The exercise programs failed to improve gait velocity. There were also no changes in joint kinematics (hip, knee and ankle ROM) and kinetics (peak extensor joint torques and power generation during stance phase). Discussion/Conclusion: The data suggest that 12-weeks of lower extremity strength training with our precise training protocol was not sufficient to improve gait biomechanics in healthy old adults who already walk at a rapid pace. There was no incorporation of the newly acquired strength into gait and the mechanism used to increase gait velocity after strength interventions in old adults remains unknown.

WHOLE BODY VIBRATION HAS A STRONGER INFLUENCE ON LEG MUSCLE ACTIVITY IN OLDER ADULTS COMPARED TO YOUNG ADULTS

Vienneau, J., Lienhard, K., Nigg, S., Nigg, B.M.

University of Calgary

Introduction Studies have found positive relationships between whole body vibration (WBV) and increased muscle activity (Rehn et al., 2007). These studies most frequently used a young adult population; the outcomes of these studies cannot be inferred to an older population. Elderly people typically have less compliant joints and stiffer tendons and muscles, and therefore may react differently to WBV (Kiiski et al., 2008). The aim of this study was to compare muscle activity using surface electromyography (EMG) during WBV between young and older adults. Methods Thirty young adults (25.9 ± 4.3 yrs) and 30 older adults (64.2 ± 5.2 yrs) participated in this study. EMG was recorded from the tibialis anterior (TA), peroneus longus (PL), gastrocnemius medialis (GM), soleus (SOL), vastus lateralis (VL), vastus medialis (VM) and biceps femoris (BF) during 20 seconds of WBV (side-alternating mode, 11Hz, 2.5mm amplitude). EMG was also recorded during 20 seconds of standing without vibration (novib). The root mean square of both EMG trials were normalized to a maximal voluntary contraction (MVC) of the respective muscle measured using a Biodex dynamometer. The normalized value during the novib trial was subtracted from the value during the vibration trial to obtain a percent increase in MVC relative to quiet standing. For each muscle, the two groups were compared using unpaired Student's t-tests with the Holm-Bonferroni correction. Results The older adults showed significantly higher EMG in the TA ($p < 0.001$), PL ($p < 0.004$), VL ($p < 0.01$), VM ($p < 0.007$) and BF ($p < 0.001$). Discussion The increased muscle activity in the older group may be due to an increase in neuromuscular fatigue. With aging, there is preferential atrophy of type II muscle fibers, which are associated with stronger and faster contractions (Klein et al., 2003). The resulting increased proportion of type I fiber area contributes to slower and weaker contractions (D'Antona et al., 2007). As a result, for tasks requiring fast movement velocities, older adults have been shown to have a greater fatigue effect than younger adults (Dalton et al., 2010). This increased muscle activity indicates that WBV may lead to greater neuromuscular adaptations in an older population, and therefore WBV training should be investigated further in this cohort. LOWER SAFETY FACTOR FOR OLD ADULTS DURING WALKING AT PREFERRED VELOCITY

Mademli, L.I, Arampatzis, A.2

(1) Aristotle University of Thessaloniki, (2) Humboldt University

Introduction Older adults are more prone to falls during walking than young adults, although they walk more slowly and demonstrate higher stability state (Bohm et al. 2012). This paradox of higher stability state but less safe locomotion let us hypothesize that older adults may move closer to their dynamic stability limits. In order to investigate this hypothesis, the present study examined the safety factor of dynamic stability in old and young individuals when walking at their preferred velocity. Methods Twelve older (68.2 ± 4.2 years, 76.6 ± 7.7 Kg; 172.5 ± 7.7 cm) and 12 matched regarding body mass and body height young male (25.2 ± 3.1 years; 77.6 ± 6.7 Kg; 178.7 ± 8.7 cm) participants walked at their (a) walk-to-run transition velocity (WRV, i.e. maximum capacity) and (b) preferred velocity (PWV, i.e. actual applied load). Whole body kinematic data and ground reaction forces were captured. Dynamic stability was assessed using the 'margin of stability (MoS)' as a criterion for the stability state of the body during walking, according to the extrapolated center of mass concept formulated by Hof et al. (2005). The safety factor was calculated as the ratio between MoS at WRV and MoS at PWV. Results Old participants demonstrated significantly greater MoS (i.e. greater stability state) but a significantly lower ($\sim 11\%$) safety factor than the young ones, when they walked at their preferred velocity. The main reason for the greater MoS in the old adults was the lower PWV compared to the young ones. The old individuals walked at significantly lower horizontal velocity of the centre of mass and performed shorter steps. However, there was a significant interaction between age and velocity on the MoS, indicating lower differences in this parameter between PWV and WRV for the old participants compared to the young ones, accounting for the smaller safety factor found for the older adults. Discussion We found that, although older participants walked slower and provided a higher stability state in terms of MoS compared to young ones, they showed a significantly reduced safety factor during preferred walking. This confirmed our hypothesis. Old adults do not walk slowly enough in relation to their maximum walking velocity, resulting to a lower safety factor during normal locomotion. Apparently, the age-related muscle degeneration affects WRV more than PWV. The resulting lower safety factor for the older participants may partly explain the increased risk of falls in their daily life, in spite of slower locomotion. GAIT BIOMECHANICAL PARAMETERS RELATED WITH FALLS IN RHEUMATOID ARTHRITIS POSTMENOPAUSAL WOMEN WITH AND WITHOUT FALLS HISTORY

Aleixo, P.1, Ivo, R.1, Coelho, P.2, Vaz Pato, J.2, Abrantes, J.1

1MovLab/Universidade Lusófona de Humanidades e Tecnologias (Lisboa, Portugal) 2Instituto Português de Reumatologia (Lisboa, Portugal)

Introduction Rheumatoid arthritis (RA) patients (Hayashibara et al., 2010) and postmenopausal women (Cangussu et al., 2012) showed an increased fall risk. Research pointed to some gait biomechanical parameters related with falls (GBP) (Winter, 1991) and found differences in these parameters between elderly and young: elderly showed higher ratio of head to hip horizontal acceleration and higher heel horizontal velocity at heel contact with the ground (Winter, 1991); elderly and young showed similar minimum toe clearance values however elders had greater variability (Barrett et al., 2010). These GBP were not studied in RA postmenopausal women. Thus, the aim of this study was compare GBP between RA postmenopausal women with and without falls history (G1 and G2, respectively). **Methods** Data were collected from 16 RA postmenopausal women. Subjects answered the question: 'how many times did you fall last year'. Vicon® Motion Capture system recorded kinematics data (9 MX1.3 cameras, 200Hz) synchronized with a force plate (AMTI BP400600-200, 1000Hz). Data analyzed by Vicon® Nexus software (1.7.1) based on an integrated model of 41 reflective markers relocation and subject anthropometric data, developing mechanical segments and joints centers. Subjects performed 14 valid trials (7 left and 7 right foot contacts with AMTI). **Results** 11 subjects had at least one fall in last year. Differences between groups (G1 and G2): heel antero-posterior velocity (0.25 and 0.47 m/s, $p=0.006$; 0.23 and 0.36 m/s, $p=0.035$; left/right contact); intra-individual coefficient of variation of left heel antero-posterior velocity (42.7 and 23.6%, $p=0.004$); centre of mass velocity (0.76 and 1.08 m/s, $p=0.004$; 0.80 and 1.05 m/s, $p=0.01$; left/right contact). Minimum toe clearance and ratio of head to hip antero-posterior velocity did not show differences between groups. **Discussion** Subjects with falls history showed lower gait speed and higher intra-individual variability at heel antero-posterior velocity. First point may indicate an adaptation to ensure a safer gait pattern. Second point may indicate a less proprioceptive control which could lead to a higher incidence of falls. Thus, may be important to improve proprioception of gait movements in RA postmenopausal women. **References:** Barrett R, Mills P, Begg R (2010). ANALYSIS OF IMPACT DECELERATION IN ADULTS OVER 50 YEARS DURING WALKING AND NORDIC WALKING

Aparicio, I., Giménez, J.V., Pérez Soriano, P., Llana Belloch, S., Lucas Cuevas, A.

UNIVERSITY OF VALENCIA

Introduction Walking and Nordic walking is a healthy physical activity practiced by many people. During human gait, musculoskeletal system is subjected to different impacts on each of the foot contacts (Kavanagh & Menz, 2008). There are many factors that could change these impacts (footwear, walk speed, surface) (Voloshin, 2000). In this sense, the aim of this study was to determine the effect of Nordic Walking (NW) and Normal Walking (W) on impact magnitudes. **Methods** 57 participants (12 male and 45 female [63.7 ± 2.5 years]) walked Nordic Walking at least one hour a day, during three days a week per month. Impact magnitudes were analyzed at 1.5 ± 0.1 m/s, with an accelerometer in two experimental conditions: Walking/Nordic Walking, and the effect before training in Nordic walking. Variables analyzed were acceleration Peak (AP), Acceleration Rate (AR), and Acceleration Magnitude (AM). **Results** AP showed significant differences between the three conditions, $X^2(2)=18.4$, $p<0.05$. It was found significant differences in AP: Wpre>Wpos ($T=0$, $p<0.0167$, $r=-0.62$), and Wpre>NW ($T=0$, $p<0.0167$, $r=-0.62$). AR showed significant differences according to the type of walking ($X^2(2)=13.17$, $p<0.05$). **Results** showed lower values in the rate of tibia acceleration in Wpost respect to Wpre ($T=0$, $p<0.0167$, $r=-0.62$), and in NW regarding to Wpre ($T=4$, $p<0.0167$, $r=-0.56$). Finally, we observed that AP and AR decreased in Wpost and NW after the training in NW. **Discussion** AP and AR decreased after the training period in NW. AP was reduced 37.72% in Wpost and 39.58% in NW, in relation to the pattern of walking before de training in NW, Wpre. AR was reduced 56.27% in Wpost and 56.49% in NW compared with Wpre. (Willson et al., 2001). Thus, the experience in NW becomes a factor (Schwameder & Ring, 2006) that determines the values of impact while walking. In addition, NW is a type of walking softer than the normal walking. **Results** suggest that training in NW could change the gait pattern decreasing impacts, which makes it a healthier activity. (Gregg & Brown, 2003). **References** Gregg EW, Brown, A (2003). Clinical Diabetes, 21(3), 113-118. Kavanagh JJ, Menz HB (2008). Gait & Posture, 28(1), 1-15. Schwameder H, Ring S (2006). DIFFERENCES IN GAIT PERFORMANCE, QUADRICEPS STRENGTH, AND FEAR OF FALLING BETWEEN FALLERS AND NON-FALLERS IN WOMEN WITH OSTEOPOROSIS

Stief, F.1, Schäfer, A.1, Vogt, L.2, Kirchner, M.3, Thiel, C.4, Hübscher, M.5, Banzer, W.2, Meurer, A.1

1:Orthopedic University Hospital Friedrichsheim gGmbH, Frankfurt/Main, 2:Goethe-University Frankfurt/Main, 3:University Hospital Heidelberg, 4:University of Applied Sciences, Bochum, 5:New South Wales

Introduction Osteoporosis is characterized by low bone mass, leading to increased bone fragility and a rapid rise in the risk of sustaining fractures from falls (Sambrook and Cooper, 2006). Prevention of falls is therefore imperative and should address the people at risk and the physiological causes of falling. This study was designed to identify differences between fallers and non-fallers in women with osteoporosis. In this way, we aimed to gain further insight into the mechanisms that may contribute to an increased fall risk to derive potentially exercise concepts aimed at reducing the incidence of falls. **Methods** Forty-one women with osteoporosis (17 fallers, 24 non-fallers) and nineteen age-matched female subjects without osteoporosis participated in the present study. We assessed gait parameters, quadriceps strength, fear of falling, state of health, as well as individual physical activity. Differences between the three groups were tested for significance using an univariate ANOVA, followed by post hoc pairwise comparison. Predictors of falls in women with osteoporosis were assessed by binary logistic regression analysis. **Results** Fallers showed a significantly increased fear of falling compared to non-fallers and controls. The maximum isometric voluntary force (MIVF) of the knee extensors was reduced by approximately 9% for non-fallers and 19% for fallers compared to controls. The logistic regression analysis indicated that low MIVF of the knee extensors and reduced ankle power generation during push-off are associated with a higher risk of falling. **Discussion** Early identification of individuals with a higher risk of falling is important for effective fall prevention. Clinically, our findings are indicative of a fall prevention program for women with osteoporosis focusing on quadriceps muscle strengthening and gait retraining with the emphasis on ankle plantarflexor power to maintain an

adequate step length, and to generate a more physiological, safely gait pattern. The identified risk factors for falls could be included in a screening tool and may therefore also contribute to the improvement of risk profiles for the identification of high risk fallers in women with osteoporosis. EFFECTS OF AGING ON NEUROMUSCULAR REACTION TIME IN KARATE ATHLETES

Fernandes, R., Vences Brito, A.M., Ferreira, D.

Escola Superior de Desporto de Rio Maior

Introduction In Karate, reaction time, presents itself as an extremely important variable in the athlete's performance (O'Donovan et al., 2006). Further, it's assumed that the aging process influences the reaction time (Vences Brito et al., 2011). This study aimed to identify the effects of aging on Neuromuscular Reaction Time (NRT) of black belts karate athletes. **Methods** It was measured, analyzed and compared the NRT in a group of black belt karate athletes with over 50 years (K50 - n=10; age=54.2±3.9; years of practice=5±9; weekly hours of training=5±1) and in a younger group (K35 - n=14; age=24.2±6.7; years of practice=13±5; weekly hours of training=5±2). NRT was considered the time between the application of the auditory stimulus and the onset of electrical activation of the first muscle to be activated in the performance of the front kick (maegeri) to a fixed target. Data of five muscles from the right lower limb (Rectus Femoris (RF), Vastus Lateralis (VL), the long head of the Biceps Femoris muscle (BF), Tibialis Anterior (TA), and the outer portion of Gastrocnemius muscle (GA)) were collected using surface electromyography (EMG). Participants were initially in a static position (zenkutsu dachi) from which held the kick in response to the applied stimulus. **Results and Discussion** The results show that the first muscle to be activated in both groups is the TA and in the K50 group it is activated slightly earlier than in K35 group (95±64ms, 99±71ms, respectively), however there were no significant differences between groups respecting to NRT of this muscle. Also, no significant differences were found in the NRT in the remaining muscles. The sequence of NRT from the studied muscles was different between the K35 group (TA, VL, RF, EG, BF) and K50 group (RT, RF, VL, BF, GE) which reflects an organization of differentiated neuromuscular recruitment in response to the stimulus. **Discussion** The results show us that the older athletes (K50) are similar to younger athletes (K35) in what NRT is concerned. This finding leads us to conclude that this should be associated with longevity of sport practice by the K50, which can minimize the effects of aging on perceptual and neural structures. We also conclude that the training effect is manifested in the pattern of initial muscle recruitment in the K50 group, identifying an adaptation that may be associated with the experience, but also in adapting to a smaller capacity motor response due to aging. **References** O'Donovan O, Cheung J, Caley M, McGregor A, Strutton P. THE EFFECT OF HIGH VERSUS LOW CONCENTRATION MALTODEXTRIN-FRUCTOSE INGESTION DURING A SIMULATED 30-KM CROSS-COUNTRY SKI RACE

McGawley, K., Stocks, B., Betts, J.

Mid Sweden University

The effect of high versus low concentration maltodextrin-fructose ingestion during a simulated 30-km cross-country ski race McGawley, K.*1, Stocks, B.*1,2 and Betts, J.*2 *1 Swedish Winter Sports Research Centre, Mid Sweden University, Sweden; *2 Department for Health, University of Bath, UK **Introduction** Long-distance cross-country ski races typically last more than 2 h, depleting muscle glycogen stores in the legs and, to an even greater extent, the arms (Bergström et al. 1973). While carbohydrate (CHO) supplementation demonstrates clear performance-enhancing effects, particularly when ingested during exercise lasting > 1 h and in multiple forms (Jeukendrup 2004), there is limited information regarding the use of CHO during cross-country skiing. Therefore, the aim of the current study was to examine the effect of ingesting two different CHO solutions on 30-km cross-country skiing performance. **Methods** 10 male and 3 female trained cross-country skiers (age: 30±7 yr; body mass: 74±9 kg; VO2max: 60±6 mL/kg/min) completed 4 x 30-km classic roller-skiing time-trial efforts (consisting of 6 x 5-km loops) on separate days in a randomised, counter-balanced order on a treadmill. Two trials used a high rate of CHO ingestion (2.4 g/min, HC) and two trials used a lower rate of CHO ingestion (1.2 g/min, LC). In addition, two trials used a high frequency of CHO feeds (6 feeds, HF) and two trials used a low frequency of CHO feeds (2 feeds, LF). The CHO was a 1:1 mix of maltodextrin and fructose and the drinks were provided at 24% and 12% concentrations for HC and LC, respectively. **Results** There were no significant differences in performance over the four trials (140±16, 139±16, 141±18 and 141±18 min for HC-HF, LC-HF, HC-LF and LC-LF, respectively) and when matched for frequency of feeds, there were no significant performance differences between the paired comparisons (i.e., HC-HF vs LC-HF and HC-LF vs LC-LF). Moreover, there were no significant differences in blood glucose concentrations at 5-km intervals when comparing HC-HF with LC-HF (p>0.05) or HC-LF with LC-LF (p>0.05). However, an order effect was detected for performance (143±17, 140±16, 140±17 and 138±15 min for trials 1-4, respectively) with significant improvements from trials 1-2 (p=0.02) and 3-4 (p=0.03). **Discussion** Results from the current study demonstrate no significant differences in 30-km cross-country ski performance when consuming either 2.4 or 1.2 g/min of a mixed CHO solution. Furthermore, there were no significant differences in blood glucose concentrations during exercise between the high and lower CHO trials. However, despite familiarisation to treadmill roller-skiing and the simulated race track, a learning effect was evident. It is concluded that race-track familiarity may have a greater effect on 30-km cross-country ski performance than the rate of CHO ingestion. **References** Bergström, J., Hultman, E. and Saltin, B. EFFECT OF COMBINED CARBOHYDRATE FEEDING DURING PROLONGED HIGH-INTENSITY INTERMITTENT EXERCISE ON EXERCISE PERFORMANCE IN YOUTH SOCCER PLAYERS

Miliotis, P.1, Geladas, N.1, Koskoulou, M.1, Ntalapera, S.1, Giannopoulou, I.1,2

1: University of Athens, 2: University of Brighton

INTRODUCTION Carbohydrate supplementation prevents hypoglycemia and delays the symptoms of fatigue towards the end of a soccer game in adults (Bangsbo et al., 1992). In adolescents, carbohydrate supplementation leads to improved endurance capacity during prolonged high-intensity intermittent exercise (Phillips, 2012). There is a lack of information on the effects of combined carbohydrate feeding, prior to and during a soccer game in adolescents. The purpose of the study was to investigate the effect of combined carbohydrate feeding on exercise performance in youth soccer players. **METHODS** Seven male young (13.5 ± 0.4 years) soccer players ($\text{VO}_{2\text{peak}}$: 56.5 ± 6.0 mL/kg/min) participated in the study. On two occasions the athletes performed an intermittent exercise protocol simulating a soccer match (60 min) (HIE), either with or without carbohydrate (CHO) supplementation, in a single-blind random and counterbalanced order. Two hours before the experiments athletes consumed a pre-exercise breakfast meal of 2.2g carbohydrate•kg/BW. Every 15 min during HIE either a CHO (6% glucose) or an isovolemic placebo drink (PLC) was ingested. After the HIE athletes performed a time to exhaustion performance test on a cycle ergometer. **RESULTS** Time to exhaustion was significantly longer in the CHO trial (123 ± 37 sec) compared to the PLC trial (81 ± 28 sec) ($p < 0.01$). Rate of Perceived Exertion at local level (RPElegs) at the end of the performance test was higher in CHO (9 ± 1) compared to PLC (8 ± 1) ($p > 0.05$), while no significant differences were found between the two conditions in overall RPE and maximum heart rate ($p > 0.05$). **CONCLUSION** The combined carbohydrate feeding significantly increased the duration of the performance test by 34% compared to the PLC. The longer time to exhaustion was possibly attained through the preservation of euglycemia (Coggan & Coyle, 1991). Hence, a pre-exercise meal of 2.2g carbohydrate•kg/BW in combination with a 6% CHO drink could delay fatigue and improve performance during a youth soccer match. **REFERENCES** Coggan AR, Coyle EF. THE EFFECT OF MASTIC AND PHYSICAL ACTIVITY EXERT AS A FACTOR RELATED TO LIPID METABOLISM, GLUCOSE METABOLISM AND BODY COMPOSITION

Fukazawa, T.1, Smyrnioudis, I.2, Konishi, M.1, Takahashi, M.1, Kim, H.1, Sakamoto, S.1

WASEDA University, Sakamoto Shizuo-labo

Introduction "Mastic" is the air-dried, resinous exudation of the mastic tree. It is *Pistacia lentiscus* var. Chia, and originates from the Island of Chios in Greece. It is a famous pharmaceutical plant and was the first natural chewing gum in the Hippocratic period. A recent study has found that *Pistacia lentiscus* var. Chia contains methyl oleonate which is an anti-diabetic compound (Petersen et al., 2011). This study aims at exploring ways in introducing Chios- mastic to Japan with focus on its therapeutic effect on lipid metabolism, glucose metabolism and body composition. **Methods** We studied 21 healthy male subjects. Group-A (n=7) received placebo powder 5g/day. Group-B (n=7) received mastic powder 5g/day. Group-C (n=7) received mastic powder 5g/day and additionally, participated in 30 min of walking, 3 times per week as physical activity. The period of the experiment is six months for all groups. We carried out the following blood test and physical measurement three times: 1st, before starting the experiment, 2nd, 3 months after having started the experiment and 3rd, 6 months after having started the experiment. **Blood test:** Group of Lipid Metabolism consists of Cholesterol, LDL, HDL, Triglycerides, L-CAT, and LPL. Group of Hepatic Function consists of SGOT, SGPT and gamma-GTP. Group of Glucose Metabolism consists of Insulin and Glucose. Group of Body Composition consists of BMI, Waist Circumference, Percentage of Body Fat, Muscle mass. **Results** Comparing the differences among three Groups: A, B and C and between the experimental periods: 1st, 2nd and 3rd. Group-B and C exhibited significant reduction of insulin in both 2nd compared with 1st, and 3rd compared with 2nd. Group-B and C exhibited reduction of triglycerides in 2nd compared with 1st, but they increased in 3rd compared with 2nd. However, they were lower than 1st. The blood-test indicated that the combination of mastic-gum with the 3 times of walking per week has a positive effect on Body Composition. **Conclusion** This study suggested that Chios-mastic extract has a potential to decrease insulin and triglycerides. However we are continuing the research in order to clarify whether the decrease of insulin is the result of the mastic intake only or due to mastic intake combined with physical exercise, and at what degree. Finally, this study will also propose culinary ways so that Chios-mastic will be introduced into Japanese society as an appropriate food for Japanese people. **References** Petersen R.K, Christensen K.B, Assimopoulou A.N, Fretté X, Papageorgiou V.P, Kristiansen K, Kouskoumvekaki I. PRIOR LOW- OR HIGH-INTENSITY EXERCISE ALTERS PACING STRATEGY, ENERGY DISTRIBUTION AND PERFORMANCE DURING A 4-KM CYCLING TIME TRIAL

Correia Oliveira, C., Santos, R., Silva Cavalcante, M., Bertuzzi, R., Kiss, M., Bishop, D., Lima Silva, A.

University of São Paulo

Introduction While it seems clear that pre-exercise, muscle glycogen availability affects the pacing during a time trial (TT), requiring athletes completing a given distance as fast as possible, to date it is not known if selective glycogen depletion of the type I or type II fibers will have different effects on pacing strategy. Therefore, we analyzed the influence of prior exercise designed to predominately reduce muscle glycogen in either type I or II fibers on pacing and performance during a 4-km cycling TT. **Methods** After preliminary and familiarization trials, ten amateur cyclists performed three 4-km TT in a randomized, repeated-measures crossover design: 1) TT after an exercise protocol in the evening before (~10 h) designed to reduce glycogen of type I muscle fibers (EX-FIB I); 2) TT after an exercise protocol in the evening before (~10 h) designed to reduce glycogen of type II muscle fibers (EX-FIB II) and; 3) TT without prior evening exercise (CON). Mean values of performance parameters were compared between conditions using repeated-measures ANOVA. A linear mixed model with Bonferroni correction was used to verify the effects of condition and distance or moment on dependent variables. **Results** Time to cover 4-km TT and power output (PO) were impaired in EX-FIB I (432.8 ± 8.3 s and 204.9 ± 10.9 W) and EX-FIB II (428.7 ± 6.7 s and 207.5 ± 9.1 W) compared to CON (420.8 ± 6.4 s and 218.4 ± 9.3 W; $P < 0.05$), without difference between EX-FIB I and EX-FIB II ($P > 0.05$). The PO and aerobic contribution were lower in EX-FIB I than in CON at the beginning and middle of the TT ($P < 0.05$). The end-spurt magnitude, anaerobic contribution, and Post-TT plasma lactate were all lower in EX-FIB II than in CON (-52.5%, -52.2%, -22%, respectively, $P < 0.05$). The integrated electromyography activity was unchanged between conditions ($P > 0.05$). **Discussion** Performance was impaired after both protocols, but PO and aerobic contribution at the beginning and middle of trial were more impaired in EX-FIB I, suggesting a reduction in the aerobic metabolism in type I fibers, while the reduced magnitude of the end spurt and anaerobic contribution in EX-FIB II may be attributed to a reduced glycogenolysis in type II fibers. The unchanged electromyography activity suggests that these impairments were

related to alterations in peripheral factors. From these findings, it may be suggested that, irrespective of either a prior low- or high-intensity exercise, an impairment in overall performance of a 4-km cycling TT is evident, but the pacing adopted, as well as alterations in the energy system distribution, occur in a specific way. THE EFFECTS OF LOW- & HIGH- GLYCEMIC INDEX FOODS ON SIMULATED TEAM SPORTS PERFORMANCE

Jaafar, M.

Republic Polytechnic, Singapore

Introduction: Pre-exercise meals or single foods containing low glycaemic index (LGI) carbohydrates (CHO) have been shown to enhance performance prior to prolonged steady state exercise compared to high glycaemic index (HGI) CHO but not during intermittent high intensity exercise (team games exercise). **Purpose:** To examine the effects of low- and high-GI foods on metabolism and performance during a simulated soccer exercise. **Methods:** Ten male athletes participated in two experimental trials (low-GI, high-GI) separated by ~7 days. Foods were consumed 3h before and halfway through 90 min of exercise circuit designed to simulate the activity pattern of soccer. Blood glucose, insulin, and lactate were assessed before, during, and after the exercise bout. Performance was assessed by vertical jump, sprint time during the 90 min of exercise and 20m sprint test after the exercise. **Results:** There was a significant interaction in glucose and insulin response ($P < 0.05$) with HGI exhibiting higher values before exercise but not during exercise. Post circuit 20m sprint time significantly lower for HGI ($P < 0.05$). Rate of perceived exertion, heart rate, vertical jump height, sprint performance and lactate did not differ between the two conditions. **Conclusion:** These findings suggest that the type of CHO ingested in a pre-exercise meal has no significant impact on performance or metabolic responses during 90 min of intermittent high intensity exercise.

EFFECTS OF AN ENERGY DRINK ON ELITE SPEED-SWIMMERS

Lara, B., Salinero, J.J., Gallo Salazar, C., Abián Vicén, J., González Millán, C., Ruiz Vicen, D., Areces, F., Del Coso, J.

Camilo Jose Cela University

Introduction Energy drinks are one of the most popular supplements among young elite athletes (Hoffman, 2010). These drinks represent a relatively new category of commercially available beverages that contain caffeine. However, the effects of the energy drinks on sports performance have not been properly investigated. The purpose of this study was to investigate the possible ergogenic effect of a caffeinated energy drink on a 50-m simulated swimming competition as well as on swimming-specific tests. **Methods** We recruited 14 male elite swimmers (age = 20.2 ± 2.6 years; weight = 73.9 ± 8.3 kg). They performed two experimental trials separated by one week: on one occasion, the swimmers ingested a caffeinated energy drink (3 mg of caffeine per kg of body weight) and on another occasion they ingested the same drink but without caffeine content (0 mg/kg; placebo). The order of the trials was randomized and counterbalanced. Sixty minutes after ingestion, the swimmers performed a countermovement jump (CMJ), a manual maximal dynamometry test, a 50-m simulated competition (with their preferred style) and 45-s test at maximal intensity in a swimming ergometer. A blood sample was withdrawn 1-min after completion of the ergometer test to assess blood lactate concentration. After the trials, participants completed a questionnaire about side-effects derived from the intake of the beverages. **Results** In comparison to the placebo drink, the intake of the caffeinated energy drink increased the height in the CMJ (49.4 ± 5.3 vs 50.9 ± 5.2 cm; $P < 0.05$) and the maximal force during the handgrip test with the right hand (49.2 ± 5.1 vs 50.9 ± 4.4 kg; $P < 0.05$). Besides, the caffeinated energy drink reduced the time to complete the 50-m swimming competition (27.7 ± 3.4 vs 27.5 ± 3.1 s; $P < 0.05$) and it produced greater peak power (272.6 ± 55.2 vs 303.2 ± 49.1 W; $P < 0.05$) and blood lactate concentration (11.0 ± 2.0 vs 11.7 ± 2.1 mM; $P < 0.05$) during the ergometer test. However, the caffeinated energy drink did not modify the prevalence insomnia (7% vs 7%) or self-reported fatigue (0% vs 0%) and muscle pain (28% vs 28%) during the hours following to the ingestion of the drinks ($P > 0.05$). **Discussion** Our study suggests that caffeine (3 mg/kg) increases swimming-specific performance when ingested via commercial energy drinks. The use of caffeinated energy drinks might represent a potent ergogenic method for speed swimmers. Besides, the side-effects derived from these beverages are marginal. **References** Hoffman, JR. BIA MODELS TO ASSESS TOTAL BODY AND EXTRACELLULAR HYDRATION IN ATHLETES

Matias, C.N., Santos, D.A., Magalhães, J.P., Judice, P.B., Minderico, C.S., Fields, D.A., Sardinha, L.B., Silva, A.M.

Faculty of Human Kinetics - University of Lisbon

Background: It is recognize the need to correctly and easily assess hydration pools in athletes, not only to determine the effectiveness of exercise training and also to monitor the health status of the athlete. Recently has been suggested that athletes should use an electrode-based system that provides raw data of resistance (R) and reactance (Xc) and apply those in an appropriate equation to predict hydration, instead of the use of predefined values automatically calculated by commercial devices. Bioelectrical impedance analyses (BIA) seem to be an easy to use and fairly inexpensive approach for hydration monitoring. Over the years several BIA equations were developed to predict total body water (TBW) and extracellular water (ECW) in non-athletic healthy populations. The main purpose of this study was to develop BIA-based models for TBW and ECW prediction based on criterion methods in a sample of national level athletes and cross-validated these new equations in a separate cohort of athletes. **Methods:** Two hundred and seventeen highly trained athletes (21.3 ± 5.0 years) were evaluated during their respective competitive seasons. Athletes were randomly split into development ($n = 145$) and validation groups ($n = 72$). Fat mass and fat free-mass were estimated using dual-energy X-ray absorptiometry. The criterion method for TBW was deuterium dilution and for ECW was bromide dilution, where ICW was the respective difference between both. Resistance (R) and reactance (Xc) were obtained with a BIA 101 RJL and used for the estimation of TBW and ECW. **Results:** Athletic BIA based models were developed for TBW and ECW: $TBW (kg) = 36.588 + 5.4681 \cdot sex + 0.0032 \cdot Weight^2 (kg) - 0.0261 \cdot R (\Omega)$ $ECW (kg) = 12.824 + 0.4404 \cdot sex + 0.0007 \cdot Weight^2 (kg) + 0.0003 \cdot Stature^2 (cm) - 0.0010 \cdot age^2 (years) - 0.0088 \cdot R (\Omega) - 0.0550 \cdot Xc (\Omega)$ Cross validation revealed a R^2 of 0.85 for TBW and 0.83 for ECW. Pure errors ranged from 1.44kg in ECW to 3.90kg for TBW and the concordance correlation coefficient between the new method and the reference procedure was 0.91 for both methods. From the agreement analysis, we observed no trend between the mean and the differences of the methods and the 95% confidence intervals were within acceptable limits (below 10%). **Conclusion:** Overall, the new equations are considered valid, with no observed bias, thus affording a practical mean to quantify TBW and its compartments in national level athletes.

THE EFFECT OF DURATION ON THE EXERCISE INTENSITY AND THE ACCURACY OF SKILL IN THE FIELDING PRACTICE OF BASEBALL

Goro, M., Kurokawa, T., Akashi, K., Nishiyama, K., Ueda, T., Adachi, T.

Hiroshima University

Introduction: The effective duration for the improvement of physical fitness and skill in the fielding practice of baseball was investigated. **Methods:** Seven collegiate baseball players participated in a fielding practice in the position of shortstop. One set of the fielding practice lasted for 5 minutes at intervals of 17 seconds, and 12 sets were continuously done. The heart rate (HR), the catching score and the throwing score were measured during the whole fielding practice. The ratings of perceived exertion (RPE) and the blood lactate concentration (Lab) were measured every 5 minutes. **Results:** The HR increased rapidly till the 3rd set which was 172bpm, and then decreased at the rate of 1~2bpm per set. The RPE increased till the 8th set which was 17, and then decreased gradually after that set. Lab increased till the 3rd set which was 5.7mmol/l, and then decreased gradually. The catching score and the throwing score decreased significantly at 7th~12th set and at the 12th set compared to the 1st set, respectively. **Discussion:** The exercise form of the fielding practice on this study was an interval exercise, repeating a rest of about 7 seconds after every throw and a comparatively long rest of 1 minute after every set. However, since the HR was maintained at a comparatively high level of around 170bpm all the time, it was considered that it had a property of endurance exercise of high intensity, and that it was effective to improve the aerobic capacity. Lab decreased gradually after the 3rd set. This may be due to the decrease of the glycogen. Lambert et al. (2002) suggested that if enough bouts are performed during multiple bout high-intensity exercise, muscle glycogen will reach a level where glycogenolysis could not be sustained. Also, skill in the fielding practice was best at the 1st set, and high scores were maintained till around the 3rd set. However, since the fielding score decreased gradually and the catching score decreased significantly after the 6th set, it was considered that the changes of movement happened. Thus, it was possible that the incorrect fielding form was acquired. Krstrup et al. (2006) suggested that the depletion of glycogen in some fibers caused the reduction of the sprint performance at the end of a soccer game. Therefore, in order to continue the fielding practice in the frequency of this study, it is necessary to take a rest every 3 sets to recover the glycogen enough, as it is the origin of energy. (2002). *Sports medicine*, 32(8), 511-522.

THE PHYSIOLOGICAL AND BIOMECHANICAL ANALYSIS OF 3 KINDS OF COACHING METHOD OF ENDURANCE RUNNINGS IN JAPANESE JUNIOR HIGH SCHOOL

Kenta, N., Kurokawa, T., Moriki, G., Akashi, K., Adachi, T., Ueda, T.

Hiroshima university

Introduction The aim of this study was to investigate the characteristics of 3 kinds of endurance runnings performed in the physical education class of Japanese junior high school, by observing continuous change in physiological and biomechanical variables during running. **Methods** Fifty-seven male junior high school students were coached by three methods. The all-out method, in which the students ran 3,000m at full exertion, the inner/outer track (I/OT) method, in which the duration of exercise was nearly equalized by having slower/faster runners use the inner/outer running tracks (210m, 250m, 300m), and the RPE method, in which the students ran 3,000m according to Borg's RPE13 (ratings of perceived exertion) scale. The heart rate (HR) was measured by a HR monitor (Polar Electro co.), and the running pace, the stride length, and the stride frequency were measured by a stride sensor (Polar Electro co.) every 5 seconds during the whole running. **Result** In the all-out method, the running speed decreased significantly within the progress of running ($p < 0.01$), was the highest speed of 280m/min at 0-1min, and was the lowest speed of 236m/min at 9-10min. The stride length and the stride frequency changed between 1.38-1.53m and 85.3-91.8steps/min, respectively. In the I/OT method and the RPE method, the running speed increased at 0-1min after starting, and then the running speed was kept between 241-260m/min and 208-218m/min, respectively. The stride length changed between 1.41-1.56m and 1.24-1.34m, and the stride frequency changed between 85.3-91.9steps/min and 83.9-87.4steps/min, respectively. **Discussion** In the all-out method, the running speed may have decreased in the middle and final stages of running due to the high energy demand by the high stride frequency in the early stage of running (Cavanagh and Williams, 1982). This result may have occurred due to the difficulty in controlling one's running pace. In the I/OT method and the RPE method, the running speed was maintained by the adjustment of stride length. It was considered that the running speed was maintained by the external information of following the other runners in the I/OT method, and by the internal information due to the ratings of perceived exertion in the RPE method. Therefore, it was suggested that the I/OT method and the RPE method were effective coaching methods in learning the pacing of running. Continuous change of heart rate showed a tendency to decrease by the all-out method, and maintained by the RPE method and the I/O method. For this reason, it was suggested that it was difficult to maintain intensity in particular by the all-out method. **Reference** Cavanagh PR, Williams KR (1982). *Med. Sci. Sports Exercise*, 14, 30-35. Contact kn.coco14@gmail.com

ANALYSIS AND COMPARISON BY GENDER OF LACTATE PRODUCTION IN YOUNG BREASTSTROKE SWIMMERS

Ciapparelli, C., Caspani, M., Romagialli, B., Invernizzi, P.L.

Università degli Studi di Milano

INTRODUCTION The aim of this study was to assess the differences by gender of lactate production in the 200 m breaststroke swimming, at the anaerobic threshold. Mader's test, proposed on 1976 and modified in distance from its original version, is used to calculate the anaerobic threshold from the lactate production after a second 200 m breaststroke, in a swimming battery test. This is very useful to assess the proper swimming speed in the seasonal training planning. **METHODS** Twelve male (age 17.3 ± 0.2 years; height 181.2 ± 4.7 m; weight 73.2 ± 2.9 kg; best time on 200 m breaststroke 131.25 s) and female national-level swimmers (age 16.0 ± 0.2 years; height 166.4 ± 3.3 m; weight 54.2 ± 2.6 kg; best time on 200m breaststroke 143.56 s) participated in the study. Tests were performed in a 25 m swim-

ming pool. Each swimmer twice swam a 200 m breaststroke trial: the first at 2 to 3 mmol/L (17 to 20 s slower than the personal record); the second, 30 minutes after the first, at the maximum speed. Blood lactate was measured (Lactate Pro Analyzer) three minutes after the end of each trial. Paired Student's *t* test was applied to compare male and female performances and lactate production at the anaerobic threshold between. RESULTS At the anaerobic threshold, male swimmers swam the 200 m breaststroke in 145.72 ± 2.76 s, while females swimmers performed 159.12 ± 3.38 s ($p < 0.01$). The male swimmers' lactate production at the anaerobic threshold was 11.0 ± 1.59 mmol/L, whereas female swimmers produced 9.3 ± 1.91 mmol/L ($p < 0.05$). DISCUSSION Males better performed the 200 m breaststroke swimming at the anaerobic threshold than females.. This can be easily explained by the difference in power between genders. With regard to the lactate production, female swimmers exhibited significantly lower values than males, probably due to the lower ratio between muscle mass and blood volume and to lower glycolytic activity of the skeletal muscles associated with a higher oxidative capacity of the lactate. High aerobic capacity is important for a good 200 m performance; in fact there is a high correlation between the speed corresponding to 4 mmol/L lactate production and the speed of swimmers during the 200 m race. POSTURAL CONTROL AND BALANCE. EFFECTS OF PROPRIOCEPTIVE FITNESS TRAINING IN A GROUP OF ADULTS.

Nart, A., Scattolin, D., Biancalana, V.

School of Motor Sciences. Carlo Bo University of Urbino

Introduction: The upright position of man in a bipodalic stance is unstable. Posture and balance adjustment are the result of the integration of different multisensory processes (Peterka, 2002). The Tonic- Postural system, through the proprioceptive reflex, ensures the immediate correction of continuous disturbances in stability. The unconscious component of the proprioceptive-archeoproprioceptive system is the base of stabilizing reflexes, allowing for static and dynamic functional stability (Riva, 2000). The object of this study was to evaluate the effects of proprioceptive exercises on the modification of parameters associated with stability and posture. Methods: 12 subjects, attended pre-skiing amateur classes, were recruited in the study (5 males, 7 females), 42-55 years of age (mean age = 48.9, SD = 3.32). The participants completed a personal data form and subsequently underwent stabilometric analyses (in static and dynamic modes, with their eyes open and then closed), as well as Fukuda Tests. They had a proprioceptive fitness training for 6 weeks. Tests were recorded at starting point (T0) and after training (T1) and then were compared. Results: Statistical analyses were conducted on the parameters measured by the stabilometric platform: confidence ellipse area (S90), length of Statokinesigram (Longr), variation in speed (Var.Vit), distribution of body weight (AVG, TalG, AVD, TalD), and speed variation index (IVV). In order to detect significant changes between T1/ T0, we used T-test for paired samples. Results showed improvements in most parameters with a p -value ≤ 0.05 . Discussion: The study confirmed the initial hypotheses: proprioceptive aspect is fundamental for stability and maintenance of the erect position of a person. We would like to underline results obtained in dynamic mode with closed eyes, to confirm the high value of proprioceptive aspect. References Nakagawa, H., Ohashi, N., Watanabe, Y., Mizukoshi, K. THE RELATIONSHIP BETWEEN SCORE AND POSITIONS OF SPORT CLUB TENNIS PLAYERS IN DOUBLES MATCH

Yoo, H.1, Hwang, Y.1, Kwon, O.1, Jang, S.1, Jeong, H.1, Kim, S.1, Lee, S.1, Park, H.2, Park, J.3, So, H.4

1: Pusan National University (Busan, South Korea), 2: Chonnam National University (Gwangju, South Korea), 3: Youngsan University (Busan, South Korea), 4: Dongseo University (Busan, South Korea)

Introduction The player position is very important in tennis competition, especially in double matches. In general, the position near net is known to be easier to get score. However, it is not clear how other positions, the degree of distance from the net, affect tennis score in double matches. Therefore, the aim of this study was to analyze how sport club tennis players would gain and lose scores in a double match depending on their positions. Methods We filmed a total of 136 men's double matches with a video camera during 2013 National Amateur Tennis Club Championship held in Siheung, South Korea. The player positions were divided into 5 areas, I, II, III, IV, and V, according to the definition of Korea Professional Tennis Association (KPTA). These areas were numbered in the order of distance from the net. The Area I is the first half and Area II is the second half from the net to the service line. In the same way, the Area III is the first half and Area IV is the second half from the service line to the baseline. Lastly, Area V is beyond the baseline. Two tennis experts determine the scores by watching the videotaped tennis matches. Data analysis was conducted by a cross tabulation analysis and a Chi-square test Results First, the scores of the winning team were the highest in Area I (35.20%, %), while the lowest in Area V (3.91%). The proportion of scores in Area II, Area III, and Area IV were 34.08%, 8.10% and 18.71%, respectively. These differences were statistically significant ($p < .001$). Second, the loss of scores in the winning team was the highest in Area II (33.84%) and the lowest in Area I (3.25%). The rest areas are in the order of Area IV (28.11%), Area V (18.93%), and Area III (15.87%). These differences were also statistically significant ($p < .001$). Third, the scores of the losing team were in Area I (32.26%), Area II (37.90%), Area III (7.26%), Area IV (15.73%) and Area V (6.85%), which was significantly different ($p < .001$). This result indicates that the loser would gain scores most often in Area II but hardly in Area V. Fourth, the loss of scores in the losing team were in Area I (2.98%), Area II (34.23%), Area III (13.64%), Area IV (24.43%) and Area V (24.72%), which was also significantly different ($p < .001$), showing that the loser would lose scores mostly in Area II but hardly in Area I. Conclusion These results suggest that the amateur such as sports club tennis players should try to play in Area I to get more scores and lose less scores for their victory in double matches. TACTICAL SKILLS INVENTORY FOR SPORTS IN YOUTH BASKETBALL: PORTUGUESE VERSION AND EXTRACTION OF THE 4-FACTOR STRUCTURE

Ribeiro Junior, D.B.1, Elferink Gemser, M.T.2, Valende dos Santos, J.3, Figueiredo, A.J.3, Furtado, G.E.3, Coelho e Silva, M.J.3

1: UNIVERSO - Universidade Salgado de Oliveira (Brazil) 2: University of Groningen (The Netherlands) 3: FCDEF-UC (Coimbra, Portugal)

Introduction: Team games such as basketball demand complex tactical skills. A 34-item Tactical Skills Inventory for Sports (TACSIS) to assess "knowing about ball actions", "knowing about others", "positioning and deciding" and "acting in a changing situation" is available (Elferink-Gemser et al., 2004). Its dimensions refer to declarative knowledge, while the last two contain items related to procedural knowledge. The purpose of this study is to obtain the Portuguese version of TACSIS. **Methods:** Each sentence from the English version was translated by 4 candidate Portuguese expressions obtained from 2 experienced sports scientists and 2 additional certified translators. The decision about the Portuguese expression that best corresponds to the original sentence was selected to be part of the preliminary Portuguese version of TACSIS that was used in a sample of 214 youth basketball players (aged 12.5-18.8 years). Exploratory factors analysis was used to extract a 4-factor solution using varimax rotation. An additional independent group of 221 youth basketball players (aged 12.1-19.2 years) were used to determine internal consistency. **Results:** Three items loaded in more than one factor and were excluded. Two items did not load in any factor. Factors were composed and interpreted as "Positioning and Deciding" (PD), "Knowing About Others" (KAO), "Knowing About Ball Actions" (KABA), "Acting in Changing Situations" (ACS). Based on sample 2, internal consistency coefficients were determined using the three items in F3 [KABA] and F4 [ACS]. For factors F1 [PD] and F2 [KAO] the four items with highest loadings were retained for the calculations. Alpha coefficients were as follows: KABA ($\alpha=0.73$), ACS ($\alpha=0.64$), PD ($\alpha=0.55$), KAO ($\alpha=0.68$). From both samples 49 players were randomly selected to fill out the questionnaire twice and to determine intraclass correlation: PD ($r=0.59$, $p<0.01$), KAO ($r=0.67$, $p<0.01$), KABA ($r=0.67$, $p<0.01$), ACS ($r=0.62$, $p<0.01$). **Discussion:** The Portuguese version of TACSIS resulted in a 4-factor solution that seemed to fit the original dimensions. In addition, the constructs derived from the exploratory factor analysis demonstrated reasonable internal consistency and reliability. **References:** Elferink-Gemser et al. (2004). *Perceptual Motor Skills*. 99: 883-895.

FUNCTIONAL CHANGES OF THE MUSCULAR-SKELETAL SYSTEM OF ATHLETES

Solovjova, J.

Latvian Academy of Sport Education

Introduction Athletes across all sports face sporting injuries stemming from overuse of specific muscle groups for that particular sport. Overuse of specific muscle groups causes functional muscle imbalance leading to postural changes. The problem professional/elite athletes face today is finding the balance between sporting advantage and injury: functionality versus detrimental change. This study is the first step in solving the problem of ensuring balance of functional muscular-skeletal changes and its advantages. It is hotly debated between coaches, athletes and support staff how, and where that balance point is to be found, and applied. **Methods** 92 athletes in Latvia; 20 swimmers, 20 ice-hockey players and 19 basketball players, 17 handball players and 16 cyclists aged 14-17 and having different preparation level were examined. Tests were completed using methods by (Vasiljeva, 1996) for visual diagnostics and by (Janda, 1994, Kendall & Kendall, 1982), for muscular functional testing. From these methods a diagnostic program was developed, (Solovjova & Uptis, 2008) which included measuring the changes of 8 sagittal points from the vertical plane along with functional testing of 11 muscle groups. **Results** Results indicate that all athletes showed functional muscular-skeletal changes at various skeletal points. In general the following peculiarities of posture statics can be marked in the athletes individual posture profile. All sporting profiles were found to fall forward; cyclists being the most pronounced. Swimmers have a round back and a slight forward rotation of the pelvis. Ice-hockey and handball players along with cyclists have explicit forward rotation of the pelvis. Muscle testing results indicate that the greatest changes were found in the postural muscles m. rectus femoris in all 20 ice-hockey players and cyclists (100%), in handball players (91.2%), in basketball players (84.2%) and swimmers (41%). **Discussion** All athletes showed individual changes from a neutral posture (deviation from the vertical line in the sagittal plane) characteristic to their sport due to overloaded muscle groups. The postural muscles that form posture have rather high tone, but if these muscles are overloaded, the tone pathologically increases and the muscle cannot contract nor relax effectively enough to allow the antagonist to work. Physically contracting muscles that provide movements have lower tone than postural muscles. If they are overloaded, their efficiency decreases, they lengthen and cannot contract effectively. **References** Janda, V. (1994). *Manuelle muskelfunktion diagnostik*. Berlin, Ullstein, Moscow. THE DIFFERENT CORTICAL CHARACTERISTICS BETWEEN SUCCESSFUL AND UNSUCCESSFUL PUTTS IN GOLF NOVICES

Shen, C., Huang, C., Hung, T.

National Taiwan Normal University

Introduction Contemporary researchers have reported that some EEG characteristics are related to expert motor performance. However, the EEG characteristic of novice performers has been less studied. Therefore, this study aimed to examine the cortical characteristics associated with performance in golf novices. **Method** Fifteen participants with no golf putting experience were recruited for this study. Participants watched a golf instruction video to familiarize themselves with putting. Then participants were required to execute 30 putts in order to determine an individualized distance from the hole so that the probability of success was approximately 50%. The test consisted

of 60 putts, during which EEG data was recorded. EEG data 1.5s prior to the initiation of putting movement was segmented into three successive 500ms epochs (T3:-1.5s~-1s, T2: -1s~-0.5s, T1:-0.5s~0s) and EEG components which related to performance (i.e., Fm θ , T3 α , and Oz α) were analyzed. Results The 2 x 3 (performance x epoch) repeated measures ANOVA showed that the only significant effect was found on the Fm θ epoch. Post hoc analysis showed that Fm θ in T3 was significant higher than in T1. No effects were found for T3 α or Oz α . Discussion In general, performance in golf novices could be affected by a variety of factors due to undeveloped skill. Psychological factors may be less significant for performance at this level. As a result, the three EEG components that have previously found relevant to motor performance in skilled participants were not related to performance in the novices.

EXPLORING THE PERCEPTUAL AND TACTICAL MERITS OF ANTICIPATION PROCESSES

Mecheri, S.1, Triolet, C.2, Benguigui, N.1

1: University of Caen, 2: University of Paris-Sud

Introduction Anticipation in dual sports may come from a combination in the use of information from the opponent's actions and from tactical situations. These sources of information are likely to be integrated by the perceptual-cognitive activity of experts and their relative importance may change according to situations characteristics. We conducted a first experiment (E1) for identifying the situations under which anticipation behaviors occur and a second one (E2) to distinguish the sources of information that are used for anticipation (i.e., opponent's action, tactical situation or both). Method and results of E1 A video-based analysis of 3000 ATP matches situations that included neutral, favorable and unfavorable balance of power was performed. The delay between the opponent's stroke ($t=0$) and the response of the player (RT) and response accuracies (RA) were recorded. The analysis outlined four specific temporal windows: (1) RT under -140 ms with RA above 80% (4.35% of the 3000 situations); (2) RT between -120 ms and +60 ms with RA under 70% (1.79%); (3) RT between +80 ms and +140 ms with a progressive increase of RA from 70% to 100% (7.28%); (4) RT equal or superior to +160 ms with a RA of 100% (86.58%). With the assumption that anticipation is based on uncertain information that can lead to erroneous decisions, we showed that anticipation behaviors occurred in between 6.14% and 13.42%. Most anticipation behaviors were observed in unfavorable situations indicating that players anticipate when the spatio-temporal constraints increased. Rationale of E2 ATP matches were recorded from a front-on perspective by two cameras located 14m from the baseline at a height of 3m (low shot, LS) and 7m (high shot, HS). Following the result of E1, only situations that imposed severe spatio-temporal constraints and in which the opponent hit a winner were selected. These sequences were occluded at the ball-racket impact of the winner stroke. Participants had to predict the future direction (left-right) of the ball. We assessed the effect of: (i) emphasizing tactical information by using the HS that allows a better perception of players positions; (ii) emphasizing opponent's action information by using the LS that better reproduce natural access to kinematic information; (iii) removing tactical information of the LS and providing a better access to opponent's action information by zooming tightly on the opponent and thereby denying the participants access to players relative positions; (iv) removing perceptual information of the HS by placing an opaque patch on the opponent. The same sequences were presented under these four conditions to four independent groups of expert players. Data will be presented and discussed in the 2014 ECSS Congress. sami.mecheri@unicaen.fr

EXAMINING CENTRAL VS. PERIPHERAL VISION IN GOLF PUTTING USING A SPATIAL OCCLUSION DESIGN.

Vine, S., Walters Symons, R., Wilson, M.R.

University of Exeter

The Quiet Eye (QE; Vickers 1996) has been shown to explain inter-individual (expert vs. novice) and intra-performance (hit vs. miss) variability. Despite being defined as a foveal fixation (within 3° of visual angle), it is still not clear to what extent the QE supports the efficient use of central (foveal) or peripheral vision. In golf putting, for example, there are several potential explanations for why fixating the ball might be beneficial for performance: (1) Spatial information is obtained through foveal vision, allowing for the effective organisation of movement parameters whilst minimising external distraction; (2) Stable gaze on the ball acts as a visual pivot to enable efficient pick up of visual information in the periphery (e.g. the line of the backswing, or the line of the hole) to guide the on-going movement. We used a spatial occlusion paradigm to assess the relative importance of central and peripheral vision during the QE period. We manipulated the visual information available during the golf putt using an occlusion cone. Participants placed their head inside the cone, which was suspended above the ball. In a central condition the cone completely occluded the peripheral view, in 2 peripheral conditions participants could see forwards peripheral (the front half of the cone was removed) or backwards peripheral (the back half of the cone was removed). Participants also putted in a no-cone condition (control). 35 golfers (M age= 21.35, SD= 4.04) with an average handicap of 7.2 (SD= 6.44) performed 10 putts in each condition from 10ft. Performance (radial error) was calculated and averaged for each of the conditions. Although a repeated measures ANOVA revealed no main effect for performance error ($F(3,99) = 1.60, p = .198$), descriptively performance was the worst in the no-cone condition ($M = 25.17, S = 13.17$), followed by the forwards peripheral condition ($M = 22.14, SD = 11.85$), followed by the backwards peripheral condition ($M = 21.37, SD = 8.29$). The best performance was in the central condition ($M = 19.86, SD = 7.74$). The trend of the data highlights the importance of foveal vision and supports our first explanation of the QE regarding the gathering of spatial information and the minimisation of external distractions. These results are in keeping with previous work (e.g. Rein-hoff et al., 2013) that has shown performance to be superior when participants received only central vision. Rienhoff, R. et al. (2012). Field of vision influences sensory-motor control of skilled and less-skilled dart players. *Journal of Sports Science and Medicine*, 11, 542-550. Vickers, J.N. (1996). QUIET EYE AND CHOKING: ONLINE CONTROL DOES NOT BREAK DOWN AT THE POINT OF PERFORMANCE FAILURE

Ruffault, A., Guichard, A., Mann, D.L., Fournier, J.F.

Institut National du Sport, de l'Expertise et de la Performance (INSEP)

Laboratory-based studies in sport science have limited value if they do not faithfully replicate performance levels seen in the natural environment. Vine et al. (2014) demonstrated that in stressful conditions, a modification of the quiet eye is observed commensurate with a performance drop in putting. However, Fournier and Bernier (2013), when comparing successful and unsuccessful putts in an outdoor training situation on real grass, could not find any modification of quiet eye duration. Because there were methodological differences between the two studies, we replicated the Vine et al. study on an outdoor putting green. Thirteen professional golfers (handicapped 2.5) wore an SMI eye tracker while taking part in a putting shootout, with a 50 euro reward for the player who successfully made the most consecutive 1.5m putts. Contrary to Vine et al. we did not find any differences in any measure of quiet eye. However, results from a con-

current test of cognitive anxiety show that participants in our study in the natural setting were not as anxious as those in Vine's laboratory study. The results highlight that key modifications to move tasks into the laboratory have the potential to profoundly change the outcomes of experiments in sport science.

ASSOCIATIVE THOUGHT CONTENTS DYNAMICS DURING EXERCISE IN TRAINED RUNNERS

Balagué, N.1, García, S.1, López, A.1, Domènec, M.1, Hernández, G.1, Fernández, M.1, Hristovski, R.2, Tenenbaum, G.3

1. INEFC Barcelona (Spain), 2. Ss. Cyril and Methodius University, Skopje (Rep. of Macedonia), 3. Florida State University (USA)

Introduction Trained runners employ associative strategies during competition. However, it is unclear whether this is a result of their spontaneous thought flow or a volitional strategy. A nonlinear model of attention focus during exercise has been proposed using a dual intrinsic-intentional paradigm (Balagué et al., 2012). The aim of this study was (a) to examine the intrinsic and intentional dynamics of thought contents during incremental running until volitional exhaustion, and (b) to examine the differences in associative thought contents dynamics between trained and untrained runners. **Method** 13 runners and 18 non-runners were familiarized with the experimental procedures, and then performed twice an incremental-load running test until volitional exhaustion to test their (a) intrinsic thought dynamics (non-imposed thoughts condition), and (b) intentional thought dynamics (imposed task-unrelated thoughts condition). Thoughts were recorded on line and then classified into 4 categories: TUT-I, TUT-E (internal and external task-unrelated thoughts), TRT-E, and TRT-I (external and internal task-related thoughts). TRT-I category was subdivided into 3 subcategories: Body Monitoring, Feelings and Affects, and Command and Instructions. The thought categories and subcategories dynamics were plotted for each participant and divided into non-overlapping temporal windows to obtain thoughts probabilities in different time intervals. Non-parametric repeated measures Friedman ANOVA was used to analyze the thoughts dynamics, and the U Mann-Whitney test was used to compare the differences between runners and non runners. **Results** A significant effect of workload on thought content was revealed in both groups and tests, defining two and three effort phases in the tests performed under the intrinsic and intentional dynamics conditions, respectively ($p < .0001$). Only the last phase, characterized by TRT stability, was longer in the trained runners group ($p < .05$). Specifically, this phase presented higher probabilities of TRT-E (pace monitoring) and TRT-I (feelings and affects) in both tests ($p < .05$). **Discussion** The results confirm the effort phases proposed by the nonlinear model of attention focus in trained runners. The higher probabilities of TRT in this group seem related to their capacity to prolong the last TRT stable phase, with increased thought contents related to pace monitoring, feelings, and affects. Cooperation with the stable TRT close to exhaustion might be an efficient coping strategy developed by runners. **References** Balagué, N., Hristovski, R., Aragonés, D. & Tenenbaum, G. (2012). *Psychology of Sport and Exercise*, 13, 5, 691-697.

NORMOXIC HYPOXIC TRAINING PROMOTES THE COGNITIVE PERFORMANCE OF OLDER PEOPLE

Törpel, A., Peter, B., Hamacher, D., Schega, L.

Otto von Guericke University Magdeburg

Introduction Aerobic physical activity has positive effects on cognitive performance as it increases the release of brain-derived neurotrophic factor (BDNF) which promotes synaptic plasticity and neurogenesis (Loprinzi et al., 2013). As similar effects can be reached by intermittent hypoxic training (IHT) (Wang et al., 2006), IHT has also the potential to improve cognitive functioning (Schega et al., 2013). Whether a combined treatment (IHT and aerobic physical training) leads to increased intervention effects is not yet evaluated. Therefore, the aim of this study is to examine the impact of a combined treatment on cognitive functions in elderly people. **Methods** In a randomized controlled trial, thirty-three elderly physically inactive people (60 to 70 years) were randomly assigned to an intervention group (IG) or control group (CG). While the IG received a normobaric IHT, the CG was supplied with a placebo air mixture prior to a similar aerobic training programme on bicycle ergometers (4 weeks, 3 times/week). Using the color-word-interference test (Stroop), executive functions (e. g. selective attention and information processing speed) as a part of cognitive performance was determined before, after and in a follow-up-test three weeks after the intervention. Time differences were examined using repeated measures t-tests. **Results** Contrary to the CG, the IG improved their performance from pre- to post-test ($p=.039$) and from pre- to follow-up-test ($p=.001$) as measured by the color-task. Although, we found in both groups significant differences in the color-word-task from pre- to post-test (IG: $p=.001$; CG: $p=.002$) and from pre- to follow-up-test (IG: $p=.000$; CG: $p=.007$), only the IG ($p=.000$) was able to enhance their performance from post- to follow-up-test. **Discussion** The data indicates that an IHT added to aerobic training augments positive effects on executive functions. It can be speculated that the improvement in the IG and partially the CG is mediated by neuronal adaptations through BDNF expression since BDNF induced newborn neurons get their full operational capability after a latency of three weeks, which explains higher cognitive performance after the four week intervention. In line with this, the authors assume that the hypoxic exposure has a certain sustainable effect on cognitive performance caused by the improvement of the IG in the follow-up-test. Further investigations should examine whether IHT has the potential to decline cognitive impairments (e. g. dementia) caused by neurogenesis. **References** Loprinzi PD, Herold SM, Cardinal BJ, Noakes TD. MEASURING SKILL IN RUGBY UNION AS PART OF THE STANDARD TEAM TESTING BATTERY

Hendricks, S., Lambert, M., Durandt, J.

University of Cape Town

Coaches, strength and conditioning coaches, and researchers typically use a standard testing battery as a screening tool to measure physical characteristics of players. The information from this testing battery is subsequently utilized to check whether a player can meet the demands of the sport, talent identification, long-term player development, squad/team selection and/or for designing training programs. Apart from these physical attributes, rugby players also need to efficiently execute a range of technical and tactical skills during a match. Attempts to assess skill in rugby union have been reported, however, little has been documented on assessing skill as part of a team testing battery. This review highlights the use of, and requirements of, a skill assessment that can be used in a team setting. Strength and limitations of current skill assessments in Rugby Union and Rugby League, such as the assessment battery of Spamer and colleagues, and skill assessments of Gabbett et al., are outlined and discussed. Before an assessment for rugby union skills can be addressed, it should be acknowledged that executing a skill within a rugby match situation is complex and demands physical ability, technical efficiency, and tactical awareness. With this mind, attempting to capture the full demand set for executing a skill within a rugby union match remains difficult. The importance of measuring skill for rugby is numerous, and range from talent identification, to team selection, to designing drills to improve players' skills. When devising an appropriate skill assessment, a number of factors such as validi-

ty, reliability, logistics, player safety, ecological validity, representative etc. need to be considered. For the usability of the assessment, the skill assessment should ideally form part of a team testing battery, having the capability to test a squad of players efficiently and accurately. Also, even though capturing the full demand set of executing a skill within a rugby match in a single test may be logistically challenging, the assessment should have a level of ecological validity and representative of some of the demands of the skill in match. MO-PM57 TT Body Composition

USING LOWER LIMBS VOLUMES ASSESSED BY DUAL ENERGY X-RAY ABSORPTIOMETRY AS SIZE DESCRIPTOR IN ALLOMETRIC MODELLING OF PEAK OXYGEN UPTAKE IN ADOLESCENT MALE SOCCER PLAYERS AGED 13-15 YEARS

Coelho e Silva, M., Valente dos Santos, J., Seabra, A., Tavares, O., Rebelo, A., Brito, J., Sherar, L.B., Elferink Gemser, M.T., Malina, R.M.

University of Coimbra

Peak oxygen uptake is routinely scaled as mL per kg of body mass (BM). However, lean body mass (LBM) and lower limbs volumes (total and lean) are also associated with peak oxygen uptake. This study was aimed to examine the contribution of pubertal status, stature, BM, LBM, total lower limbs mass (TLLM), lean lower limbs mass (LLM), and training experience to inter-individual variability in $\dot{V}O_{2peak}$ in adolescent soccer players. Total body and segmental (lower limbs) composition were obtained with DXA in 31 male pubertal players aged 13-15 years. Participants were assessed in pubic hair development (PH3: n=8; PH4: n=23). An incremental maximal exercise test on a motorized treadmill was adopted to assess oxygen uptake. Allometric models were used to obtain scaling exponents for each size descriptors. Subsequently, multiplicative allometric modelling was explored to incorporate descriptors combined with chronovariables (age, maturation, years of training). Exponents for body size descriptors varied according to size descriptors: $k = 2.03$ for stature, $k = 0.86$ for body mass, $k = 0.96$ for lean body mass, $k = 0.74$ for TLLM, $k = 0.70$ for LLM (R^2 ranged from 19% to 51%). The combination of body descriptors and pubertal status marginally increased the explained variance for two indicators: TLLM and LLM (adjusted $R^2 = 41\%$). Years of training and age were not significant predictors in multiplicative allometric models. Variation in scaling exponents during pubertal years is considerable for different size descriptors. LBM explained most of the inter-individual variability in peak oxygen uptake among youth soccer players. Appendicular descriptors when combined with pubertal status explain more inter-individual variance compared to allometric models uniquely derived from respective size descriptors.

NATIONAL FOOTBALL LEAGUE VS ITALIAN FOOTBALL LEAGUE : COMPARISON OF BODY SIZE/COMPOSITION AND PERFORMANCE CHARACTERISTICS

Vitale, J., Roveda, E., Montaruli, A., Carandente, F., La Torre, A.

University of Milan

INTRODUCTION NFL and IFL are top leagues for American football, respectively in the U.S.A and Italy. Competing in the NFL requires exceptional skills and physical abilities, for this reason recruits that join the NFL draft have to perform the NFL Combines; physical attributes are examined by 6 tests: 40-yard dash, 225-lb bench press, vertical jump, broad jump, pro-agility shuttle test and the 3-cone drill. Combines are not only performed by recruits but also by the 32 professional teams (Mcgee KJ & Burkett LN, 2003; Sierer SP et al, 2008). The aim of this study is to evaluate the differences between American football players of NFL and IFL in height, weight, body composition and in Combine performance measures to better understand what is the gap between the two leagues. METHODS 55 Italian football players of Rhinos AFT of Milan were recruited for this study to evaluate the anthropometric measures, the body composition with impedenziometry (Tanita BCM) and the athletic level by using the 6 physical tests of the NFL Combines. For the analysis of the athletic tests we grouped the players into 3 groups: Skill players (SP): Wide Receivers (WR), Defensive Backs (DB) and Running Backs (RB). Big Skill players (BSP): Linebackers (LB), Tight Ends (TE) and Defensive Ends (DE). Lineman (LM): Offensive Lineman (OL) and Defensive Lineman (DL). RESULTS Body composition: among Rhinos AFT players, we observed, as expected, that OL, DL and TE had higher height, weight, BMI and fat mass if compared to the other players ($p < 0.05$). Italian players, for all the positions, had lower height, weight, BMI ($p < 0.05$) and fat-free mass (Cohen's $d = 1.31$) in relation to the NFL players, only the body fat was higher ($M = 19.75$, $SD = 6.3$ vs $M = 13.56$, $SD = 6.04$; Cohen's $d = 1.003$). Combines results: Statistical significance was found between Italian and American football players for all 6 physical tests in SP, BSP and LM groups: NFL players always scored higher results than IFL players ($p < 0.001$). DISCUSSION NFL players are taller, heavier, less fat, faster, stronger and more agile than Rhinos AFT. Using these results could be the key to better understand that the gap between the two leagues is huge, Italian football has to be addressed toward a greater professionalism. IMPLEMENTING A COMBINED PHYSICAL ACTIVITY/LOW CALORIC DIET DAILY REGIMEN FOR OBESE PEOPLE

Panayotov, V.

National Sports Academy of Bulgaria

Introduction The rate of obesity among people in many countries escalated in recent years. A lot of different methodologies were implemented to address this problem. In this study we tried to evaluate the impact of a daily schedule, consisting of physical activity of anaerobic-lactic type (duration of 20-30 sec), combined with an energy deficient diet on body composition, weight and WHO Quality of Life Index.

Methods The participants were 40 healthy adults of both sexes with Body Mass Index (BMI) values above 27. They were randomly assigned to 3 groups – the subjects in the first (experimental) one underwent an energy deficient (30% below the theoretically estimated balance) diet using food substitutes for 3 of their daily meals. The second (experimental) group participants achieved the energy deficit adhering to a diet consisting of conventional food sources. The rest of the subjects were treated as controls and no dietary restrictions were imposed on them. All participants performed 30 min. circuit training sessions of resistance exercises 3 times a week. The study was 8 weeks long. The differences between the initial and the final values of BMI, body mass, percentage of the fat tissue and WHO Quality of Life Index were compared. **Results** The observed differences between the initial and the final values of the studied variables were statistically significant ($p < 0.05$) only for experimental groups (except for the percentage of the fat tissue in group 2) with bigger values for group 1. **Discussion** There is evidence that a diet with food substitutes is superior to a conventional diet for losing body weight and fat tissue. Using an anaerobic-lactic type of physical activity during a weight-loss process favors positive changes in body composition. In our opinion physical activity alone is insufficient factor for achieving weight loss. **References** Brill JB, Perry AC, Parker L, et al. ASSESSMENT OF PHYSICAL PERFORMANCE ALTERATION DUE TO PRE-SEASONAL TRAINING IN ELITE FOOTBALL LEAGUE PLAYERS

Michaelides, M., Koulla, P.
UCLAN Cyprus

Introduction During the pre-season soccer training period, repetitively strenuous training programs are enforced. This study examined the effect of pre-seasonal physical training preparation on body composition and aerobic performance in a selected group of elite soccer players. **Methods** Fifty eight male elite professional soccer players (mean age (SD) of 27 (4) years, mean height 180.7 (5.2) cm) underwent anthropometric measurements (using bioelectrical impedance for body fat % determination) and then performed cardiopulmonary exercise testing (CPET) (using the modified Heck protocol) (Santos-Silva et al 2007) during which various aerobic and anaerobic performance parameters were measured) e.g. $\dot{V}O_2$, $\dot{V}VO_2$, run times, $\dot{V}LT$, speed at respiratory compensation point ($\dot{V}RCP$), HR max etc. All tests were performed immediately before the onset of the pre-seasonal training and they were repeated upon completion of the 8-week training period, just before the beginning of the competitive football league season. **Results** Results were analyzed using paired- t tests. Participant athletes who followed pre-seasonal training demonstrated significant decreases in body weight by 2.1% ($t(48) = 2.33$ $p < 0.05$), and body fat percentage by 9.91% ($t(47) = 4.32$ $p < 0.001$). Pre-seasonal training also resulted in increased run times of 10.18% ($t(42) = -9.86$, $p < 0.001$), increased $\dot{V}O_2$ max of 4.7% ($t(40) = -6.32$, $p < 0.001$), increased $\dot{V}VO_2$ max of 5.29% ($t(42) = -6.01$, $p < 0.001$), increased $\dot{V}LT$ by 9.33% ($t(42) = -3.01$, $p < 0.05$) and increased running speed at respiratory compensation point ($\dot{V}RCP$) of 9.33% ($t(14) = -5.14$, $p < 0.001$). **Discussion** Physical training of football league athletes was previously demonstrated to have minimal effects during the competitive season period (Kalapotharakos et al., 2011). This study shows that pre-seasonal training improves significantly both body composition through reduced fat deposition and physical performance variables defined by standardized CPET testing. Based on presented results, pre-seasonal training can prove beneficial for elite soccer player performance since it significantly enhances physiological responses. Additionally, it provides training coaches with normalized performance indicators that could potentially serve as determinants of off-season training performance assessment, allowing training program adjustments at the team and player-levels. The performance assessment may allow coaches to selectively recruit new players that meet the physical fitness level in addition to their skill levels. **References** Kalapotharakos V, Ziogas G, Tokmakidis P. (2011). *J Strength Cond Res*, 6, 1502-7. Santos-Silva P, Fonseca A, Castro A, Greve J, Hernandez A. (2007) *Clinics (Sao Paulo)*, 4, 391-6. Contact marcos_uark@hotmail.com

PHYSICAL AND PHYSIOLOGICAL CHARACTERISTICS IN CHILDREN INVOLVING VOLLEYBALL TRAINING

Karanastasis, G., Gortsila, E., Dellis, D., Tampaki, M.
National & Kapodistrian University of Athens

Introduction Volleyball is a power sport which includes sudden shifts, fast movements and jumpings. Quick actions, speed, different jumping abilities, high power and strength are important and necessary skills (condition factors) in volleyball. The aim of this study was to record the anthropometric profile and to consider the physical skills in pre-pubertal children. **Methods** Two hundred volleyball players (105 boys and 95 girls, age: 10-12 yrs) participated in this study. Measurements of anthropometric characteristics (body mass, body height, four skinfold thicknesses) were conducted. Participants performed vertical jump in Tandem Sport Vertical Challenger Jump Tester, where the best jump of two attempts was recorded. Speed test of 20m was counted by Sprint Timing System and the best sprint of two attempts was recorded. Peak (PPO) and average power (MPO) were calculated according to formula of Harman. Results are presented as mean \pm SE. **Results** Mean body mass was 39.4 ± 6.2 kg, body height 148.6 ± 6.5 cm, body mass index 17.9 ± 2.1 kg/m². The mean of skinfold thicknesses were: biceps 5.9 ± 2.2 mm, triceps 9.9 ± 3.6 mm, subscapular 7.6 ± 3.2 mm, suprailiac 7.1 ± 3.8 mm. Body fat percentage calculated from Siri equation was 16.5 ± 0.3 . Performance in 20m speed test was 3.9 ± 0.5 sec and in vertical jump was 27.4 ± 7.2 cm. PPO and MPO were 3120.7 ± 455.1 Watts and 1487.7 ± 185.4 Watts, respectively. **Discussion** Every athlete has to own unique skill sets and performance characteristics to prevail. Modern volleyball is a sport that requires a well-balanced combination of physical abilities and technical skills to determine the level of performance (Lidor et al., 2007; Melrose et al., 2007) which developed from childhood. The results indicate that after 2 years of volleyball training children could jump higher than other population at the same age, which have been trained 16 weeks (27.4 vs. 24 cm) (Gortsila, 2013). Moreover the BMI and body fat percentage was lower than BMI and mean body fat of children that they don't make exercise (Lohman et al., 2013). **References** Gortsila E. (2013). Unpublished thesis. VALIDITY OF ADULT STATURE PREDICTION, AND PERCENTAGE OF ADULT STATURE ESTIMATION, USING KHAMIS AND ROCHE METHOD, IN A SAMPLE OF PORTUGUESE CHILDREN AND ADOLESCENTS OF BOTH SEXES.

Fragoso, I.I., Teles, J.I., Albuquerque, J.I., Barrigas, C.I., Massuca, L.2

1: FMH-UL (Lisbon, Portugal); 2: ULHT (Lisbon, Portugal)

Introduction Maturity and adult body size estimates are considered to be of great significance in youth sports talent selection models. The purpose of this study was to validate a non-invasive method of predicting adult stature (PAS) and percentage of predict adult stature (PPAS), using TW3 skeletal age (SA) as a reference. **Methods** A sample of 200 boys and 171 girls, between 11 and 15 years of age, was assessed. PAS and PPAS were estimated based on the equations proposed by Khamis and Roche (1994). Maturity reference measures were: skeletal age (SA) done according to TW3-Method and physical maturity (PM) calculated by the formula: $PPAS = PS/PAS \times 100$, predicted through skeletal age (Tanner et al., 2001). Intraclass correlation coefficient (ICC), ANOVA and correlation analysis were performed dividing the sample according to maturity status: average, late and early maturing (SA-CA). **Results** A mean ICC of 0.80 (0.75-0.85) and 0.85 (0.79-0.89), concerning predicted mature stature, and of 0.91 (0.88-0.94) and 0.94 (0.92-0.95), regarding achieved PPAS, was obtained, for boys and girls respectively, considering the two methods. Significant main effect of maturity status was found ($F=68.828$; $p<0.001$), on the differences between SA and Khamis and Roche method. **Discussion** The higher ICC regarding percentage of mature stature suggests that the model is more adequate to define maturity status, than to predict actual mature stature. The significant main effect of maturity status shows that the Khamis and Roche method seems to underestimate PAS in late maturing subjects, and overestimate PAS in early maturing subjects as described by Malina et al. (2012). **References** Khamis HJ, Roche AF (1994). Predicting adult stature without using skeletal age: the Khamis-Roche method. *Pediatrics*. 94(4):504-507. IMPACT OF A REGIMEN CONSISTING OF PHYSICAL ACTIVITY AND ENERGY DEFICIENT DIET ON CARDIOVASCULAR FITNESS AND BLOOD CHOLESTEROL AND GLUCOSE CONCENTRATIONS IN OBESE PEOPLE

Petkov, K.

National Sports Academy of Bulgaria

Introduction The rate of obesity among people in many countries escalated in recent years. In this study we tried to evaluate the impact of a daily schedule, consisting of physical activity of anaerobic-lactic type (duration of 20-30 sec), combined with an energy deficient diet on the cardiovascular disease risk factors in obese people. **Methods** The participants were 40 healthy adults of both sexes with Body Mass Index (BMI) values above 27. They were randomly assigned to 3 groups – the subjects in the 1st one underwent an energy deficient (30% below the theoretically estimated balance) diet using food substitutes for 3 of their daily meals. The 2nd group participants achieved the same energy deficit adhering to a diet consisting of conventional food sources. The rest of the subjects had no dietary restrictions imposed on them. All participants performed 30 min. circuit training sessions of resistance exercises 3 times a week. The study was 8 weeks long. We measured the following variables twice – once in the beginning and once at the end of the experiment: 1. Glu; 2. CH; 3. HDL; 4. LDL; 5. TG; 6. VO2max. **Results** We found no statistically significant differences ($p \leq 0.05$) in the blood serum variables for the participants as a whole and within groups. The differences in the VO2max values were significant for the whole group of subjects, but not within groups. **Discussion** We found no evidence of any favorable effects of a daily regimen consisting of anaerobic-lactic type of physical exercises and low calorie diet on the serum levels of cholesterol and glucose, but there are some on the cardiovascular fitness. When interpreting the results one must consider two facts (important in our opinion): 1. The relatively low number of the subjects and 2. the duration of the study, which was only 8 weeks. It is possible that such a methodology has to be applied for longer periods of time for the achievement of significant results. **References** van Aggel-Leijssen DP, Saris WH, Wagenmakers AJ, et al. RELATIONSHIP BETWEEN ANTROPOMETRY AND PHYSICAL PERFORMANCE IN TURKISH ADOLESCENTS

Yilmaz, A., Gürses, V.V., Temeltaş, O., Şahin, N., Ersöz, G.

Basket University, Ankara University

Introduction Several authors have already discussed the importance of anthropometric variable in youth (Lidor et al., 2005; Matthys et al., 2011; Mohamed et al., 2009; Ziv & Lidor, 2009). Such factors as maturation, heredity, physical activity and environment may effects physical performance, especially for youth (Ernst et al., 2006; Pangrazi & Corbin, 2008). In addition, for younger players, their coaches, parents, and trainers, developmentally related changes in performance and physical characteristics are important to be aware of (Nakata et al., 2013) **Methods** Nine hundred and fifty seven boys participated in this study voluntarily (Mage: 12.06 ± 0.27 yrs, Mheight: 164.88 ± 9.82 cm, MBW: 56.78 ± 12.88 kg, Mfat: 20.7 ± 3.40 %). The following anthropometric measurements were taken using standardised protocols (Lohman, Roche, & Martorell, 1988): height (0.1 cm, Seca 707, UK), sitting height (0.1 cm, Seca 707, UK), body mass (0.1 kg) and body fat percentage (0.1%) with a total body composition analyser (TANITA SC-330, Japan) Arm span and leg length (0.1 cm) was assessed with a measuring tape. The physical performance measures consisted of specific tests assessing strength, speed and agility. To assess strength, players performed three single counter movement jumps (CMJ) with arm swing (Newtest power timer 3000, Finland). Participants performed two maximal sprints of 20 m (0.001 s) with a split time at 10 m. For the proagility shuttle run, the subjects started on a centerline facing the researcher. The subjects sprinted 4.55 m to the left, then 9.1 m to the right, and finally 4.55 m back to finish as they crossed the centerline. **Results** Pearson Product Moment Correlation analysis indicated significant correlations between BMI and CMJ ($r = -.203$; $p = .000$), long jump ($r = -.221$; $p = .000$), 20m sprint ($r = .214$; $p = .000$), and proagility performance ($r = .163$; $p = .000$). In addition Sitting height was significantly correlated with CMJ ($r = .287$; $p = .000$), long jump ($r = .173$; $p = .000$), 20m Sprint ($r = -.242$; $p = .000$) and proagility ($r = -.225$; $p = .000$). No significant correlation was observed between body weight and counter-movement jumps and 20m sprint performance and proagility ($p > .05$). **Discussion** As a conclusion it can be said that BMI and sitting height highly related with CMJ, long jump, 20m sprint and

proagility, however body weight and leg length is not related with physical performance parameters in Turkish adolescent. References Nakata, H, Nagami, T, Higuchi, T, Sakamoto, K, and Kanosue, K. SLEEP BENEFITS ADAPTATION OF A GROSS-MOTOR SKILL

Birklbauer, J.1, Eibenberger, P.1, Schabus, M.2, Mueller, E.1, Hoedlmoser, K.2

1: Dept Sport Sci & Kin (Salzburg, Austria), 2: Sleep, Cog & Conscious Res Lab (Salzburg, Austria)

Introduction Among the multiple functions of sleep, a growing body of evidence suggests an important role of sleep in memory consolidation of declarative, emotional and procedural knowledge (Diekelmann and Born, 2010). In contrast to fine-motor tasks, corresponding data on gross-motor skills are mostly neglected despite their importance in sports and every day life and against the background that principles derived from simple skills do not always generalize to gross-motor learning (Wulf and Shea, 2002). **Methods** 12 healthy male subjects were tested in a between-subjects design. All subjects underwent a 2h exploratory practice session in order to learn to ride an inverse steering bike. Half the subjects practiced in the evening and were tested immediately after training, after 8h of overnight sleep and in the evening following diurnal wakefulness. The other half trained and performed a test in the morning as well as tests after 8h of wakefulness and after 8h of nocturnal sleep. Gross-motor performance was quantified by steering angle and riding time for 5x30m with the inverse bike. A 16-channel ambulant EEG system was used for polysomnography records during sleep adaptation and experimental nights. **Results** Sleep in comparison to wakefulness was found to support consolidation in both retention intervals. In the first, steering accuracy and riding time of awake subjects decreased by 25.9% and 28.9%, while sleep substantially retained the performance with a marginal decrease of 6.2% and 5.1% (Cohen's $d(\text{time} \times \text{group}) > 0.87$). Similar trends were found for the second interval where sleepers again showed better retention in both performance variables than awake subjects (Cohen's $d(\text{time} \times \text{group}) > 0.40$). The functional role of sleep during retention is also affirmed by a robust relationship between fast (13-15 Hz) sleep spindle intensity and performance changes over night. Higher spindle intensity (C4, F4) was found to better preserve riding accuracy ($r(6) = 0.83$) and riding time ($r(6) = -0.67$) during the night right after training as well as during the night after an 8h interval of wakefulness ($r(6) = 0.51$ and $r(6) = 0.80$). **Discussion** These findings provide preliminary evidence that a retention interval containing nocturnal sleep helps to maintain the adaptation of a real-life, routine gross-motor task. The link between sleep related consolidation and fast spindle activity is well in line with results regarding fine-motor learning. However, despite the medium to large effect sizes, power analysis predicts a doubling of the actual sample size to reach statistical verification. *This study was funded by the Austrian Science Fund. PARSIMONY PRINCIPLES IN ANTICIPATORY POSTURAL ADJUSTMENTS FOLLOWING LONG-TERM MOTOR TRAINING

Iodice, P., Cesinano, S., Pezzulo, G.

National Research Council Italy

Introduction Executing voluntary movements destabilizes posture; to prevent so, humans use an internal (forward) model to perform anticipatory postural adjustments (Massion 1992). The purpose of the study was investigating the development of anticipatory postural adjustment strategies during the acquisition of novel motor skills. **Methods** Twelve healthy subjects were trained for 4 months and exposed to external perturbations to their posture induced by a mechanical platform device. Electrical activity of specific neck and leg muscles (EMG) was recorded bilaterally. The EMG device (FREEMG 1000, BTS Bioengineering Corp. Brooklyn, NY, USA), startle-like acoustic stimulation (SAS) and platform movement signals were synchronized and recorded by a dedicated device. Data were analyzed off line, EMG signals for each muscle and each subject were integrated with time windows of testing phases (Epochs) and normalized to peak magnitude across all conditions (Mohapatra et al 2012) **Results** Pattern of muscles activity showed a significantly change after training, in onset of muscle activity ($p < 0.05$) and energetic cost of the task ($p < 0.05$). After long term training muscle activity was further delayed and the muscles become active only after perturbation and not at SAS; e.g. Tibialis anterior become active at 120 ± 15 ms followed by soleus (75 ± 12 ms), biceps femoris (61 ± 14 ms) after the perturbation. EMGs integrated data showed a decrease of muscular activity in all observed epochs: before SAS (300ms, $p < 0.001$), after SAS (300ms, $P < 0.01$), before perturbation (300 ms, $p < 0.01$) and after perturbation (300 ms, $p < 0.05$). A significantly reduction of muscle activity was documented in 2s after perturbation ($p < 0.05$). **Discussion** Our data show that long-term training produces a reduction of muscular activation and a more efficient posture control strategy, plausibly associated to a better capability to predict the perturbation onset (and thus to re-adapt just-in-time rather than far earlier). This result is consistent with neuronal data showing similar 'parsimony principles' in area M1 (Picard et al 2013). The development of new motor skills makes anticipatory postural adjustments more parsimonious. THE EFFECT OF A VARIABILITY TRAINING DEVICE ON PHYSIOLOGICAL PARAMETERS IN MALE RUNNERS BEFORE AND AFTER ACCOMMODATION

Haudum, A., Birklbauer, J., Müller, E.

University of Salzburg

Much attention in running research has focused on energy expenditure (EE) (Ferrauti et al., 2010). A range of experiments tried to improve running technique or coordination to optimizes EE (Saunders, et al., 2004). A different approach may be to increase variability and induce a search process for new, more efficient running patterns. Thereby, variability is a functional element in movement production that helps to self-organize behavior. Such alternative could be put into practice by applying rubber tubing (RT) constraints, which increase the de-

degrees of freedom and thus, the variability in reactive phenomena (Bernstein, 1967). Therefore, we investigated the effect of repeated RT running on selected physiological and metabolic variables during constant running speed in healthy male subjects before and following a 7-week intervention (18 treadmill running sessions). In a between-subjects design 18 subjects underwent three tests of 30 min at constant speed of 10.5 km/h. Test 1 was conducted in the beginning with and without RT in both groups, followed by test 2 after 7 weeks, and again 7 weeks after the final test. The experimental group trained with the device while the control group trained without RT throughout 7 weeks and conducted the same constant running training sessions. Repeated measure analysis of variance revealed no significant difference for oxygen uptake minute ventilation, breathing frequency, tidal volume, caloric unit cost ($P > 0.05$). There were significant differences in blood lactate in test 1 to 2 for the experimental group while running with rubber tubes ($P < 0.05$). There was a significant reduction in blood lactate from test 1 to 2 for the experimental group while running with rubber tubes ($P < 0.006$) and for the control group while normal running ($P < 0.05$). There were no statistical differences found for either training condition after 7 weeks retention at test 3. Furthermore, no transfer effect of training on normal running was documented as result of the intervention. Despite the beneficial effects of the RT running intervention on lactate, it is argued that the variable training intervention did not result in a measureable improvement. The implication to arise from these results is that if there are relevant effects the intervention must be longer than 7 weeks to observe changes in physiological parameters in the long run. THE GENETIC POLYMORPHISM OF A DOPAMINERGIC ENZYME AFFECTS MOTOR SKILL AUTOMATIZATION

Krause, D.1, Agethen, M.1, Beck, F.2, Blischke, K.3

1: University of Paderborn (Paderborn, Germany), 2: TUM (Munich, Germany), 3: Saarland University (Saarbrücken, Germany)

Introduction Depending on genotype the enzyme catechol-O-methyltransferase (COMT) affects resorption of dopamine in the synaptic clefts. There are 3 genotypes differing in the number of met-alleles (val/val, val/met and met/met) which is positively correlated to enzymatic activity and therefore influences prefrontal dopamine level as well as executive functions (Witte & Flöel, 2012). Coherences with the development of motor representations are currently discussed (Witte et al., 2012). In a post-hoc analysis, we examined if development of motor skill automaticity (indicated by dual-task cost reduction) is correlated with the number of met-alleles in the COMT-genotype. **Methods** The post-hoc analysis included 22 participants from different original experimental groups. A DNA-analysis enabled to identify the COMT-genotypes. All subjects practiced an elbow-extension-flexion-sequence with 3 movement reversals. Practice settings differed with respect to terminal feedback on angular precision provided for each of the 3 movement reversals: 100% feedback frequency ($n = 6$); 100% feedback frequency with a 10 degree-bandwidth ($n = 6$); 50% feedback frequency ($n = 5$); dual-task practice with a 50% feedback frequency ($n = 5$). During pre- and retention test the motor task and an attention-demanding visual-spatial Sternberg task were executed under single- and dual-task conditions. For each subject, an individual effect size (iES; standardized mean difference) for dual-task cost reduction (errors in the Sternberg task) was determined as a measure of automatization. In consideration of the different practice conditions these iES were relativized to the effect size of the respective experimental group (relativized iES). **Results** The number of COMT-genotype met-alleles is positively correlated with the relativized iES, r (Spearman) = .553; $p = .004$. **Discussion** The data indicates that the COMT-genotype affects motor skill automatization. We assume that higher prefrontal dopamine levels in the met carriers promote rapid development of a cognitive (i.e. attention-dependent) movement representation. Subsequently, repeated execution on the basis of a stable attention-dependent representation might facilitate the formation of an attention-independent motor representation, which enables a more automatic mode of control. Furthermore, differential dopamine-dependent reward processing (Dreher et al., 2009) might also act as an additional underlying mechanism. **References** Dreher JC, Kohn P, Kolachana B, Weinberger DR, Berman KF (2009). *PNAS*, 106, 617-622. EVENT-RELATED EEG CHANGES DURING MOTOR ADAPTATION

Thürer, B.1, Stockinger, C.1, Focke, A.1, Putze, F.2, Schultz, T.2, Stein, T.1

Karlsruhe Institute of Technology

Introduction Several studies showed electrophysiological changes in the motor cortex due to movement execution (Neuper and Pfurtscheller, 2001). EEG signals influenced by motor adaptation are less investigated. Adaptation to a kinematic perturbation seems to result in a decrease of the Event-Related Desynchronization (ERD) over ipsilateral areas in gamma frequencies (Perfetti et al., 2011). Whether gamma ERD is also influenced by a dynamic adaptation task is unknown. Therefore, we examined changes in ERD of gamma oscillations due to reaching movements in a baseline measurement and while adapting to a novel force-field. **Methods** 24 right handed subjects performed 2d (point-to-point) reaching movements handling a robotic manipulandum. During this dynamic adaptation task we recorded both handtrajectories and EEG activity of 256 trials in a force-field adaptation paradigm. Performance was quantified by the enclosed area between the hand trajectory and the straight line from start to target. Electrophysiological data was corrected of ocular artefacts and then bandpass filtered between 35 and 45 Hz (gamma oscillations). We analyzed the Event-Related Desynchronization and Synchronization (ERD/ERS) for every subject, every condition (early, late adaptation) and every channel with the classical method (Pfurtscheller and Lopes da Silva, 1999). Epochs were divided into seven intervals each of 500ms (three intervals prior to the movement, four after movement offset). Time intervals of 31 baseline trials, 31 early adaptation trials and 31 late adaptation trials were statistically analyzed using ANOVA with repeated measurements. **Results** We found that motor adaptation is associated with decreased gamma oscillations after execution of movement. These changes were present at channels over the frontal and sensorimotor areas (Fz, FC1, FCz, FC2, Cz). No significant changes were found prior to the movement onset. **Discussion** Our findings indicate changes in the ERD/ERS of the gamma frequencies due to a force-field motor adaptation task. Our results are in line with the repetition suppression phenomenon (Fiebach et al, 2005). Recurrence of a movement task, regardless of kinematic or dynamic type, seems to occur in lower gamma oscillations over central and sensorimotor areas. Potentially, motor adaptation is not coded by gamma frequencies in EEG. **References** Fiebach CJ, Gruber T, Supp GG (2005). *J Neurosci*, 25(13): 3414-3422 Neuper C, Pfurtscheller G (2001). *Int J Psychophysiol*, 43(1): 41-58 Perfetti B, Moisello C, Landsness EC, Kvint S, Lanzafame S, Onofri M, Di Rocco A, Tononi G, Ghilardi F (2011). *J Neurosci*, 31(41): 14810-14819 Pfurtscheller G, Lopes da Silva FH (1999). *Clin Neurophysiol*, 110(11): 1842-1857 Contact benjamin.thuerer@kit.edu

ACUTE EFFECTS OF A NOVEL TREADMILL DEVICE ON GAIT AND POSTURAL CONTROL IN PERSONS WITH PARKINSON'S DISEASE

Bernhardt, S., Devan, S., Novokreshchenova, L., Steib, S., Pfeifer, K.

Friedrich-Alexander University of Erlangen-Nürnberg

Introduction Treadmill training has been shown to be effective in improving gait performance in persons with Parkinson's disease (PD) (Mehrholtz et al., 2010). Further, highly challenging balance exercises have been suggested to counteract postural instability (Allen et al., 2011). The purpose of this ongoing study is to examine the feasibility of a novel treadmill training device applying additional postural challenges during walking, and to investigate spontaneous adaptations to a single training session. **Methods** Twelve PD patients, aged 47 to 73 years (Hoehn and Yahr stage 1 – 3) were randomly assigned to a) training on the novel, oscillating treadmill device (OTT; n = 6) or b) conventional treadmill training (CTT; n = 6). After a 5 minute familiarization period on the treadmill, participants performed a single session of 15 minutes treadmill walking (three 5 minute blocks), either with the oscillating stimulus (OTT) or without (CTT). We assessed over-ground walking speed (10 meter), stride length and cadence with a treadmill-integrated pressure plate (FDM-T, zebris medical GmbH), and center of pressure sway velocity (vCOP) in quiet stance. Outcomes were measured prior to and 10 minutes after treadmill walking. A 2x2 ANOVA with one within- (time) and one between-subject factor (training protocol) was used to analyze differences between groups. **Results** Participants in both groups completed the training with no adverse events reported. The statistical analysis of this preliminary data revealed no significant main effects or interaction effect. Over-ground walking speed increased by 0.15 ± 0.38 km/h in the OTT-group and decreased -0.08 ± 0.39 km/h in CTT-group. Increased stride length (OTT 2.94 ± 5.65 cm; CTT 2.69 ± 3.87 cm) and reduced cadence (OTT -4.01 ± 6.89 steps/min; CTT -2.65 ± 3.76 steps/min) were present in both groups following treadmill walking. Additionally, vCOP decreased in both groups after the training (OTT -0.31 ± 1.45 cm/sec; CTT -0.78 ± 1.79 cm/sec). **Discussion** The novel treadmill training with an additional oscillating stimulus was well accepted by the participants. Thus, this intervention appears to be feasible in PD patients with early disease stages. Our preliminary data of acute effects suggest that patients might respond differently to OTT compared with CTT. **References** Allen NE, Sherrington C, Paul SS, Canning CG (2011). *Movement Disorders*, 26 (9), 1605-1615. INVESTIGATION OF DYNAMICAL SYSTEMS PHENOMENA IN DISCRETE ACTIONS EXEMPLIFIED BY A TABLE-TENNIS TASK

Wan Zakariah, W.R., Chow, J.Y., Rein, R.

Nanyang Technological University

Introduction Over the years, studies on human movement coordination and Dynamical Systems Theory (DST) have been criticized for its biasness towards cyclical movement. As few empirical studies exist, little is known about its theoretical implications to discrete action. Based on the study by Sorensen et al. (2001), the aim of this study is to investigate DST phenomena in a discrete action task. **Methods** Skilled participants (n=10) were required to return balls delivered by a feeding machine to nine locations back to a target under two conditions to examine the presence of attractors, hysteresis and critical slowing down. 3D kinematic data of the upper body was captured and digitised and results were obtained using the cluster analysis approach. A six point nominal scale was used to record performance. **Results** In both conditions, one way ANOVA indicated no significant differences between mean performance points and clusters. In condition 1, cluster analysis resulted 5 clusters. Kinematic data show clear differences between movement clusters; notably between cluster 3 (CL3) and the rest with respect to upper body rotation (z), elbow, wrist and bat flexion (x). CL3 was most utilised (56.1%) across participants with cluster 1 (38.3%), 2 (4.8%), 4 (1.6%) and 5 (1.2%) used interchangeably. The movement patterns did not vary across ball delivery location except at location 4 (CL1 at 61.6%) and 5 (CL3 at 81.6%) indicating a narrow hysteresis region. In condition 2, cluster analysis resulted 2 clusters, with a single cluster solution adopted by all participants at location 2 and 8. Mean Critical slowing down at location 4 and 5 are 2.15 trials and 1.27 trials respectively. **Discussion** The cluster solutions supported by kinematic data correspond to the attractor strokes in table-tennis with CL1, 2, 4 and 5 being variations of the forehand and CL3 the backhand. Previously hysteresis was limited to identifying the influence of an attractor. However, results show that it could also be used to suggest the performers' ability to adopt the most suitable task solution. Critical slowing down was previously suggested as an indicator of system instability, however in this study it could be suggested that if performance was unaffected despite evidence of cluster switches, critical slowing down may be an indicator of skill proficiency and may be used as a tool to dichotomise skill levels. **Reference** Sorensen, V., Ingvaldsen, R. P., & Whiting, H. T. A. (2001). The application of co-ordinative dynamics to the analysis of discrete movements using table-tennis as a paradigm skill. *Biological Cybernetics*, 85, 27-38. CHANGES IN ERROR VARIABILITY ACCORDING TO ACCURACY REQUIREMENTS. INTERPRETING THE ROLE OF INTENTION.

Urbán, T., Caballero, C., Barbado, D., Moreno, F.J.

Universidad Miguel Hernández

Introduction Despite intentionality being a central issue in voluntary human movement, the role of intentions in laboratory experiments have usually been ignored (Vollmer, 2001). Complexity science has emphasized the role of intentions as constraints on emergent behavior, requiring that cognition stays open to outside factors to promote intended goals (Van Orden, Kloos & Wallot, 2011). The aim of this study was to assess the role of intention modifying task accuracy requirements as a constraint on motor behavior, analyzing error fluctuation during a continuous pointing task. **Methods** Eleven participants (6 male; 5 female) were asked to perform two sets of pointing movements (24 cm. amplitude) with and without accuracy requirements. Movement pace was set in 1 Hz. Participants carried out 600 continued cycles for each situation. Movement kinematics was recorded by a Stylus sensor of the Polhemus Liberty. The X and Y coordinate values of the end point and the movement time of each cycle was treated as a time series. Sample entropy (SampEn), Permutation entropy (PE) and Detrended Fluctuation Analysis (DFA) were computed to analyze the variability structure of error time series. A repeated measures analysis was carried out to compare the two conditions. **Results** The results show significant differences in DFA of the X and Y axis time series data between the two conditions. DFA analysis showed lower autocorrelation with alpha values close to 0.5 when the task required being accurate towards a target, and values close to 1 when the movement was not constrained. Entropy analysis showed a significant increase of complexity both in X and Y axis when participants were required to adjust to a target. There were no differences in movement time. **Discussion and conclusions** The requirements in accuracy modify the structure of movement variability in a pointing

task. The intention to adjust to an external factor increased the complexity of the outcome. The results in DFA analysis showed departures from white noise on accuracy requirements towards pink noise on non-accuracy requirement. Despite previous studies having suggested an increase in alpha exponent associated with an increment of voluntary movement (see van Orden, et al 2011), our results agree with Kutznetsov & Wallot (2011) showing whiter behavior when participants were provided with accuracy feedback. The results can help to infer up to what extent individuals intend to perform accurate adjustments towards a target in precision tasks. References Van Orden, G. C., Kloos, H., & Wallot, S. (2011). INTERMITTENT PRACTICE AFFECTS ACQUISITION AND RETEST PERFORMANCE IN FORCE FIELD ADAPTATION TASKS

Stockinger, C.I, Focke, A.I, Thürrer, B.I, Potthast, W.2, Stein, T.I

1: KIT (Karlsruhe, Germany)

Introduction: It is widely accepted that the CNS plans movements using so-called internal models (neural representations of the physics of the body and environment) that allow predictive force generation (Kawato, 1999). Adaptability of internal models is often examined in force field studies. Thereby, subjects adapt their reaching movements to robot-induced force field perturbations. To unmask predictive force compensation by internal models, so-called catch trials (CTs) are commonly induced during practice (Thoroughman & Shadmehr, 2000). Hereby, the disturbing forces are randomly and without prior announcement turned off (usually 20% of trials) to detect aftereffects of adaptation. However, inducing CTs leads to intermittent practice schedules and thus to large sensed motor errors. As trial-to-trial motor adaptation was shown to be proportional to this motor error, it is widely accepted that CTs affect execution of immediately following movement trials (Thoroughman & Shadmehr, 2000). However, the influence of CTs on the overall motor adaptation process (i.e. ability to form an internal model) as well as on retest performance is far from clear. Thus, we examined the influence of intermittent practice schedules using various CT-ratios on motor adaptation of reaching movements. Methods: 105 subjects performed 2d center-out reaching movements at a robotic device that produced a viscous curl force field affecting subjects' hands. Subjects were randomly assigned to five groups, receiving CTs during adaptation with 0, 10, 20, 30, or 40% probability. In total, subjects performed 400 movements and were retested in the same force field 48h later. We quantified performance as perpendicular deviation of hand path from straight line. Results: With increasing CT-ratio, subjects' motor performance during adaptation decreased as indicated by significantly higher deviations in force field trials. In CTs, however, an increase of CT-ratio led to decreasing deviations (i.e. smaller aftereffects). At retest, performance did not differ between the four groups receiving catch trials, but the no-CT group (0%) performed better than the CT-groups. Discussion: Our results indicate that increasing intermittency induced by CTs impairs internal model formation and therewith accurate force field prediction. This leads to decreased motor performance and decreased aftereffects during acquisition phase. At retest, however, groups receiving catch trials exhibited similar performance level indicating partial compensation of impaired acquisition performance. However, this compensation was not sufficient to achieve retest performance of no-CT groups. References: Kawato, M (1999). Cur Opin Neurobiol, 9, 718-727. Thoroughman KA, Shadmehr R (2000). EFFECTS OF THREE SELECTED DIETS & EXERCISE PROGRAMS ON LIPID PROFILE AND SERUM LEPTIN LEVELS OF OBESE AND OVERWEIGHT WOMEN

Minasian, V.

University of Isfahan

Introduction Unfortunately, obesity as in other countries is also prevalent in Iran, and recent literature has reported that from 8998 subjects between the ages of 35-81, 25% were overweight and 28% obese, respectively (Bahrami H., 2006). The purpose of the present study was to evaluate the effects of 8-week selected exercise programs on the lipid profile and leptin of obese and overweight women. Methods A number of 45 obese or overweight teachers volunteered to participate in the study. Subjects were randomly grouped into the aerobic step exercises, endurance exercises with/without dieting groups. The average amount of calories needed to be reduced was also measured. The participants took part in 3 sessions/weeks of exercise for 8 weeks in a gym. We used factorial ANOVA statistic to analyze data ($\alpha=0.05$). Results The results showed that there were significant differences between cholesterol ($F_{2,39}=9.15, p=0.001$); LDL ($F_{2,39}=8.13, p=0.001$), and BMI ($F_{2,39}=2.18, p=0.047$) of three groups, but there were no significant differences between triglyceride ($F_{2,39}=2.041, p=0.144$); HDL ($F_{2,39}=0.496, p=0.613$) and leptin levels ($F_{2,39}=0.496, p=0.613$) of groups. Findings also revealed that there were significant differences between cholesterol, BMI and LDL of endurance with/without dieting groups, compared to aerobic step group. Discussion The results of study revealed that training protocols had significant effects on the cholesterol, LDL and BMI of subjects. Training protocols also led to serum leptin levels reduction, while its change was not significant. Lipid metabolism increases due to aerobic exercises, that may cause changes in lipid profile of subjects that were reported by other studies. The leptin levels were reduced, but this changes in leptin concentrations are concordant with previous observations, and are in conflict with other studies (Fleisch, 2007; Hsu YH, 2006). In endurance and dieting intervention groups, the leptin levels, BMI and lipid mass were lowered and the leptin level changes seem to be related to BMI variations. Previous studies stated that physical activities reduce the leptin levels not only because of the lipid mass reduction but also through increase in leptin sensitivity. Generally, it seems that more intensive exercises with higher volumes are needed to have more influence on the leptin level of the obese people, but the exact training intensities, volume and mode of training for every individual are not clear. INTRAMYOCYLLULAR TRIACYLGLYCEROL, ABDOMINAL FAT DEPOTS AND ENERGY EXPENDITURE: LARGE-SCALE MAGNETIC RESONANCE IMAGING STUDY

Gepner, Y., Shelef, I., Rein, M., Kenigsbuch, S., Schwarzfuchs, D., Bril, N., Serfaty, D., Cohen, N., Chassidim, Y., Golan, R., Rudich, A., Shai, I.

Ben Gurion University of the Negev

Background: Intramyocellular triacylglycerol (IMTG), the predominant storage of intramyocellular lipids, is utilized as metabolic fuel during physical exercise but is related to insulin resistance and abdominal fat among non-extremely active individuals. We aimed to address the relation of IMTG to the fat storage in the specific abdominal sub-adipose tissue and liver and with energy expenditure components. **Methods:** We used 3-T magnetic resonance imaging (MRI) to evaluate IMTG percent's using region of interest (ROI) method in the middle hip at four point, abdominal fat area square at L4-L5 level; [superficial subcutaneous adipose tissue (superficial-SAT), deep subcutaneous adipose tissue (deep-SAT) and visceral adipose tissue (VAT)], and hepatic fat percent (HFP), using ROI method. We performed indirect calorimeter measurements to evaluate resting energy expenditure (REE) and analyzed 6-day accelerometer parameters to calculate spontaneous (NEAT; 1-3 MET) and planned physical activity (PA; 4-8 MET). **Results:** Across the 282 sedentary participants [86% men, age=47.9±9.3years, body mass index (BMI)=30.6±3.9kg/m², waist circumference (WC)=106±10cm], women had higher IMTG than men (3.4% vs. 2.3%, p<0.001). Higher IMTG was directly associated with aging (r=0.18;p<0.01), WC (r=0.18;p<0.01), BMI (r=0.17;p<0.01), area of superficial-SAT (r=0.22;p<0.01), deep-SAT (r=0.16;p<0.01), and VAT (r=0.14;p<0.01), and was not likely to be associated with HFP (r=0.06;p=0.34). IMTG was inversely associated with REE/kg (r=-0.15,p=0.016), planned PA (r=-0.17,p=0.009) and spontaneous PA (r=-0.14,p=0.033). In sex and BMI- adjusted regression model deep-SAT (beta=0.19;p=0.032) and VAT (beta=0.18;p=0.008), but not superficial-SAT (beta=0.014;p=0.87), were independently and directly associated with increased IMTG (p<0.05). **Conclusions:** Accumulation of IMTG in sedentary participants is related to increased amount deep-SAT and VAT and to decreased energy expenditure components, but not to superficial-SAT and hepatic fat. These finding may contribute to clarify the underline pathophysiologic mechanism of IMGT. (ClinicalTrials.gov Identifier: NCT01530724)

EFFECTS OF GUARANA INGESTION ON EXERCISE LIPID METABOLISM AND ANTIOXIDANT POTENTIAL IN OVERWEIGHT MALES

Hsieh, S.S., Liu, Y.C., Liu, Y.H., Dong, X.Y., Yang, C.Y.

National Taiwan Normal University

Introduction Guarana (Paullinia cupana) from the Amazon region has long been used for ergogenic purposes (Salvadori et al., 1994). Previous studies have often combined guarana with other herbs (Boozer et al., 2001), thus the pure effect of guarana is not well understood. This study examined the effects of different doses of guarana on exercise lipid metabolism and oxidative stress in overweight males. **Methods** Using a counter-balanced crossover design, 12 overweight males (over 25% body fat) performed a 30-min treadmill exercise at 75% heart rate reserve after guarana ingestion, 1000 mg (low dose, Low), 2000 mg (high dose, High) or 1000 mg flour (control, Con). Blood samples were taken before exercise (Pre), immediate post (IP), 30 min post (P30), 60 min post (P60) and 24 hrs after (P24H) exercise. Blood samples were analyzed for glycerol, lipase activity, and anti-oxidant variables (thiobarbituric acid reactive substance, TBARS; superoxide dismutase, SOD; glutathione peroxidase, GPx; and catalase, CAT). **Results** The glycerol concentration of High at IP (186.9±43.6 µmol/L) was significantly higher than that of Low (165.9 ± 51.5 µmol/L) and Con (130.1 ± 22.9 µmol/L). At P30 and P60, the glycerol levels of High and Low were significantly higher than that of Con. The lipase activity of High at IP (81.3 ± 19.3 U/L) was significantly higher than that of Con (70.6 ± 17.1 U/L). At P30, lipase activity of Low and High was also significantly higher than that of Con. The TBARS of High at P30 (5.0 ± 2.2 µM) was significantly lower than that of Con (9.9 ± 3.2 µM). At P60, the TBARS of High was also significantly lower than that of Low and Con. At P24H, the TBARS of High and Low was significantly lower than that of Con. The High and Low CAT activity at IP was significantly higher than that of Con. Effects of guarana on SOD and GPx were not observed. **Discussion** Guarana ingestion resulted in increased lipid metabolism after exercise. This effect may due to the high caffeine and theophylline content in guarana, and can lead to weight loss for overweight individuals (Lima et al., 2005). The antioxidant effect of guarana is evident for overweight people, and habitual intake of guarana can also benefit the elderly due to antioxidant effects (Krewer et al., 2011). **References** Boozer CN, et al. COMPARATIVE EFFECTS OF EIGHT WEEKS OF AEROBIC EXERCISE AND VITAMIN E ON THE NON ALCOHOLIC FATTY LIVER DISEASE IN HIGH SCHOOL STUDENTS OF SHAHROOD

Younesian, A., Razavian Zadeh, N., Moradi, H.

Shahrood University, Azad University of Medical sciences

Purpose: The purpose of this study was to compare the effects of aerobic exercise and vitamin E on liver of non-alcoholics fatty liver disease in high school students of Shahrood. **Materials and Methods:** for this study BMI and WHR of 2028 boys of high school students were measured. BMI of more than 107 numbers were above 30 and their WHR was 0/9 t 44 of these subjects participated in this study. To evaluate the risk of having fatty liver administrated ultrasound and have been done blood tests for measuring liver enzymes (ALT and AST). Then for measuring their blood tests (AST / ALT / HDL / LDL / CHOL / TG / FBS) were sent to the laboratory. Average age if subjects was 15/7 years, and all of them have fatty liver and then randomly divided into 4 groups : 1; Aerobic training with diet, 2; Vitamin E and diet, 3; Aerobic exercise - Vitamin E and diet, 4; Diet group. Protocol of intervention for each group was defined for eight weeks. - 1 - Aerobic training group, aerobic exercise training 3 times a week, each session lasting 30 to 45 minutes running on the treadmill with intensity 60 to 75% of maximum heart rate, and diet equal with 1,800 -2,400 BMR calories per day, self-reported. 2- Vitamin E and diet: 400 mg daily oral intake of vitamin E and diet as group 1. 3- aerobic exercise and vitamin E with diet group, aerobic exercise like the first group and vitamin E intake at a dose of 400 mg daily. 4- Diet group, with BMR between 1800 to 2400 calories per day in self-reported. **Results:** The results of this research showed in the first group and within group comparison, variable of weight, BMI, WHR, TG, CHOL and liver fat were significant and in the variables of FBS, LDL, HDL, ALT and AST statistically were not significant. In variables of second group, WHR, TG, CHOL, ALT and liver fat accumulation was a significant reduction and decrease in weight factors, BMI, FBS, LDL, HDL, and AST statistically were not significant. And in the third group the differences between pre-test and post-test variables, weight, BMI, WHR, ALT and liver fat accumulation was significant and differences between variables of FBS, TG, CHOL, LDL, HDL, and AST were not

significant ($P < 0.05$). In the fourth group differences in variables and reduction of weight, BMI, CHOL, LDL and lipid accumulation in the liver observed and differences and reduction in variables of FBS, WHR, TG, HDL, ALT and AST were not seen. In comparison between-group were not significant differences between the groups showed except in reduction of the CHOL and HDL variables. Conclusion: This study showed that after 8 weeks of weight loss intervention improvement in liver enzyme levels, blood lipid levels, BMI, WHR, and liver fat accumulation occurs in all groups. But to achieve a therapeutic agents and strategies and assess how best to influence, non-alcoholics fatty liver disease need of further research and ways to prevent obesity at an early age and the intervention of urban life.

FAT OXIDATION DURING AND AFTER MODERATE- AND LOW- INTENSITY EXERCISE: FOCUSED ON THE INTENSITY OF MAXIMAL FAT OXIDATION

Tabata, H.1, Kim, H.K.1, Endo, N.2, Konishi, M.3, Sakamoto, S.3

1:Waseda University, 2:Japan Institute of Sports Sciences, 3:Waseda University

Introduction The exercise intensity which induces the highest rate of fat oxidation (Fatmax) is observed at low- to moderate- exercise intensity (Achten et al, 2002). Therefore, many guidelines for exercise prescription recommend moderate intensity for prevention and treatment of obesity. In contrast, moderate- to high- intensity exercise elicits an increase in fat oxidation following exercise (Warren et al, 2009). Thus, it is unclear which intensity induces more fat oxidation total of during and after exercise. The purpose of this study is to clarify ideal exercise intensity which elicits maximal fat oxidation. **Methods** Eight healthy men (mean \pm SD; age 21.4 ± 1.3 years, height 171.6 ± 6.1 cm, body weight 56.7 ± 8.5 kg, body fat $10.9 \pm 2.3\%$) participated in this study. Maximal oxygen uptake (VO₂max) and Fatmax were determined with indirect calorimetry using a graded exercise test on a treadmill. Energy expenditure and substrate oxidation rate during equicaloric low-intensity (Fatmax trial, 37%VO₂max for 53min) and moderate-intensity (65% trial, 65%VO₂max for 30min) exercises on a treadmill and during 2h post-exercise recovery period were determined with indirect calorimetry. Blood sample was taken pre and after immediately, 30, 60, 120 min of exercise to determine plasma free fatty acids and noradrenaline. **Results** The mean of VO₂max was 65.8 ± 6.5 ml/kg/min and Fatmax was observed at 37.3 ± 4.6 %VO₂max. Net fat oxidation during exercise in Fatmax trial was significantly greater than in 65% trial (Fatmax trial, 15.6 ± 5.1 g, 65% trial, 8.0 ± 3.4 g, $P < 0.01$). In contrast, there was no significant difference in the net fat oxidation during post-exercise recovery period (Fatmax trial, 7.8 ± 3.4 g, 65% trial, 8.7 ± 2.6 g). Noradrenaline and free fatty acids concentrations at immediately after exercise in 65% trial were significantly higher than at pre exercise. Additionally, noradrenaline concentration at immediately after exercise in 65% trial was significantly higher than in Fatmax trial. **Discussion** Net fat oxidation during exercise in Fatmax trial was more significantly than in 65% trial. 65% trial was higher lipolysis than Fatmax trial, whereas net fat oxidation was not significantly different in both trials during post-exercise recovery period. These findings suggest that Fatmax exercise oxidized more fat than 65%VO₂peak in matched for energy expenditure during and after exercise. **References** Achten J, Gleeson M, Jeukendrup AE. (2002), *Med Sci Sports Exerc*; 34 : 92-97. Warren A, Howden EJ, Williams AD, Fell JW, Johnson NA. (2009), *Int J Sport Nutr Exerc Metab*; 19 : 607-623.

EFFECTS OF REPETITIVE SHORT-TERM HYPOXIC TRAINING ON METABOLIC RISK FACTORS

Ogita, F.

National Institute of Fitness and Sports

Introduction Recently, several investigations have reported that moderate exercise under hypoxic conditions for around 1 month could improve more effectively risk markers of metabolic syndrome, such as glucose tolerance, body composition, blood pressure, serum lipid level, and so on (Lee 2006, Ogita 2010). However, it has not been clarified whether such beneficial effects can be also obtained by a repetition of relatively short-term hypoxic training. The present study aimed to examine the effects of repetitive short-term hypoxic training on metabolic risk markers. **Methods** Fourteen healthy male subjects (24 ± 3 yrs) were matched for baseline measurements into two groups, and then randomized to normoxic exercise group (N, n=8) and hypoxic exercise group (H, n=6). The subjects had a 30-min aquatic exercise at the intensity of 50%VO₂max level for consecutive 4 days, and repeated a series of the training following 2 weeks of detraining period. H had the exercise in hypobaric hypoxic conditions corresponding to 2500m above sea level, and was exposed to the hypoxic condition for 2 hours/session. Before and after the first and second 4 days training period, serum lipoproteins, body mass, preperitoneal fat thickness, and %body fat were measured. Also, 3-h oral glucose tolerance test (OGTT) was conducted. **Results** After a series of the training, no significant changes in all measured values were observed in N. On the other hand, in H, the calculated area under the curve of insulin concentration during OGTT decreased significantly after the first 4 days training ($P < 0.05$). Furthermore, after the second 4 days training, the area under the curve of both blood glucose and insulin concentrations during OGTT significantly decreased. Body mass, preperitoneal fat thickness, and %body fat also decreased significantly in H after the first 4 days training ($P < 0.05$), and those were kept throughout the experimental period. However, total cholesterol, triglyceride, low-density and high-density lipoprotein levels remained unchanged. **Discussion/Conclusion** These results suggest that the repetitive short-term (i.e. 4 days) hypoxic training with 2 weeks of detraining could bring more effectively a decrease in body mass with a reduction in body fat and an improvement of glucose tolerance, as well as long-term (i.e. 4 to 8 weeks) hypoxic training, when compared to the exercise in a normal condition. **Reference** Lee, W.-C., et al. ARE CAPE PENINSULA BABOONS RAIDING THEIR WAY TO OBESITY AND TYPE II DIABETES? A COMPARATIVE STUDY

Kohn, T.A., Leith, D., Van Velden, J., Lovette, J., Goyaram, V., Ojuka, E.O., Reed, C.

University of Cape Town

Introduction Over indulgence on a diet rich in processed carbohydrate and fat has been associated with obesity and type II diabetes (Katz, 2014). This highly palatable diet and its abundant availability have since been discovered by the chacma baboons (*Papio ursinus*) residing on the Cape Peninsula, mostly from direct contact with humans. However, nature conservation has since indicated that these animals appear overweight, are lethargic and present with ill health (hair and teeth loss) (Drewe et al., 2012). This study therefore aimed to provide evidence that these baboons may be at risk of developing insulin resistance. **Methods** Carcasses of ten adult male baboons from the Cape Peninsula (urban) and 6 from the rural countryside (no access to processed food) were donated towards this study. Body composition was determined using dual energy X-ray absorptiometry (DXA). Muscle samples from the vastus lateralis were analysed for insulin response substrate-1 (IRS-1) and citrate synthase (CS) activity (Kohn et al., 2007; Shao et al., 2002). **Results and Discussion** Urban

baboons were larger than the rural group, but similar total body fat % ($12 \pm 2\%$ for both). CS activity, a marker of oxidative capacity in muscle, was higher in rural baboons (urban vs. control: 4.2 ± 0.9 vs. 5.4 ± 0.9 $\mu\text{mol}/\text{min}/\text{g}$ wet weight, $P < 0.05$), indicating that urban baboons may have reduced physical activity. The content of IRS-1 (associated with insulin resistance) was lower in urban baboons compared to rural (1.0 ± 0.5 vs. 1.8 ± 0.2 a.u., $P < 0.01$), indicating that these baboons may present with a reduced insulin sensitivity. Our results complement the observations by the authorities that the urban group has a reduced physical activity (lethargic). Conclusion This study provides indirect evidence that baboons, frequently consuming a Western diet, are at risk of developing insulin resistance in the wild. References Drewe, J. A., O'Riain, M. EFFECTS OF CIRCADIAN RHYTHM AND ACUTE ENDURANCE EXERCISE ON BLOOD GLUCOSE AND SALIVARY CORTISOL

Ando, K.I, Kim, H.I, Konishi, M.2, Nishimaki, M.1, Tabata, H.1, Xiang, M.1, Sakamoto, S.2

Waseda University

Introduction Exercise therapy is effective for the treatment and prevention of diabetes. Endurance exercise has beneficial effects on insulin sensitivity via PPAR γ , C/EBP α . Biological response to exercise must have circadian rhythm because of the fact that materials related to the metabolism are under the involvement of clock genes. Although salivary cortisol and PPAR γ , C/EBP α are affected by clock-genes, effects of exercise performed in different timing on salivary cortisol, blood glucose, lactate, PPAR γ , C/EBP α are not clear. Considering more effective exercise therapy against diabetes, especially insulin sensitivity, it is important to investigate the impact of exercise timing. The purpose of this study was to examine whether the timing of exercise influences salivary cortisol and blood glucose, lactate in humans. Methods Seven healthy young men completed a graded exercise test to exhaustion on a treadmill, and are participating in three trials in a randomized cross-over design: (1) morning exercise trial (0900-1000) (2) evening exercise trial (1800-1900) (3) morning/evening control trials. At exercise trials, participants walked for 60 minutes at 60% of maximal oxygen uptake on a treadmill. We took samples before and immediately, 1h, and 2h after exercise/control trials to assess blood glucose and lactate, salivary cortisol, and other salivary related substances. Also, we measured expired gas during subject's trials. Before each trial we measure subject's heart rate variability and body temperature. All subjects answered the morningness-eveningness questionnaire and the Pittsburgh sleep quality index, profile of mood states. Results Subjects' average maximum oxygen uptakes per body weight were not significantly different between in the morning and evening. Only fat oxidation was significantly higher in the evening than in the morning. The additional data; salivary and blood samples, the results of questionnaire are now under analysis. Especially we focus on cortisol level, which is affected by circadian rhythm and exercise. Discussion Previous studies that investigated the effects of circadian rhythm on maximal oxygen uptake reported contradictory results. As for our data showed there was no significant difference between morning and evening trials except fat oxidation. It suggested that the effect of exercise on metabolism was influenced by the timing of exercise. The difference may be caused subject's body clock; circadian rhythm. References Mohebbi, H., et al. TEKO - SAFETY IN SCHOOL SPORTS PROJECT'S EVALUATION

Jussila, A., Oksanen, R., Parkkari, J.

UKK Institute for Health Promotion Research

Introduction The Sports and Exercise Safety program (2006-) aims to reduce sport injuries in Finland based on the model presented by van Mechelen in 1992. TEKO - Safety in School Sports is one of its implementation projects. The primary target group for TEKO is PE and health education teachers in secondary schools. TEKO implements national and international research findings and produces educational material and methods to the internet to encourage PA, to increase quality and contents of PE classes and to promote safety of sports and exercise widely in school settings. Safety promotion focuses on 10 segments; PA, sports skills, maturation, nutrition, rest and sleep, environment and equipment, health care, atmosphere and rules, sports injuries and support network. Methods TEKO has built up education material e.g. information packages, homeworks, posters, videos and PP-slides for teaching since 2010. Total investment to the project has been 150.000 euros per year. The main delivery channel has been website www.tervekoulu.fi. The materials have been available free of charge for all schools. TEKO has also provided further education and used various marketing procedures among teachers. Evaluation has been ongoing during the project. A web-based project evaluation survey was done in 2013 to PE and health education teachers ($n=900$). The response rate of the survey was 20% ($n=177$). Results After 4 years of project development the websites attracts 8000 visits per month and YouTube videos have been watched 30000 times. TEKO has kept over 40 education events and taken part to numerous international and national events. TEKO has also built up a large collaborator network, which enables the wide spreading of sports safety message. According to the survey 54% of the Finnish PE and health education teachers knew TEKO. Half of those estimated that the content they use in sports safety education has been expanded and the methods they use are now more diverse. Teachers who had used TEKO material at schools were pleased to it, mean grades (at the scale of 4-10) they gave were: expertise 9,0, exterior 8,7, feasibility 8,6 and suitability for the target group 8,3. TEKO projects evaluation findings using a RE-AIM framework (Glasgow et al. 1999) will be reported in 2014. Discussion The reach of teachers has been rather good with the used methods and financial investment per year. Modern technology is still rarely used in Finnish schools and the main delivery channel TEKO has chosen has received good feedback. The real effects of the TEKO project to the number and severity of sport injuries will be seen within 5 to 10 years. KNOWLEDGE OF AND DEALING WITH SWIMMING DURING MENSTRUATION –GIRL SWIMMERS AND COACHES-

Fujiwara, Y., Fujitsuka, C., Kimura, K., Yonetani, S.

Kawasaki university medical and welfare

Introduction: Swimming is an exercise that is popular among children regardless of gender. However, it is quite noticeable that Japanese girls in puberty avoid swimming classes at schools due to menstruation. At the swimming clubs has swimming lesson though one year unlike school swimming classes of the summer limitation. Girl swimmers have the opportunities they swim during menstruation. The purpose of this study was to get advice from girl swimmers at swimming clubs on how girls can have swimming lesson during menstruation. **Methods:** We created original questionnaires survey to 45 swimming clubs in A prefecture for girl swimmers who is higher than a fourth grader and coaches in 2008. The survey contained the following questions. For swimmers Q1: Characteristics of the swimmers Q2: Do you swim during menstruation? –Yes or No. Q3: How dealing with swimming during menstruation? Q4: A true-false test about swimming during menstruation. For example, it is not good for a body swimming during menstruation. For coaches Q1: What kind of advice about swimming during menstruation do you give swimmers? Q2: What kind of consultation about it did you have with swimmer and parents? Q3: A true-false test was the same as swimmers. **Results** (It shows on the result of the girls swimmers mainly): 86 girl swimmers and 17 swimming coaches completed the questionnaires. Q1; age was from 9 to 18 years old and average was 13.4±2.2years old. 70 percent of girl swimmers experiences menarche. 58.7percent of them felt physical change during menstruation. Q2: 82 percent of the girl swimmers swam during menstruation. Q3: 42 percent of the girl swimmers swam without sanitary protections. 23percent swam with tampon. Q4: As to the girl swimmers' knowledge of swimming during menstruation, it was almost on the same level as the one that non-swimmer girls have in general. **Discussion:** It suggests that the girl swimmers need to be offered further knowledge which is based on scientific facts, too. 42 percent of the girl swimmers swam without sanitary protections or other methods while other swimmers used tampons, which were shown to be effective as a practical solution to swim during menstruation. EMPIRICAL EVALUATION OF THE HEALTH PROMOTION PROGRAMME "HEALTHYPEP" IN PHYSICAL EDUCATION

Demetriou, Y., Höner, O.

University of Tübingen, Institute of Sports Science

Introduction Health promotion is one of the main targets of physical education, and further empirical evidence on the design, content, and effects of such programmes on students' health are needed (Demetriou & Höner, 2012). In this study, a process and an outcome evaluation were carried out to examine the effects of the eight-week Healthy Physical Education Programme "HealthyPEP" for sixth grade students in Germany. **Methods** Short- and middle-term (immediately after and 3 months after HealthyPEP) intervention effects were analysed using a quasi-experimental design examining 516 (IG: N=297, CG: N=219; 54.7% girls) students in the sixth grade. Students' data were assessed on three different levels (Demetriou, 2012): Health and fitness (motor performance, BMI, health-related quality of life), behaviour (physical activity), and psychological determinants of physical activity (motivation, attitudes, self-efficacy, and knowledge). To examine the degree of the programme implementation a process evaluation (lessons observations, interviews with the teachers, and student questioning) was carried out. Intervention effects were analysed separately for the two genders using ANCOVAs, wherein the initial values of the depended variable and BMI were used as a covariate. Additionally, Cohen's d effect sizes were provided. **Results** The results revealed significant positive intervention effects of HealthyPEP on BMI in both genders (girls: d=.38; boys: d=.14) and on girls' motor performance (d=.30). Positive tendencies were shown for girls' knowledge about (d=.43) and attitudes towards physical activity (d=.41) but negative intervention effects were measured on their self-efficacy (d=.47). In boys, negative intervention effects were revealed for their attitudes towards physical education (d=.58). These results were in line with the process evaluation, in which girls evaluated HealthyPEP to a more positive extent than boys. **Discussion** These results have shown that only few and small positive intervention effects could be observed. This is due to several reasons: First, the underlying theoretical models and the measurement instruments used must be improved and adjusted for use in children and adolescents. Second, the results revealed that gender-specific programmes are needed that also correspond to the needs of boys. Finally, it can be questioned whether programmes focusing on health promotion during physical education that are carried out only for a limited amount of time are in a position to lead to positive intervention effects. **References** Demetriou Y (2012). EFFECTIVENESS OF A HYDRATION EDUCATION PROGRAMME ON HYDRATION KNOWLEDGE AND BEHAVIOURS OF ADOLESCENT MALE FIELD HOCKEY PLAYERS

Chia, M., Huang, D., Mukherjee, S.

National Institute of Education

Introduction Singaporean youth athletes are at a higher risk of heat-associated ailments due to inadequate hydration knowledge and exposure to hot and humid weather all year round. To enhance sports safety, a hydration education programme was developed to imbue hydration knowledge and hydration practices among youth. The study examines the effectiveness of a 5-week "Hydration for Champions" education programme (HCEP). **Methods** Forty-one adolescent male hockey players (14.11±1.17 years, 51.86±12.61 kg, 1.63±0.09 m, BMI 19.40±3.40,) participated in the study. 22 boys were in the control group (NI) and 19 boys in the education intervention (EI). EI received a 5-week HCEP with 1-hr lecture, four 30-min weekly hydration tips, hydration ambassadors, hydration posters and banners, and customised personal water bottles and hydration message pins. Both groups completed a hydration quiz based upon ACSM and NATA guidelines (Casa et al. 2000; Sawka et al. 2007) to assess pre-post knowledge changes. Urine samples were collected in the morning and prior to exercise. Outdoor field (WGBT, DryBulb, RH: 26.6±0.4°C, 30.7±0.1°C, 65.7±4.2%) drinking behaviours were monitored. Weigh-in was conducted prior to training and immediately after, upon towelling down. The EI also completed a feedback survey of the HCEP programme. Paired-sample t-tests were used to evaluate pre-post changes and independent t-tests were used to evaluate differences between the EI and NI groups. Statistical significance was accepted as p<.05. **Results** Hydration knowledge in EI increased (Pre-post scorediff: NI=-1.29±8.37, p>.05; EI=7.43±4.86, p<.05). EI were better hydrated before exercise (UsgAM: NI=1.026±.007,

El=1.021±0.007; UsgPreEx: NI=1.023±0.006, El=1.018±0.008; $p<.05$) and maintained their body mass (Δ BM: NI=-1.23±0.67%, El=0.02±0.36%, $p<.05$). There was no difference in sweat rate (NI=1.22±0.36L/h, El=1.16±0.35L/h, $p>.05$). Drink rate was higher in El (NI=0.87±0.22L/h, El=1.18±0.29L/h, $p<.05$). El had replaced 102.63±15.25% of fluid lost compared to NI, which replaced 73.79±13.45% ($p<.05$). El rated weekly field tips (4.00±1.13) and providing personal water bottles and message pins (4.08±1.00) as the most effective components of HCEP. Others include hydration banners and posters (3.83±0.84), lecture (3.73±0.79), coaches' reminders (3.67±0.89), hydration ambassadors' reminders (3.25±1.22). Discussion The 5-week HCEP was effective in improving the hydration knowledge and behaviour of youth athletes. PE teachers and coaches can incorporate elements of the hydration education programme for their students. References Casa DJ, et al. (2000). *J Athl Train.* 35(2): 212-224. Sawka MN, et al. WHAT'S HEALTH FOR YOUTHS IN THE AGE OF FIFTEEN?

Ahlberg, A.

Malmö University

Introduction The aim of my study, in the outset of the school subject Physical education and health (PEH), is to analyse how pupils think about health, interpret the conception and what they think is relevant to get more knowledge regarding health. I also discuss teaching contents and pedagogy set-up regarding health with the pupils. Methods Aaron Antonovsky's salutogenic perspective on health and the sense of coherence, John Dewey's theory about individuality as well as Thomas Ziehe thoughts about 'cultural release' has inspired the methods I have used (Antonovsky, 2005; Dewey, 2009; Ziehe, 1986). To answer my questions I have used three steps of empirism founding my qualitative study: • focus group and questionnaire – 69 pupils, autumn 2012 • epistolary dialog – between me and 24 individual pupils via facebook/email, March-April 2013 • completeive questionnaire – 47 pupils, May 2013 Results So far my analyse have shown that when the pupils describe health, the three most frequently answers are: • physical health – to exercise so you manage to do what you like • to eat a balanced diet • psychological health – to be pleased with yourself Other answers are rest/recovery, being outdoor, look/feature and that too much alcohol, smoking and drugs has a negative impact on ones health. The pupils like to know how they can live a healthy life and how different aspects influences and affect each other. They also want to learn more about physical training and what constitute a healthy diet and how you prioritize your time if you like to get time for both homework, physical exercise, friends, food, leisure time and recovery. Discussion The results points out that the pupils as a group are aware of many aspects of health, they have an interest of this concept and they prefer teaching that integrate theory and practice. Putting all parts together is the tricky part, and something many of them like to learn more about. The study will be concluded in the autumn of 2014. THE PLAY ON THE FIELD—THE RELATION BETWEEN THE SUBJECT OF PHYSICAL EDUCATION AND HEALTH AND LEISURE TIME SPORTS

Londos, M.

Faculty of Education and Society

This study deals with physical education (PE) in upper secondary school. The purpose of the study is to analyze the relationship between PE in secondary schools and leisure time sports. Questions were directed towards discovering what PE teachers recognise as valuable in their teaching, and how physical education is related to factors that characterize the field of sports. The teaching practice of Physical Education and Health Course is described. Statements from interviews of sixteen PE teachers regarding educational objectives, content, rating and implementation serve as the empirical basis of this study. A cultural-sociological approach, inspired by Bourdieu, was used to interpret the statements. The results showed that the teachers' main objectives in teaching PE were to challenge the students physically and to allow them to experience the fun of physical activity. Ball sports, such as football and floor ball, are often used to meet these objectives. The fact that the 'weaker' students—those who are dominated by more athletic students—find ball sports to be boring was taken for granted. These students thereby are subjected to symbolic violence. The grading system aggravates the situation, as physical prowess is taken into account. In addition, social skills in sports are included in the teacher's assessment. The study found that teachers used students that play ball sports for club teams to create interest in their classes. These dominant students gained influence in the PE class, and had a say in both the content of the class and in how activities were conducted. How PE is implemented using the logic of the field of sports is discussed. The conclusion addresses why the content of PE classes often fails to match up with the values of the school system, and why PE teaching is influenced by the field of sports, especially competitive sports. The findings of this study bring up many important issues with pedagogical implications for PE programs and their development. Will PE classes continue to be shaped by the logic of the field of sports, or can the content of the classes be modified to integrate into the schools' logic? By paying careful attention to how power and symbolic violence work, it is possible to make the sports-oriented doxa visible and thereby catalyze change.

PHYSICAL ACTIVITY OF GIRLS AND BOYS IN OUTDOOR PLAY AREAS OF KINDERGARTEN

Diketmüller, R.1, Studer, H.2, Mairinger, F.1, Lischka, J.1, Spoerl, S.1, Mairhofer, R.2, Gungl, B.2, Kogler, C.1

1: *University of Vienna*, 2: *tilia Vienna*

Introduction Studies showed that childcare center environments affect physical activity behavior of preschoolers (Bower et al, 2008). Nevertheless, little is known about preschool children's physical activity habits. Hinkley et al. (2012) found out in the HAPPY-study that preschool children spend a great deal of time being sedentary (85% of waking time), and less than 50% of the children meets physical activity recommendations (Tucker 2008, Nicaise et al. 2011). So the aim of the baseline study in the "KinderGarten"-project (<http://kindergarten.univie.ac.at/>) was to analyze how girls and boys behave in unstructured outdoor play periods in kindergarten, how active they are (steps, physical activity levels) and how factors like sex, age, migration background/SES, BMI, practice/attitude of kindergarten teachers and environmental aspects influence their engagement in physical activity. Methods In the baseline survey physical activity behavior of 333 children of 8 kindergartens (2,5-6yrs) was collected on three time-points during outdoor play time through direct observation and accelerometer. In addition, pictures of the preschoolers about their favorite outdoor activities were analyzed. Finally types of activities of girls and boys were identified and located within activity-maps of the kindergarten. Results The findings show that boys spend a higher proportion of time in moderate-to-vigorous intensity physical activity (MVPA) than girls, older children more than younger, boys with migrant background have the highest proportion of time in MVPA. BMI seems to have no influence on physical activity

patterns and physical activity levels of preschool children. There is some indication that lower temperature and specific physical activity programs lead to higher activity levels. Large-sized outdoor areas do not automatically lead to higher levels of activity. The results differ between the 8 kindergartens as well as between different groups within single kindergarten. Discussion Although there are some concerns using accelerometer data in preschool children, in combination with the activity maps of each kindergarten accelerometer-derived physical activity data were very useful to ensure awareness of kindergarten teachers and parents. Promoting physical activity during early childhood needs initiatives and strategies to achieve national guidelines for daily physical activity and to focus on less active groups (f.e. girls with migrant background and low SES). THE EFFICACY OF INTERNET-BASED PHYSICAL ACTIVITY PROMOTION PROGRAMME AMONG SECONDARY STUDENTS

Leung, F., Sum, R., Fong, S.

The Chinese University of Hong Kong

Purpose: The current study aimed to tackle the problem of insufficient physical activity (PA) level of the secondary students by promoting PA through an Internet-delivered program. With the advantage that most teenagers are familiar with computer use, it was expected that such an innovative intervention would have significant impact on their PA levels. The purpose of study was to examine the effectiveness of an Internet-based PA promotion programme among secondary students. Methods: A total of 127 secondary four students from a school were recruited and participated in the current research project. They were group-randomized by class and placed into two groups, i.e. the Internet-based group (IB) and the control group (C). Participants of the IB group received the online behavior change program entitled "Active Living Every Day (ALED)" which was designed for PA promotion among secondary school students. It is a theory-based, the Transtheoretical Model (Prochaska and DiClemente 1983) and Social Cognitive Theory (Bandura 1986), on-line program designed with a step-by-step exercise plan. The IB participants were instructed to visit the program for two months at their convenience time and venues. Participants of group C did not receive any intervention treatment. They were requested to maintain their present lifestyle for two months. The assessments of PA level and stage of change were conducted at baseline, one month and two months after the commencement of the intervention. Results: At the 1st and 2nd month assessments, increases in total PA scores were found in the IB group, but they were not statistically significant ($p > 0.05$). There were slight falls in the total PA scores in the C group, but these were not statistically significant ($p > 0.05$). In addition, no statistically significant changes in the stage of change of both the IB and C groups' participants at the 1st and 2nd month assessments were observed. Conclusion: The results showed that the Internet-based programme was not effective in elevating the PA level of the secondary students. The lack of intervention effects might be attributed to the lack of programme contents engagement. Computer tracking showed only 23% ($n=15$) of the IB group participants at the 1st month intervention and 23 (35.4%) at the 2nd month intervention had visited the website. The study illustrated some of the challenges in using Internet as a mode of delivery of PA promotion programme. In order to have more understanding on the potential of using this new technology for PA promotion, future studies should be on how people respond to Internet-based programme, strategies to increase the interactivity of the Internet contents. PEAK VO₂ IN PREPUBERTAL AND PUBERTAL GIRLS DURING A MAXIMAL LABORATORY TREADMILL TEST: DIFFERENCES BETWEEN SWIMMING PRACTITIONERS AND GIRLS WITHOUT ANY SPORT PRACTICE

Rodrigues Ferreira, M.A.^{1,2}, Vences Brito, A.M.², Fernandes, R.², Mendes, J.^{1,2}, Romero, F.², Fernando, C.¹

1: University of Madeira (Funchal, Portugal); 2: Sport Sciences School of Rio Maior, Polytechnic Institute of Santarém (Rio Maior, Portugal)

Introduction The participation of prepubertal and pubertal female athletes in sport raises questions about the understanding of the physiological responses to training (McManus & Armstrong, 2011). Thus, the aim of this study was to evaluate the peak VO₂ in prepubertal (S1) and pubertal (S2) girl's swimmers and in prepubertal (C1) and pubertal (C2) girls not involved in any regular sport practice. Methods The sample was composed by: 6 S1 (9.83±0.75 yr.; 140.4±3.88 cm; 32.95±4.42 kg; tanner's stage, 1) and 10 S2 (11.3±0.68 yr.; 152.7±5.37 cm; 46.35±6.85 kg; tanner's stage, 3.4±0.52), with an average of 2.17±0.41 and 2.7±0.48 years of training practice and competition, respectively; and 6 C1 (9.83±0.41 yr.; 141.75±5.54 cm; 37.18±9.5 kg; tanner's stage, 1) and 10 C2 (11.2±0.79 yr.; 150.04±6.83 cm; 41.12±7.16 kg; tanner's stage, 3.5±0.53). The peak VO₂ was measured with direct gas analysis, breath-by-breath (Cosmed K4b2, Rome, Italy), during a incremental treadmill protocol (Modified Balke), where the participants ran until exhaustion (volitional fatigue or maximum criterion was achieved). Normality (Shapiro-Wilks test) and homogeneity (Levene's test) were satisfied for a significance level of .05. The one-way analysis of variance (ANOVA) and LSD Post-Hoc was used (SPSS, version 17.0), with a significance level of $p < 0.05$. Results S1 and S2 obtained a higher relative peak VO₂ (56.55±4.34 and 60.66±4.65 ml•kg⁻¹•min⁻¹, respectively), compared with the C1 and C2 (43.59±8.92 and 49.34±7.6 ml•kg⁻¹•min⁻¹, respectively). Peak VO₂ was significantly higher in S1 and S2 compared to C2 ($p=.000$) and between S1 ($p=.044$) and S2 ($p=.006$) compared to C1. No differences were found between S1 and S2 ($p=.233$), neither between C1 and C2 ($p=.152$). Discussion Those results were in agreement with the fact that children and young girls involved in sport generally obtain a higher peak VO₂ than their untrained peers (Armstrong et al., 2011; Armstrong & Barker, 2011). C1 and C2 might benefit from a regular sport practice to improve the peak VO₂ and consequently the aerobic fitness (Armstrong et al., 2011). In conclusion, it has been found a sport practice effect on peak VO₂, however, no maturation effect was observed in each group. References Armstrong N, Barker AR (2011). *Med Sport Sci*, 56, 59-83. HYPEROXIA AFTER MAXIMAL EXERCISE ACCELERATES THE SKIERS RECOVERY

Koryagina, U., Reutskya, E., Aikin, V.

Siberian state university of physical education and sport

Introduction Ability quick recovery is one of the decisive factors determining the achievement of high results in skiing. The aids and methods that increase adaptive capacity of an athlete are noteworthy. One such method may be use of hyperoxic mixtures (Han, Kim, Lim, & Kim, 2011). **Methods** The purpose of the study is to determine the influence of hyperoxic gas mixture on urgent restoration processes. 35 skiers performed maximal treadmill test. During 20 minutes of recovery they were breathing hyperoxic gas mixture with an oxygen content of 93%. Indicators recorded: heart rate (beats / min) Polar SX800, blood pressure (mmHg) and also were assessed HRV and athletes respiratory systems indicators. **Results** The 20 minutes hyperoxic inhalation after the maximum load contributes to the acceleration of the urgent restoration of the cardiovascular and respiratory systems skiers. VC athletes by recover normally was $4,94 \pm 0,23$ l, after hyperoxic breathing gas mixture was $5,39 \pm 0,18$ l ($p < 0,05$). Skiers HR by 20 min recovery normally was 100 ± 4 beats / min, after hyperoxic breathing gas mixture - 2 ± 93 beats / min ($p < 0,05$). **Discussion** Under the conditions of hyperoxic inhalation functional state of the cardiovascular system skiers characterized by the lower heart rate ($p < 0,05$), that indicating that reducing the energy needs of the heart. Breathing hyperoxic mixture leads to a faster recovery VC athletes. Probably hyperoxia leads to increased oxygen consumption and an increase in the coefficient of its use, which contributes to the rapid elimination of the oxygen debt. Inhalation of air breathing mixtures containing 93% oxygen for 20 minutes after the emergency rehabilitation of the maximum load leads to a decreasing of sympathetic influences on heart rate skiers and increasing activity of the parasympathetic division of the autonomic nervous system. **References** Kay B., Stannard S.R., Morton R.H. HOUSING CONDITIONS INFLUENCE THE POSITIVE EFFECTS OF SPONTANEOUS RUNNING ON BRAIN MONOAMINE LEVELS IN RATS

Yanagita, S., Kubota, N., Takano, Y., Matsuzawa, T., Takeda, K.

Tokyo University of Science

Introduction Spontaneous wheel running (SWR) is a common experimental model to investigate the beneficial effects of physical exercise in animal study. Numerous studies have shown that SWR is associated with health benefits especially for brain and behavior. In these studies, the rodents are housed individually in the cage with attached running wheel to calculate the running distance of each rodent correctly. On the other hand, it is well known that social isolation (individual housing) can exacerbate the negative impact of stress in rodents. Therefore, the individual housing condition may blunt the positive influences of SWR for brain and behavior. In this study, we examined the effects of individual and social housing conditions during SWR on brain monoamine levels, which is crucial for health benefits on brain, in male Wistar rats. **Materials and Methods** We employed microchip and radio frequency identification technology, which have been used as individual identification of cattle, in order to calculate running distance of each rat. The rats were implanted with subcutaneous microchips, i.e., electronic identification devices, providing each rat with a unique identification number. After surgery, the rats were randomly assigned to either individual or social housing conditions. The rats in both conditions were allowed free-accessible wheel running 4 weeks. All cages were equipped to monitor an individual access to running wheel of each rat. After 4weeks running sessions, we assessed the levels of brain dopamine, serotonin, noradrenaline, and its metabolite using high-performance liquid chromatography (HPLC). This assessment was performed in various brain regions, such as the prefrontal cortex, striatum, nucleus accumbens, paraventricular nucleus of the hypothalamus, hippocampus and central nucleus of the amygdala. The levels of plasma ACTH were also measured as an index of stress response. **Results** Four weeks of SWR made differences in daily running distance between individual and social housing conditions. HPLC analysis showed that the brain levels of dopamine and serotonin were influenced by housing conditions during SWR in the several brain regions. **Discussion** The results of the present study showed that difference of housing conditions during SWR influenced increasing volume of daily spontaneous running distance and monoamine levels in several brain regions related to physiological and psychological benefits, and suggest that social housing conditions influence mental health benefits and physical exercise performance during SWR.

TRAINING LOAD AND RECOVERY IN ELITE SYNCHRONIZED SWIMMING

Schaal, K., Le Meur, Y., Hausswirth, C.

National Institute of Sport, Expertise and Performance, Paris, France, UC Davis

Elite synchronized swimming is an aesthetic and highly technical judged sport evolving quickly. The emphasis on technical perfection within increasingly difficult and physically demanding routines requires a very high level of fitness and precision, attained through numerous hours of daily training. In order to follow such rigorous training while avoiding excess fatigue accumulation, integrating adequate recovery quality and quantity into the athletes' training plan is key. We present a summary of the physical demands and recovery needs of elite synchronized swimmers, with an emphasis on both acute and chronic recovery. Execution of a single competition routine requires maximal aerobic work production with large anaerobic contributions. Hence, in the context of repeated performances separated by a short time period (1 hr), as can be the case during competition, acute recovery strategies should be aimed at improving blood lactate clearance and reducing muscle fatigue to enable repeated maximal work production. We demonstrated that active recovery and whole body cryotherapy (WBC) were similarly effective in this regard, while WBC also afforded a large cardiac parasympathetic reactivation within 1 hour after performance (1). Parasympathetic reactivation may improve the quality of passive recovery after intense training sessions and promote better sleep quality (2). In a context of intensified training (IT) periods, particular attention must be paid to the quality of day-to-day passive recovery, in order to help avoid excess fatigue accumulation. We recently described the daily recovery quality of these

swimmers and its degradation during IT periods, as they show impaired sleep quality and reduced sleep quantity, while failing to increase caloric intake sufficiently to meet sharply increased energy needs. Increased sleep disturbance, fatigue, and changes in autonomic function hinted at the onset of an overreached state (3, 4), while changes in the swimmers' endocrine profile pointed to a state of energy conservation during this important pre-competition period. Integrating daily WBC sessions during IT, however, helped reduce some of the adverse effects of IT on sleep, fatigue, autonomic function, and exercise performance, but did not influence food intake. Greater emphasis must be placed on identifying the nutritional and sleep needs of elite synchronized swimmers, in order to program adequate recovery strategies that will help them train effectively to maximize performance gains. 1. THE EFFECT RAMADAN FASTING ON PEAK OXYGEN UPTAKE WHILE WALKING/RUNNING AND CYCLING

Al Rahamneh, H.

University of Jordan

Introduction Fasting during the holy month of Ramadan is one of the five Islamic religion pillars. During this holy month Muslims has to abstain from food and drinks from the dawn time until the sunset. These changes in food and drink intake have effects on sleeping patterns (Roky et al., 2004) and this might be one cause of motor vehicle accidents that happens during Ramadan (Shanks et al., 1994). Some important sport competitions might take place in Ramadan such as the Olympic Games in London in 2010. As such we might need to measure peak oxygen uptake in Ramadan especially for aerobic sports such as marathon and long distances races. This study assessed the effect of Ramadan fasting on peak oxygen uptake while walking/running on treadmill and cycling. In other words, can we really push people to the upper limit during Ramadan? Methods Ten male physical education Muslims student (mean \pm SD, 22.3 \pm 1.5 y, 176.0 \pm 4.9 cm, fasting weight 83.8 \pm 17.0 kg) volunteered to take part in the study. Each participant completed two graded exercise tests on the treadmill using Bruce protocol one in Ramadan and one after Ramadan and two cycling graded exercise tests one in Ramadan and one after Ramadan to measure peak oxygen uptake. These exercise tests were conducted in counterbalanced order. That means in Ramadan five students, were chosen randomly, performed the cycling exercise test first and the other five students performed the treadmill exercise test first. Results There were no significant differences ($P > 0.05$) between peak oxygen uptake values in Ramadan and after Ramadan for the treadmill (59.6 \pm 8.4 ml. kg.min⁻¹ vs. 58.2 \pm 12.3 ml. kg.min⁻¹, respectively) and for the cycling (52.1 \pm 9.4 ml. kg.min⁻¹ vs. 49.6 \pm 11.5 ml. kg.min⁻¹, respectively). Similar findings were observed for physical parameters (power output, speed and incline), heart rate and rating of perceived exertion ($P > 0.05$). However, respiratory exchange ratio values were significantly lower ($P < 0.05$) in Ramadan compared to after Ramadan for the cycling (0.95 \pm 0.04 vs. 1.06 \pm 0.09, respectively) and lower for the treadmill (1.05 \pm 0.05 vs. 1.09 \pm 0.08, respectively). Pulmonary ventilation values were significantly higher after Ramadan compared to Ramadan for both treadmill and bike exercise tests ($P < 0.05$). Discussion Peak oxygen uptake can be measured accurately in Ramadan for both treadmill and cycling exercise modes. However, it should be noted that respiratory exchange ratio was lower during Ramadan compared to after Ramadan. References Roky R, Houti I, Moussamih S, Qotbi S, Aadil N. (2004). *Annals of Nutrition and Metabolism*, 48, 296–303. Shanks NJ, Ansari M, Al-Kalai D. (1994). *Public Health*, 108, 27–34. Contact: harran81@gmail.com & h.rahamneh@ju.edu.jo

THE EFFECT OF PHYSICAL EXERCISE UNDER HIPOXIC CONDITION IMPROVES SLEEP QUALITY

Lemos, V.A.1,2, Bittar, I.G.L.1, Caris, A.V.1, Santos, R.V.T.1,3, Antunes, H.K.M.1,3, Lira, F.S.1,2, Tufik, S.1,2, De Mello, M.T.1,2

1: UNIFESP (São Paulo, Brasil), 2: CEPE (São Paulo, Brasil), 3: UNIFESP (Santos, Brasil)

Introduction Hypoxia worsens sleep quality, whereas physical exercise can improve sleep in normoxia. The aim of this study was to evaluate the influence of acute physical exercise under hypoxic condition on sleep quality. Methods Thirty-eight healthy men were enrolled in this study, randomly distributed into four groups: Normoxia n=10, Hypoxia n=10, Exercise in Normoxia n=10 and Exercise in Hypoxia n=8. The mean values were: aged 23 \pm 8 years, weight 71 \pm 7 kg, height 1.76 \pm 0.6 m, BMI of 22 \pm 9 kg/m² and VO₂ peak 47 \pm 4 ml/kg/min. The groups exposed to a hypoxic condition equivalent to 4500-m remained in the room for 24 hours (Colorado Altitude Training™/12 CAT-Air Unit). After 4 hours in the hypoxic condition, at midday, the groups performed a 60-minute session of physical exercise at 50% of VO₂ peak. The sleep quality was evaluated using polysomnography, recorded between 10:00pm and 8:00am in all groups. The comparisons were made using ANOVA of repeated measurements followed by the post hoc Tukey's test with a significance of $p \leq 0.05$. Results There was a significant reduction in sleep efficiency (%) (61 \pm 9 vs. 89 \pm 2; $p=0.002$) and total sleep time (min.) (279 \pm 49 vs. 364 \pm 26; $p=0.002$), and a significant increase in sleep latency (min.) (39 \pm 9 vs. 13 \pm 4; $p=0.007$) and number of awakenings (108 \pm 58 vs. 43 \pm 18; $p=0.003$) in the hypoxia group compared with the normoxia group. In the exercise in hypoxia group there was a significant increase in sleep efficiency (%) (76 \pm 21 vs. 61 \pm 9; $p=0.005$) and total sleep time (min.) (337 \pm 52 vs. 279 \pm 49; $p=0.01$), and a significant reduction in sleep latency (min.) (27 \pm 6 vs. 39 \pm 9; $p=0.02$) and number of awakenings (65 \pm 27 vs. 108 \pm 58; $p=0.02$), compared with the hypoxia group. In the exercise in normoxia group there was a significant increase in total sleep time (min.) (419 \pm 24 vs. 364 \pm 26; $p=0.02$) compared with the normoxia group. Discussion These results show that acute physical exercise performed under the hypoxic condition improves sleep quality, a response similar to the experimental situations observed in normoxia (Youngstedt et al., 1997). Our data confirmed a previous study that shows that hypoxia worsens sleep quality (De Aquino Lemos et al., 2012), whereas physical exercise can reverse this worsening, possibly due to changes in the concentration of neurotransmitters and the protection against oxidative stress in the central nervous system due to the hypoxic response. EFFICACY OF INGESTING A NOVEL REHYDRATION SOLUTION DURING EXERCISE AND RECOVERY

Fan, P.W.1, Ang, W.H.1, Burns, S.F.2, Lee, J.K.W.1,2,3

1. DSO National Laboratories, Singapore; 2. Nanyang Technology University, Singapore; 3. National University of Singapore, Singapore

Introduction Suboptimal sodium level in most commercially available sports drinks is mainly due to poor palatability with increased sodium concentration (Maughan & Leiper, 1995). The Drip Drop solution has overcome this barrier by increasing sodium concentration without compromising the drink's palatability. This study aimed to investigate the rehydration efficacy of the Drip Drop solution during exercise and recovery. Methods Nine healthy males aged 24 \pm 2 (mean \pm SD) years, with peak oxygen uptake 55.2 \pm 5.9 mL/kg/min completed three experimental trials in a randomised manner ingesting water (WA), a carbohydrate-electrolyte drink (SD; carbohydrate: 62

g/L, sodium: 31 ± 3 mmol/L, potassium: 5.3 ± 0.3 mmol/L) or the Drip Drop solution (DD; carbohydrate: 33 g/L, sodium: 60 ± 3 mmol/L, potassium: 18.2 ± 0.4 mmol/L). A total volume equivalent to 150% of sweat loss was ingested during the preceding 75 min cycle at 65% VO₂ peak (temperature: $30.4 \pm 0.3^\circ\text{C}$, relative humidity: $76 \pm 1\%$, wind speed: 8.0 ± 0.6 m/s) and within the first 2 h of recovery (temperature: $23.0 \pm 1.0^\circ\text{C}$, relative humidity: $67 \pm 2\%$). A pre-load time trial consisting of a 45 min cycle at 65% VO₂ peak followed by a 20 km time trial was conducted after a further 3 h of recovery. Results Fluid retention was higher with Drip Drop ($30 \pm 15\%$) than with water ($-4 \pm 19\%$; $p < 0.001$) and sports drink ($10 \pm 15\%$; $p = 0.002$). Drip Drop (6.03 , 0.10 – 7.46 ; $p < 0.001$) and sports drink (4.71 , 0.04 – 6.32 ; $p = 0.008$) were rated saltier than water (0.10 , 0.02 – 2.06) but similar between Drip Drop and sports drink ($p = 0.48$). Mean ratings of palatability were similar between the trials (WA: 4.25 ± 2.60 ; SD: 5.61 ± 1.79 ; DD: 5.40 ± 1.58 ; $p = 0.33$). Although time trial performance was similar across all three trials (WA: 2365 ± 321 s; SD: 2252 ± 174 s; DD: 2268 ± 184 s; $p = 0.65$), completion time was faster in 8 participants with sports drink and 7 participants with Drip Drop compared to water. Comparing sports drink with Drip Drop, completion time was reduced in 5 participants and increased in 4 participants. Conclusion The Drip Drop solution is more effective at restoring fluid balance during recovery from exercise than a commercially available sports drink and water without compromising the drink's palatability with increased sodium concentration. There is a tendency towards better performance with Drip Drop and sports drink than with water. References Maughan, RJ, Leiper, JB. (1995). CARDIOVASCULAR TIME COURSES DURING MAXIMAL DRY APNEA IN OXYGEN

Sivieri, A., Fagoni, N., Taboni, A., Ferretti, G.

University of Brescia

Introduction In static apnea, cardiovascular responses are such that, after an initial decrease in heart rate (HR) and increase in blood pressure (BP) (phI, ~30 s), there are ~2 min of steady values (phII). Then HR decreases and BP increases again, up to the end of apnea (phIII), possibly due to chemoreflex activation. We hypothesize that the end of phII corresponds to the physiological apnea breaking point. This being so, if apneas are carried out in O₂, thus with larger organism O₂ stores, duration of phII would be longer than in air. **Methods** 7 divers (38±14 yrs) performed voluntary maximal apneas at rest: A) sitting in air; B) supine in air; C) sitting in O₂; D) supine in O₂. BP (finger photo-plethysmography) and arterial O₂ saturation (SaO₂; infrared spectroscopy) were continuously recorded before, during and after apnea. Beat to beat HR, systolic (Ps) and diastolic (Pd) BP were obtained. **Results** A) apnea lasted 237 ± 32 s. In phI (29 ± 6 s), HR increased from 83 ± 20 b/min (control value, ctrl) to 94 ± 20 b/min at the minimum systolic peak (msp), Ps decreased ($p < 0.05$) from 144 ± 14 to 99 ± 31 mmHg. In phII (111 ± 22 s), all parameters were stable, then in phIII (99 ± 13 s) HR fell to 66 ± 14 b/min, while Ps and Pd increased, respectively, to 194 ± 22 mmHg and 93 ± 15 mmHg. SaO₂ was $93 \pm 2\%$ at end of phII and $73 \pm 7\%$ at end of apnea. B) apnea lasted 252 ± 47 s. In phI (26 ± 3 s), HR increased from 78 ± 17 b/min to 92 ± 14 b/min at msp. Ps decreased ($p < 0.05$) from 139 ± 14 to 103 ± 11 mmHg. In phII (118 ± 39 s) cardiovascular parameters were stable. In phIII (108 ± 27 s), HR attained 67 ± 17 b/min, Ps 186 ± 24 mmHg and Pd 93 ± 16 mmHg. SaO₂ at end was $72 \pm 8\%$. C) apnea lasted 455 ± 155 s. In phI (33 ± 6 s), HR increased from 78 ± 13 b/min in ctrl to 90 ± 16 b/min at msp, while Ps decreased ($p < 0.05$) from 135 ± 19 mmHg to 98 ± 23 mmHg. In phII (166 ± 59 s), all parameters were stable, then HR decreased to 71 ± 10 and Ps increased ($p < 0.05$) to 183 ± 18 mmHg at the end of phIII (255 ± 59 s). SaO₂ was stable at 100%. D) apnea lasted 549 ± 189 s. In phI (30 ± 6 s), HR increased from 73 ± 11 to 85 ± 18 b/min at msp, Ps decreased ($p < 0.05$) from 140 ± 16 to 106 ± 21 mmHg. In phII (191 ± 48 s), all parameters were stable, then HR decreased to 71 ± 12 b/min and Ps increased ($p < 0.05$) to 187 ± 27 mmHg at end of phIII (330 ± 177 s). SaO₂ was stable at 100%. In C) and D), HR and Ps at end of phII and phIII did not differ from those found, respectively, in A) and B). **Conclusion** In apnea with O₂ with respect to apnea in air, phII and phIII duration was higher, but at end of each phase the values of cardiovascular variables were the same. So, phIII started in similar physiological conditions. Our hypothesis that phII ends when the physiological breaking point of apnea has been attained is confirmed. **References** Ferretti 2001. *Eur J Appl Physiol* 84:254-71 **Contact** andrea.sivieri1@gmail.com

MO-PM61 HF Ageing Cognitive

EFFECTS OF COMBINED TRAINING OF PHYSICAL ACTIVITY AND INTELLECTUAL ACTIVITY ON COGNITIVE FUNCTION AND PHYSICAL FITNESS IN HEALTHY OLDER ADULTS.

Shimura, Y.1, Nakagaichi, M.2, Shigematsu, R.3, Okura, T.4, Komori, Y.1, Tanaka, K.4

1: Osaka International University (Osaka, Japan), 2: Nagasaki University (Nagasaki, Japan), 3: Mie University (Mie, Japan), 4: University of Tsukuba (Ibaraki, Japan)

Introduction Older adults generally have reduced functional fitness, including muscle strength, endurance and balance than young adults. Furthermore, they have less cognitive function. So it is very important to improve not only physical fitness but also cognitive function for vitality aging in older adults. Some studies suggest that physical activity could be also an effective means to improve cognitive function (Lautenschlager et al., 2008). However the cognitive benefits of physical activity may be less than intellectual activity. The purpose of this study was to investigate the intervention effects of combined training of physical activity and intellectual activity on cognitive function and physical fitness. **Methods** Participants were twenty-eight healthy older adults. Sixteen participants performed combined training program for 90 min, 2 days a week, for 12 weeks (CT group). In this study, we adopted square-stepping exercise (SSE) as a combined training. SSE was performed using a thin-felt mat that was partitioned into 40 squares (Shigematsu et al., 2006). On the other hand, twelve participants performed physical activity program for 90 min, 2 days a week, for 12 weeks (PA group). We adopted well-rounded training as physical activity. Cognitive function (Five-Cog. Test: Yatomi et al., 2005) and physical fitness (hand-grip strength, 10-m walking, timed up & go, 8-foot up & go, functional reach, single limb stance with eyes open, single limb stance with eyes closed, sit & reach, 30-sec chair stand, 30-sec arm curl, and stand-up from lying position) were measured 2 times (first day session, 3 months after the initial session) in all participants. **Results** Regarding cognitive function, CT-group had significant beneficial effects in the position judgment task (pre: 34.5 ± 16.8 , post: 40.9 ± 16.8 , $P < 0.05$), word memory task (pre: 59.5 ± 12.0 , post: 62.8 ± 12.7 , $P < 0.05$), and animal name imagination task (pre: 49.6 ± 9.3 , post: 54.0 ± 9.3 , $P < 0.05$). On the other hand, PA-group had significant improvement only in word memory task ($P < 0.05$).

Furthermore, there showed significant positive changes in the physical fitness including 10-m walking, 8-foot up & go, timed up & go, and 30-sec chair stand in both groups ($P < 0.05$). Discussion: This study suggests that combined training of physical activity and intellectual activity has more beneficial effects to improve the cognitive function than physical activity alone. Additionally, in spite of low-intensity exercise, the combined training has yielded similar effects to moderate-intensity physical activity on physical fitness. RELATIONSHIP BETWEEN THE PERFORMANCE OF FUNCTIONAL FITNESS AND GLOBAL COGNITIVE FUNCTION IN THE COMMUNITY-DWELLING OLDER ADULTS IN TAIWAN.

Yang, S.Y., Hou, M.T., Chen, J.J.

Institution of physical therapy and assistive technology

Objective : Aging rate increases every year in Taiwan. There are many people suffering from dementia also increased year by year. The burden of the care for people with dementia, regardless of society, family, the medical units offering care service and economic are continued to increase and the considerable. Thus, we have to must pay more attention to prevent rather than treat. So the first purpose of this study was to understand the status of the functional fitness and the cognitive function in community-dwelling older adults in Taiwan. The second one was to disclose the relationship between the performance of functional fitness and global cognitive function. Apart from this, it can be used to predict the risk of decline in cognitive function, and as a reference for exercise intervention model for further study. Method : The N=130 were recruited from Taipei City and Changhua County. All participants need to complete the Montreal Cognitive Assessment - Taiwan version (MoCA-T) and the Senior functional fitness test. Used SPSS 17.0 version to conduct the statistical analysis. Result : N=123 in this study, the average age was 70.34 ± 6.47 y/o. Functional fitness - Age groups showed that, poorer functional fitness performance in older group (30s chair stand up and sit [$p = .005$], Chair sit and reach(R't) [$p=.002$], Chair sit and reach(L't) [$p=.001$], 30 s one leg standing(R't) [$p<.001$], 30 s one leg standing(L't) [$p<.001$], 8 feet time up and go [$p=.001$], 2min steps [$p=.004$], among the three groups were significant difference). Functional fitness - cognitive function groups showed that, the poor cognitive function group indicated poorer functional fitness performance(30s chair stand up and sit [$p = .000$], arm curls(R't) [$p = .002$], Chair sit and reach(R't) [$p=.017$], Chair sit and reach(L't) [$p=.009$], Back grasps(L't) [$p=.033$], 30 s one leg standing(R't) [$p=.001$], 30 s one leg standing(L't) [$p=.008$], 8 feet time up and go [$p=.000$], 2min steps [$p=.000$] were statistically significant difference). Pearson correlation showed that, cognitive function had moderate correlation with 30s chair stand up and sit, 8 feet time up and go and 2min steps test(Coefficient: 0.408, -0.480,0.402). Regression analysis indicated that, functional fitness could explain 30.1% variability of global cognitive function. In all predict variable, only 8 feet time up and go test had predictive power [$p=.003$]. Conclusion : Whether the functional fitness or cognitive function, it demonstrated that the older the worse performance in older population in Taiwan. In addition, the poorer cognitive function elderly indicated the worse performance of all functional fitness. Which indicated among the age, functional fitness and cognitive function may have interaction. On the other hand, the results showed the 8 feet time up and go test can be used as a factor to predict cognitive changes. The 8 feet time up and go is kind of the integrated skills, it able to have powerful affect on global cognitive function. This result can be used as a reference for exercise intervention model in the further exploration.

PROGRESSIVE RESISTANCE TRAINING IMPROVES EXECUTIVE COGNITIVE FUNCTION IN A HEALTHY ELDERLY POPULATION

Coetsee, C., Terblanche, E.

Stellenbosch University

Introduction The literature reports inconsistent findings on the effect of resistance training on cognitive function. It is also not known whether there is a direct relationship between increasing muscle strength and enhanced cognitive function. The primary aim of the study was to investigate the time-course of changes in muscle strength and cognitive function in older individuals over 16 weeks of resistance training. Methods Forty-one sedentary individuals (55 to 75 years) volunteered for this intervention study. Participants were randomly allocated to a resistance training group ($n=22$; 3 training sessions per week) and a control group ($n=19$). Executive cognitive function was assessed every four weeks with the Stroop test, while muscle strength was tested with a 10RM bench and leg press test. Data were analysed using the ANOVA for repeated measures and $P < 0.05$ was considered statistically significant. Ethical approval was obtained from Stellenbosch University (HS891/2013). Results Upper and lower body strength in the experimental group improved by 39% (SD 27) and 167% (SD 125), respectively ($P < 0.05$), while no changes were observed for the control group. Both groups showed a statistically significant improvement in reaction time over 16 weeks ($P < 0.05$). After 4 weeks both groups improved their reaction time on C3 (5.5 s and 8.4 s for the experimental and control groups, respectively), while after 16 weeks a further improvement of 15.3 s and 12.4 s, respectively, were observed. The percentage correct answers on the complex cognitive task improved by approximately 2.4% after 16 weeks in the experimental group, while task performance weakened by 1.9% in the control group. Discussion The resistance training program was successful in improving upper and lower body strength in a group of healthy elderly volunteers, as well as the executive functions of selective attention, shifting and the inhibition of habitual responses. Although both groups showed a statistically significant improvement in reaction time over 16 weeks, the experimental group improved consistently from one testing session to the next, while the control group seemed to reach a plateau after 4 weeks. The control group's initial improvement in cognitive performance could be attributed to a learning effect. However, the improvement shown by the experimental group was more than this apparent learning effect. Considering that the control group exhibited a higher error rate during post-testing, it is suggested that their improved reaction time could be due to a speed-accuracy trade off. Our results suggest that a 4 month resistance exercise program has significant positive effects on muscle strength and executive cognitive function. Contact 15365484@sun.ac.za

DUAL TASK PERFORMANCE: AGE-RELATED DIFFERENCE IN YOUNG AND OLDER WOMEN

Brustio, P.R.1,2, Magistro, D.3, Rabaglietti, E.2, Liubicich, M.E.1

1: University of Turin (Italy), 2: University of Turin (Italy), 3: Tohoku University (Japan)

Introduction Simultaneous performances of physical and cognitive tasks are common in the activity of daily living. The concurrence of a motor and another activity, termed Dual Task (DT) performance, typically alters the motor pattern in older adults (Priest et al., 2008), un-

derlining as normal postural control requires attentional processing resources (Al-Yahya et al., 2011). The aim of this cross-sectional study on a sample of young and older women was to examine the performance difference of a mobility task, assessed by means of the Timed Up and Go Test (TUG), with an additional cognitive or motor task and the age-related difference in dual-task cost (DTC). Methods Nineteen older women ($M = 75.15 \pm 3.9$ yrs) and 19 young women ($M = 25.10 \pm 2.9$ yrs) were tested under three different trials of Timed Up and Go Test (TUG) (Podsiadlo and Richardson, 1991). The three different trials consisted in the TUG test, the TUG test with an additional cognitive load (TUGcog) (counting backward by 3) and the TUG test with an upper-extremity motor task (TUG mot) (carrying a full cup of water in the participants' preferred hand). A 2 X 3 mixed ANOVA with between-factor Age and within-factor Tasks was conducted to assess the effect of aging on performance of mobility tasks and one-way ANOVA was conducted to assess the difference in DTC between groups. The level of significance was set at $p < .05$. Results The 2 X 3 mixed ANOVA showed a statistically significant interaction between the age and the three different mobility tasks ($F(2,72) = 8.252$, $p < .05$). One-way ANOVA showed a significant difference ($F(1,36) = 6.75$, $p < .05$) in DTC of the TUGcog ($M = 23.01$ SD = ± 10.18 % for Older Group and $M = 10.18$ SD = ± 11.83 % for Younger Group) but not in DTC of TUGmot ($p > .05$). Discussion The results of this study confirmed previous findings about age-related deficits in mobility task with a simultaneous cognitive or/and motor task load. Furthermore, basing on DTC, our data suggested that mobility task was especially vulnerable to cognitive loading. Such task combinations are common in everyday life and this issue may be useful to better understand the deterioration of motor coordination and to prevent the risk of falling in older adults. DEVELOPMENT OF A PROTOCOL FOR ASSESSING FUNCTIONAL AUTONOMY FOR THE ELDERLY: IS THE COGNITIVE AND SENSORY DIMENSION A CONFOUNDING FACTOR FOR THE ANALYSIS OF THIS DIMENSION?*

Furtado, G.E.1, Pedrosa, A.F.M.1, Letieri, R., Silva, A.O.1, Teixeira, A.M.1, Ferreira, J.P.1

Faculty of Sports Sciences and Physical Education

Introduction The assessment of functional autonomy, commonly used in researches in elderly populations, is an epidemiological measure of physical fitness related to perform daily tasks independently (Ricky and Jones, 2001). It can be quantified by objective measures (physical-functional fitness tests) or subjective measures, through questionnaires (Chou et al., 2012). However these assessments are able to quantify and/or qualify only the "physical" dimension. This proposal sustains the hypothetical existence of a model for assessing global functional autonomy (GFA), understood as a multidimensional construct. Methods From this perspective, what is intended in this study is to present, from a conceptual model, the steps for developing a protocol for measuring the GFA, which incorporates simple and representative epidemiological measures of the four dimensions of the model. This model supports the hypothesized relationship between four dimensions that may characterize the GFA and are seen as intervening in the performance of motor tasks (Gallahue, Ozmun and Goodway, 2011). The psychological dimension related to cognitive abilities, the dimension of physical fitness and health, sensory dimension related hearing/visual conditions and the dimension characterized by fear or risk of falling. Partial results From sensory tests (hearing, vision and communication), a test for assessing the cognitive abilities, a battery of physical/functional fitness tests, and the assessment of falls risk, an evaluation model of the GFA was created. The result of the measures of each dimension was grouped into an arithmetic equation, to generate a final score/rating that represents the GFA in the elderly. Discussion The cognitive, sensory dimension or even the risk or physical/psychological trauma caused by a fall may act as a 'confounding factor' in the evaluation of functional autonomy and should be considered (Moniz-Pereira et al., 2013). From the integrated assessment of these dimensions it will be possible to measure the GFA of older people within a multidimensional approach, considering important factors that may interfere directly or indirectly (Rogerson, 1995) in their motivation for a good physical performance and subsequently, in the quality of life. This can be if it reveal a promising option for screening and detection of frailty in elderly person. References Jones C.J., Rikli R.E. (2002) *The Journal on Active Aging*, pp. 24-30. Chou CH et al. GENDER AND PHYSICAL ACTIVITY AS DETERMINANTS OF PERCEIVED HEALTH STATUS IN THE SEPTUAGENARIANS TO NONAGENARIANS

Rodrigues, T.M.1, Rodrigues, L.P.1,2, Costa, N.M.C.1, Silva, B.1, Fernandes, F.1, Leitão, R.1, Bezerra, P.1,2

1: IPVC (Viana do Castelo, Portugal), 2: CIDESD (Portugal)

Introduction: Health status in the elderly is crucial to remain independent, autonomous and to be active in society. The health-related quality of life has been assessed by a number of measures including the individual perception of health. Physical activity (PA) has been reported as determinant in improving health. However, the cumulative effect of gender and PA on self-perception of health has not been thoroughly studied. This study aims to investigate the influence of gender and physical activity in self-rated health and to examine differences between septuagenarians (70'), octogenarians (80') and nonagenarians (90'). Methods: The 1060 elderly without physical or mental disease [31.8% Male (M) and 68.2% Female (F)] aged from 70' to 90' (74.2 ± 2.8 ; 83.5 ± 2.6 ; 92.1 ± 1.7 , $p < 0.05$) were recruited from Viana do Castelo, northern Portugal. Participants were classified as Systematic (SPA) or Non Systematic PA (nSPA) group and completed the SF-36v2 questionnaire including the sub-dimensions General Health Perception (GH), Role Physical (RP), Physical Functioning (PF), and Vitality (VT). Univariate ANOVAs with Post-Hoc Tukey tests were used to assess differences between study groups of Age, Sex, and PA on each variable of interest (GH, RP, PF, VT). Significance was set at 0.05. The study was approved by Human Research Ethics Committee of IPVC. Results: There was no significant interaction between factors (Sex*PA; Sex*age; PA*age and PA*age*Sex) for all variables tested. Males showed higher scores on GH (55.2 ± 17.7 ; 45.9 ± 20.2 , $p < 0.001$), RP (88.1 ± 19.7 ; 79.3 ± 26.7 , $p < 0.001$), PF (72.1 ± 26.8 ; 54.4 ± 30.7 , $p < 0.001$) and VT (75.3 ± 20.5 ; 61.6 ± 24.7 , $p < 0.001$). The SPA group had better scores on GH (51.9 ± 19.6 ; 44.2 ± 19.5 , $p < 0.001$), PF (65.8 ± 29.1 ; 51.2 ± 30.9 , $p < 0.001$) and VT (69.2 ± 24 ; 60.9 ± 23.9 , $p < 0.001$) than nSPA, but not on RP. 70' showed significantly higher scores than 80' and 90' on RP (84.1 ± 23.2 ; 79.5 ± 26.4 ; 79.9 ± 29.9 , $p = 0.014$) and PF (66 ± 28.5 ; 53.2 ± 31.4 ; 50.2 ± 33.2 , $p \leq 0.001$). However, on GH (50.4 ± 19.6 ; 46.2 ± 19.9 ; 51.9 ± 21.6 , $p = 0.003$) and on VT (68.5 ± 23.5 ; 61.9 ± 24.8 ; 68.6 ± 24.6 , $p < 0.001$) 90' showed significant higher scores than both 70' and 80'. Men and women of SPA and nSPA, have showed differences on PFIM_SPA_70'-80' (80.7 ± 22.3 ; 69.9 ± 28.4 , $p = 0.018$), on PFIF_SPA_70'-80' (65.8 ± 27.6 ; 53.5 ± 30.2 , $p \leq 0.001$), on PFIF_nSPA_70'-80' (51.8 ± 28.9 ; 41.3 ± 31.5 ; 30.4 ± 25.5 , $p = 0.014$ and $p = 0.001$), on VTIM_SPA_70'-80' (81.7 ± 17.8 ; 73.9 ± 21.2 , $p = 0.027$) and on VTIF_SPA_70'-80' (66.3 ± 23.7 ; 60.6 ± 25.6 , $p = 0.035$). Discussion: Gender, PA and age grade are determinant factors on subject's perception of health. Despite all, 90' doesn't differ in anything from the 70' and 80', except on PF in female nSPA.

DEVELOPMENT OF DIFFERENT EXERCISE PROGRAMS IN INSTITUTIONALIZED ELDERLY PATIENTS WITH MILD COGNITIVE IMPAIRMENT: A PRELIMINARY STUDY FOR A PROJECT ON HORMONAL MEDIATION OF EXERCISE ON COGNITION*

Pedrosa, A.F.M., Furtado, G.E., Colado, J.C., Ferreira, J.P., Teixeira, A.M.

1: Faculty of Sport Science and Physical Education - University of Coimbra; 2: DPES-UV (Valencia, Spain)

Introduction The development of intervention programs for improving the overall health of institutionalized elderly (InEI) seems to require the use of methodological strategies in which the established guidelines by executive committees like ACSM (2009) suffer slight adjustments, given the specific clinical features of this type of population. The aim of this study was develop three different models of exercise programs (EP) for InEI patients with MCI. **Methods** For this preliminary stage of the study, a multi-method approach (Graves and Farbus, 2006) was used that consisted of the following steps (performed simultaneously): [1] visits to 13 nursing homes and day centers in the Coimbra area, Portugal, to observe some exercise sessions; [2] dialogue with health professionals who develop EP in institutions and nursing homes for the elderly; [3] a systematic review of the literature to search for a selection of the eligible criteria; [4] presentation of the EP first version; [5] subsequent consultation with experts in the area of EP for adjustments in the programs [6] pilot study for presentation of the adjustments in PE; [7] latest version presentation of the PE selected for intervention in InEI. **Results** The specific guidelines are usually aimed at populations of elderly individuals affected by cardiometabolic, bone and cardiovascular diseases, with few references to programs for senior citizens suffering from mild cognitive impairment (MCI) (AHA/ACSM; 2007). Three different EP (strength training, aerobic activities and flexibility) were developed taking into account the guidelines from these agencies and adapted for the initial functional fitness status of each group (ACSM, 2009). **Discussion** However the search in the text books and dialogue with professional experts in the area of exercise prescription for older people proved an important strategy for implementing programs in these institutions. In terms of exercise prescription for individuals with MCI or any other type of the emotional disorder (Fox, Stathi and McKenna, 2007), the generic adaptations suggested are: the rest interval between exercises and sessions should be the longest interval recommended in the initial stage of programs; Yoga is an interesting option for systematization of flexibility training for the elderly; the elastic-band resistances are able to produce a great system of resistance training, considering the cost-benefit ratio; the integrated or combined training is a good option of PE intervention in this population. *Financed by FCT (PTDC/DTP-DES/0154/2012) **References** ACSM (2009). *Med & Sci In Spor & Ex*, 2009. DIFFERENT KINDS OF PHYSICAL EXERCISE FOR THE PREVENTION OF DEMENTIA IN OLDER ADULTS

Fiorilli, G.1, Iuliano, E.1, Aquino, G.1, Mignogna, P.1, Cristofano, A.1, Calcagno, G.1, Di Cagno, A.2, Di Costanzo, A.1

1: University of Molise (Campobasso, Italy), 2: University of Rome

Introduction Several studies have shown that physical activity delays the onset of cognitive disability in healthy older adults (Bherer et al., 2013). However, there are few specific studies regarding the more effective kind of training (Fox and Hodgkinson, 2013). The aim of this study is to compare the effects of different trainings on older adults, in order to identify the one that brings the greater benefits. **Methods** A Randomized controlled trial of 12 weeks of monitored physical activity was conducted in Campobasso, Italy. Eighty subjects aged 67.0 ± 6.2 years were screened for eligibility. The subjects were randomly assigned in four group: STRENGTH Group (n=20), performed resistance training for the 6 main muscle groups (from 60% to 85% of 1RM); AEROBIC Group (n=23), performed aerobic exercises at intensity range of 75-90% of MaxHR; POSTURAL Group (n=19), performed postural exercise and CONTROL Group (n=18), which has not received any treatment. Outcome measures were Mini-Mental State Examination (MMSE), Frontal Assessment Battery (FAB), Rey's word list recall tests, Attentional Matrices, Raven's Progressive Matrices, Stroop test, Prose memory test, Copying of Drawings with and without landmarks, Trial Making Test (TMT) version A and B, and Memory Assessment Clinics-Questionnaire (MAC-Q). **Results** Repeated Measures Analysis of Variance (RM-ANOVA) showed significant differences between the 4 groups in the Raven's Progressive Matrices both in time and correct answers ($p < 0.05$), in the second test of Attentional Matrices ($p < 0.05$), in the time for Copying of Drawings ($p < 0.05$) and in the MAC-Q ($p < 0.05$). No significant difference was found in the other tests. Post hoc analysis showed the following results: in the Raven's Progressive Matrices, the AEROBIC group reached the best results in comparison to CONTROL ($p < 0.05$). Similarly in the second test of attentive matrix the AEROBIC group reached the best results vs. CONTROL ($p < 0.05$). In the Time for Copying of Drawings the best result was reached from STRENGTH group vs. CONTROL ($p < 0.05$). In the MAC-Q, all the 3 experimental groups obtained better scores vs. CONTROL ($p < 0.05$). **Discussion** Preliminary results show that different protocols of physical exercise produce different effects on cognitive function. The scores of the 3 experimental groups were generally better than CONTROL. Probably a longer time of observation is required to obtain more significant results also in the other tests. **References** 1 Bherer L, Erickson KI, Liu-Ambrose T. PHYSICAL ACTIVITY LEVELS OF ADULTS AND SENIORS WITH INTELLECTUAL DISABILITY

Oviedo, G.R.1, Javierre, C.2, Fortuño, J.1, Barnet, S.1, Massó, C.3, Guerra, M.1

1 University Ramon Llull; 2 University of Barcelona; 3 Fundació Ramon Noguera

Introduction: Individuals with intellectual disabilities (ID) have low physical activity (PA) levels (PAL) and daily energy expenditure (DEE)(1;2). Aging process begins earlier in adults with ID(3). Nowadays it is possible to assess PAL, intensity, steps and DEE objectively through accelerometry in this population(4). **Purpose:** To analyze the PAL of adults (AID) and seniors (SID) with mild to moderate ID. **Methods:** An AID group (AIDG; 22 male/16 female) 20-44 years old and a SID group (SIDG; 21 male/15 female) 45-70 years old were recruited from an Occupational Day Center for people with ID (Girona, Spain). After obtaining the informed consent and the approval of the IRB, a health screening questionnaire was completed by each participant's parent(s) and/or legal guardian. Height and weight were obtained to calculate BMI. PAL was obtained using the GT3X Actigraph accelerometer. Data were collected during 7 days obtaining total PA (TPA), steps per day (DS), time spent in sedentary (ST), light PA (LPA); moderate PA (MPA), vigorous PA (VPA), moderate to vigorous PA (MVPA) and DEE. One-way ANCOVA was applied to compare differences between groups controlling for possible confounding variables (BMI and ID level). One-way Anova was performed to examine differences between groups in MVPA across the 7 days. Partial correlation adjusted for BMI and ID level was performed to analyze relations between age and MVPA. **Results:** ANCOVA showed that the SIDG had significant lowers values in the TPA ($p=.030$) and higher values of ST ($p=.026$) when compared with the AIDG. When comparing the 7 week-days, ANOVA showed significant differences on Monday and Friday ($p < .050$), when the AIDG spent more minutes in MVPA than the SIDG. Partial correlation showed that age is adversely related with DEE ($r=-.24$; $p=.044$); TPA ($r=-.34$; $p=.004$); AFM ($r=-.29$; $p=.015$); AFV ($r=-.44$; $p < .001$); AFMV ($r=-.30$; $p=.012$) and positively related with ST ($r=.27$; $p=.026$). **Conclusions:** These groups of individuals with ID

showed low PAL. The TPA is higher in the AIDG when comparing to the SIDG, who also presented more ST. Higher age is related to lower PAL. Well designed preventive health strategies and interventions to raise PAL in people with ID are needed. References: 1. Melville, C. PHYSICAL TESTING AS A METHOD FOR DISCRIMINATING ELITE AND NON-ELITE JUNIOR MALE CRICKETERS.

Paul, J., Petroczi, A.

Kingston University

PHYSICAL TESTING AS A METHOD FOR DISCRIMINATING ELITE AND NON-ELITE JUNIOR MALE CRICKETERS. Introduction There has been considerable research into the physiological requirements of athletes competing in several sports, particularly as it relates to talent identification. Cricket, as one of the oldest organised sports has failed to attract a similar level of empirical interest. The current study sought to redress this gap by examining the efficacy of a pre-selected battery of fitness tests in differentiating between junior male elite (competing at the national level and above) and non-elite (less than 6 months playing experience) cricketers. Methods Fifty-nine elite ($n = 30$; age = 14.53 ± 0.82 yrs) and non-elite ($n = 29$; 14.69 ± 0.81 yrs) cricketers from Trinidad and Tobago participated in the study. The fitness battery consisted of the standing long jump (SLJ), push-ups (PHU), pull-ups (PLU), 20m sprint (ST), 505 Agility Test (505) and a 20m shuttle run tests (O2max). Results Elite cricketers performed significantly better on the SLJ [$F(1, 57) = 9.18$, $p = 0.004$], PHU [$F(1, 57) = 14.07$, $p = 0.001$], PLU [$F(1, 57) = 20.18$, $p = 0.001$], ST [$F(1, 57) = 6.08$, $p = 0.017$] and 505 [$F(1, 57) = 36.45$, $p = 0.001$]. Similarly, elite cricketers achieved a higher O2max however this was not found to be significant [$F(1, 57) = 1.71$, $p = 0.196$; $d = 0.34$]. Discussion Distinct group differences emerged in the power, strength, speed and agility tests. No significant differences were found between the elite cricketers and their non-elite counterparts in the O2max test. The lower physical demands of cricket (intense play typically punctuated by long periods of standing) may result in less emphasis being placed on aerobic training, thus explicating the lack of significance. The results of this study compares favourably with previous research in other sports using similarly aged male participants of varying playing abilities (Hoare, 2000; Reilly, Williams, Nevill & Franks, 2000). This novel study demonstrated the effectiveness of physical testing methods for discriminating between cricketers of varying abilities. Combined with psychological and other measures, the results of this study have major implications for talent identification in cricket. References Hoare, D. G. (2000). OXYMETRY, TIME-MOTION AND OTHER INDICATORS OF EXERTION IN ELITE HANDBALL REFEREES DURING AN OFFICIAL MATCH

Estriga, M., Carvalho, J., Santiago, C.

Sports Faculty

Introduction The purpose of this study was to evaluate the physical exertion of handball referees in a live situation by combining different biometric indicators (HR, kinematics, oxygen consumption). **Methods** Two male referees of EHF-level2 were involved in this study. An official match of the second national division was selected and special authorizations obtained. The referees and the players were familiarized with the experimental setup prior to the match. Three cameras (1024x768/24bit/30 fps) were placed in the arena ceiling and the live images processed with a new method for almost real-time video content extraction (Santiago et al., 2012), with a linear accuracy of 16 cm. The referees were equipped with tri-axial accelerometers (10bit/128Hz) and two channel ECG devices (10bit/256Hz). One of the referees was equipped with a portable oxymeter (Cosmed-K4b). After the match (<48 hours) the anaerobic threshold and maximal oxygen uptake of the referees was determined. **Discussion** Kinematic analysis shows an overall covered distance per referee of $4.20 \text{ km} \pm 1\%$, less than obtained for the first-level competitions (Estriga, 2012). The average velocity for the referee with the oxymeter was $3.70 \text{ km/h} \pm 1\%$ while for the other referee was $3.40 \text{ km/h} \pm 1\%$. During 88% of the time the velocity was less than 9.0 km/h and 7.2 km/h (respectively). From the oxymetry we computed an energy expenditure of 200.34 kCal in the first half (33:33) and 188.42 kcal in the second half (36:08). This discrepancy of 6% is significant and similar to what we obtained from accelerometry and HR by the methods of (Brage et al. 2007). However the absolute values obtained by the two methods differ by 75% (overestimated by indirect methods). The results also show that in this population, the acceleration has a high correlation with the running speed. The HR is particularly sensitive to psychological stress situations. **References** Brage S, Ekelund U, Brage N, Hennings M, Froberg K, Franks P, Wareham N (2007). TIME-COURSE OF PHYSIOLOGICAL AND RATING OF PERCEIVED EXERTION RESPONSES DURING JUDO COMBATS

Julio, U.F.1, Panissa, V.L.G., Esteves, J.V.C., Cury, R.L., Agostinho, M.F., Hardt, F., Franchini, E.

School of Physical Education and Sport - University of São Paulo

Introduction As judo combat can last from few seconds up to more than 5-min, it is important to understand the physiological responses in different time frames (Franchini et al., 2013). Thus, the objective of the present study was to compare the physiological and perceptive responses to judo combats with different durations. **Methods** Ten male adult judo athletes (74 ± 11 kg; 176 ± 6 cm) performed five combats with different durations (1, 2, 3, 4 and 5 minutes) randomly determined, against the same opponent, in different days and blinded to the time duration. After each combat the rating of perceived exertion (RPE) and heart rate (HR) were measured. Blood lactate concentrations ([La]) were measured at rest and 1, 3 and 5 min after the combat. Delta of [La] was determined using the highest minus the rest values. Moreover, the increment in RPE and [La] per minute of combat was also determined. An one-way ANOVA with repeated measurements and the Bonferroni test were used to compare the different time durations. Effect sizes were calculated (eta squared; η^2). Significance level was set at 5%. **Results** RPE was affected by combat duration ($P < 0.001$; $\eta^2 = 0.66$), with lower values for 1min (11 ± 2) compared to 2min (14 ± 1), 3min (14 ± 2), 4min (16 ± 2) and 5min (16 ± 2) conditions, and lower values in the 2min compared to 5min condition. HR also differed between conditions ($P < 0.001$; $\eta^2 = 0.45$), with lower values in the 1min (159 ± 13 bpm) compared to 2min (172 ± 8 bpm), 3min (173 ± 8 bpm), 4min (175 ± 6 bpm) and 5min (174 ± 6 bpm) conditions. The delta [La] ($P < 0.001$; $\eta^2 = 0.63$) values in the 4min (8.55 ± 1.88 mmol.L⁻¹) and 5min (9.42 ± 1.86 mmol.L⁻¹) were higher than in the 1min (4.78 ± 1.59 mmol.L⁻¹) and 2min (6.22 ± 1.41 mmol.L⁻¹) conditions. The values in the 5min were also higher than in the 3min (6.73 ± 1.77 mmol.L⁻¹). When time of combat was considered a decrease ($P < 0.001$; $\eta^2 = 0.90$) in the RPE was observed, with significant differences between all conditions: 1min (11 ± 2 a.u.min⁻¹), 2min (7 ± 1 a.u.min⁻¹), 3min (5 ± 1 a.u.min⁻¹), 4min (4 ± 0 a.u.min⁻¹) and 5min (3 ± 0 a.u.min⁻¹). The increase in [La] per min also differed between conditions ($P < 0.001$; $\eta^2 = 0.77$), with higher increase in the 1min (4.78 ± 1.59 mmol.L⁻¹.min⁻¹) compared to the 2min (3.11 ± 0.71 mmol.L⁻¹.min⁻¹), 3min (2.24 ± 0.59 mmol.L⁻¹.min⁻¹), 4min (2.14 ± 0.47 mmol.L⁻¹.min⁻¹) and 5min (1.88 ± 0.37 mmol.L⁻¹.min⁻¹) conditions and higher in the 2min compared to the 5min condition. **Discussion** The highest changes in the magnitude of physiological and perceptive responses occur at the beginning of the match, which suggest that judo athletes seem to modulate their effort thereafter, suggesting the occurrence of a pacing strategy. **References** Franchini E, Artioli GG, Brito CJ. (2013). *Int J Perform Analysis Sport*, 13, 624-641.

PREDICTION OF MOVEMENT INTENSITIES OF FOOTBALLERS FROM HEART RATE DURING ION FOOTBALL MATCH PLAY

Gupta, S., Goswami, A., Udupa, A.L.

University of West Indies, FMS,

Introduction Workload of footballers varies tremendously from moment to moment and is reflected on their heart rate (HR). HR can be used to predict different intensities of movement e.g., walking, jogging, cruising, and sprinting. **Methods** Forty two footballers (age 24.4 ± 4.2 years), attending a selection camp, volunteered in this study. Numbers of G, D, M, and F were 6, 13, 12, and 11 respectively. Maximum HR was recorded on treadmill by graded exercise protocol. HR range for four different intensities – walking, jogging, cruising, and sprinting were measured on football ground, 1 to 4 days before their matches, by heart rate telemeter. On the days of matches, similarly, HR were recorded at an interval of 5 s. Before matches, players had adequate warm up. Resting HR was considered as the minimum HR recorded before warm up. Maximum heart rate reserve (MHRR) was calculated as (Exercise HR-Resting HR)/Maximum HR-Resting HR). **Results** 'Walking and standing' corresponds to MHRR less than 51.1 (± 5.2)%. Similarly, jogging, cruising, and sprinting represent 57.2 ± 4.9 to 74.3 ± 6.7 %, 74.4 ± 6.5 to 92 ± 4.2 %, and $> 92.1 \pm 2.2$ % MHRR. A considerable overlapping of MHRR was found in two adjacent zones of intensities. Goalkeepers played almost all the time (96.3 ± 0.8 %) in the 'standing and walking' intensity zone, jogged only 3.1 ± 2.8 % of the playing time, and cruised just 0.6 ± 0.2 % time. Similarly, midfielders' walking and standing, jogging, cruising, and sprinting times were 33.6 ± 5.0 , 32.5 ± 7.1 , 28.7 ± 6.1 , and 5.2 ± 1.1 % respectively. The corresponding values for midfielders were 27.2 ± 3.3 , 32.3 ± 7.2 , 29.3 ± 4.2 , and 11.1 ± 3.0 %. Forwards spent longest time by walking and standing (40.2 ± 4.9 %) and also by sprinting (18.1 ± 6.5 %) than other outfield players. **Discussion** Forwards sprinted more frequently than players of any other position. Forwards are often required to run "off the ball" to create space for team mates, to divert opponent defenders by sudden and rapid increase in their speed. Less involvement of F in defence and not much effort in chasing the ball when the ball is with opponent, is probably responsible for spending long time in the least intensity zone (walking or standing). Midfielders and defenders were more involved in linking, defending, and distributing the ball to their teammates. This makes D and M more than 60% of the total playing time in jogging and cruising zones. Sudden accelerations were also noted in D and M and were required to save the ball and taking a significant role in attack as well. The study concludes that: (1) sprinting is most common in forwards than others, (2) forwards also spend more time than other outfield players in the least intense movement zone, and (3) defenders and midfielders show more frequent jogging and cruising than others. **References** Ali A, Farrally M. SPECTATOR PERCEPTIONS OF PHYSICAL FACILITY AND TEAM QUALITY: A STUDY OF A IRANIAN SUPER LEAGUE BASKETBALL MATCH

Ayazi, M.

faculty member

Spectator Perceptions of Physical Facility and Team Quality: A Study of a Iranian Super League basketball Match Islamic Azad university Roudehen branch Ayazi.M , khangholi.S Faculty member, Physical Education Department, Islamic Azad University at Roudehen International instructor swimming and Diving **Introduction** Sport industry is one of the essential elements of economic growth for a country (Mohd Pilus, 2013). Attracting people to sporting events is a major avenue for many sports teams to increase revenue and distinguish themselves from other teams. it is important for sport marketers to determine which factors most influence people to attend sporting events (Crompton, 1997). The purpose of this study was to examine the relationship between stadium factors and team quality on spectators' satisfaction. **Method** Data were collected from spectators who attended a Super League basketball game of Iran. The participants completed the sportscape instrument physical facility were measured using the scales developed by Greenwell, (2001) with Cronbach's alpha of 0.93 and The perceptions of team quality were measured using items from Zhang et al.'s (1997) scale, with Cronbach's alpha of 0.85. To analyze the data , Multi regression test and co-relation method at the level of Alpha 0.05. **Result** Results showed that the team quality features, significantly predicted spectators' satisfaction and physical facility (sportscape) their intentions to attend Super League basketball Match ($R \text{ square} = .734$, $\beta = .731$, $p \geq 0/05$, $R \text{ square} = .783$, $\beta = .734$, $p \geq 0/05$). it was concluded that team quality affect

spectators' satisfaction. The R square of .734 explained 34% of the variance/variation in the spectators' satisfaction. Also sportscape affect spectators' intentions to attend Super League basketball Match. The R square of .83 explained 83% of the variance/variation in the spectators' intentions to attend . Conclusion Results from this study revealed that overall team quality significantly predicted spectators' satisfaction and intentions to attend Super League basketball Match . Besides overall sportscape and features, was important element in predicting intentions to attend in this study. In the literature, team quality has consistently been viewed as the main factor in selling tickets to sports consumers and some studies suggest that fans attend matches of winning teams to be associated with and identified with a winner (Wann, 2001). PHYSICAL AND PHYSIOLOGICAL DEMANDS WHEN VARYING THE NUMBER OF TEAMMATES DURING FOOTBALL SMALL-SIDED GAMES PLAYED BY PROFESSIONALS AND AMATEURS

Torres Ronda, L.1, Torrents, C.1, Gonçalves, B.2, Marcelino, R.2, Vicente, E.1, Sampaio, J.2,3

1: National Institute of Physical Education of Catalonia (INEFC), University of Lleida, Spain. 2: CreativeLab, Research Center in Sports Sciences, Health Sciences and Human Development (CIDESD), Vila

Introduction The aim of this study was to explore how the number of teammates (none, 2 and 4 teammates) affects the external and internal workload, when three professional and three amateurs footballers play small-sided games. **Methods** Six professional (age: 29.1 ± 3.2 years; height: 181.5 ± 7.4 cm; weight: 74.7 ± 6.8 kg) and six amateur football players (age: 23.2 ± 0.6 years; height: 179.8 ± 6.4 cm; weight: 74.2 ± 3.3 kg) participated in a cross-sectional study. Twenty-four small-sided games were played by four teams (two professional and two amateur) of three players. These 3 players faced always a team of 4 opponents and were involved in 3 game formats: without teammates, with 2 teammates, and with 4 teammates. The analysis consisted in monitoring the same three players across all conditions. All games were played in a 40x30 meters pitch in a random order and with a total of 3 min duration. The time-motion and body impact data were collected using a 15Hz non-differential global positioning system with integrated 1Hz heart rate belts. Differences in external workload (body load, BDL; total distance covered, DC; exertion index, EI) and internal workload (TRIMPMOD) between the different game formats were compared using Cohen's dumb Effect Sizes with 95% Confidence Intervals. Results Both professional and amateurs players presented lower values across all performance indicators when the number of teammates increases. These differences were clearly higher when playing with 4 teammates compared to the none condition: professionals, BDL (mean differences, [95% CI], dumb: -14.24 [-18.58, -9.91], large), DC (-63.03 [-88.20, -37.86], large), EI (-1.39 [-1.94, -0.84], very large), TRIMPMOD (-3.11 [-3.92, -2.29], large); amateurs, BDL (-15.44 [-19.81, -11.06], large), DC (-77.77 [-105.17, -50.36], large), EI (-1.71 [-2.29, -1.13], very large), TRIMPMOD (-2.09 [-4.00, -0.19], moderate). Also, when compared to amateurs, the professional players showed higher external and internal workload values. **Conclusions** Increasing the number of teammates and maintaining the number of opponents, considerably decreased the physical and physiological players' demands. This evidence was similar to both professional and amateurs players. However the professionals presented higher physical and physiological demands across games. Therefore, coaches should be aware of these stimuli variability responses when planning the training tasks.

PHYSIOLOGICAL PROFILE OF ELITE ICE HOCKEY PLAYER

Dostal, J., Matous, M.

Institut sportovniho lekarstvi a.s.

Introduction: Goal of the study was to set the standard physiological parameters of elite ice hockey player with focus on cardiopulmonary testing **Methodology:** 126 elite ice hockey players from NHL, KHL, and ELH (Czech national league) underwent medical examination and cardiopulmonary (VO2max) testing. 15 players out of those 126 were active members of national teams of Czech, Sweden, Finland and Slovakia. All tests were performed in summer 2012 and 2013 at the beginning of the season. The exercise test was performed on bicycle ergometer equipped with Schiller-Ganshorn PowerCube gas analyzer and ECG. The gas analysis averaging time was set for 10 sec. All players performed the spiroergometry test (VO2max) to the maximum exhaustion via ramping protocol with continuous ramp 0.8W/kg/min reaching max oxygen uptake between 6 and 10 min of the load. **Results:** The following results were recorded (Mean, SD, Min, Max). Age (25.8, 4.9, 18, 39), Height (183, 10, 168, 196), Weight (88, 6, 75, 103), Fat % from 10 skinfolds (11.2, 3.3, 2.1, 21), Max load W (535, 40, 455, 664), Max load W/kg (6.2, 0.4, 5.0, 7.6), VO2MAX ml/min/kg (53.6, 5.1, 38.4, 62.3), VO2 at ventilatory threshold ml/min/kg (38.1, 4.6, 28.2, 51.8), FVC liter (6.25, 0.8, 4.1, 8.4), FVC % norm (108, 13, 79, 147), Tidal volume at max load liter (3.4, 0.5, 2.2, 4.9), Ventilation in max load liter/min (189, 23, 140, 246), Breathing frequency at max load f/min (57, 9, 38, 83), O2pulse at max load (24.4, 2.7, 17.8, 31.2), Heart rate at rest BPM (65, 10.1, 40, 88), Heart rate at ventilatory threshold BPM (165, 9, 140, 190), Heart rate at max load (185, 8.5, 166, 207), Post-exercise lactate at 3-5-10-20min (13, 2, 8, 20 – 13, 2, 9, 24 – 12, 2, 8, 17 – 10, 2, 5, 17), Lactate elimination 3min-20min % (26, 13, -15, 52). **Discussion:** There is very limited amount of valid data on typical physiology profile of cardiopulmonary testing of elite ice hockey players. Our findings on 126 players give the picture of typical profile of elite European ice hockey player. The transfer of those results to the NHL should be taken with caution, as the amount of NHL players in the group was limited (4 players). The mean VO2max is lower than some of the previously published data, most likely due to new technologies used like breathe to breathe gas analyses. The typical profile and distribution is needed to identify individual players with limiting factors, that needs a special training regimen, or in some cases even medical care, mainly in the area of respiratory physiotherapy. **References:** H.A.Quinney, R. COGNITIVE FUNCTION IMMEDIATELY AFTER MAXIMAL EXERCISE

Sudo, M., Komiyama, T., Aoyagi, R., Higaki, Y., Nagamatsu, T., Ando, S.

Physical Fitness Research

Introduction Cognitive function is fundamentally important to most human activities. In many sports, high-level cognitive function is required under psychological and physiological stress. Increasing evidence suggests that cognitive function improves during a single bout of moderate exercise (Briswalter et al. 2002; McMorris et al. 2011). However, little is known about how cognitive function is altered by

psychological as well as physiological states immediately after exhaustive exercise. The purpose of this study was to examine the association between cognitive function and mood state immediately after exhaustive exercise. Methods Ten participants performed a cognitive task at rest and immediately after maximal exercise. Cognitive function was assessed with a combination of a Spatial Delayed Response task (working memory) and a Go/No-Go task (executive function). We used accuracy of the cognitive task and reaction time in the Go trial to evaluate cognitive function. We examined the association between cognitive function and mood state (pleasure, relaxation, and anxiety) immediately after exercise. Results Maximal oxygen uptake was 49.0 ± 4.8 ml/min/kg. One participant was not able to complete the cognitive task due to exhaustion. Accuracy of the cognitive task was 90.0 ± 5.5 % at rest and 85.0 ± 12.0 % after exercise. Reaction time in the Go trials was 882 ± 331 ms at rest and 810 ± 222 ms after exercise. Delta reaction time tended to be negatively correlated with the decrease in relaxation state ($p = 0.06$). Discussion Both accuracy of the cognitive task and reaction time in the Go trials slightly decreased immediately after maximal exercise. However, we did not observe significant differences, probably due to the large inter-individual differences. Given the association between cognitive function and relaxation state, the present results suggest that cognitive function and mood state may be mutually interactive under fatiguing condition. Cognitive function seems to be affected by multiple factors including psychological state. References Brisswalter J, Collardeau M, Arcelin R (2002). Sports Med, 32, 555-566. MO-SH22 Social Significance of Sports

DESIGN AND VALIDATION OF A QUESTIONNAIRE ON THE CREATION OF NATIONAL IDENTITY IN FANS OF THE SPANISH NATIONAL FOOTBALL TEAM

Viuda Serrano, A., Esteban Molina, C.P.

Universidad Camilo José Cela

DESIGN AND VALIDATION OF A QUESTIONNAIRE ON THE CREATION OF NATIONAL IDENTITY IN FANS OF THE SPANISH NATIONAL FOOTBALL TEAM (NIF-SNAFT) Introduction Global communication facilitates transmission of national values linked to sports: national anthems, colored uniforms, national flags... Sports events not only are powerful public expressions of group identities, but also the way to exploit mass sentiments mixing the sensation of superiority over 'the other' with the threat and rejection of 'the different'. Some sports are more effective than others to serve as significant objects of cultural national identity. Football is the ideal space for expressing collective identities and local, regional and national rivalries. Since football is a perfect space for the growing and expression of national ideas clashing ones with the other ones in a sphere of exciting feelings, it seems to be important the creation of a tool to know how this construction is based and why football is so special to generate national identity. Objective The objective of this research was to design a questionnaire and check its validity and reliability to know the way football can help to build fans national identity. This paper study how successes of the Spanish Football Team during the last 7 years (2008-2014) at the international level (World Cup and Eurocup) has influenced the generation of national senses into the society, highlighting national identity. Methods Content validation was achieved through 12 expert judges: 3 university professors on Sociology and History of Sport, 3 sports journalists, 3 football coaches (national level) and 3 football players (BBVA or Adelante Spanish Leagues). With their ratings and contributions along two subsequent rounds, mainly at issues of content, modifications were made on the items of the questionnaire. Reliability was achieved through the application of the test-retest proof to a sample of 100 fans of the Spanish National football team with an interval of 2 weeks to check the variability of responses. Factorial analysis was calculated using also the Cronbach alpha coefficient to check internal consistency of the scale. Results The final scale has 50 items divided into 4 factors. In accordance with the results of our study we can assume the present questionnaire has reached high levels of validity and reliability, in such a way it provides sufficient guarantees of use for the knowledge of how football fans do the process of national identification with a football team. So the final scale to be presented in Amsterdam, July 2014, will open new possibilities of research in Spain and in other countries by adapting it to the circumstances of each nation. FRAMING THE SPORTS COVERAGE: LONDON OLYMPIC ISSUES IN JAPANESE NEWSPAPER

Ohhashi, M.

Kyushu University

Introduction Sports coverage generally creates images and narratives such as heroic injuries or achievements by exaggerating the spectacular (Coakley, 2009). Although sports television coverage has had a short history of the research, sports newspaper coverage could have profound effects on consumers (Wanta, 2006). In the meanwhile, framing qualitative research studies have potential for bias of researchers (Guangying, 2007). However, there are few studies about media sports which examined using quantitative methods. For this reason, the purpose of this study were 1) to map frames about media sports in Japanese newspaper articles through investigating the Olympics coverage with newspaper and 2) to analyze the contents of these articles examining these frames. **Methods** This method is based on quantitative analysis of 1191 newspaper articles of the 2012 London Olympic Games in the online version of Asahi Shimbun (newspaper). These articles published between 27 June and 12 September 2012 (around Olympic period). These articles were analyzed through comparisons with sports section and the other sections. Output from SPSS Text Analytics by IBM® software analyzed to discern the frames in texts of news coverage. **Results** The results of this study were as follows: 1) the different keywords of the frequency of appearance were statistically extracted from the London Olympic coverage on sports section and the other sections and 2) extracted different frames between the sports section and the other sections. **Discussion** The analysis revealed that Japanese press made a different "reality" on each section. In fact, this suggests that each writer's presumed readership or desired news coverage are different. These results show that extracted frames meant that these were most significant terms in the Olympic coverage. Namely, the results indicate that the method provides the feature and tendency of recent Olympic reports in Japanese newspaper. The results of the present study show that content analysis might be necessary to be informed explicitly based on not only qualitative methods used by many researchers but quantitative approaches. **References** Jay Coakley (2009). THE HOOLIGAN LANDSCAPE

Radmann, A.

Malmö University

The purpose of this presentation is to understand and explain how the narrative image of the Swedish hooligan and hooliganism is created and recreated in various (media) descriptions. Different types of media and in-depth interviews constitute the source material for the study, which provides new insights into Swedish and international hooligan culture. The key conclusions of the study are (1) that media images in both old and new media have strengthened the individual and collective identity of members of the hooligan cultures, (2) that physical as well as symbolic violence is an important aspect of the hooligan narrative in both old and new media (3) that supporter violence has been professionalised, (4) that hooligan culture manifests a number of different (and sometimes contradictory) masculinity traits and (5) that the stigma attached to the expansion and character of hooliganism and the resulting anxiety has elements of a moral panic in the population. My conclusions both support and problematize existing research on hooliganism and the media. Whilst traditional media had the sole right of interpreting the phenomenon and exercised this right through selection criteria and gatekeeper functions, the new media landscape is producing a multitude of voices and descriptions of hooliganism. Today, there are numerous "prosumers" – actors who both produce and consume media images of hooliganism, and it is significant to understand that hooligans themselves are amongst these "prosumers". Moreover hooliganism is also part of a pop-cultural hypertextuality in the digital landscape. The descriptions of both symbolic and physical violence vary greatly between different types of media. The old media describes the violence as meaningless while new media producers, hooligans in particular, describe violence as important and essential to the sense of community and camaraderie in the hooligan culture. The source material indicates a professionalization of violence; elements of the firm culture claim to have a monopoly on violence, stating that only firms are allowed to decide who can fight "in the club's name". The old media perpetuates the stigmatisation of different supporter categories, but the stigma is even greater in some new media. The hooligan culture manifests several different masculinity characteristics. Hooligans are expected to be tough, strong and not to be "pussies", but emotions, community and camaraderie are emphasised as equally important ingredients within the subculture. POSTURE, HEART AND VISION FEATURES IN GIRLS OF RHYTHMIC AND AESTHETIC GROUP GYMNASTICS

Venevtseva, Y., Melnikov, A., Niznik, L., Tsarev, N.

Tula State University

Rhythmic Gymnastics (RG) belongs to the most attractive and beautiful disciplines and requires a very high corporal flexibility and motor activity. Aesthetic Group Gymnastics (AGG) is a discipline of gymnastics based on stylized, natural total body movement combined into a high level competitive sport. Teamwork and unity are essential. There is the top-level club "Rockset" in Tula participating in World AGG Championships. The aim of the study was to compare the medical examination results in girls aged 6-17 yrs engaged in RG or AGG having more than 2 years training course. 306 girls were studied in the pre-sport participation and then annually provided screening. 180 girls were RGs and 126 – AGGs, including 45 and 31 high level gymnasts, accordingly, trained more than 20 h/week >8 years with strict dietary restrictions in most cases. There was tendency to increasing the minimal flat-foot rate with sport mastery from 13.0 in the 6-11 yrs group to 24.4% in 12-17 yrs group in RGs and from 16.3 to 32.2% in AGGs. Minimal idiopathic juvenile or adolescent scoliosis was detected in 3.7 vs 26.6% in RGs and 1.1 vs 16.0% in AGGs ($P < 0.05$). Mean scoliotic curve in high level gymnasts was only 5.5 Cobb degrees. Poor posture (increased lumbar lordosis, protruding scapulae, round back, back asymmetry) was seen in 42.2 and 44.4% of girls in RG and 44.2 and 54.0% - in AGGs. 6.6% of gymnasts had mild Osgood-Schlatter disease. The small heart abnormalities (benign mitral or tricuspid valve prolapse, chordae tendineae) were detected by echocardiography examination slightly frequently in AGG group (34.7 and 41.9%) than in the RG ones (27.1 and 27.6%). Refraction abnormalities (mild myopia) were obtained in 24.4 and 26.6% of RGs and in 16.8 and 25.8% of AGGs. The benign autonomic dysfunction syndrome was higher in girls during puberty, i.e. in high level gymnasts (3.7 and 11.1% in RGs and 2.1 and 12.9% in AGGs). After the retire from competitions only 3 of 12 physical education students aged 20 yrs former high level RGs or AGGs reported low back pain complaints. The mean self-rated health status in this group was 73.2% ranging from 65 to 80%. In conclusion, girls aged 6-17 yrs engaged in RG and AGG with high corporal flexibility and dietary restriction may have different minimal foot, posture, spine, and heart and vision abnormalities. More attention from coaches and doctors must be paid to care these symptoms using corrective exercise and education.

INDIRECT ESTIMATION OF THIGH MUSCLE MASS IN CHILEAN SOCCER PLAYERS VALIDATED BY DXA.

Zapata Gómez, D., Burgos, C., Andrade, D.C., García, N., Báez San, E.M., Henriquez Olguin, C.

Clínica MEDS

The aim of this study was to determine the thigh muscle mass through a multiple regression equation using kinanthropometry variables validated with dual-energy x-ray absorptiometry (DXA) in Chilean soccer players. Were evaluated forty-two young soccer players from the U-17 (17 years) and U-20 national team (19 years). Variables as weight, height, skinfolds, circumferences, diameters and Somatotype was used to determine our multiple regression model to predict the thigh muscle mass (TMM) determined by DXA. Pearson's correlation coefficient and concordance Bland & Altman correlation coefficient was applied to determinate concordance between real and predictive data. The correlation between our model and DXA for TMM values using Pearson was ($R=0.91$; 95% CI: 0.822- 0.946); furthermore the agreement of concordance through Bland & Altman was (Bias: 0.025; SD of Bias: 0.819; 95% Limit of Agreement: -1.580 to 1.631). In conclusion, our model has a high correlation and prediction to determined TMM validated by DXA in soccer players, furthermore has a lower difference mean (bias) between real and predictive data. This prediction model can be usefully to improve the anatomy knowledge to determined TMM difference between both thigh and providing a feedback in the injury prevention, improve of strength and training planning in soccer players.

THE RELATIONSHIP BETWEEN FREE RADICALS AND ANT AND VO2MAX IN PROFESIONAL SOCCER PLAYERS

Handziski, Z., Hnadziska, E.

Faculty of medical sciences, Un.Goce Delce-Stip, Republic of Macedonia

Introduction: Free radical (FR) levels may show changes following to acute and prolonged physical exercise. These parameters have certain activity and concentration characteristics and changes in these parameters may mean adaptation or maladaptation of reserves. The aim of this study was to evaluate the relationship between free radicals and AnT and VO2 max in professional soccer players during a competition half-season. Methods: We included 30 professional soccer players from a soccer club of our National soccer league in this study. All sport medical examinations were conducted three times: before preparation phase, before competition phase and after finishing the competition phase. Venous blood was taken before and after maximal exercise test and free radicals were determined by method of DEROM. AnT (km/h and beat/min) was determined with Conconi protocol and VO2 max (ml/kg/min) by indirect protocol on treadmill. We used descriptive statistics and correlations ($p<0.05$). Results: Taking into account all three phases of training process, FR plasma levels increased significantly at the end of half-season (269.25 ± 39.49 ; 295.98 ± 31.57 ; 333.29 ± 40.74). There were significant changes of VO2 max (48.31 ± 4.08 ; 51.31 ± 4.16 ; 49.5 ± 4.81) during the season, with insignificant changes of AnT (12.7 ± 0.80 ; 12.73 ± 1.71 ; 12.2 ± 1.47). There were significant negative correlation between FR plasma levels after maximal exercise test and VO2 max before the competition phase. Discussion: The significant increasing of FR plasma levels at the end of half-season suggest that oxidative stress increased at the end of prolonged training and competitions. The antioxidant defense mechanisms maybe depleted at the end of a season. This study shows that a significant increase of aerobic capacity is connected with a lower oxidative stress. BONE MINERAL DENSITY IN ACTIVE AND FORMER ELITE BALLET DANCERS

Amorim, T.1,2, Maia, J.1, Machado, J.1, Franklim, M.1, Wyon, M.2, Koutedakis, Y.1,3

1: University of Porto (Portugal), 2: University of Wolverhampton (UK), 3: University of Thessaly (Greece)

Introduction Insufficient or low bone mineral density is a major concern of individuals engaged in physical activities that emphasise low body weight (Kuennen et al., 2007). Therefore, the aim of this study was to examine the prevalence of low bone mineral density in active and former elite professional ballet dancers. Methods Thirty-two dancers (age 34.4 ± 9.7 years old; weight 55.6 ± 10.6 Kg; height 166.2 ± 7.0 cm) volunteered. Twenty of them (age 28.9 ± 6.8 years old; 55.8 ± 10.4 Kg; 166.9 ± 6.8 cm) were current members of the National Ballet Company, while the remaining 12 dancers (age 43.7 ± 6.1 years old; 55.8 ± 10.8 Kg; 165.1 ± 7.0 cm) were former (retired) members of the same dance company. Dual-Energy X-Ray Absorptiometry (DXA) - Lunar apparatus - was used to determine T-scores at the femur neck, lumbar spine (L1-L4), non-dominant forearm (radius) and total body. The criteria for osteopenia was a T-score < -1.0 and for osteoporosis a T-score < -2.5 . Results Apart from the differences in age, the groups were similar in weight and height. Current dancers demonstrated 20% osteopenia at the lumbar spine, 5% at the femur neck, and 50% at the forearm. None of this group revealed a T-score below -1.0 at the total body. Regarding the former dancers, 25% revealed osteopenia at the lumbar spine, 33% at the femur neck, 50% at the forearm, 17% at the total body, and 8.3% osteoporosis at the forearm. A significant difference between groups at the femur neck was detected ($p<0.001$). Discussion A high prevalence of osteopenia was found among active dancers. This prevalence seems to increase after retirement, and cases of osteoporosis are emerging in individuals at their mid 40's. This study supports the idea that ballet dancers are at risk of developing osteopenia and osteoporosis in later life. Further studies are required to identify the putative causes of this risk. THE EFFECT OF FINGER GRIP STRENGTH TO REACTION TIME IN MOTORCYCLE SPORTS

Tekin, D.

Institute of Health Science

Aim: In motorcycle sports, the physical properties significantly affect performance as in all sports. For someone having well reaction time is as remarkable good as having a strong body. Control of movement for all parts in the body is very important. However, there isn't any study that analyses the effect of the importance of the hand grip strength. Therefore, the aim of our study is to understand the effect of strength on the motorcycle riders reaction time. Metod: A total of 64 motorcycle rider (mean age 34.30 ± 6.18 yrs) who joined the first Leg

of the Turkey Track Championship that took place between 13 and 15 April 2012, voluntarily participated in the study. Right and left finger strength was evaluated by the Jamar Finger Dynamometer. The reaction time was measured by the Nelson Hand Reaction Test. For the measurement of the finger strength each test was repeated for three times and the average of the test results were taken. For reaction time the tests were repeated five times and the average of them were taken. Result: The finger grip strengths of right and left hand were found 20.46 kg and 20.12kg, respectively. The extremity reaction times were found 11.41/1000 sec. and 10.83/1000 sec., respectively. Although both the reaction time of the right extremity and strength of the right finger were higher than left ones, no significant differences between them were found. (the relationship between the reaction time and the strength of the right finger: $p=0.357$, the relationship between reaction time and strength of the left finger: $p=0.726$) Conclusion: In our study, it's shown that there is an insignificant relationship between the finger strength and the reaction time. We believe that this study should be executed for different branch and age groups. authors here

CORTISOL, PROLACTIN, THYROID HORMONES, LEUKOCYTES COUNT AND NGAL DURING THE WINTER SWIMMING COMPETITION

Zeman, V.1, Novak, J.1, Topolcan, O.2, Racek, J.3, Windrichova, J.2, Smejkal, J.1, Rajdl, D.3, Trdlickova, P.1, Pecen, L.2, Silerova, I.4

Faculty of Medicine Charles University and Faculty Hospital (Plzen, Czech Republic)

Introduction Swimming in ice cold water means a great stress stimulus resulting in sympathetic nervous system irritation with catecholamine (especially norepinephrine) release resulting in free fatty acids (FFA) and leukocytes count increasing. However there is also activated the whole endocrine system. Changes in cortisol levels are discussed most frequently. **Methods** During the winter swimming competition in the natural water 78 swimmers both men (44) and women (34) were investigated before and until 15 minutes after the race. Blood samples were drawn in the same time from the cubital vein. Swimming distances were 100, 250, 500, 750 and 1000 m, water temperature (Tw) 5.8 °C, air temperature (Ta) 8 °C. Swimming time ranged between 3:20 and 22 minutes dependent on the distance and velocity of swimming. Wilcoxon's paired test was used for statistic evaluation. **Results** Body temperatures (Tb) decreased in all swimmers. The lowest measured Tb value was 32.1°C. Leukocytes count increased from 8.0 ± 2.4 to $11.0 \pm 4.0 \cdot 10^9/l$ ($p<0.001$). Serum osmolality increased from 290 ± 5 to 296 ± 8 mmol/kg ($p<0.0001$), FFA from 0.31 ± 0.2 to 0.47 ± 0.23 mmol/l ($p<0.0001$), cortisol from 358 ± 109 to 626 ± 130 nmol/l ($p<0.0001$), prolactin from 160 ± 123 to 237 ± 130 nmol/l ($p<0.001$), NGAL from 195 ± 83 to 366 ± 201 µg/l ($p<0.0001$). TT4 decreased from 103 ± 17 to 94 ± 18 nmol/l ($p<0.01$) in women and from 90 ± 9 to 81 ± 11 ($p<0.01$) in men. Changes in TT3 were non significant. **Discussion** Our results confirm considerable stress response during the combination of physical activity and an outstanding cold exposure in winter swimmers (Hermanussen et al., 1995; Leppäluoto et al., 2008). Biomarker NGAL (Neutrophil Gelatinase Associated Lipocalin) indicates kidney ischemia with possible reduced glomerular filtration rate (Itenov et al., 2014; Wu et al., 2013). **References** Hermanussen M, Jensen F, Hirsch N, Friedel K, et al (1995), Arctic Med Res, 54, 45-51. HIP KINEMATIC DURING INSIDE SOCCER KICK IN SUBJECTS WITH A HISTORY OF GROIN INJURY

Takahashi, S., Kawamoto, R., Fukubayashi, T.

Waseda University

Introduction Groin injury is one of the most common lower-limb injuries and crucially affects performance in soccer (Meyers et al., 2000 ; Holmich P., 2007). Although previous studies have reported that inside kicking movements could cause groin injury, the mechanism of groin injury remains unknown. The purpose of this study was to examine the characteristics of inside kick and correlation between the inside kick movement and groin injury. **Method** 12 male subjects (Control group: 6 healthy subjects and Groin injury group: 6 subjects who have a history of groin injury) were required to perform a maximum inside kick towards 0 angled direction based on their approach-run pathway. Twenty-six reflective markers were placed on the head, upper-limb, trunk, pelvis and lower-limb, and eight-camera motion analysis system (Sampling rate: 250Hz) was used to record a lower-limb movement during inside kick. The hip kinematics (extension/flexion, abduction/adduction, internal/external angle) and kicking velocity were calculated in this study. **Result** There were no significant differences in the kicking velocity, the extension/flexion, abduction/adduction angles between Control group and Groin injury group. On the other hand, Groin injury group had significantly larger internal/external angle than Control group **Discussion** Hip internal/external angle was larger in Groin injury group than in control group, demonstrating that the inside kick movements in Groin injury group was different from control group. This indicates that hip internal/external movements in inside kick may relate to Groin injury. **References** Meyers WC, Foley DP, Garrett WE, Lohnes JH, Mandelbaum BR.(2000).Am J Sports Med.(28):2-8 Holmich P.(2007).Br J Sports Med.(41):247-252 Contact Waseda University of Sports Science, Fukubayashi Lab, 2-579-15,Mikajima,Tokorozawa Saitama , Japan. VIDEO-BASED MARKER-LESS MOTION ANALYSIS OF ERGOMETER ROWING USING STATISTICAL MOTION FEATURES

Yoshikawa, F., Kawasaki, F., Tsukuda, F.

Biwako Seikei Sport College

Introduction Rowers requires improving the rowing techniques and increasing the physical capabilities for lasting optimal motion sequences both to maximize the stroke power and efficiency (Baudouin A, 2002) and to prevent themselves from injuries e.g. around lumbar spine (Buckeridge et. al. 2012). In order to make rower's performance-enhancing activities more efficient, on-the-spot feedback of the performance data is needed to be conducted timely according to coaches and/or rower's requests. This paper proposes a novel video-based method that can extract kinematic and temporal variables of ergometer rowing and provide the video and the quantitative data in an efficient manner. **Methods** The proposed method extracts primitive motion features from the binary images both by employing cubic higher-order local auto-correlation (CHLAC) (Kobayashi & Otsu, 2009) and directionally-grouped CHLAC (DgCHLAC) (Yoshikawa et.al. 2011). These motion feature extraction methods can characterize object motions of in terms of gradients (velocity) and curvatures (acceleration) with less computational cost than conventional methods, which make it more suitable for real time processing. These model-free methods require neither prior knowledge nor marker attachment to athlete's body. Furthermore, DgCHLAC features enable automatic and robust estimation of dominant direction of object motion and displacement. For exploring the asymmetry and laterality with re-

spect to upper and lower limb motion, the present method applies principal component analysis to motion feature vectors. Experimental results and discussion Experiments were performed to demonstrate the utilities of the proposed method for characterizing the rowing movements on ergometer. Four volunteers were video-captured during ergometer rowing. Two digital cameras recorded a posterior and lateral view of the volunteers relative to their starting position. By applying the proposed method to images in each view, vertical and horizontal displacements of the volunteers were quantified and then kinematic and temporal variables were acquired. As a result, the proposed method could enable automatic scene synchronization of each performance between the posterior and lateral view image sequences. The present prototype tool for data feedback could enable monitoring of indicators that relate to asymmetry and laterality. References Baudouin A, Hawkins D. MO-SH23 Intellectual Disabilities & Activity

AUTONOMIC CARDIAC REGULATION AT REST AND IN EXERCISE IN PERSONS WITH INTELLECTUAL DISABILITY

Sarabia, J.M., Guillén, S., Reina, R., Moya, M.

Miguel Hernández University

Introduction Impaired autonomic cardiac regulation is related to an increased cardiovascular risk. This is frequently shown in people with intellectual disability (I), especially in Down syndrome. It remains unclear which system, sympathetic or vagal is predominant, the primary causes and also the effect of regular physical activity (2, 3). Methods Forty six individuals took part in the study, divided in three groups: 28 gymnasts with intellectual disability (IDG), 11 gymnasts without intellectual disability (NIDG) and 7 with intellectual disability and sedentary lifestyle (IDSG). Participants with intellectual disability, 51.4% had Down syndrome and 38.8% congenital cardiopathy (22% fully repaired, 25% with residual defects). A cardiologic evaluation reported data for heart rate (HR) at rest, blood pressure (BP) and left ventricular ejection fraction by echocardiography. Heart rate variability (HRV) at rest was recorded by RR intervals in 15 min supine position. HRV in exercise was obtained by ergospirometry in a maximal treadmill test for persons with intellectual disability. Parameters in time and frequency-domains were determined and statistical analysis was done using one-way ANOVA. Results Significant differences between disabled and non-disabled groups were obtained for systolic BP at rest (102 in NIDG vs. 117 mmHg in IDSB, $p < 0.05$), body mass index (17.7 in NIDG vs. 25.23 in IDG and 25.3 in IDSB, $p < 0.01$), left cardiac ejection fraction (71% in NIDG vs. 64% in IDSB, $p < 0.01$). At rest, no significant differences in HR or in time and frequency-domains parameters between groups were found. During ergospirometry, HRmax was higher in non-disabled gymnasts (201 in NIDG vs. 169 in IDG and 166 bpm in IDSB, $p < 0.001$). IDG showed a significantly higher LF and lower HF than IDSB, both calculated according fast transform Fournier ($F_{43} = 3.16$, $p < 0.05$) and auto regression model ($F_{43} = 4.05$, $p < 0.05$). No differences between disabled and non-disabled gymnasts were obtained in both, rest and maximal effort. These findings were not related to structural defects in the heart. Conclusions No differences in HR or HRV parameters have been determined in individuals with intellectual disabilities at rest. During a maximal treadmill test, gymnasts with or without intellectual disabilities had the same HRV pattern. However, sedentary disabled persons show a depressed sympathetical and increased vagal activity. These findings were not influenced by the diagnosis of cardiopathy. CORRELATION OF AIR DISPLACEMENT PLETHYSMOGRAPHY WITH A FIELD-BASED BODY COMPOSITION TECHNIQUE IN INTELLECTUALLY DISABLED ADULTS.

Boer, P., Moss, S.

North West University

Introduction Obesity is a condition that affects many individuals with intellectual disability (ID) (Salaun et al., 2012; Rubin et al., 1998). An ideal body composition holds many advantages related to an individual's health and well-being. The primary purpose of this study was to determine whether a less expensive, field-based body composition technique correlated well with a laboratory-based instrument for measuring body composition in men and women with ID. The secondary objective of this study was to determine which variable(s) (BMI, waist circumference (WC), waist to hip ratio, body fat % as assessed via skinfold technique) predict body fat % as determined by air displacement plethysmography (ADP). Methods Forty-four men (40 ± 10 yrs) and forty women (41 ± 9 yrs) participated in the study. Each participant underwent a body composition assessment which included BMI, 3-site skinfolds (SF), waist and hip circumference and ADP (BOD POD®). SF measurements were performed by a trained professional. ADP assessment was performed according to manufacturer's instructions. Results There was a significant difference between mean body fat % measured with ADP (32.3) and SF's (27.9) ($p < 0.01$). Pearson correlations revealed strong relationships between body fat % obtained by SF's and ADP for men ($r = 0.83$) and women ($r = 0.86$) ($p < 0.01$). Best subsets multiple regression analysis revealed a significantly high coefficient of determination ($R^2 = 0.87$) to predict body fat % in men. SF's body fat % was the only variable included in the model ($p < 0.05$). Best subsets multiple regression analysis revealed a significantly high coefficient of determination ($R^2 = 0.82$) to predict body fat % in women. SF's body fat % and BMI were the only variables included in the model ($p < 0.05$). Discussion The SF body composition technique under-estimates body fat % compared to ADP. Similar to studies performed on female athletes and young adults in the general population (Shim et al., 2014; Hillier et al., 2014), the results of the present study indicate that a strong correlation exists between body fat % as determined by skinfold measurements and ADP. However, a study with a small sample size ($n = 14$) found moderate correlations ($r = 0.54$) between these variables amongst ID adults with Down syndrome (Usera et al., 2005). The multiple regression model is similar to studies performed on young African-American adults who also

reported strong predictions by SF body fat % to determine body fat % as measured by the BOP POD (Wi-Yoimg et al., 2012). References Hillier S, Beck L, Petropoulou A, Clegg M. (2014). A SENSORY-MOTOR PROGRAMME FOR AUTISTIC BOYS: TWO CASE STUDIES

Hagemann, C.R., Africa, E., Welman, K., De Vries, P.

Stellenbosch University

Background: An autistic child may find it difficult to coordinate themselves visually and it has been proposed that if a disturbance is present in the vestibular system. This can lead to dysfunctions in gross motor development such as balance and proprioceptive feedback for the ability to perform skilled movements. Some sensory-motor intervention treatments for children with Autism concentrate on the underlying sensory sensitivities so that the child can receive adequate arousal or stimulation best needed for reaching a sense of stability in their systems. Sensory-Motor exercises have been presented as a multifaceted approach which is aimed to improve the standard of movement and motor planning for children with special needs (Youssefi & Youssefi, nd). **Methods:** This case study (N=2) included two Autistic boys six (Subject G) and eight (Subject A) years of age. The two boys attended individualised sessions of 30 minutes each, twice a week in order to complete a 12-week sensory-motor programme which focused on vestibular and proprioceptor variables. The Quick Neurological Screening Test-3 (QNST III) was used to evaluate the above-mentioned at baseline. The researcher continued to monitor the variables every 4 weeks for 3 months with a 4-week retention period at the end of the intervention. Based on the results from the subtests in the motor skill tests a self-designed sensory-motor programme was integrated into the planning of the intervention programme for each boy according to their motor needs. **Results:** Total QNST III scores improved by 50% and 35% over the 12-weeks in Subject A and G, respectively. These improvements in gross motor skills did not deteriorate over the 4-week retention period (greater than 4% change). Subject A responded after 4 weeks; however Subject G did not respond to the training until week 8 of the intervention with a 24% improvement. Additional analysis revealed that subject A mostly improved in vestibular function (67%) and subject G in proprioception (52%) from pre- to post-intervention. Static balance improved in both subjects (22% – 60%), but the improvement was not maintained after retention and worsened by 14% and 50% in Subject G and A respectively. **Discussion:** The outcome of the individualised programmes improved the boys' gross motor skills through enhancing the stimulation of their vestibular and proprioception systems. Even though both subjects showed an improvement over time, they struggled to integrate the two. There is a need for further research in the area of sensory-motor individualised programmes for children with ASD. Suggestions for future research interventions are to conduct the individualised programmes either over a longer period of time or more frequently such as three times a week. **References:** MUTTI, C., MARTIN, NA., SPALDING, NV. & STERLING, HM. (2012). Quick Neurological Screening Test. 3rd Edition. USA: Academic Therapy Publications.

THE BENEFITS OF TRAMPOLINE TRAINING ON MOTOR PROFICIENCY AND BODY MASS INDEX IN CHILDREN WITH AUTISM SPECTRUM DISORDERS

Lourenço, C.

University of Beira Interior

Introduction It is generally agreed that regular physical exercise promotes several benefits in people with Autism Spectrum Disorders (ASD) (SOWA, 2012). Children with autism spectrum disorders present hence a weaker motor performance (Pan, 2009), problems in maintaining balance and in motion planning (Vernazza-Martin et al. 2005). The use of trampolines potentially improves balance and motor proficiency of children with learning disabilities (Giagazoglou, 2013). This study aims to evaluate the efficacy of a twenty-weeks trampoline training (TT) program on motor proficiency and body mass index (BMI) for children with ASD. **Methods** Seventeen children (5 girls and 12 boys, age 4-10) were assigned to either a supplemental trampoline training (TG) or control group (CG). Both groups continued to participate in their regular education curriculum. The groups were evaluated in the beginning (baseline), after 10 weeks and in the end of program (after 20 weeks). BMI was evaluated by height and weight measurement and motor proficiency used the Bruininks-Oseretsky Test of Motor Proficiency (2nd ed.), (BOT). Group results were compared using multivariate analysis of variance (ANOVA). **Results** The TT program resulted in significant increases motor proficiency ($p=.000$): TG children evolved from a total BOT score of 21.33 ± 17.682 (baseline) to 35.17 ± 17.747 after 20 weeks, while control group evolved from a total BOT score of 28.27 ± 10.001 to 30.27 ± 7.55 . No statistical differences were found on BMI. **Discussion** Trampoline training is an effective option to develop motor proficiency for children with ASD. **References** Pan, C.-Y., Tsai, C.-L., & Chu, C.-H. 16:20 - 17:50**Invited symposia****IS-PM11 The Future of Sports Nutrition sponsored by GSSI *****THE FUTURE OF SPORTS NUTRITION**

Jeukendrup, A.

University of Birmingham

The future of sports nutrition Gatorade sports Science Institute, Barrington IL, USA Sports nutrition has evolved rapidly in the last 50 years and is likely to continue to evolve. The purpose of this symposium is to discuss some of the major trends and expected areas of development of the field. The discussions will center around 3 major topics: (1) Development of guidelines and personalization of advice as well as products (2) Regulatory changes with an impact on advice, athlete behaviour as well as product development (covered by Dr Maughan) and (3) The continued introduction of technology into sports nutrition (Discussed by Dr Close). A little history of development of guidelines provides an insight into the trends towards more specific advice that is dependent not only on the activity, the goals, the environmental conditions but also on differences in individual physiology and body composition. Although steps in the right direction have been made, there is still a lot of missing information and future research should try to address those gaps. Asker

TECHNOLOGY AND SPORTS NUTRITION

Close, G.

Liverpool John Moores University

Over the past decade we have witnessed a remarkable increase in the use of technology in sport. This technology is not only targeted at elite and professional athletes but also recreational athletes who are striving for personal improvements in both performance and health. Although all departments of sports science are now heavily technology driven, the increase in nutrition technology appears to be particularly popular. For example, it is increasingly common to witness people in supermarkets scanning bar codes with smart phones or inputting data in restaurants to check the macronutrient composition of the meal, often without really knowing what they are looking for. The assessment of energy intake and expenditure are perhaps two of the most difficult of all physiological measurements, especially in professional athletes. Consequently, despite energy intake and expenditure being key determinants of athletic performance, data from professional athletes is still somewhat lacking in the scientific literature. Whilst without question some emerging technology is helping to simplify the assessment of energy intake and expenditure, there are also examples where the technology is adding a layering of complexity to an already over complicated discipline. It is not uncommon to witness athletes seeking their diet and exercise plans from faceless technology rather than seeking professional science backed advice. Perhaps more importantly, in many cases the basic scientific questions regarding this technology have not been fully examined, such as how valid and reliable are the tools in question? This presentation will look at some of the emerging trends regarding the use of technology in sports nutrition and will examine if mobile technology has a place in the toolbox of the sports nutrition practitioner. Finally the presentation will hypothesise where the technology is going next and how as practitioners we can utilize this technology to improve our practice.

SPORTS NUTRITION SUPPLEMENT AND THE FUTURE

Maughan, R.

Loughborough University

The future of sports nutrition supplements Ron Maughan, Loughborough University, LE11 3TU, United Kingdom The current situation with sports supplements is that they are used by most athletes at the elite level of sport, but the products used and the prevalence of use vary between sports and with the level of competition. It seems unlikely that the prevalence of use will decrease and the commercial interest in this sphere will therefore continue. This financial interest emphasises the development of new and effective supplements, especially those capable of changing physique (by promoting muscle gain and fat loss) and enhancing physical and mental performance. The person who can predict what those specific products will be is sure to become enormously rich. Some trends might be predicted, though. Better understanding of the factors that limit performance will lead to the identification of new opportunities for interventions. The safety concerns over both adverse health outcomes and positive doping tests will surely lead to a change in the way supplements are regulated. The increasing demands of evidence-based practice in the sports nutrition community should also lead to a better evaluation of the products that are currently in use as well as closer scrutiny of new products. It seems unlikely, though, that some of the existing practices will change and athletes will continue to use products that have limited evidence of safety and efficacy.

IS-BN08 Developmental changes of neuromuscular control and muscle-tendon mechanics in children: Implications for muscular force production and movement performance**DEVELOPMENTAL CHANGES IN STRUCTURAL AND FUNCTIONAL CHARACTERISTICS OF THE MUSCULOSKELETAL SYSTEM**

Baltzopoulos, V., Waugh, C.

Brunel University

During growth and development in children, there are changes in the dimensions of the musculoskeletal system that alter the structural and mechanical characteristics of muscles and tendons. These changes can affect their functional characteristics with implications for maximal muscular force production. Our recent work on muscle-tendon structural and functional properties in children (8-9 years old) and young adults examined the effects of growth and development on the dynamic interactions of muscle and tendon function in the musculoskeletal system. Tendon stiffness and Young's modulus were up to 99% different in children than in adults. Fascicle length was longer in adults although pennation angle was not significantly different. The ratios of muscle to fascicle length and muscle fascicle to tendon length were similar between the age groups for all the quadriceps muscles. Moment arms were larger in adults but there were predictable from relevant anthropometric characteristics only in children. These results show that the lengths of muscle fascicles, muscles and tendon grow proportionally. Changes of moment arms during contraction are an important consideration for in-vivo movement mechanics and we have previously shown that the Achilles tendon moment arm, for example, increased by 1–1.5 cm (22–27%) during maximum plantarflexion contractions in adults compared to rest. Some preliminary results from in vivo Achilles tendon moment arm changes during hopping indicate that there are similar percentage increases in children in dynamic conditions. Growth related and in vivo changes in muscle-tendon mechanics in children and adults are likely to affect muscular force production and complex movement performance.

DEVELOPMENTAL CHANGES IN MUSCLE-TENDON MECHANICAL PROPERTIES AND THEIR IMPACT ON MUSCULAR FORCE PRODUCTION

Waugh, C.M.

Brunel University

Differences in movement kinematics and kinetics between children and adults are often attributed to an 'immaturity' of the neuromotor system. Until recently, the importance of the mechanical properties of the muscle-tendon complex on muscular force production has received little attention in children. There is growing evidence that the mechanical properties of the muscle-tendon complex, in particular its stiffness, adapts to changes in growth- or training-related loading. These changes, in addition to age-related changes in muscle activation parameters, appear to have a significant effect on rapid muscle force production, an important parameter linked to movement success or failure. Age-related differences in tendon stiffness between children and adults may also influence the differential movement of muscles and tendons for a given muscle tendon unit length change due to differences in series elastic energy utilisation and muscle shortening velocities during dynamic tasks. Such differences have the potential to contribute to age-related differences in cyclic task efficiency which is functionally relevant, particularly for tasks involving the stretch-shortening cycle. With recent evidence demonstrating that the mechanical properties of the 'immature' muscle-tendon complex are adaptable, it has been suggested that undertaking specific training regimes could enhance force production for athletic or general movement performance in children. This presentation aims to give an overview of our current knowledge of developmental changes in both the neural and mechanical factors that influence muscular force production characteristics in children. In addition, possible implications for complex movement, motor control strategies and movement disorders will be discussed.

THE INTEGRATION OF MUSCLE-TENDON CHARACTERISTICS AND NEURAL CONTROL DURING MULTI-JOINT, REBOUNDED EXERCISE IN CHILDREN

Oliver, J.

Cardiff Metropolitan University

Current knowledge regarding the development of muscle-tendon characteristics throughout childhood and towards adulthood is heavily influenced by well-controlled laboratory studies, which have often examined muscle-tendon structure and function around a single joint. However, there is a need to translate this research to understand the integration of the muscle-tendon system with the neural system and how these interact to control complex, multi-joint movements. Changes in muscle-tendon size and architecture and development of proprioceptive mechanisms during growth have obvious implications for movement. Continued intrafusal fibre development and reduction in Golgi Tendon Organ size and number promote a shift to a more excitatory response during rebounding tasks; with research showing that younger, more immature children have a more inhibitory neural control response with less short-term reflex activity, when performing rebounding activities. Perhaps most interesting is that with development there is a greater reliance on and contribution from anticipatory feed-forward muscle activity during rapid rebounding tasks. The exact mechanisms that drive this heightened feed-forward, preactivated response is not clear, but there is an interaction between age/maturation and speed of movement. It is speculated that the inherent stiffness of the muscle-tendon and its ability to produce a rapid reflex response are implicit in a preprogrammed feed-forward motor plan. Throughout childhood and into adulthood performance markers of rebound ability can be well-explained by the contribution of feed-forward and feedback activity. Fatigue research in children also shows that rebound performance and neural control change in unison, supporting a cause and effect relationship between neuromuscular control and rebound performance.

DEVELOPMENTAL CHANGES OF NEUROMUSCULAR CONTROL AND MUSCLE-TENDON MECHANICS IN CHILDREN: IMPLICATIONS FOR MUSCULAR FORCE PRODUCTION AND MOVEMENT PERFORMANCE

Korff, T.

Brunel University

Motor development is a multifactorial process. Much attention has been given to the influences of the maturation of neurological and physiological processes, whilst mechanical processes have largely been neglected. With the arrival of imaging techniques such as MRI and ultrasonography, our understanding of the mechanical properties of muscles and tendons in adults has increased dramatically. Only recently have these techniques been applied to children, adding a new dimension to the investigation of the mechanisms underlying developmental changes in neuromuscular control and movement performance. This symposium will provide an overview of our current understanding of age-related changes in muscle-tendon mechanics and their influence on neuromuscular control, muscular force production and movement performance. Prof Baltzopoulos will give a synopsis of developmental changes in muscle-tendon mechanics. Dr Waugh will discuss the implications of such changes within the context of neuromuscular control and muscular force production. Dr Oliver will conclude this symposium by exploring the implications for complex movement performance. This symposium is targeted at a scientific audience with an interest in the mechanisms underlying improvements in motor performance during childhood. As practical implications will also be discussed, the target audience includes applied paediatric scientists and practitioners with an interest in evidence-based practice.

IS-SH08 Applying the Exercise Science Model to the Prevention of Chronic Disease * - Sponsored by: The Coca Cola Company

PHYSICAL INACTIVITY: THE BIGGEST PUBLIC HEALTH PROBLEM OF THE 21ST CENTURY

Blair, S.

University of South Carolina

Non-communicable diseases are the leading health problem in the world, and this applies to both high and middle/low income countries. These diseases cause more deaths than any other cause, and the economic and social costs are very high. The primary cause of these diseases is an unhealthy lifestyle. This includes unhealthy diet, smoking, failure to appropriately manage stress, sleep disturbance, and physical inactivity. Physical inactivity is likely the most harmful of these risk factors, and even conservative estimates are that it causes more than 5 million deaths per year. We must implement policies and strategies to address the problem of inactivity in numerous sectors of society. One of the key sectors is health care. It is of crucial importance that health care professionals give more attention to helping patients become and stay more physically active. This will require some fundamental changes in the system.

THE CHALLENGE OF IMPLEMENTING PHYSICAL ACTIVITY INTO THE HEALTH CARE SYSTEM

Borjesson, M.

Swedish School of Sports and Health Science

Few question the evidence on the importance of physical activity to increase health. The great challenge now remaining for the health care-system, is to translate this knowledge into clinical practice. Several barriers exist for PA to be an integrated part of treatment options provided by the health care system. More evidence on the efficacy of different methods to increase the level of PA have emerged in recent years, but still needs further study. However, great barriers to overcome include the motivation of the patient, as well as of the health care providers. The latter will play a key role for the success and implementation of PA into normal clinical practice. Education will increase motivation and knowledge of health care professionals, and should start at University level and continue in professional life. Logistical problems exist, and full integration of lifestyle parameters into the medical records of the patients goes a long way to address this. In addition, further studies on the efficacy of increased PA in the clinical hospital setting are needed. National and international recommendations are also important, to increase the pressure on the health care system to push implementation fully. Many scientific and professional bodies (WHO, IOC, ECSS, EACPR, EFSMA, HPH, EIM, ACSM, HEPA) are now addressing the problem of non-communicable diseases from different angles. Unified efforts from all these organisations, will greatly improve the possibility of PA being increasingly used, in the usual treatment of chronic disease, in the future.

IMPLEMENTING PHYSICAL ACTIVITY PROGRAMS IN REAL LIFE - WHAT IS THE ROLE FOR ECSS MEMBERS AS INDIVIDUALS AND AS HEALTH PROFESSIONALS?

Khan, K.

Aspetar Orthopaedic and Sports Medicine Hospital

The challenge for 'Exercise is Medicine' initiatives world-wide is their execution - 'roll out'. A tremendous starting document - a blue-print - is the "7 investments" document (<http://www.globalpa.org.uk/investments/>). This is a critical operational plan for physical activity promotion. It, and the US National Physical Activity Plan (<http://www.physicalactivityplan.org>), are complementary. Among the 7 'investments' (or practical solutions) are plans to focus physical activity solutions in: 1. The "whole of school" environment. 2. Transport policies to prioritize walking, cycling, and public transport. 3. Urban design regulations and infrastructure changes. 4. Physical activity integrated into primary healthcare systems. 5. Public education. 6. Community-wide programs involving multiple settings and sectors. 7. Sports systems and programs that promote "sport for all" and encourage participation across the lifespan. In my presentation I will highlight those areas where participants in the ECSS - sports scientists, rehabilitation providers, strength and conditioning experts, may engage with elements of this master plan.

16:20 - 17:50

Invited symposia

IS-PM14 Interval Training revisited *

INTERVAL TRAINING REVISITED: INTERVAL TRAINING IN CARDIAC DISEASE

Christle, J.W.

Technical University of Munich

Coronary artery disease (CAD) and heart failure (HF) are cardiovascular diseases that are two of the leading causes of mortality and morbidity worldwide. In the former, coronary vessels become blocked, often leading to angina, ischemia and myocardial infarction, and in the latter, the myocardium becomes injured leading to cardiac remodeling and dyspnea. The risk factors for both are often lifestyle-related and physical activity plays an important role in prevention and therapy. Long-term observational studies such as NHANES have shown clearly that cardiovascular risk is reduced in individuals who are more physically active and/or have higher exercise capacity. The large HF-ACTION trial has shown that exercise is safe in the HF population and has a dose- response effect on mortality. In these studies, however, IT was not investigated. Recently, several investigations have been conducted using IT in both CAD and HF patients with promising results. Most clinical trials have been on small sample sizes, and these have been reviewed and meta-analyses have been performed, with the results being strongly in favor of a superior effect of IT compared to MCT. The SMARTEX-HF trial is the first and largest to compare IT with continuous moderate exercise and usual care in HF. In this trial the potential of IT to induce reverse remodeling was investigated in a large cohort of systolic HF patients. This presentation will discuss the findings of the most current data on the application of IT in these populations, as well as some of the benefits and concerns that remain in the practical application of this potentially superior exercise therapy.

INTERVAL TRAINING IN LUNG DISEASE

Gloeckl, R.

Schoen Klinik Berchtesgader Land and TU Munich

Chronic obstructive pulmonary disease (COPD), a disease which effects respiratory capacity as well as skeletal muscles and therefore the ability to perform activities of daily living, is the most common lower respiratory tract disease worldwide. Furthermore, COPD often leads to increased hospitalizations, morbidity and shorter life expectancy. Exercise training is a fundamental component of traditional COPD therapy, but the potential for interval training (IT) as an endurance training modality has only recently been evaluated. In the few randomized controlled trials that have been conducted, IT has been shown to be similar effective than continuous endurance training with regards to improved exercise capacity and health-related quality of life. However, there are indications that patients in the most advanced stages of COPD (i.e. lung transplantation candidates) may tolerate IT better in terms of perceiving lower grades of dyspnoe during exercise. In this presentation, these topics will be discussed, as well as the most recent data concerning the use of IT in COPD patients will be provided. Furthermore concrete recommendations on applying IT in moderate to severe COPD will be given here

SYMPOSIUM ON INTERVAL TRAINING IN DISEASE POPULATIONS

Tjønnå, A.

Institute for Circulation and Medical Imaging

Metabolic diseases The prevalence of metabolic diseases, including metabolic syndrome and diabetes, is increasing worldwide in all age groups and is strongly linked to cardiovascular disease and increased risk of morbidity and mortality. In the overweight and obese, metabolic syndrome and diabetes have also been linked to lower levels of self- esteem, physical activity levels and quality of life. Lifestyle related risk- factors including nutrition and physical activity play pivotal roles in prevention and therapy, and in fact are the primary forms of therapy applied in intervention programs. The acceptance of exercise as an effective preventative and therapeutic strategy in metabolic disease is currently well accepted in adults as well as children. However, less is known about the relative importance of exercise intensity on disease specific markers of metabolic disease or which form of exercise training (including Interval Training) may have the greatest clinical relevance in this population. Recently, trials have also been conducted in this population investigating what effect, if any, IT may have in this population, with fairly consistent results suggesting that IT may also be more effective in treating this population when compared to moderate exercise. In this presentation, both improvements in exercise fitness as well as disease and risk status through IT will be discussed, as well as the advantages and disadvantages of using this form of exercise therapy in individuals at risk for and affected with metabolic disease.

16:20 - 17:50**Invited symposia****IS-BN09 Propulsion in swimming and rowing****OPTIMIZATION OF PROPULSION IN SWIMMING: HOW INTER-LIMB COORDINATION CAN CONTRIBUTE?**

Seifert, L.

University of Rouen

The index of coordination and the total time gap have been proposed to be an essential variable in swimming. But is it related to the efficiency of coordination, and if so how? And more generally, how can the swimming performance be optimized. Can the index of coordination and total time gap be used in this regard? Similar questions are also raised and addressed with respect to the intra-cyclic fluctuations and some other indicators (such as stroke index, hand speed in comparison to hip speed) in swimming speed.

OPTIMIZATION OF PROPULSION IN ROWING

Schaffert, N.

University of Hamburg

The reduction of intra-cyclic fluctuations in propulsion speed has been proposed as a means to enhance the efficiency of propulsion in rowing. Boat acceleration was found to be a reliable measure for the effectiveness of the rowing stroke as it is the direct result of all forces acting on the system (boat and rower) at any given moment (the sum of stretcher force, handle force, frictions, etc). By coordinated movements of the athletes, intra-cyclic occurring variations in boat speed can be reduced particularly during the propulsive-critical phase of the rowing cycle (recovery) (Kleshnev, 2009). Since there is evidence that listening to complex sound sequences improves the precision in motor control for an exact timing and regulation of movement-patterns (Thaut, 2008), an auditory feedback system (Sonification in rowing) has been developed for technique training in on-water rowing. The additionally provided acoustic information, produced synthetically by sonification, maps the boats' acceleration data to sound to monitor changes in data. Empirical results from investigations with elite athletes in on-water training and theoretical insights obtained in the context of this application will be presented. More specifically, it will be shown how the presentation of acoustic feedback can affect the time-structure of the rowing cycle by providing detailed information about its characteristic phases. DRAG REDUCTION IN SPORTS

Westerweel, J.

Delft University of Technology

Drag resistance of a moving body in a fluid, that is air or water, comprises of form drag and skin friction drag. In most water-based sports, also wave drag contributes to the total drag. Evidently, drag implies a loss of the available power an athlete can utilize to improve his or her performance. Shape drag and wave drag can be reduced by means of the optimization of the athlete's posture or shape of sports equipment. Skin friction depends on the properties of the material that is in contact with the moving fluid. In this paper we review the physical aspects of skin friction drag, and we consider different approaches that achieve an effective reduction of the skin friction. The flow adjacent to a surface is determined by the geometric, mechanical and physical properties of that surface. The skin friction can be reduced by means of changing the surface properties, or the flow conditions at the surface. Well-known examples are the application of strips or trip-wires to change the flow condition and induce a favorable transition to a turbulent flow. Also polymer additives and small gas bubbles can achieve a reduction of the skin friction by modifying the turbulence. Other approaches use structured surfaces, such as riblets and superhydrophobic surfaces or coatings.

16:20 - 17:50**Oral presentations****OP-PM32 Training and Testing****USE OF DUAL-ENERGY X-RAY ABSORPTIOMETRY TO EVALUATE CHANGES IN BODY COMPOSITION AND THE ASSOCIATION WITH PERFORMANCE CHANGES IN SKELETON ATHLETES**

Colyer, S., Roberts, S.P., Robinson, J.B., Thompson, D., Stokes, K.A., Bilzon, J.L.J., Salo, A.I.T.

University of Bath

Introduction Body composition contributes to explosive performance by influencing the power to body mass ratio (Cronin & Hansen, 2005). Measurement errors are seldom considered when evaluating body composition changes determined with DXA. We assessed the reliability of DXA in an applied setting, quantified body composition changes across a training year, and investigated their association with physical performance. Methods Forty-eight athletes (12 skeleton (7 elite; 5 talent squad), 8 rugby union, 14 swimming, 14 athletics) underwent two DXA scans, typically within 48 hours. Typical error of the measurement (TEM; %) for total body mass (TBM), non-bone non-fat (lean) mass (LM), fat mass (FM), and leg lean mass (LLM) were calculated. Elite skeleton athletes underwent three further scans (representing two training blocks and the competition season) alongside physical tests (countermovement jump and leg press). Training block 1

focussed on hypertrophy, whereas block 2 involved higher velocity, sprint-based training. Body composition changes between each scan were calculated. Relationships between changes in body composition and performance were tested using Pearson correlation coefficients. Results TEMs for all participants were: TBM, 0.6%; LM, 0.9%; FM, 3.9%; and LLM, 1.2%. Mean (\pm SD) changes in TBM for elite skeleton athletes were $1.6 \pm 2.7\%$, $1.1 \pm 2.0\%$ and $0.7 \pm 2.3\%$ across training block 1, block 2, and the competition season, respectively. LM and LLM increased across block 1 (LM, $3.0 \pm 2.4\%$; LLM, $2.7 \pm 2.6\%$) with decreases occurring across block 2 (LM, $-0.9 \pm 2.6\%$; LLM, $-1.6 \pm 2.4\%$) and the competition season (LM, $-1.6 \pm 3.1\%$; LLM, $1.1 \pm 2.4\%$). FM decreased across both training blocks (block 1, $-4.3 \pm 8.5\%$; block 2, $-3.0 \pm 7.2\%$) and increased across the competition season ($12.9 \pm 7.4\%$). Significant relationships ($p < 0.05$) were found between changes in LM and performance (jump, $r = 0.61$; leg press, $r = 0.40$) and between changes in LLM and jump performance ($r = 0.65$). Discussion Many body composition changes observed in this study were above the TEM even with a less stringently controlled scanning protocol than previously suggested (Nana et al., 2012). Therefore, DXA was able to detect real body composition changes, which appear to reflect the emphases of each training block and the nature of the competition season. Relationships between changes in LM and performance demonstrated the important influence of body composition on strength and power indices. References Cronin, J. & Hansen, K. (2005). *J Strength Cond Res*, 19, 349-57. Nana, A., Slater, G., Hopkins, W. & Burke, L. (2012). *Med Sci Sports Ex*, 44, 189-9. Contact S.Colyer@bath.ac.uk

EFFECT OF WHEEL SIZE ON PERFORMANCE IN ELITE CROSS-COUNTRY MOUNTAIN BIKERS

Steiner, T., Müller, B., Maier, T., Wehrli, J.P.

Section for Elite Sports, Swiss Federal Institute of Sport (SFISM)

Introduction With the appearance of mountain bikes with 29-inch wheels (29er), debate arose among elite mountain bikers regarding the benefits compared to the traditional bike with 26-inch wheels (26er). While the 26er is usually lighter, stiffer, and is said to be easier to accelerate, it is assumed that the 29er offers lower rolling resistance, better traction, and a higher riding smoothness. So far, the bike choice has been made subjectively by every rider, depending on the course. The aim of the present study was to analyse the effect of different wheel sizes on performance on a simulated cross-country course to objectify the decision-making for the athletes. **Methods** Power output (Powertap, Madison, USA), time and average heart rate (HR) were recorded for 11 Swiss National Team mountain bikers (8 male, 3 female) when riding two laps (total 1230 m, ascent 28 m) on a specially-built cross-country course. It consisted of two separate sections, assumed to favour the 29er (348 m) and 26er (267 m), respectively. All athletes completed 6 heats with 35 min of active recovery in between. Three heats were performed with their own 26er (bike weight including Powertap: 9.3 ± 0.6 kg) and 3 heats with their 29er bike (10.1 ± 1.0 kg). Five athletes started with the 26er and six athletes with the 29er. The bike was changed for every heat and athletes received no feedback on performance throughout the procedure. Paired t-tests were used to identify differences between the two wheel sizes. Results Athletes were faster ($p < 0.01$) with the 29er (302 ± 25 s) than with the 26er (309 ± 28 s) while having a nearly identical ($p = 0.96$) power output (29er: 264 ± 46 W; 26er: 264 ± 45 W). No difference ($p = 0.94$) was observed for average HR between the two wheel sizes (29er: 174 ± 10 bpm; 26er: 174 ± 11 bpm). The 29er was also faster ($p < 0.01$) when sections were analysed separately, while no differences in power output were observed. All athletes had their fastest heat on the 29er. **Discussion** The 29er seems to be superior to a 26er for elite mountain bikers, even on course-sections supposed to favour 26er bikes. It is emphasized that also athletes who trained considerably less on the 29er prior to the study took advantage of the bigger wheels. Whether these findings are limited to the short course used in this study cannot be concluded definitely. However, it can be assumed that, due to the reduced workload (same power output but faster times for a given distance), athletes will benefit even more from a 29er during cross country competitions usually lasting 100-135 min (Impellizzeri et al., 2007). ACCURACY OF ENERGY EXPENDITURE ESTIMATED BY FIVE COMMERCIAL FITNESS TRACKERS

Roos, L.1,2, Börner, J.1, Balanche, C.1, Ammann, R.1,2, Wyss, T.1

1: Swiss Federal Institute of Sports Magglingen SFISM, Switzerland, 2: University of Fribourg, Switzerland

Introduction Recently there has been a surge of interest in lifestyle gadgets such as fitness trackers. These devices can be worn e.g. in a trouser pocket or as a bracelet on the wrist. Among other features, these devices are able to measure steps, distance and energy expenditure (EE). Thus, the aim of this study was to investigate the validity of the EE estimation of five fitness trackers. **Methods** EE estimation of Nike+ FuelBand SE (NFB; Nike Inc., OR, USA), Jawbone Up (JBU; Jawbone, CA, USA), Withings Pulse (WP; Withings, MA, USA), Polar Loop (PL; Polar Electro Oy, Finland) and Fitbit Flex (FBF; Fitbit Inc., CA, USA) were compared to EE calculated using indirect calorimetry (IC; MetaMax 3B, Cortex Biophysik GmbH, Germany). Ten subjects (5 men and 5 women, mean age 40.9 ± 15.6 years, height 1.7 ± 0.1 m, weight 64.8 ± 9.5 kg) wore all fitness trackers and the MetaMax simultaneously while performing seven activities for 10 minutes each: resting, office work, household tasks, walking, running, badminton and cycling. Mean EE of every device was registered for each activity. Data were analyzed using Pearson correlation and Oneway ANOVA with Bonferroni post-hoc test. Results Considering all activity classes, significant correlations between mean EE assessed by IC and fitness trackers were $r=.76$, $r=.64$, $r=.72$, $r=.73$ and $r=.59$ for NFB, JBU, WP, PL and FBF, respectively. Further, the fitness trackers showed a small, though, not significant underestimation of the mean EE by -12.5% (NFB), -31.1% (JBU), -1.6% (WP), -15.9% (PL) and -18.7% (FBF) compared to IC (5.6 ± 3.6 kcal/min). However, the fitness trackers significantly ($p < 0.001$) underestimated mean EE for the activity classes cycling (58-85%) and badminton (40-66%, with the exception of NFB and PL). Further, no statistical differences between measured and estimated EE for resting, office work, household tasks, walking and running (exception WP +65.3%) were observed. **Discussion** In accordance with Adam Noah et al. (2013), the five devices showed to be adequately precise in estimating EE during resting, office work, household tasks, walking and running, but not for cycling or badminton. Therefore, these new lifestyle gadgets seem viable to monitor daily physical activities but not physical training or sport activities. The smallest difference between estimated and measured EE was observed for WP. Thus, it might be that the device placement at the hip is preferable to the wrist. Some devices' EE estimation accuracy can be improved by assigning the performed activities afterwards to intensity categories or by simultaneously wearing a heart rate monitor. PERFORMANCE PREDICTORS IN AGE GROUPS SWIMMING EXPLAIN ADULT SPORT SUCCESS

Alves, F., Antunes, M., Rama, L.

CIPER, Faculty of Human Kinetics

Introduction Talent identification in swimming has been the focus of research for several decades, with special emphasis on selected physiological and anthropometrical traits, combined with maturation. However, the effectiveness of these strategies remains broadly debatable. The aim of this study was to confirm retrospectively if the performance-correlated variables in age group swimmers were effective in predicting later sport success as adults. **Methods** The sample of this study comprised 178 females (13.0 ± 0.8 years old) and 205 males (14.9 ± 1.0 years old) swimmers, selected at national level according to their best season performance. The swimmers were categorized in two groups according to the criterion of ranking among the 10 best annual national times in any swimming event, in the next two Olympic cycles following age group evaluations that occurred from 1999 to 2005. Data collected at the time, consisting of week load volumes and training experience, standard anthropometric measurements, hydrodynamic drag force influencing characteristics as glide distance after a wall push-off (GD) and buoyancy test (B) and performance protocols as the 15 m sprint velocity (SV) and mean velocity and stroke rate at a 30 minutes continuous swimming (T30), were compared between the Elite and the Subelite groups thus formed. **Results** Swimmers integrating the Elite group had been late maturers, as determined by the ratio between bone and chronological ages ($p=0.03$ and 0.05 , for males and females, respectively) and were already better performers at young age ($p \leq 0.001$ for both sexes). They had been also taller and had longer limbs ($p \leq 0.001$ for males and $p=0.003$ for females). Adding to this, both boys and girls of the Elite group presented higher trunk flexion ($p \leq 0.02$ for males and $p \leq 0.04$ for females) and B ($p \leq 0.001$ for both sexes) and boys also had higher GD ($p=0.01$) and had been through lower week volumes than their counterparts ($p \leq 0.04$). Finally, the Elite group, in both sexes, has had better results in T30 distance ($p=0.001$ for males and $p=0.005$ for females) and had lower mean stroke frequency during this test ($p=0.002$ for males and $p=0.02$ for females). **Discussion** In a previous report, explanatory models were developed identified the T30 aerobic test as the strongest predictive variable of race performance (1). We looked back to age group evaluation protocols and concluded that young swimmers predictive variables of performance were powerful on discriminating the success at adult level. Maturity status at the moment of the age-group evaluations is confirmed as a key variable for talent identification in swimming. Remarkably, if week training volumes did not influence future success in female swimmers, top ten male swimmers seem to have had even better results with less training when they were younger. **References** (1) Rama L, Santos J, Gomes P, Alves F (2006). *Rev Port C Desp*, 6 (supl.2) 246-249.

MONITORING ANGULAR RATE BY STANDARD INERTIAL SENSOR IN TWISTING MOVEMENTS OF MECHANICAL HUMAN BODY MODEL

Schäfer, K., Paffhausen, J., Alt, W.

Universität Stuttgart

MONITORING ANGULAR RATE BY STANDARD INERTIAL SENSOR IN TWISTING MOVEMENTS OF MECHANICAL HUMAN BODY MODEL Schäfer, K., Paffhausen, J., Alt, W. **1:** University of Stuttgart, Department of Sport- and Exercise Science **Introduction** Rotational velocity is, beside flight time, the most critical parameter for successful rotational jumps in sports like figure skating (King et al., 2004). Therefore the ability to monitor rotational velocity is necessary for optimizing jump performance. The purpose of this study was to validate a standard inertial sensor system with a mechanical model of a twisting human body to monitor rotational velocity. **Methods** Inertial sensor (XSens MTw) was mounted to a styrofoam cylinder dummy, which was aligned in the centre of an electrically driven rotary disk. The sensor was placed with a distance of 15cm to and consecutively with different angles (0° , 10° , 20° , 30°) against the styrofoam cylinder axis. In a second condition the styrofoam cylinder was aligned 6cm outside the rotational centre. Within about 2s the human body model was rapidly accelerated from $99^\circ/\text{s}$ to $999^\circ/\text{s}$ and after a short moment of constant rotational velocity rapidly decelerated to $99^\circ/\text{s}$. Angular rate data were sampled by XSens MTw (120Hz) and trials were simultaneously recorded with high speed digital camera (Casio Exilim EX-F1, 1200Hz) for kinematic analysis. Angular rates of sensor and kinematic analysis were tested for agreement in accelerating, constant and decelerating phase and entire trial using Bland-Altman-Plots (Bland&Altman, 1999). **Results** We found similar results for all tested conditions (angle, alignment). Bland-Altman-Plots showed good agreement in all tested conditions with limits of agreement within $35^\circ/\text{s}$ and bias $< 10^\circ/\text{s}$ for accelerating and constant phase and entire trial. Deceleration phase showed worse limits of agreement ($51.9^\circ/\text{s}$, $-18.5^\circ/\text{s}$) and bias up to $27^\circ/\text{s}$. Small signal time shift in deceleration phase was considered in some trials and was non-systematic distributed among the different tested conditions. **Discussion** Inertial sensors can be used for valid monitoring rotational velocity in rapid accelerating twisting movements. Despite the problems with signal time shift in the deceleration phase angular rate values are sufficient to evaluate the rotation characteristic with respect to the angular velocity. We recommend further investigations with real human subjects and an inertial sensor range up to $2000^\circ/\text{s}$ (Knoll&Hildebrand, 1998). **References** Bland J, Altman D. ASSESSMENT OF CARDIOMETABOLIC RESPONSE DURING HORSE RIDING

Marongiu, E., Sainas, G., Corona, F., Loi, A., Tocco, F., Concu, A., Crisafulli, A.

University of Cagliari

Introduction Few studies have addressed the physiological demands of riding. Oxygen uptake has been demonstrated ranging between 40% and 80% of maximal aerobic capacity ($\text{VO}_{2\text{max}}$) previously assessed, depending on different equine gaits. From these studies it can be inferred that the metabolic requirement of riding is similar to that of other physical activities, such as aerobics or gymnastics. The aim of the present study was to investigate on the cardiometabolic response in a group of riders during different gaits of equine movement. **Methods**. Ten riders were enrolled. They underwent two different tests: A) a standard incremental cardiopulmonary test (CPT) until exhaustion on an electromagnetically braked cycle ergometer. Oxygen uptake (VO_2), carbon dioxide production (VCO_2), pulmonary ventilation (Ve), and heart rate (HR) were measured by a gas analyzer (Ultima CPX, MedGraphics, USA). B) Riding session (RS), which consisted in 5 minutes of walking, 10 minutes of trot, and 10 minutes of cantering. Throughout RS, VO_2 , VCO_2 , Ve and HR were collected by a portable telemetric metabolimeter (VO_{2000} , MedGraphics, USA). Excess of carbon dioxide production (CO_2 excess) was also calculated as an index of anaerobic energy supply engagement. Parameters collected during RS were compared to values achieved during CPT. Moreover, parameters' levels during each gait were compared. **Results**. VO_2 , Ve , VCO_2 and HR mean values gathered during RS were below the maximum reached during CPT. Furthermore, all these parameters were below the level achieved at the anaerobic threshold. VO_2

raised significantly from 505.1 ± 130.8 ml•min⁻¹ during walking to 1133.9 ± 230 ml•min⁻¹ during cantering ($p < 0.05$). Cantering also increased HR with respect to walking (149.6 ± 24.7 bpm vs. 100 ± 14.9 bpm respectively, $p < 0.05$). Finally, statistics revealed significant increase in CO₂ excess during cantering (200.4 ± 98.1 ml•min⁻¹) with respect to trotting (102.8 ± 58.8 ml•min⁻¹) and walking (48.7 ± 34.5 ml•min⁻¹) ($p < 0.05$ in both cases). Conclusions. Data from the present investigation demonstrate that each of the different gaits of equine movement requires different metabolic response. It appears that, while walking and trotting involve predominantly the aerobic metabolism, during cantering the anaerobic metabolisms are recruited. This fact probably reflects the diverse pattern of riders' muscle contraction during each of the equine movements. References: • Westerling D. Eur J Appl Physiol 50: 373-382, 1983. • Devienne MF. IS-SH07 Long-term Follow-up & Implementation of School-based PA-Interventions: Myth or Fact? * - Sponsored by: The Coca Cola Company

SCHOOL PHYSICAL ACTIVITY INTERVENTIONS - EFFECTS ON HEALTH AND LEARNING OUTCOMES

Pate, R.

University of South Carolina

Promotion of physical activity to enhance health and prevent obesity in children has become a worldwide public health priority. In addressing this issue both researchers and practitioners have given great attention to the potential of school-based interventions to increase children's physical activity and contribute to prevention of obesity. However, school personnel often resist school-based health promotion initiatives on the premise that such activities may detract from the schools' primary mission to meet academic goals. Accordingly, much attention is currently being given to the effects of physical activity and interventions to increase physical activity on children's learning and attainment of academic outcomes. This presentation will review the current bodies of knowledge on: 1) the effects of school-based physical activity interventions on health outcomes including weight status; and 2) the effects of such interventions on learning and academic achievement.

KEY FACTORS FOR SUCCESSFUL IMPLEMENTATION AND DISSEMINATION OF A SCHOOL-BASED PHYSICAL ACTIVITY MODEL : A REPORT FROM THE TRENCHES

McKay, H.

University of British Columbia

The importance of physical activity (PA) for child health is widely known; however, the prevalence of PA is low in children in Canada and around the world. Schools may represent the most effective channel to intervene to enhance child health given they reach a large number of children from a range of ethnic and socioeconomic backgrounds. A number of systematic reviews support this contention. However, very few studies addressed factors deemed essential for sustained implementation and scale up of effective evidence-based PA initiatives. In 2004 we developed a comprehensive school-based health model in British Columbia, CANADA. Action Schools! BC utilizes a socio-ecological approach to provide children with healthier opportunities for physical activity and healthy eating at school. In partnership with government stakeholders (Ministries of Health and Education) we evaluated the model's efficacy (cluster randomized efficacy trial). To support implementation at the school level, Action Schools! BC adopted unique design features (e.g. a flexible model enabling and empowering elementary school teachers to create individualized 'school environment specific' action plans). In 2008 Action Schools! BC was scaled up and we evaluated its 'roll out' (cluster randomized effectiveness trial) across British Columbia. To support implementation and scale-up at the provincial level – the model provided practical and relevant professional development opportunities, customized resources and training for teachers and peer-to-peer physical activity and healthy eating leadership training and resources for students. Importantly, the Action Schools! BC interdisciplinary research team developed essential government and community partnerships across sectors (horizontal) and with teachers and administrators (vertical) to establish a supportive provincial environment, organizational context and resources necessary to implement a systematic scale up strategy. Action Schools! BC is now implemented in more than 90% of BC schools (450,000) children. Therefore, in 2012, 4 - years after scale-up, we examined the structural influences that created a supportive environment for the uptake and sustainability of this school based physical activity model (implementation trial). In this session on the 10th anniversary of Action Schools! BC, I share the story of Action Schools! BC including: i) practical lessons learned conducting school-based trials, and ii) evidence from efficacy, effectiveness and implementation trials from the inception of Action Schools! BC in 10 schools to its scale up in > 1500 schools.

WHY DO SCHOOL-BASED PA INTERVENTION WORK IN THE SHORT BUT NOT ON IN THE LONG-TERM?

Kriemler, S.

Institute of Social and Preventive Medicine

More than half of the physical activity intervention studies in children show beneficial effects on health in the right after the intervention. However we do not know whether these effects do persist over time once the intervention is withdrawn. The talk will have 3 aims: 1. To give an overview about results from school-based long-term follow-ups of physical activity interventions on health, 2. To give you an example of a long-term follow-up of a school-based randomized controlled trial (KISS) that was successful right after intervention with some maintained effects 3 years after the intervention stopped, and 3. To discuss with you why so few long-term follow-ups exist at all and what the implications are.

OP-PM33 Cardiovascular Exercise Physiology 2

THE HEALTHY WORKFORCE PROJECT: CARDIOVASCULAR EFFECTS OF REDUCING WORK PLACE SITTING TIME

Hopkins, N., Murphy, R., Shepherd, S., Graves, L.E.F.

Liverpool John Moores University

Background: Excessive sitting time is an independent predictor of cardiovascular disease (CVD) mortality and morbidity. Given that office based staff are largely sedentary during working hours, targeting reduction of sitting time in the workplace may have a significant impact on CVD risk. This pilot study utilised sit to stand workstations to assess the impact of 8 weeks sitting time reduction on cardiovascular risk parameters. Study Design and methods: Forty-two (38+9yrs, BMI 25+5, 20% male) asymptomatic office workers from Liverpool John Moores University were recruited and randomly allocated into 2 groups; intervention (INT, n=21) who received a sit-stand workstation for 8 weeks, or a comparison group (COM, n=21) who maintained normal working practices. Self-reported daily workplace sitting time (min) was assessed via ecological momentary assessment diaries at 0 and 4 weeks of the study. Anthropometrics and blood pressure were measured via standard techniques. Brachial artery flow mediated dilation (FMD), an independent predictor of CVD events, was used to assess endothelial function at baseline and at post test. A mixed ANOVA, with age and gender entered as covariates, was used to assess within and between group differences. Results: Groups were similar at baseline across all variables ($p>0.05$). During the intervention, there was a significant reduction in the amount of daily workplace sitting time in INT compared to COM (INT -87min+46min, COM 12+55 min, $p=0.01$). The intervention did not result in significant differences ($p>0.05$) between groups for weight (INT -0.20+0.02kg, COM 0.06+0.27kg) or systolic blood pressure (INT -3+4mmHg, COM -4+7mmHg). However, there was a non-significant trend for an improvement in INT diastolic blood pressure (INT -5+1mmHg, COM 5+15mmHg, $p=0.07$) and FMD (INT 1.40+0.17%, COM 0.35+0.40%, $p=0.16$). Discussion: Installation of a sit stand work station successfully reduced the sitting time of sedentary office workers, however these behavioural changes did not result in any significant improvement in cardiovascular risk parameters in this short study. Nonetheless, our data indicate that by reducing sitting time by ~90 minutes/day over 8 weeks, small but potentially clinically significant improvements in FMD and diastolic blood pressure can be induced. Further research is needed to elucidate whether long term use of sit stand workstations result in further improvements in these or other surrogates of CVD risk. Contact: n.d.hopkins@ljmu.ac.uk

POST-RESISTANCE EXERCISE HEMODYNAMICS IS SIMILAR IN MEDICATED AND NON-MEDICATED HYPERTENSIVE MEN: A DOUBLE-BLIND, PLACEBO-CONTROLLED CROSS-OVER STUDY

Forjaz, C.L.M., Queiroz, A.C.C., Sousa, J.S.C., Silva Jr, N.D., Tobaldini, E., Ortega, K., Oliveira, E.M., Brum, P.C., Montano, N., Mion Jr, D., Tinucci, T.

University of São Paulo, Sao Paulo, Brazil; University of Milan, Milan, Italy.

Introduction A session of resistance exercise (RE) promotes blood pressure (BP) reduction in hypertensives (HT), but the mechanisms involved and the effects of antihypertensive drugs, such as captopril, were unknown. The purpose of this study was to evaluate the effect of RE on post-exercise BP and its mechanisms in HT, verifying the effects of captopril use. Methods Twelve HT (50±3years) were evaluated after 4 weeks of placebo (PLA) and captopril (CAP - 3x50mg/day), administered in crossover and double-blind design. In each period, HT underwent 2 sessions: Control (rest) and RE (7 exercises, 3 sets to moderate fatigue, 50% of 1RM). Measurements were taken before interventions and after 30-60min (Post1) and 7h (Post2), and ambulatory BP was monitored for 24h. Results Hemodynamic responses after RE did not differ between PLA and CAP. At Post 1, systolic and diastolic BP decreased after RE (PLA= -13±2 and -9±1 mmHg; CAP= -12±2 and -10±1 mmHg, $P<0.05$). RE decreased cardiac output in some subjects and systemic vascular resistance in others. Heart rate and cardiac sympathetic modulation increased while stroke volume and baroreflex sensitivity decreased after RE (PLA: +13±2 bpm, +21±5 nu, -11±5 ml, -4±2 mmHg/bpm; CAP: +13±2 bpm, +35±4 nu, -17±5 ml, -3±1 mmHg/bpm, $P<0.05$). At Post2, all variables returned to pre-intervention, and ambulatory BP was similar between the experimental sessions. Conclusions In HT men, RE effects were similar between non-medicated and medicated periods. RE promoted BP reduction and this post-exercise hypotension (PEH) lasted for 1 hour after exercise. The hemodynamic determinant of PEH varied from one subject to another, and it was accompanied by stroke volume reduction and heart rate increase promoted by cardiac sympathetic modulation elevation and baroreflex sensitivity reduction. CIRCULATORY CONTROL DURING EXERCISE: MUSCLE PRESSOR REFLEX

Vinogradova, O.L., Borovik, A.S., Kuznetsov, S.Y., Miller, T.F., Bavyi, Y.R., Tarasova, O.S.

Institute for Biomedical Problems

Introduction Blood pressure (BP) and heart rate (HR) are increased during physical exercise as a result of enhanced sympathetic activity. The relative role of central command, muscle pressor reflex (MPR) and baroreflex in initiation of that reaction during rhythmic isometric contractions of different muscle groups was investigated. Methods Dynamics of BP, HR and muscle sympathetic nervous activity (MSNA) during rhythmic isometric contractions 30% MVC of wrist joint flexors or extensors of knee joint in regime 20 s contraction – 20 s rest till exhaustion were investigated in relation to way of contractions initiation (voluntary or evoked by electrical stimulation), force increase gradient, position of the body and adaptation of subject to physical loads. Coherent accumulation method used in the experiment allowed to expose fine dynamics of haemodynamic indices during muscle contractions. Results and discussion During rapid increase of muscle tension MSNA, BP and HR dynamics demonstrated decaying fluctuations at the background of general increase with frequency near 0.1 Hz. This finding points to baroreflex origin of these fluctuations. With lower rate of tension increase these fluctuations decrease as well. That means mechanical component of MPR plays an important role in baroreflex resetting during exercise. Reaction of cardiovascular system to muscle contractions of the same value is increased with development of fatigue. Dynamics of BP during contractions evoked by electrical stimulation practically does not differ from reaction during voluntary contractions with the same pattern of strength develop-

ment. That is central command does not contribute to BP control and baroreflex changes during physical exercise. The force training is shown to decrease muscle pressor reflex activity during rhythmic short-term static contractions and does not affect its manifestation during long-lasting static effort. Hemodynamic response does not depend on morphological characteristics and mass of contracting muscles. Comparison of BP and HR dynamics during equal contractions performed in supine and sitting position demonstrates that hemodynamic response is determined not only by reflex influences but by hydrodynamic situation. Thus not central command but MPR and hydrodynamics modulate baroreflex activity during moderate rhythmic muscle contractions. Contact Olga Vinogradova, email: ovin@imbp.ru

HIGHER ALTERATIONS IN PWV VALUES ARE ASSOCIATED WITH HIGHER AEROBIC CAPACITY AND AGING IN YOUNG MALE SOCCER PLAYERS

Lorenz, C., Hofmann, M., Baron, R., Bachl, N.

Institute for Sports Science

Introduction Arterial Stiffness (AS) is regarded as an important marker of cardiovascular risk (Laurent et al. 2006). Measured in Pulse Wave Velocity (PWV), the gold standard in non-invasive assessment, AS has shown a strong independent prediction concerning cardiovascular events and mortality (Willum-Hansen et al. 2006). Further, several studies demonstrated a decrease in AS with regular aerobic exercise (Seals et al. 2008). Still, reference values, especially in children are scarce. The aims of this study were: The acquisition of (1) PWV reference values, (2) PWV values after exercise to exhaustion and (3) to identify correlations between pre and post exercise PWV values, respectively and the aerobic workload capacity in young, physical active males. **Methods** 125 active soccer players were classified into five groups according to the youth squads of a Viennese football club (U10 n=13; U12 n=27; U14 n=27; U16 n=32; U18 n=26). PWV was measured by the Arteriograph (Colson) before and after an ergometry to exhaustion (start 1Watt/kg; increments 25Watt/min; cadence 70-100). Statistical differences were determined using ANOVA with Bonferroni post-hoc tests, correlations were characterized by Spearman-Rho correlation coefficients (IBM SPSS). **Results** PWV values at rest differ between the age groups ($p<0.001$). Post-hoc analysis revealed a difference between U18 to all younger groups ($p<0.02$), except U16. In addition U12 also differed to U16 ($p<0.05$). PWV values after ergometry showed a significant influence of time ($p<0.001$) over all groups between the pre and post physical load values ($p<0.001$). Moreover, the interaction term showed a significant result ($p<0.001$), indicating that a difference between age groups were detected. A larger increase of values was found for the U14, U16, U18 compared to U10 and U12 ($p<0.001$). In addition U14 differed to U10 and U12 ($p<0.002$). Correlation analyses revealed that Δ PWV were associated with Watt/kg ($p<0.02$; $p=0.214$). **Discussion** To our knowledge this is the first study investigating PWV values concerning physical workload capacity. Moreover no data regarding interactions of PWV values at rest and after exhaustion in young active males exist. We were able to detect alterations reaching adulthood, which suggests that even in young years differences in the AS and its regulation exist. Further, higher physical performance in young active men appear to be associated with higher alterations in PWV which propose a wider spectrum of aortic adaptability. **References** Willum-Hansen T, et al. EFFECT OF CONTRACTION INTENSITY ON SYMPATHETIC OUTFLOW TO ACTIVE HUMAN SKELETAL MUSCLE

Boulton, D.I, Taylor, C., Macefield, V.G.1,2, Green, S.1,2

1: University of Western Sydney, 2: Neuroscience Research Australia

Introduction Understanding the neural contribution to the control of skeletal muscle vasodilation and regulation of arterial blood pressure during exercise depends on knowing the effect that muscle contraction has on muscle sympathetic nerve activity (MSNA) to active muscle. The few studies that have involved direct recordings of MSNA to active limbs provide limited and inconsistent findings (Wallin et al., 1992; Hansen et al. 1994). Furthermore, the effect of contraction intensity on MSNA to active human limbs has not been established. **Methods** To address this, MSNA was recorded using microneurography performed from the left peroneal nerve in 8 healthy subjects during and after dorsiflexion contractions. The contractions, performed by the left leg, were sustained for two minutes at ~10, 25 and 40 % maximal voluntary contraction. To explore the involvement of the muscle metaboreflex, limb ischaemia was imposed midway during six additional contractions and maintained during recovery. **Results** Compared with total MSNA at rest (11.5 ± 4.1 mv/min), MSNA in the active leg increased significantly at the low (21.9 ± 13.6 mv/min), medium (30.5 ± 20.8 mv/min) and high (50.0 ± 24.5 mv/min) intensities. This intensity-dependent effect was more strongly associated with increases in MSNA burst amplitude than burst frequency. Total MSNA then returned to resting levels within the first minute of recovery. Limb ischaemia had no significant influence on the intensity-dependent rise in MSNA or its decline during recovery in the active leg. **Discussion** The present findings show that sympathetic outflow to contracting muscle is increased significantly even at very low forces (10 %MVC), and rises in proportion to contraction force. These intensity-dependent increases in total MSNA and burst amplitude to contracting human skeletal muscle do not appear to involve the muscle metaboreflex. This challenges previous theories, given that such an effect opposes the need to increase muscle blood flow to the contracting muscles during exercise. However, constraint of vasodilation in contracting muscle helps to regulate arterial blood pressure by preventing vasodilation from outstripping the pumping capacity of the heart (Savard et al., 1987), and thus serves the whole organism. Finely-tuned control of any vasculature in response to variation in tissue need requires both vasoconstricting and vasodilating mechanisms. **References** Hansen J, Thomas JD, Jacobsen TN, Victor RG. NANDROLONE ATTENUATES EXERCISE-INDUCED MITOCHONDRIAL ADAPTATION OF LARGE VESSELS

Shen, W.

Shanghai Institute of Hypertension

Introduction Anabolic androgenic steroids (AAS) abuse has been linked to a variety of cardiovascular side effects. However, the mechanisms responsible for deleterious cardiovascular events reported in athletes improperly using AAS are poorly understood. In this study we investigated the interaction between exercise-induced mitochondrial adaptation of large vessels and effects of chronic AAS. **Method** Four groups of Sprague Dawley (SD) rats were studied: (1) sedentary, (2) sedentary+nandrolone-treated, (3) aerobic exercise trained, and (4) trained+nandrolone-treated. Blood vessel function was studied by using Wire Myograph system. Aorta ultrastructure was observed under transmission electron microscope. Expression of Microtubule-associated protein light chain 3(LC3), Beclin1, Mitofusin1/2, peroxi-

some proliferator-activated receptor- γ coactivator 1 α (PGC-1 α), dynamin-related protein 1(Drp1), mitochondrial manganese superoxide dismutase (MnSOD) and catalase were analyzed by Western Blot. Results Aerobic physical training improved acetylcholine-induced vascular relaxation. The beneficial effect was associated with induction of mitochondrial complexes I and V, increased mitochondrial DNA copy number, and greater expression of transcription factors involved in mitochondrial biogenesis/fusion. We also observed enhanced mitochondrial autophagy pathway activity, including increased conversion of LC3-I to LC3-II and greater expression of Beclin1 and autophagy-related protein 7 (ATG7). We observed significant increases in catalase and MnSOD levels in aortas from trained animals compared with sedentary controls. Nandrolone increased oxidative stress biomarkers and inhibited exercise-induced increases of catalase, and MnSOD expression. It also attenuated elevated PGC-1 α and MFN2 expression and further up-regulated LC3II conversion, Beclin1, ATG7, and DRP1 expression. Discussion This study demonstrates that nandrolone attenuates aortic adaptations to exercise via its effects on mitochondria dynamic remodeling, including mitochondrial biogenesis down-regulation and intensive autophagy induction. These findings suggest that altered mitochondrial dynamics induce mitochondrial dysfunction related to cardiovascular pathophysiology and provide new insights for the prevention AAS abuse. OP-PM34 Exercise Therapy in children with CP & COPD

AGE AND DISEASE RELATED DIFFERENCES IN SPRINT POWER OUTPUT BETWEEN CHILDREN WITH CEREBRAL PALSY AND TYPICALLY DEVELOPING CHILDREN

Dallmeijer, A.J., Balemans, A.C.J., Brehm, M.A., Van-Wely, L., Becher, J.G.

VU University Medical Center

Introduction Children with cerebral palsy (CP) experience limitations in mobility and other daily activities, caused by the primary motor deficits like spasticity, impaired motor control and reduced muscle volumes. The ability to sustain short duration, high intensity exercise is assumed to be a relevant outcome in children because their activities of daily living are characterized by short bursts of intensive exercise. Previous research indicates that this ability is reduced in children with CP (Moreau et al 2012). The aim of this study is to assess age and disease related differences in sprint power output between ambulant children with CP in comparison with typically developing children (TD). **Methods** A total of 203 children aged 6-14 years participated, including 120 ambulant children with spastic cerebral palsy walking without (gross motor function classification system [GMFCS] levels I [n=66], II [n=38]) and with walking aids (GMFCS level III [n=16], unilateral CP: n=40), and 83 typically developing (TD) children. All children performed a 20-s sprint test on a child-adapted electronically braked cycle-ergometer. The child was asked to cycle as fast as possible for 20 sec against a constant workload. Mean (P20mean, W/kg) and peak sprint power (P20peak, W/kg) output over 20s were calculated (Dallmeijer et al 2013). To assess differences in sprint power output between children with CP and TD, a multiple linear regression analysis was performed. Disease group, defined as severity level of CP (categorical variable with GMFCS I, II and III as dummy variables, and TD as reference) was included as independent variable, as well as age, sex, body weight and height, and their interaction with disease group. **Results** On average children with GMFCS level I, II and III showed significantly lower values for P20mean (mean \pm SD: 4.2 \pm 1.37, 2.8 \pm 1.24, 1.5 \pm 0.82W/kg) than TD children (6.2 \pm 1.07, p<0.001), explaining 64% of the variance. However, further analysis showed that, apart from an increase in P20mean (W/kg) with higher age, the differences between CP and TD were also age dependent (as shown by an age-disease group interaction), showing a larger difference with higher age. In the final regression model, disease group, age, body weight, height, and the interaction of age and height by disease group, explained 76% of the variance of P20mean (W/kg). There were no differences between boys and girls. Similar results were found for P20peak. **Conclusion** Sprint power output is considerably reduced in children with CP (30-72%) compared to TD children, and these differences tend to increase when children grow older. As this is expected to impact their activities of daily living, possibilities for improving sprint power should be explored. Future research should also focus on the further development of sprint power output into adolescence. **References** Dallmeijer AJ, Scholtes VA, Brehm MA, Becher JG (2013). *Am J Phys Med Rehabil* 92, 762-7. EFFECTIVENESS OF A LIFESTYLE PROGRAM AMONG ADOLESCENTS AND YOUNG ADULTS WITH CEREBRAL PALSY; A RANDOMIZED CONTROLLED TRIAL

van den Berg Emons, R., Slaman, J., van der Slot, W., van Meeteren, J., Stam, H., Roebroek, M.

Erasmus Medical Centre

Introduction Sufficient physical activity and fitness is considered of major benefit to a healthy lifestyle. Nevertheless, research has consistently shown that persons with cerebral palsy (CP) have low levels of physical activity and fitness. Furthermore, this unfavorable lifestyle is expected to negatively affect fatigue and quality of life. To assure healthy aging, a lifestyle program to increase daily physical activity and fitness seems beneficial in adolescents with CP. **Methods** We conducted a multi-centre single blind randomized controlled trial in 57 adolescents and young adults with spastic CP level I-IV (Gross Motor Functioning Classification System), recruited from 2 university hospitals and 4 rehabilitation centres in the Netherlands. Participants were randomly assigned to either an intervention or control group. The control group received no intervention, which is regular care in the Netherlands. The intervention group followed a lifestyle program aiming to permanently increase physical activity and fitness. The intervention had a duration of 6 months and consisted of individual counseling on daily physical activity and sports. Fitness training was offered during the first 3 months. Participants were measured before, directly after, and 6 months after finishing the intervention. Fitness was measured by peak oxygen uptake using oximetry during a progressive protocol on a cycle or armcrank ergometer. Daily physical activity was objectively measured for a period of 3 days using accel-

erometry-based activity monitors. Fatigue and quality of life were assessed by questionnaires. GEE-models were applied to examine longitudinal effects. Results No significant effects over time were found for daily physical activity between the two groups. A significant effect, in favor of the intervention group, was found for fitness, 3 months after finishing the fitness training ($p < 0.01$). However, this effect was no longer present 9 months after finishing fitness training. Favorable intervention effects were found on fatigue ($p = 0.02$) during the intervention and quality of life with respect to bodily pain ($p = 0.01$) and mental health ($p = 0.03$) during follow up. Discussion The lifestyle program did not achieve a behavioral change toward increased daily physical activity. However, results of the intervention on fitness were promising as still 3 months after finishing the fitness training favorable effects were seen. Nevertheless, this effect on fitness did not last on the long term. The lifestyle intervention favorably affected secondary outcomes as fatigue and quality of life. LONGITUDINAL RELATIONSHIP BETWEEN AEROBIC CAPACITY, ANAEROBIC CAPACITY AND MUSCLE STRENGTH IN CHILDREN WITH CEREBRAL PALSY

Balemans, A.C.J., van Wely, L., Becher, J.G., Dallmeijer, A.J.

VU University Medical Center, Amsterdam

Introduction There is increasing evidence that children with cerebral palsy (CP) have decreased aerobic capacity, anaerobic capacity and muscle strength (1). Decreases in muscle strength and anaerobic capacity might be expected in light of the impaired muscle activation in CP, whereas aerobic capacity seems to be more closely related to physical inactivity (1). Due to the differences in coordination and muscle function between unilateral and bilateral involved CP, (2) a different relationship among fitness components might be expected in these groups. The aim of this study was to determine the longitudinal relationship among fitness components aerobic capacity, anaerobic capacity and muscle strength in children with CP. **Methods** Children with spastic CP (bilateral $N = 24$ or unilateral $N = 22$ involved), aged 7-13 years, participated in aerobic and anaerobic fitness measurements on a cycle ergometer and isometric muscle strength tests. Peak oxygen uptake (VO_{2peak} [ml/kg/min]), peak O_2 pulse (VO_2/HR [ml/beat]), peak ventilation (VE_{peak} [L/min]) and the anaerobic threshold (AT) were determined in a maximal exercise test. As an estimate of anaerobic capacity, sprint performance was determined as mean power over 20s (P_{20mean}) in a Wingate test. Isometric muscle strength of the knee extensors and hip abductors of the most affected leg was measured using a hand-held dynamometer. Longitudinal relationships over one year were analyzed using randomized coefficient analysis ($p < 0.05$). **Results** In children with bilateral CP, aerobic fitness parameters (VO_{2peak} ($p < 0.001$), AT and O_2 pulse ($p < 0.05$) were related to P_{20mean} , while aerobic capacity (VE/VO_2 only) showed a weak relationship with muscle strength (knee extensors and hip abductors) ($p < 0.05$). P_{20mean} was not related to muscle strength. In children with unilateral CP, no relations among fitness components were found. **Discussion** The strong longitudinal relationship between anaerobic capacity and aerobic capacity in children with a bilateral CP indicates that increased aerobic or anaerobic fitness relates to improvements in the other fitness component, while this was not found in children with unilateral CP. Muscle strength of the most affected leg appears to be less related to aerobic and anaerobic capacity, as indicated by weak relationships. Whether muscle strength of the least affected leg shows stronger relationships to aerobic and anaerobic capacity should be investigated in future research. **References** 1) Balemans ACJ, Van Wely L, De Heer SJA et al. INTERVAL EXERCISE IMPROVES EXERCISE TOLERANCE IN COPD PATIENTS WITH NO ALTERATIONS IN ABDOMINAL FAT DEPOSITION

Giannopoulou, I.1,2, Koutsikos, I.3, Spetsioti, S.2, Vasilopoulou, M.2, Ntalapera, S.2, Spyridaki, K.2, Vasilogiannakopoulou, T.2, Vogiatzis, I.2,4

1: University of Brighton (Eastbourne, UK), 2: University of Athens (Athens, Greece), 3: 401 General Military Hospital (Athens, Greece), 4: University of the West of Scotland (Glasgow, UK)

Introduction Abdominal obesity has been recognized as an important contributor to the respiratory problems and overall health of patients with chronic obstructive pulmonary disorder (COPD). Interval exercise has been shown to improve exercise capacity and quality of life of COPD patients. However, no studies have investigated whether interval exercise affects the abdominal fat depots of COPD patients. The purpose of this study was to investigate the effect that interval exercise has on the abdominal obesity of COPD patients and whether its change is related to improvements seen in exercise capacity. **Methods** Twelve overweight COPD patients ($FEV_1 = 54.87 \pm 20.8\%$, $BMI = 27.29 \pm 3.55$ kg/m²) volunteered to participate in the study and signed an informed consent. Patients participated in a 12-week exercise rehabilitation program that consisted of interval exercise on a cycle ergometer (30 sec at 100% of work rate max (WRmax) and 30 sec active recovery) for a total of 40 minutes for 3 times/week. Prior to and at the end of the exercise rehabilitation program, all patients completed pulmonary function tests, a 6-min walk test, a WRmax test on a cycle ergometer and dual energy absorptiometry (DEXA) assessment. **Results** Patients exhibited a high level of abdominal fat deposition as evident from a mean abdominal to gluteal fat ratio of 1.1 ± 0.1 . Abdominal fat was the sole parameter significantly correlated with FEV_1 ($r = -0.59$, $P < 0.01$), the 6-min walk test ($r = -0.76$, $P < 0.01$) and the WRmax test ($r = -0.67$, $P < 0.05$). Interval training improved the exercise capacity of the patients with significant improvement in the WRmax test (pre: 78.8 ± 21.3 , post: 98.5 ± 28.4 watts, $P = 0.004$). No significant changes from pre to post in body weight, total percent body fat and abdominal fat were found ($P > 0.05$). However, gluteal fat was significantly reduced from pre to post (pre: $38.5 \pm 5.2\%$, post: $36.3 \pm 5.1\%$, $P < 0.01$). **Conclusions** In COPD patients with high abdominal fat deposition, abdominal fat significantly correlates with respiratory and exercise capacity. However, interval exercise training does not alter the body weight and abdominal fat deposition despite the significant improvements in exercise capacity. As with other clinical populations, it is possible that the addition of a diet program is necessary to reduce the body weight and abdominal fat and possibly lead to greater health improvements in these patients. **References** Rutten EP, Breyer MK, Spruit MA, Hofstra T, Van Melick PP, Schols AM, Wouters EF. INTRODUCTION There is evidence that adapted physical activity is effective for improving the exercise tolerance (Vogiatzis et al., 2002). Nevertheless, there are no univocal indications about modalities and components of training program to be prescribed to patients affected by chronic obstructive pulmonary disease (COPD). The aim of the study was to evaluate the effects of two 16 weeks training programs (endurance and endurance+strength) on cardiovascular (basal and under effort heart rate, systolic and diastolic arterial pressures) and respiratory parameters (FVC%, FEV1%, FEV1/FVC%), exercise capacity (V'O2 peak), muscle strength (quadriceps femori MVC) and functional exercise capacity. **METHODS** COPD patients were randomly assigned to endurance training (ET) or to endurance + strength training (EST). All Patients underwent 3 sessions per week for 16 weeks. For ET, as upper intensity training limits were considered 40-50% heart rate reserve; for EST training limits were considered 40-50% heart rate reserve and 50% 1RM (ACSM, 2006). Before and after training program, patients underwent: clinical assessment, respiratory functionality tests, maximal cardiopulmonary test. MVC and functional exercise capacity (6 min walk test, repeated chair stands and timed up and go test) were assessed. **RESULTS** Thirty-five patients (14M/21F; age 71±9 y; FEV1 61 ± 14% of predicted) completed the ET program; 30 patients (18M/12F; age 74±6 y; FEV1 59 ± 18% of predicted) completed the EST program. Basal diastolic arterial pressure improved in EST program (78±6 vs 75±6 mmHg, p=0,01). In both ET and EST there was a trend toward improvement of the other cardiovascular and respiratory parameters. A significant improvement was observed for V'O2 peak (ET: 17,7±3 vs 18,7±3,3 ml/kg/min, p <0,01; EST: 18,8±5 vs 19,7±6 ml/kg/min, p <0,05). Quadriceps femori MVC, 6 min walk test, repeated chair stands and timed up and go test significantly improved in both ET (17,2±8 vs 20±6 kg, p < 0,0001; 384±71 vs 448±68 m, p=0,0001; 13±2 vs 10±2 s, p < 0,0001; 7,6±1,3 vs 5,9±1 s, p < 0,0001 respectively) and EST (17,5±5 vs 22,3±6 kg, p < 0,0001; 408±90 vs 459±90 m, p=0,0001; 13±2,9 vs 9,4±2 s, p < 0,0001; 7,5±1 vs 5,6±1 s, p < 0,0001 respectively) programs' patients. **Discussion** Both training programs produced significant improvements on exercise capacity, muscle strength, and functional exercise capacity. **References** Vogiatzis I, Nanas S., Roussos C. (2002). *Eur Respir J*; 20: 12-19. ACSM's Guidelines for Exercise Testing and Prescription. (2006) 7th Edition. Williams & Wilkins. EFFECT OF SAND VERSUS GRASS TRAINING SURFACES DURING AN 8-WEEK PRE-SEASON CONDITIONING PROGRAMME IN TEAM SPORT ATHLETES

Binnie, M.J.1,2, Dawson, B.1, Arnot, M.2, Pinnington, H.3, Landers, G.1, Peeling, P.1

1UWA (Perth, AUS), 2WAIS (Perth, AUS), 3ND (Fremantle, AUS)

Introduction When compared to firmer and more traditional training venues such as grass, sand exercise is associated with a higher energy cost and lower impact-training stimulus (Impellizzeri et al., 2008; Pinnington & Dawson, 2001a; 2001b). There is recent evidence to suggest that sand training can be beneficial in a team sport training environment (Binnie et al., 2013a; 2013b), however there is limited research to show the long-term training impact. This study aimed to investigate the training benefits of sand versus grass surfaces, during an 8-week pre-season conditioning program in team sport athletes. **Methods** Participants (n=24) were tested pre- and post-training for leg strength and balance, vertical jump, agility, speed, repeat speed, and maximal oxygen consumption (VO2max). Heart rate (HR), training load (session-RPE), movement patterns (GPS), and perceptual measures were monitored throughout. Participants completed 2x1 h conditioning sessions per week on sand (SAND) or grass (GRASS) surfaces, incorporating interval training, sprint and agility drills, and small-sided games. **Results** Significantly higher (p<0.05) HR and training load in the SAND versus GRASS group throughout each week of training, plus some moderate effect sizes to suggest lower perceptual ratings of soreness and fatigue on SAND. Significantly greater (p<0.05) improvements in VO2max were measured for SAND compared to GRASS. **Conclusion** Substituting sand for grass training surfaces throughout an 8-week conditioning program can significantly increase the relative exercise intensity and training load, subsequently leading to superior improvements in aerobic fitness. Overall, using sand surfaces in a team sport pre-season training programme may allow for more optimal athlete preparation, by maximising the training response and reducing performance limiting effects that may arise from heavy training loads on firm surfaces. **References** Binnie, MJ, Dawson, B, Pinnington, H, Landers, G, Peeling, P. THE PHENOMENON OF DOPING FROM SPANISH PROFESSIONAL FOOTBALL PLAYERS' PERSPECTIVE

Morente Sánchez, J., Garrido Blanca, G., Zabala, M.

Faculty of Sport Sciences, University of Granada (Spain)

Introduction Doping in Spanish professional football has never been investigated from a psychosocial perspective. The aim of this study was to examine the phenomenon of doping in Spanish professional football players focusing on attitudes towards doping and other related information. **Methods** The sample was comprised of 612 Spanish professional football players (24.6±5.22 years; response rate: 79.48%), from the different categories: Elite -ELI- (1st and 2nd Division; n=304) and non-elite Professional -PRO- (2nd Division B; n=308).

Descriptive design was carried out using a validated questionnaire (Performance Enhancement Attitudes scale: PEAS) (Petroczi & Aidman, 2009) to assess attitudes towards doping. Additionally, a bespoke qualitative open-ended questionnaire, which had been used (similar version) in previous studies (Morente-Sánchez, Mateo-March & Zabala, 2013), was used to get complementary information. Results Overall mean score from PEAS (17–102) was 32.43 ± 10.68 (ELI: 30.61 ± 9.91 ; PRO: 34.23 ± 11.13 ; $p=0.000$). The sample analyzed stated that 13.5% of professional footballers used banned substances (projected use): ELI, 11.61 ± 14.15 ; PRO, 16.04 ± 16.22 ($p=0.000$). Regarding knowledge, only 9.3% of total sample knew the meaning of WADA, and a few recognized to know the prohibited list (2.7%); nearly half of the sample (46.30%) used supplements; almost five percent (4.5%) recognized having used banned substances, and 22.3% knew dopers; the most mentioned word associated with “doping” was “cheating” (23.20%), and for the “responsible agents of doping” the most mentioned was “doctor” (33.5%); the “main reason for doping” was “performance” (36.9%), and the major proposed solution was “more doping controls” (15%; 74.30% “no response”). Besides, 77.6% stated that regarding doping “a different treatment among sports” existed, considering cycling as the most persecuted (51.9 %), and team sports as the less (33.7%: and football just 12%). Discussion Spanish professional football players appear not to be tolerant in relation to doping. However, a risky lack of knowledge about this phenomenon is shown, highlighting that anti-doping prevention and education programs in football are needed. References Petroczi, A., Aidman, E. (2009). Measuring explicit attitude toward doping: Review of the psychometric properties of the Performance Enhancement Attitude Scale. *Psychology of Sport and Exercise*. 10: 390–396. VISUAL PERFORMANCE OF ELITE HOCKEY PLAYERS – A LONGITUDINAL ANALYSIS

Oertzen Hagemann, V., Jendrusch, G., Platen, P.

Ruhr-Universität Bochum, Faculty of Sports Science

Introduction Visual performance in sports, especially sports and racket games, undisputably influences sporting performance. In Germany, however, eyesight tests for the analysis of visual performance and the detection of ametropia/defective vision are only integrated in the routine health check or performance diagnostics in few sports. The aim of this study was to analyze, if regular visual testing of competitive sportsmen is effective in the sense of visual performance optimization and which further consequences will occur. Methods Visual test data from the male ($n=110$, mean age 20.4 ± 2.7 years) and female ($n=143$, mean age 20.7 ± 3.3 years) national field hockey teams were evaluated, which were collected over a period of seven years (2006–2013) in annual health and performance diagnostics. The players (female: $n=25$; male: $n=27$) that were included in the longitudinal analysis took part in the eyesight tests at least four times during the testing period. The rate of ametropia, the compliance (related to the medical recommendation) and the group-related development of monocular visual acuity (VA) were analyzed. Results For the complete sample ($n=253$) the median of visual acuity was $VA=1.60$ for both eyes ($P25=1.27$, $P75=2.00$). It is notable that during the first eyesight test 24 % of the athletes were classified as “ametropic” (i.e. in need of correction). In the group-related longitudinal section VA of the men increased significantly from the first test (right eye (R.E.)= 1.61 , $P25=1.06$, $P75=1.85$; left eye (L.E.)= 1.59 , $P25=1.22$, $P75=1.95$) to the second test (R.E.= 2.00 , $P25=1.60$, $P75=2.25$; $2p=0.001$ / L.E.= 2.00 , $P25=1.60$, $P75=2.00$; $2p=0.009$) and then stayed on a very high level ($VA=2.00$). VA of the women showed no significant difference between the four tests (first test: R.E.= 1.60 , $P25=1.26$, $P75=1.70$ / L.E.= 1.60 , $P25=1.26$, $P75=1.80$; fourth test: R.E.= 1.80 , $P25=1.41$, $P75=2.00$ / L.E.= 1.60 , $P25=1.60$, $P75=2.00$; $p=0.069$) – related to the men on an overall low level. The reason is the higher rate of ametropia – which developed during the testing period – in the women group (36 %) compared to the men (11 %). VA of the men improved significantly during the multiannual testing compared to the median of the complete sample ($p<0.01$). The compliance of the men (with 50 %) is better than those of the women, from which only 45 % followed the medical advices. Conclusion The results show the necessity of regular visual testing concerning sporting performance and the prevention of injuries and accidents. Ametropia often develops in the ages in which competitive sports are practiced and may have negative influences on sports performance. The partly bad compliance confirms that the trainers and athletes need to strengthen their awareness of the problems concerning eyesight for the sake of safety and performance. RELATING BALL FLIGHT CHARACTERISTICS, VARIABILITY IN RELEASE LOCATION AND GAME SUCCESS IN ELITE BASE-BALL PITCHING

Whiteside, D., McGinnis, R.S., Deneweth, J.M., Holstad, R., Martini, D.N., Zernicke, R.F., Goulet, G.C.

University of Michigan

Introduction Although pitching coaches in baseball often focus on mechanics, descriptions of ball flight kinematics have enhanced understanding of the pitching skill. For example, measuring ball velocity now provides a straightforward method to appraise performance. The ability to impart spin to the ball and disguise pitches is equally critical to success, but has garnered less research interest. With a view to informing coaches and directing more pertinent pitching evaluations, the aim of this study was to compare ball flight kinematics in three types of pitches and relate them to game success. Methods Nine NCAA Division I pitchers threw 4 fastballs (FB), 4 curveballs (CR) and 4 sliders (SL) from a regulation pitching mound at their practice facility. Initial ball flight was recorded by a high-speed (600 Hz) camera positioned ≈ 2 m behind the pitcher and facing home plate. Custom ball-markings were digitized in post-processing and used to calculate the magnitude and orientation of the spin axis (Jinji & Sakurai, 2006) as well as variability in the ball release location. A radar gun measured maximal pitch velocity. One-way repeated measures ANOVAs, with post-hoc comparisons, assessed differences in ball velocity and spin axis across the pitch types. To evaluate how ball kinematics related to one another, and to pitching success, they were inserted into a bivariate correlation with earned run average (ERA—a prevalent indicator of pitching ability) from the previous season. Results The FB (39 m/s) was significantly faster than the CR (32 m/s) and SL (34 m/s) ($p<0.001$). Spin rate (≈ 33 revs/s) did not differ significantly across pitches. The FB spin axis — declined 13° from the horizontal and rotated -58° from the line of ball flight (toward 3rd base) — was significantly different to the CR and SL spin axes (both inclined $\approx 19^\circ$ and rotated $\approx 7^\circ$; $p<0.01$). Overall, the elevation and transverse rotation of the spin axis shared significant strong negative correlations with ball spin and ball velocity, respectively ($p<0.05$). Finally, ERA shared a strong positive ($R^2=0.878$, $p=0.002$) correlation to release location variability (namely, lateral location), but was not significantly correlated to velocity, spin rate or spin axis orientation. Discussion Based on these results, pitchers should aim to orientate the spin axis in fastballs slightly below the horizontal and parallel to the pitching rubber (i.e. roll the fingers downward over the back of the ball, producing backspin). In breaking balls (CR & SL), the spin axis should be elevated from the horizontal and roughly pointing toward home plate (i.e. the fingers roll downward, roughly over the side of the ball to produce combined side/top spin). Perhaps most importantly, variability of the release location appears more closely related to ERA than velocity or spin rate. This suggests that pitchers should aim to refine a consistent release location to reduce the anticipatory cues available to the batter and enhance pitching performance. References Jinji T, Sakurai S. (2006). *Sports Biom*, 5(2), 197–214.

REHABILITATING THE INJURED THROWING SHOULDER: A COMPREHENSIVE EMG ANALYSIS OF ROTATIONAL SHOULDER EXERCISES

Alizadehkhayat, O.1, Hawkes, D.H.2, Frostick, S.P.2

1: Liverpool Hope University (Liverpool, UK), 2: University of Liverpool (Liverpool, UK)

Introduction Effective overhead throwing, a key component of many professional sports, requires a balance between rotational shoulder strength and flexibility. Injuries are common and rehabilitation protocols are central for successful and timely treatment. There is an absence of comprehensive studies with regard to shoulder rotational exercises. Hence this electromyographic study aimed to describe shoulder girdle muscle activation strategies during eight common rotational shoulder exercises. **Method** EMG was recorded in 30 healthy subjects from 16 shoulder girdle muscles (surface electrodes: anterior, middle and posterior deltoid, upper, middle and lower trapezius, upper and lower latissimus dorsi, upper and lower pectoralis major; fine wire electrodes: supraspinatus, infraspinatus, subscapularis and rhomboid major) using a telemetric EMG system. Five external rotation (EXT.R.) exercises (0° and 90° of abduction, and with towel, prone external rotation, side lying internal rotation) and three internal rotation (INT.R.) exercises (0° and 90° of abduction, zero-position internal rotation) were included. EMG amplitude was normalised to external or internal rotation MVC as appropriate. Mean EMG amplitudes between exercises were compared using repeated measures ANOVA. **Results** EXT.R. Exercises: significantly higher activation of deltoid was seen in EXT.R. at 90° abduction compared to other exercises (73.7% vs 12.4-27.2%; $p < 0.001$). Peri-scapular muscle activation was highest in EXT.R. at 90° abduction and prone EXT.R. (76.7-83.2% vs 28.2-45.5%; $p = 0.013 - < 0.001$). Activation of latissimus dorsi and teres major was significantly higher during prone EXT.R. (64.1% vs 18.1-48.4%; $p < 0.001$). Activation of the rotator cuff muscles was similar across all exercises. INT.R. Exercises: the highest deltoid activity was seen during INT.R. at 90° abduction, followed by zero-position internal rotation and lowest during INT.R. at 0° abduction (261.6% vs 190.1% vs 40.9%; $p = 0.003 - < 0.001$). A similar activation pattern was seen for peri-scapular muscles. The highest activation of pectoralis major was in zero-position INT.R. (25.4% vs 4.9-15.7%; $p = 0.002 - < 0.001$). Significantly higher levels of rotator cuff activation were seen during INT.R. at 90° abduction (325.0% vs 94.0-188.3%; $p = 0.005 - 0.017$). **Discussion** This study provides a comprehensive description of muscles activation during common rotational shoulder exercises. It enables sport medicine professionals to target specific shoulder girdle muscles during rehabilitation protocols while minimising the effect of others, forming the basis for exercise prescription. Furthermore, the information can be used for tailored and targeted training of muscles involved in throwing sports. alizado@hope.ac.uk

PHYSIOLOGICAL PROFILE OF PROFESSIONAL FAST-MEDIUM BOWLERS DURING COMPETITIVE CRICKET MATCHES

Johnstone, J.1, Ford, P.2, Watson, T.3, Mitchell, A.4, Hughes, G.2, Gordon, D.1, Baker, J.1, Garrett, A.5

1Anglia Ruskin University; 2British Olympic Assoc; 3University of Hertfordshire; 4University of Bedfordshire; 5University of Hull

Introduction Coaches require more applied data accessed from competitive in-match environments to provide a better insight into players' performance. Previous research on fast bowling has used simulated bowling events to collect physiological data which lacks ecological validity. Mobile physiological monitoring devices now permit the capture of competitive in-match data which may better inform coaches about performance. The aim of this study was to develop an in-match physiological profile of fast-medium bowlers, using a mobile monitoring device across One Day (OD) and Multi Day (MD) formats of professional cricket. **Methods** After securing ethical agreement 10 cricket bowlers (24.8 ± 5.2 yrs; 89.7 ± 10.8 kg; 186.9 ± 7.9 cm) wore the Bioharness monitoring device during 80 hours of competitive OD and MD matches. The Bioharness measures 5 variables simultaneously (Heart rate, Breathing frequency, Accelerometry, Skin temperature, Posture). This exploratory analysis utilised the heart rate (HR) data which was organised into match states of bowling, between over and fielding, using notational analysis and accelerometry data. **Results** OD cricket stimulated higher mean HR (OD, 142 vs MD, 137 b.min⁻¹, $P < .05$; Effect Size (ES) ≥ -0.13) when compared to MD matches. During OD bowling higher mean HR (OD, 142 vs MD, 137 b.min⁻¹), age-related HR (HRage) (73.1 vs 70.9%), HR min (126 vs 116 b.min⁻¹) and age-related HR min (HRminage) (65.6 vs 59.9%) were reported ($P < .05$; ES = -0.12 to -0.41). Between over data reported higher ($P < .01$; ES = -0.27 to -0.45) HR in OD matches for HR mean (129 vs 120 b.min⁻¹), HR min (118 vs 104 b.min⁻¹) and the age-related values of each (HRage 65.7 vs 62.0%; HRminage 60.8 vs 55.0%). Fielding activity in OD matches reported higher ($P < .01$; ES = -0.20 to -0.45) HR mean (115 vs 106 b.min⁻¹), HR min (99 vs 87 b.min⁻¹) and age-related values of each (HRage 58.8 vs 54.4 %; 51.3 vs 45.3%) compared to MD matches. **Discussion** This study is one of the first to present in-match HR data from professional cricket providing a better insight for exercise scientists of the cardio-vascular (CV) requirements of fast-medium bowling. The Bioharness identified the OD format has greater CV stress for bowlers. Also there was varying CV stress for the three match states with bowling eliciting the highest HR responses. These outcomes question the validity of previous simulated bowling research, which reported higher HR responses. Coaches should now consider match specific physiological preparation for and recovery from bowling. Future research should utilise mobile monitoring devices so further informing training strategies to optimise performance. james.johnstone@anglia.ac.uk

OP-PM36 Exercise training

MAXIMAL STRENGTH IN UPPER-BODY SEGMENTS AS PREDICTORS OF DOUBLE POLING PERFORMANCE IN FEMALE CROSS-COUNTRY SKIERS

Østerås, S., Hegge, A.M., Welde, B., Van den Tillaar, R., Sandbakk, Ø.

Nord-Trøndelag University College

Introduction Upper-body strength and endurance capacity is of high importance for cross-country skiing performance and especially relevant in the double poling movement. This study aimed to investigate how maximal strength in the elbow, shoulder and trunk segments (measured in isolation) influence double poling efficiency, endurance and sprint performance in female cross-country skiers. To provide further insight into the mechanisms related to these relationships poling technique and body composition was analyzed. Meth-

ods 13 well trained female cross-country skiers (age 22 ± 3 yrs, body mass 61 ± 5 kg, VO_2max running 65 ± 4 ml/kg/min) tested maximal strength (1RM) in elbow extension, and shoulder and trunk flexion exercises. Double poling was performed on a Concept2 SkiErg where all skiers completed three 4-min submaximal stages, as well as 3-min and 30-sec all-out tests. Work rate and cycle rate were measured with the ergometer's internal software which had been validated with force and velocity measurements. Average work rate determined performance, whereas gross efficiency (GE), calculated as work rate divided by aerobic metabolic rate, was estimated at 90 W. Body composition was measured using dual-energy X-ray absorptiometry. Results Both the 30-sec test and the 3-min test showed significant correlations with 1RM in elbow, shoulder and trunk (30-sec $r=0.85, 0.88, 0.64$, all $P<0.001$; 3-min $r=0.54, 0.58, 0.66$, all $P=0.05$). Submaximal GE correlated significantly only with trunk 1RM ($r=0.55, P=0.03$). Stepwise multiple regression analyses revealed that elbow and shoulder 1RM together were the best predictors of 30-sec performance ($R^2=0.88$), and that trunk 1RM alone was the best predictor of 3-min performance ($R^2=0.39$). The average work produced per cycle during the 30-sec test showed significant correlation with all strength tests ($r=0.61-0.85, P<0.05$) but not with 3-min performance or gross efficiency, whereas total arm and trunk lean body mass both correlated with the 1RM strength and performance ($r=0.55-0.87$, all $P<0.01$). Conclusions This study demonstrates that the impact of maximal strength in elbow and shoulder segments increase with increasing demands of work rate production, whereas maximal trunk strength has a similar importance for poling efficiency and performance across the whole intensity spectrum. Since both poling performance and maximal strength were associated with high lean body mass in arms and trunk, enhanced upper-body muscle mass may be advantageous for female skiers.

ENDURANCE TRAINING TYPE EFFECT ON NEUROMUSCULAR PARAMETERS DURING 8-WEEKS CONCURRENT TRAINING

Robineau, J.1, Babault, N.2, Piscione, J.1, Lacome, M.1, Bigard, X.A.3

French rugby federation

1: FFR (Marcoussis, France), 2: CEP 'Gilles Cometti' (Dijon, France), 3: AFLD (Paris, France) Introduction Some studies emphasized an impairment of strength development following concurrent strength and endurance training, in comparison to strength training alone (Wilson et al., 2012). Most of these studies used moderate intensity continuous training ($\sim 70-80\%$ VO_2max). In our study, we proposed to measure the influence of two types of high intensity interval training on the likely interferential effect on strength development. Therefore, the aim of this research was to identify a training model to optimize strength adaptations induced by concurrent training. Methods Thirty amateur rugby players volunteered for the experiment. Subjects mean (\pm SD) age, height and mass were 26.4 ± 3.0 yrs, 179.7 ± 8.0 cm, 89.3 ± 10.3 kg, respectively. Three training groups were proposed whose one strength only group and two concurrent groups differentiating by the type of endurance training. A delay of 24h was applied between resistance and endurance sequences. Strength training consisted in 3-4 sets of 3-10 repetition maximal (RM) for bench press (BP), bench row (BR), half-squat (HS) and leg press exercises. Two types of endurance training aimed to develop VO_2max using 1) intermittent exercise (30s at 100% of maximal aerobic velocity (MAV)/30s of active recovery at 50% MAV) and 2) sprint interval training (30s all-out effort/4 min passive recovery). 1RM on HS, BP and BR exercises was assessed before (pre) and after (post) each 8-weeks training period. Maximal voluntary contraction (MVC) of knee extensors has been evaluated on an isokinetic dynamometer (Contrex, Switzerland). Leg power was determined during counter movement jump (CMJ) using an Optojump system (Microgate, Italy). Results Variations of performance were analyzed using the magnitude based inference approach (Hopkins et al., 2009). Significant increases of MVC of knee extensors at $60^\circ \cdot \text{s}^{-1}$ and 1RM BP were observed for all training groups but were lower following concurrent strength and sprint interval training period. Also, significant increases of CMJ height were measured for all training groups but were lower after the two concurrent training periods. Conclusion Our study highlighted an interferential effect on strength production capacity of lower and higher-limb, induced by high intensity interval training. This interference seemed to be dependently of aerobic exercise. Sprint interval training could induce lesser gain of maximal strength and maximal power. MUSCLE STRENGTH, EMG-ESTIMATED NEURAL DRIVE AND MUSCLE ARCHITECTURE IN RESPONSE TO 14 WEEKS OF LINEAR AND DAILY NON-LINEAR RESISTANCE TRAINING

Ullrich, B., Soleimani, M., Holzinger, S., Pelzer, T., Stening, J., Pfeiffer, M.

Olympic Training and Testing Centre of Rheinland-Pfalz/Saarland

Introduction Periodized resistance training results in greater performance enhancements than non-periodized regimens (Fleck, 2011). Common periodization models are classic linear and daily non-linear periodization that implies frequent alterations in training volume and intensity among successive sessions (Fleck, 2011). Comparisons among linear and non-linear strength training regimens often failed to show differences of performance outcomes (Fleck, 2011). Little information exists about alterations in neural drive and muscle architecture in response to linear and non-linear strength training exercising with similar overall training volume and intensities. Methods Thirteen recreational active students (25 years, 3 men and 10 women) performed 14 weeks of isometric strength training for the knee extensors. Subjects exercised one leg using classic linear periodization and the other leg using daily non-linear periodization. Exercise intensities varied among 60% to 80% of MVC and the overall intensity zones and training volume were similar among both legs. Isometric and isokinetic knee extension MVC, EMG estimated maximal voluntary neural drive of the M. quadriceps femoris (QF) and muscle architecture of the M. vastus lateralis (VL) were measured in both legs before, after 6 weeks and after 14 weeks of training using dynamometry, surface EMG and ultrasonography. ANOVA with repeated measures was used to analyze possible time and time * leg (periodization) effects. Results Significant increases in isometric and isokinetic knee extension MVC occurred in both legs among all three testing occasions. Compared to baseline, maximal integrated EMG activity of the QF showed significant enhancements after 6 weeks and after 14 weeks of training in both legs. Muscle architecture remained unchanged following 6 weeks of training, but VL-muscle thickness and VL-fascicle length displayed significant enlargements after 14 weeks of training in both legs. Notably, no significant time * leg effect was detected for any analyzed parameter during the study. Discussion Classic linear or daily non-linear periodization of isometric strength training showed no influence on strength, integrated EMG and muscle architecture. Mechanical parameters such as training volume and intensity may act as key triggers for neuromuscular adaptations rather than periodization. Future work might analyze more complex periodization models with athletes. References Fleck, S.J. (2011). *Journal of Human Kinetics* (Special Issue), 41-45.

METABOLIC RESPONSES TO INTER-REPETITION REST MANIPULATION IN SQUAT STRENGTH TRAINING

González Hernández, J.M.1, Andrés López, R.1, García Peñuela, A.J.1, Jiménez Reyes, P.2

1University Alfonso X, UAX, Madrid, Spain 2Catholic University San Antonio - UCAM, Murcia, Spain

1University Alfonso X, UAX, Madrid, Spain 2Catholic University San Antonio - UCAM, Murcia, Spain An observation that is apparent during traditional strength or power training is the speed and power loss as fatigue increases (Lawton et al. 2006). Training with this structure can be very stressful and it would be very important to monitor the speed loss during sets repetition (Sánchez-Medina 2011). A solution to this issue would be the inter-repetition rest manipulation (Hardee et al. 2012). Thus, an alternative model to performing a designated number of fatiguing continuous repetitions is to introduce an inter-repetition rest, that is, a rest interval after every repetition or after a certain number of repetitions (Lawton et al. 2006). Therefore, the aims of this study were (i) to analyse the mechanical response examining power and speed associated with continuous-repetition (CR) and inter-repetition rest (IRR), and (ii) to examine lactate concentration comparing CR and different IRR protocols. Twelve sport science students and well-trained in strength participated in this study. Subjects performed 2 CR protocols and 5 IRR protocols with the same volume (30 repetitions) in squat. The movement velocity and power output for each repetition was recorded using a linear encoder sampling each 1ms (1000 Hz). CR consisted in 3 sets of 10 repetitions and 6 sets of 5 repetitions compared to 5 IRR protocols of 3 sets of 10 repetitions 2 sec (IRR2), 5 sec (IRR5), 10 sec (IRR10), 15 sec (IRR15) or 30 sec (IRR30). Each protocol (IRR2, IRR5, IRR10, IRR15, IRR30) was performed in a randomized order on different days each separated by at least 72 hours. A timer was used to follow all IRR protocols. Significantly ($p < 0.001$) greater repetition power outputs (25–49%) were observed in the later repetitions (4–6) of the IRR2, IRR5, IRR10, IRR15 and IRR30 in comparison to CR. Mean propulsive velocity significantly decreased by 50% and 25% in CR of 10 and 5 repetitions, respectively in comparison to decreases between 3% to 12% in IRR protocols. CR resulted in increased blood lactate concentrations significantly ($p < 0.01$), while only in IRR2 were significant. These findings demonstrate IRR periods allow for maintenance of power and this may have implications for improved training adaptations, and thus, using IRR could enable greater power output in comparison to CR. Coaches should quantify and consider IRR to determine and individualize training loads and exercises to optimize the power output while not fatiguing so much athletes, and in turn performance. MUSCLE STRENGTH AND MUSCLE CONTRACTILE PROPERTIES IN RESPONSE TO 16 WEEKS OF HIGH AND MODERATE INTENSITY LINEAR VERSUS DAILY NON-LINEAR RESISTANCE TRAINING

Holzinger, S., Rasche, C.1, Soleimani, M.1, Ullrich, B.2, Pfeiffer, M.1

1 Section for theory and practical performance of physical activities, JGU uni of Mainz, Germany, 2 Olympic training and testing center of Rheinland-Pfalz/Saarland, Bad Kreuznach/Mainz, Germany

Introduction Classic linear (CLP) and non-linear (NLP) strength training periodization result both in significant strength gains. Some studies indicate daily nonlinear periodization (dNLP) possibly more effective for strength gains (Kok et al., 2009). Others show motor performance and power increases are not significantly different between dNLP and CLP (Hartmann et al., 2009). Studies lacked to clarify the controversy of preference of CLP or NLP strength training regimes. There is rare information about adaptations in muscle contractile properties in response to CLP and dNLP isometric strength training exercising a specific muscle group with similar overall training volume and intensities. Methods Thirteen recreational active students (25 years, 10 women/ 3 men) participate on a 16 wks supervised isometric strength training program for the knee extensors: 7 wk training phase 1 (TP1), 2 wk brake, 7 wk training phase 2 (TP2). Subjects exercised one leg using CLP and the other leg using dNLP. Exercise intensities varied among 60% to 80% of MVC, the overall intensity zones and training volume were similar among both legs. Isometric knee extension MVC and mechanical muscle response by tensiomyography (TMG) (Šimunič B., 2012). were measured in both legs (m.vastus lateralis) at the beginning (T1/ T3) and end (T2/ T4) of each TP. ANOVA with repeated measures was used to analyze possible time and time * leg (periodization) effects. Results MVC increased significant in both legs among all four testing occasions. TMG showed a significant increase from T1 to T2 for maximal displacement (Dm) and sustain time (ts). Delay time (Td), contraction time (tc) and relaxation time (tr) indicated no significant changes over time. No significant method relating effects could be observed, except Tr with a significant increase for CLP. Discussion Results indicated no method related differences of CLP or dNLP on strength. Muscle contractile properties Dm and ts increased from T1 to T2 and decreased from T2 to T3 as a possible result of reduced muscle stiffness after 2 wks brake. The significant increase of Tr for CLP might be a marker for higher muscle stiffness and less muscle flexibility compared to dNLP. Stronger contrasts in terms of undulating periodization might be a future approach. References Hartmann H, Bob A, Wirth K, Schmidbleicher D. (2009). J Strength Cond Res; 23:1921-1932. DIFFERENT PARAMETERS FOR LOAD CONTROL DURING RESISTANCE TRAINING IN OLDER ADULTS: INTENSITY- VERSUS REPETITION-CONTROLLED

Morat, T., Luenzer, S., Mechling, H.

German Sport University Cologne

Introduction Older adults need sufficient strength to perform task of daily life, e.g. stair climbing, getting up from a chair (Brill et al., 2000). Within a training of muscular strength, objective (load intensity, number of repetitions) and subjective parameters (perceived exertion) are used to control resistance training (Froehlich et al., 2002). The aim of this study was to examine the implementation of different parameters of load control (intensity through percentage [%] of maximum strength [1RM]; number of repetitions; perceived exertion) during resistance training with older adults. Methods 14 (10 males, 4 females) older adults (mean age of 64.8 ± 3.1 years; mean body height of 176.3 ± 11.8 cm; mean body weight of 83.5 ± 13.5 kg) participated in this cross-sectional test-retest study and were measured in two sessions at an interval of one week with two different treatments in the exercise "seated bench press". During the pretest (T1), participants executed 4 sets at 85% of their One-Repetition maximum (1RM) with constant load intensity (Clnt), during the posttest (T2), 4 sets with 8 repetitions with a constant number of repetitions (CRep) were executed. Participants had to state their perceived exertion using the OMNI-RES scale (OR). Time-under-tension (TUT), physical work and OR were measured. At T1, the maximal number of repetitions (reps) and at T2, the maximum load and additional reps were recorded. Results Within Clnt, means of reps reduced by about 49% (set 1: 10.3 ± 3.1 ; set 4: 5.0 ± 2.9 reps); in CRep the load was reduced by about 20% (set 1: 49.5 ± 13.4 ; set 4: 41.2 ± 10.9 kg). There was no significant difference with respect to executed reps and TUT between Clnt and CRep, but between single sets ($p < .001$). In Clnt means of OR showed a significant increase ($p < .05$). Physical work demonstrated a significantly ($p < .05$) higher amount within CRep. Discussion The older adults in

this study reached a higher mean number of repetitions than younger adults in former studies (Froehlich et al., 2002; Hoeger et al., 1990), but showed a greater variability within single sets. The results lead to the assumption that repetition-controlled resistance training could result in provoking the desired hypertrophy effects in the form of adaptations in muscle mass. OP-BN10 Balance Control

EFFECTS OF ACHILLES TENDON VIBRATION ON CORTICOSPINAL AND GROUP I AFFERENT PATHWAYS EXCITABILITY DURING UPRIGHT STANDING

Baudry, S., Duchateau, J.

Université Libre de Bruxelles

Introduction Previous work indicates that, at rest or during isometric contraction, tendon vibration depresses Hoffmann (H) reflex (De Gail et al., 1966), and increases motor evoked potential (MEP; Siggelkow et al., 1999) by transcranial direct current stimulation (TMS). However, whether these changes occur during upright standing that involves specific modulations of corticospinal and Ia afferent pathways (Baudry et al., 2014) remains unknown. The first objective of this work was to investigate the effects of Achilles tendon vibration on corticospinal excitability and synaptic efficacy of Ia afferents to discharge soleus spinal motor neurones during unperturbed upright standing. The second objective was to further study whether the opposite modulation in H-reflex and MEP amplitude during upright standing may reflect close compensatory adjustments between the two pathways. **Methods** Eighteen subjects volunteered to participate to this study. MEP and H reflex were recorded for the soleus muscle in response to TMS and tibial nerve stimulation, respectively, with or without bilateral Achilles tendon vibration (80 Hz) during bipodal upright standing on a force platform. Surface electromyography (EMG) was recorded for soleus, gastrocnemius medialis and tibialis anterior muscles. **Results** Achilles tendon vibration altered postural stability and increased leg muscles EMG activity. Furthermore, tendon vibration induced an increase in MEP amplitude ($+27.5 \pm 34.7\%$; $p=0.001$) accompanied by a decrease in H-reflex amplitude ($-67.7 \pm 14.9\%$; $p<0.001$). No significant correlation was observed between changes in MEP and H-reflex amplitudes. **Discussion** These original findings indicate that Achilles tendon vibration has similar effects on MEP and H-reflex amplitude during upright standing that those previously reported during isometric contractions or when tested on muscle at rest. The results also suggest that adjustments in synaptic inputs onto spinal motor neurones from group I afferents and corticospinal pathways are not closely associated during upright standing. **References** Baudry S, Penzer F, Duchateau J. *Acta Physiologica* doi: 10.1111, 2014 De Gail P, Lance JW, Neilson PD. *J Neurol Neurosurg Psychiatry* 29:1-11, 1966. THE RELATIONSHIP BETWEEN ANKLE JOINT PHYSIOLOGICAL CHARACTERISTICS AND BALANCE CONTROL DURING UNILATERAL STANCE

Amin, D., Herrington, L.

University Centre Doncaster

Background: The role that the ankle's physiological characteristics play in maintaining balance during quiet stance has been well documented (Cote et al., 2005; Gatev et al., 1999). However, the role of the ankle in maintaining balance during more challenging conditions is questionable (Horak and Nashner, 1986). As such, the objectives of this study were to identify any significant relationships between the physiological characteristics of the ankle joint and the ability to maintain more challenging unilateral stance. **Participants:** 21 athletes (age = 24.67 ± 5.42 years; height = 175.34 ± 7.48 cms; weight = 79.09 ± 14.07 kgs). **Procedures:** Passive resistance and joint position sense in the sagittal plane of the ankle, and active dorsiflexion range of motion of each subject was assessed, in addition to centre of pressure parameters during 20 s unilateral stance. **Results:** Pearson's product moment correlation coefficient found significant positive correlations between DpeaktorqueAngle and sway area ($r = .554$); Ax range ($r = .449$); and Ay range ($r = .471$). Significant negative correlations were found between DpeaktorqueAngle and sway area ($r = -.538$, $p = .012$), Ax range ($r = -.590$, $p = .005$) and Ay range ($r = -.439$, $p = .046$). **Discussion:** The results highlighted limited relationships between unilateral stance balance control and the ankle characteristics commonly associated with quiet stance balance control and has, thus, further questioned the role that the ankle plays during more challenging stance conditions. The majority of balance training protocols in the athletic community focuses on the distal joints (Di Stefano et al., 2009) however, this needs re-addressing in order to maximise performance. **References:** Cote K, Brunet M, Gansneder B. LOAD DEPENDENCY OF POSTURAL CONTROL – KINEMATIC AND NEUROMUSCULAR CHANGES IN RESPONSE TO OVER AND UNDER LOADING

Ritzmann, R.

Albert-Ludwigs-Universität Freiburg

Introduction Load variation has a considerable impact on balance control and is associated with changes in joint torque, somatosensory feedback and compensatory reflex activation (Mergner, 1998). Previous studies dealing with over (OL) and under loading (UL) used water

buoyancy or additional weight with the negative side effects of increased friction and inertia resulting in substantially modified test paradigms (Dietz, 1992). To provide identical test conditions, changes in gravitational forces are required. This can be achieved in partial-gravity parabolic flights (CNES/DLR/ESA JEPPF-2). To gather knowledge about the effect of loading, this study aimed to (1) identify load-dependent modulations in postural control and (2) to assess the influence of over and under loading on balance strategy and neuromuscular control. Methods In 8 subjects, sensorimotor performance was recorded in normal loading (NL, 1g) as well as UL (0.2g) and OL (1.8g) conditions while maintaining postural equilibrium in monopodal stance. Center of pressure (COP) displacement and COP frequency distribution (low 0.15-0.5Hz (LF), medium 0.5-2Hz (MF), high 2-6Hz (HF)) as well as ankle, knee and hip joint kinematics were assessed. Electromyographic activity of the soleus (SOL) was recorded and spinal excitability was assessed by means of H/M-recruitment curves (H/M-ratios). Results Compared to NL, OL caused an increase in ankle joint excursion ($P < 0.05$), COP HF domain ($P < 0.05$) and H/M-ratio ($P < 0.05$). Concomitantly, hip joint excursion ($P < 0.05$) and COP LF decreased ($P < 0.05$). Modulations in UL occurred in the opposite direction: UL caused a decrease in ankle joint excursion ($P < 0.05$), COP HF ($P < 0.05$) and H/M-ratio ($P < 0.05$). At the same time, hip joint excursion ($P < 0.05$) and COP LF increased ($P < 0.05$). COP displacement ($P < 0.05$) was augmented in UL and OL compared to NL. Discussion Under increased gravitational loading, balance control was characterized by a shift from hip to ankle strategy. Concomitantly, the COP frequency distribution shifted from LF to HF and H-reflex sensitivity was progressively enhanced. It is suggested that in OL, the augmented joint torques (Mergner, 1998) are compensated by quick reflex-induced postural reactions in the proximal muscles. In contrast, UL is associated with diminished joint torques and postural equilibrium is controlled by the distal segments to appropriately adjust the center of gravity above the base of support (Mergner, 1998). The HF predominance in OL and the LFs seen under UL conditions support these modulations. In conclusion, gravitational loading induces tremendous shifts in balance control, which require specific neuromechanical adjustments. References: Dietz et al. (1992). Exp. Brain Res. 98:229-31. DIFFERENCES BETWEEN KAYAKERS AND HEALTHY CONTROLS IN STABILIZING FUNCTIONS OF THE TRUNK

Voglar, M., Sarabon, N.

University of Primorska, Science and research center Koper

Introduction Anticipatory postural adjustments (APAs) are typically initiated before voluntary movements and/or expected external perturbation while unexpected postural perturbation elicits postural reflex reactions (PRRs). Both APAs and PRRs are important components in the control of spinal stability that can be modified by training (Pedersen et al 2007). In kayaking good spinal control and balance are required that could potentially result in adaptations of stabilizing functions of the trunk. Therefore the aim of present study was to investigate if athletes trained in wild waters kayaking represent different spinal control than healthy control subjects. We hypothesized that kayaking trained individuals will represent earlier APAs and shorter PRRs than healthy controls. Methods Sixteen kayakers (4 W, 21.0 ± 4.0 years, 174.7 ± 8.9 cm, 70.6 ± 10.6 kg) and 12 healthy controls (4 W, 23.4 ± 3.5 years, 179.7 ± 9.0 cm, 73.8 ± 13.7 kg) without spinal or neurological disorders participated in the present study. In measurements of APAs participants performed fast voluntary arm raises on a self-selected timing after visual cue. In measurements of PRRs the participants were standing with elbows flex at 90° when the load (7 kg) was suddenly released in random timing (5 to 15 s) onto their hands. The instruction was to stop the load as quick as possible. In both tests 20 repetitions were performed and surface electromyography was used for recording activation of the following muscles: multifidus, erector spinae, obliques internus and externus abdominis. Results There were no statistically significant differences between the two groups of subjects as concerns APAs ($p > 0.05$). Only obliques externus showed a moderate tendency, however, not reaching the level of statistical significance ($t = 1.85$, $p = 0.07$, $ES = 0.12$). In the sudden loading test the reflex latency of two muscles were statistically significantly shorter in the group of kayakers (multifidus: $t = 1.96$, $p < 0.05$, $ES = 0.16$ and obliques internus: $t = 2.32$, $p < 0.05$, $ES = 0.20$), however, no differences were found in the other two muscles ($p > 0.05$). Discussion Results confirmed our hypothesis that kayakers have more efficient postural control presented as shorter PRRs of some trunk muscles but in contrast we found no effects on APAs. Results are also in agreement with findings from Pedersen et al (2007) who suggested that PRRs can be trained. Further research of seated balance training effects on sport performance and also on spine stability in terms of prevention and rehabilitation of low back pain is needed. References Pedersen MT, Essendrop M, Skotte JH, Jørgensen K, Schibye B, Fallentin N (2007) Back muscle response to sudden trunk loading can be modified by training among healthcare workers. FIELD TESTS TO MEASURE TRUNK STABILITY: VALIDITY AND RELIABILITY ANALYSIS

Juan Recio, C., Barbado, D., López Plaza, D., García Vaquero, M.P., Vera Garcia, F.J.

Universidad Miguel Hernandez de Elche

INTRODUCTION: Although muscular fitness tests [e.g. Biering-Sorensen test (BST)], single leg stance balance tests [e.g. three plane core strength test (TPCST)] and lumbo-pelvic postural control tests [e.g. double-leg lowering test (DLLT)] are usually performed to assess trunk/core stability in field settings (Leetun et al., 2004; Weir et al., 2010), some doubts still exist about the validity and reliability of these measures (Sharrock et al., 2011; Weir et al., 2010). The aim of this study was to analyse the relationship between BST, TPCST and DLLT and gold standard tests to measure trunk stability, and to evaluate the reliability of these protocols. METHODS: 27 recreational male athletes participated in this study. Two protocols were used as gold standard tests to assess trunk stability: a) Trunk balance control test: a battery of static and dynamic tasks was performed to measure trunk balancing while sitting on stable and unstable seats placed on a force plate (Kistler 9286A). Postural and dynamic sway were assessed by analyzing the displacement of the centre of pressure; b) Sudden load test: quick and unexpected trunk loads in anterior, posterior and lateral directions were applied to the thorax by a pneumatic mechanism, while the participant was seated with the pelvis fixed. Trunk angular displacement was measured and the damping and stiffness coefficients of the trunk were calculated from the first 110 ms of data. One month after the gold standard measurements were carried out, the BST, TPCST and DLLT were performed in another recording session. Pearson and Spearman correlation coefficients were used to analyse the relationship between all variables. Each test was performed twice and the ICC was calculated to assess the reliability of the measures. RESULTS: Most variables showed good reliability (ICCs > 0.70), except for the damping coefficient in anterior loading direction and for all the variables of the TPCST (ICCs < 0.43). The DLLT was not sensitive enough to discriminate between most participants. No significant correlations were found between the BST score and the variables of the gold standard tests. Some significant correlations were found between the TPCST and several tasks of the trunk balance control test, but in such cases, the proportion of variance explained was low ($17.38\% < R^2 < 37.33\%$). DISCUSSION: Although the 3 field tests have been widely used as trunk stability measures, our results question their reliability and validity and confirm the complexity of assessing trunk stability in field settings. THE EFFECT OF UNICYCLE RIDING COURSE ON TRUNK STRENGTH AND TRUNK STABILITY FUNCTIONS IN CHILDREN

Kocjan, A., Sarabon, N.

University of Primorska, Science and Research Centre of Koper

INTRODUCTION The impact of unicycling on trainability of trunk muscle strength and trunk stability functions is unknown. Because of a unicycle's small mass and the saddle placed just above the wheel, it is evident that the system is unstable in medio-lateral and antero-posterior directions (Sharp, 2010). Consequently, riding a unicycle could have an effect on the development of trunk neuromuscular functions. Therefore, the aim of this study was to assess the effect of unicycling course on trunk maximal voluntary strength and trunk stability functions. **METHODS** Twenty-four 12-year old children volunteered for the study. They were divided into number balanced control and training group. The latter underwent a 12-hour course of unicycling. The programme started with key information about bike handling, which was followed by riding a unicycle with assistance. It finished with basic jumping and riding a unicycle around the marks. We assessed maximal voluntary isometric strength of the trunk in frontal and sagittal planes in standing position. Furthermore, anticipatory postural adjustments that accompany rapid shoulder flexion and postural reflex responses to unexpected loading over the hands were assessed. Postural actions of erector spinae and multifidus muscles were measured by surface electromyography. Two-way repeated measures analysis of variance was applied to test for the pre-post differences between the two groups. **RESULTS** Subjects in the control group did not show pre-post changes in any of the analyzed parameters (all $p > 0.05$). In the training group, on the contrary, maximal voluntary isometric force improved at a statistically significant level for all the measured tasks ($t = 4.66 - 4.97$, $p < 0.01$). After the training period, there was also a significant ($p < 0.05$) shortening of the onset latency of the back muscles to postural perturbation, while no change could be found in the timing of anticipatory postural adaptations. The interaction effect was statistically significant for all of the measured tests ($p < 0.05$, $\eta^2 > 0.19$) except for the anticipatory postural adjustments. **DISCUSSION** Probably the increases in maximal strength occurred as a result of neural changes (Aagaard, 2003). Due to a relatively short exercise intervention in the present study, the gain in trunk muscle strength is probably the consequence of improved neural activity that can be also seen as more vivid postural stabilization reflexes. **REFERENCES** Aagaard, P. (2003). Training-induced changes in neural function. *Exerc Sport Sci Rev*, 31(2), 61-67. Sharp, R. (2010). 18:00 - 19:30**Oral presentations****OP-PM37 Exercise Therapy & Insuline****IMPACT OF EXERCISE TRAINING ON GLYCAEMIC CONTROL IN ADOLESCENTS WITH TYPE 2 DIABETES**

Naylor, L., Davis, E., Jones, T., Kalic, R., Paramalingam, N., Yusof, N., Green, D.

The University of Western Australia

Despite the increase prevalence of type 2 diabetes (T2DM) in adolescents, there are no optimal management strategies. We have demonstrated exercise training improved glycaemic control in pre-diabetic adolescents. However no randomised controlled studies have assessed the impact of exercise training on whole body insulin sensitivity in T2D adolescents. This study therefore determined the effects of a structured 12-wk exercise training program on insulin sensitivity in T2DM adolescents. We also assessed whether changes persisted beyond the conclusion of the program. Thirteen subjects with T2DM (13-21 yrs) were randomised into an exercise program, or a control group for 12 weeks. The exercise program consisted of 3, 1 hour supervised circuit weight training sessions per week. Assessments were conducted at study entry and following the intervention. To determine whether changes persist following training, those in the exercise group were followed for a further 3 months. Whole body insulin sensitivity (M) was assessed using a euglycaemic, hyperinsulinaemic clamp and body composition using dual energy x-ray absorptiometry (DXA) to determine whole and regional fat and lean mass. Statistical significance was set at ($P < 0.05$). The control group showed a statistically significant increase in body weight, which was attributable to an increase in fat mass (+1959 (561g)) over the 12 week intervention period. There was also a clinically significant decline observed in M (5.7(0.8) to 5.1 (1.2)). Exercise training attenuated the increase in body weight (+0.04(1.1kg) , and the decline in M (4.7 (1.7) to 4.9 (1.9)). Following the detraining period, increases in LBM and decreases in fat mass were maintained, whilst M declined (-0.6(0.2)). In conclusion, 12 weeks of supervised exercise training attenuated the decrease in insulin sensitivity in adolescents with T2DM. This was coupled with improvements in body composition, which persisted beyond the end of the exercise program.

EXERCISE TRAINING EFFECTIVELY IMPROVES INSULIN SENSITIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS.

Introduction Premature cardiovascular disease is considered to be the major cause of mortality in Systemic Lupus Erythematosus (SLE)¹. It has been suggested that the increased cardiovascular risk in SLE patients may be partially attributed to a higher prevalence of insulin resistance when compared with healthy subjects². Although exercise training has been consistently proved effective in enhancing insulin sensitivity in a number of chronic diseases³, no studies have evaluated its efficacy in SLE. **Objective** To investigate the effects of a three-month exercise training program on the insulin sensitivity of women with SLE. **Methods** Eleven inactive SLE patients (32.2±6.5 years; BMI: 24.1±3.5 Kg/m²) were randomly assigned into two groups: trained (T, n=6, three-month exercise program, thrice a week) and non-trained (NT, n=5). A BMI-, and age-matched healthy control group (C, n=5; 29.6±4.8 years; BMI: 24.9±4.8 Kg/m²) was also selected for baseline measurements only. Subjects were assessed at baseline (PRE) and after 12 weeks training (POST). Main measurements included insulin sensitivity (assessed by a meal tolerance test-MTT and by the HOMA2 IR index), body composition (assessed by DXA), food intake, lipid profile, and safety analysis (assessed by SLEDAI, and levels of complement- C3 and C4, aldolase, uric acid, CK and CRP). **Results** All groups were similar at baseline with regard to BMI, body composition and age ($p > 0.05$, between-group comparisons). Food intake, body composition, lipid profile, and safety measurements remained unchanged in both T and NT overtime ($p > 0.05$, within- and between-

group comparisons). Furthermore, no changes were observed in the glycemic and the triglyceridemic responses to the MTT test in either T or NT groups ($p>0.05$, within- and between-group comparisons). In contrast, the T group showed a lower HOMA2 IR index (T PRE: 1.12 ± 0.58 , POST: 0.66 ± 0.30 , $p=0.04$, within-group comparison) and an improved insulinemic response to the MTT test when compared with the NT group at POST (T PRE: 6087 ± 2561 , POST: 4593 ± 3067 $\mu\text{U/mL/min}$; NT PRE: 7832 ± 1918 , POST: 8945 ± 3754 , $p=0.03$, between-group comparison). Conclusion These results demonstrated that a three-month exercise program was safe and effective in improving insulin sensitivity in SLE patients, further supporting its role as an important adjuvant treatment in this disease. BLOOD GLUCOSE HOMEOSTASIS DURING SUCCESSIVE DAYS OF PROLONGED WALKING EXERCISE IN PATIENTS WITH TYPE 1 DIABETES

Nyakayiru, J.1, van Dijk, J.W.1, Eijssvogels, T.M.2, Schreuder, T.H.2, Hopman, M.T.2, van Loon, L.J.C.1, Thijssen, D.H.2,3
1:NUTRIM, MUMC+, Maastricht, The Netherlands 2:Radboud UMC, Nijmegen, The Netherlands 3:LJMU, Liverpool, United Kingdom

Background Despite the well-established benefits of regular exercise for health, exercise complicates the maintenance of stable blood glucose concentrations in patients with type 1 diabetes. This can be largely attributed to the complex interaction between exercise-stimulated glucose disposal, insulin administration, and carbohydrate consumption. The aim of the current study was to explore changes in food intake, insulin administration, and 24-h glycemic control in response to multiple days of prolonged walking exercise (~8h daily) in patients with type 1 diabetes. Methods Ten individuals (1 male/9 female) with type 1 diabetes participating in the Nijmegen Four Days Marches were recruited for this observational study. Simultaneous measurements of 24-h glycemic control (continuous glucose monitoring), insulin administration (dose and frequency) and food intake (food diary) were performed during a non-walking control day and three subsequent days during which prolonged walking exercise (daily 40 or 50 km) was performed. Paired Student's t-tests or Wilcoxon signed rank tests were applied to compare data obtained during the control day and the three walking days combined. All data are presented as mean \pm SD. Results All subjects successfully completed the walking event. Subjects walked $8\text{h}12\text{min}\pm0\text{h}41\text{min}$ daily, representing an average walking speed of 5.0 ± 0.3 km/h. Despite a profound increase in total energy ($31\pm18\%$ kcal ($p<0.01$)) and carbohydrate ($82\pm71\text{g}$ ($p<0.01$)) intake during the walking days, daily insulin use was lowered by $26\pm16\%$ compared with the control day ($p<0.01$). This decrease in insulin use was largely explained by the $49\pm25\%$ decrease in prandial insulin use during walking days compared with the control day (10.0 ± 6.7 versus 19.8 ± 8.8 IU, respectively). Average 24-h blood glucose concentrations, the prevalence of hyperglycemia (blood glucose >10 mmol/L) and the prevalence of hypoglycemia (blood glucose <3.9 mmol/L) were comparable between the control day and walking days ($p>0.05$ for all variables). Nevertheless, the days with prolonged walking exercise were associated with a modest increase in glycemic variability compared with the control day, as indicated by higher CONGA1 and CONGA2 values ($p<0.05$ for both variables). Conclusion Prolonged walking exercise allows for profound reductions in daily insulin administration in patients with type 1 diabetes, despite large increments in energy and carbohydrate intake. These exercise-induced adjustments in insulin administration and food intake do not necessarily impair 24-h glycemic control. Contact jean.nyakayiru@maastrichtuniversity.nl

RESVERATROL IMPROVES INSULIN SENSITIVITY AND REDUCES SKELETAL MUSCLE MITOCHONDRIAL H2O2 EMISSION IN DEVELOPING RATS

Kwak, H.B.1, Cho, H.S.2, Shin, M.S.2, Kim, C.J.2, Park, D.H.1, Kim, K.H.1
1Inha University; 2Kyung Hee University

Introduction Resveratrol (RSV) is a natural polyphenol mainly found in the skin of grapes and red wine. RSV as an effective antioxidant compound is well known to improve health and extend the lifespan of diverse species. Previous studies using antioxidant interventions showed a protection of insulin sensitivity by improving mitochondrial function (Houstis et al., 2006; Anderson et al., 2009) in the pathological animal models. However, there is poorly understood to link between insulin sensitivity and mitochondrial function in the skeletal muscle of developing animals with RSV treatment. The purpose of this study was to determine the effects of RSV treatment on insulin sensitivity, mitochondrial H2O2 emission, and mitochondrial Ca2+ retention capacity in the skeletal muscles of developing rats. Methods Four week-old male Fischer-344 rats were treated with or without RSV (50mg/kg/day) via oral gavage for 3 weeks (N=10 rats/group). Oral glucose tolerance test (OGTT, 2 g glucose/kg) was performed to measure blood glucose levels. Mitochondrial H2O2 emission and Ca2+ retention capacity were measured in the permeabilized skeletal muscles in both slow-twitch muscle (e.g., soleus) and fast-twitch muscle (e.g., white gastrocnemius). Results Glucose tolerance as assessed by OGTT was significantly improved by RSV treatment. This was paralleled by a significant decrease in fasting glucose levels (-15% , $P<0.05$) and areas under the curves. Mitochondrial H2O2 emission was reduced in permeabilized soleus muscle (-40.2% , $P<0.05$) and white gastrocnemius muscle (-23.3% , $P=0.12$) supported by various substrates (e.g., glutamate+malate, succinate, and glycerol-3-phosphate) compared with control. However, treatment of RSV did not have significant effects on mitochondrial Ca2+ retention capacity in both soleus and white gastrocnemius muscles. Discussion Treatment of resveratrol protected against insulin resistance and reduced mitochondrial H2O2 emission in permeabilized skeletal muscles of developing rats. However, mitochondrial Ca2+ retention capacity was not affected by resveratrol treatment, suggesting that the improvement of insulin sensitivity in the resveratrol-treated rats may be mediated by attenuating mitochondrial ROS production in skeletal muscles. HIGH INTENSITY INTERVAL TRAINING VERSUS STRENGTH TRAINING TO IMPROVE INSULIN SENSITIVITY AND BODY COMPOSITION IN WOMEN WITH POLYCYSTIC OVARY SYNDROME. A RANDOMIZED CONTROLLED TRIAL

Almenning, I.1, Rieber-Mohn, A.1, Garnæs, K.2, Moholdt, T.2
Norwegian University of Science and Technology

Background: Polycystic ovary syndrome (PCOS) is an endocrine disorder affecting 6-20% of reproductive-age women and associates with metabolic complications and adverse cardiovascular disease profile. The prevalence of insulin resistance (IR) and abdominal fat accumulation is higher in PCOS woman compared with weight-matched controls. Limited knowledge exists on the effect of high intensity interval training (HIT) and strength training (ST) on IR and body composition in this population. Methods: Thirty-one previously sedentary women

with PCOS were randomized to: HIT (n = 10), ST (n = 11) three times/week for ten weeks or control (CG; n = 10). HIT was two weekly sessions of 4x4 minutes intervals at 90-95% of heart rate maximum and one weekly session of 10x1 minute at maximal effort. ST consisted of drills for large muscle groups, with three sets of ten repetitions at ~75% of 1 repetition maximum. We measured IR (HOMA-IR), fasting plasma glucose and insulin c-peptide, body composition (InBody impedance scale) and maximal oxygen uptake (VO₂max) at baseline and after ten weeks. The change in each group was reported as the estimated margin of the mean (EMM), as assessed by 95% confidence interval (CI). Covariance analyses (Bonferroni adjusted) were used to test differences between groups. Results: HOMA-IR was improved by 21% after HIT [EMM: -0.30, 95 % CI: -0.45 to -0.15] and by 17% after ST [EMM: -0.23, 95 % CI: -0.43 to -0.02], and not in the CG. Insulin c-peptide was reduced after HIT [EMM: -0.11 nmol/l, 95 % CI: -0.9 to -0.04], after ST [EMM: -0.11 nmol/l, 95 % CI: -0.20 to -0.02], and not in CG. Plasma glucose or body weight did not change in any group. Fat percentage was reduced after HIT [EMM: -0.9, 95 % CI: -2.2 to -0.01], after ST [EMM: -1.6, 95 % CI: -2.5 to -0.7], and not in CG. We found no between-group differences in the change in insulin sensitivity (p=0.41) or fat percentage (p=0.39). VO₂max improved only after HIT [EMM: 3.7 ml/min/kg, 95 % CI: 2.62 to 4.83], with significant between-group difference (p<0.01). Discussion: Our data indicate that HIT and ST had beneficial effect on IR and body composition in women with PCOS. A previous non-randomized study (1) found IR to improve by 16% after 12 weeks of intense aerobic exercise. Further, another study (2) has shown reduced fat percentage in PCOS women after exercise in combination with a hypocaloric diet. However, in our study fat percentage was reduced by exercise training alone and without reductions in body weight. References: 1. Harrison et al, 2012, Clin Endocrinol (Oxf), 76, 351-57 2. SHORT-TERM MUSCLE DISUSE ATROPHY IS NOT ASSOCIATED WITH INCREASED SKELETAL MUSCLE LIPID ACCUMULATION OR IMPAIRED OXIDATIVE ENZYME ACTIVITY IN YOUNG OR ELDERLY MEN

Wall, B.T., Dirks, M.L., Snijders, T., Stephens, F.B., Senden, J.M.G., van Loon, L.J.C.

University of Maastricht

Aging is generally accompanied by a progressive loss of skeletal muscle mass and impairments in metabolic function. A short period of muscle disuse (such as during injury or illness) also brings about muscle atrophy. The accumulation of brief periods of muscle disuse atrophy through the lifespan has been proposed as a key factor in the age-related loss of muscle mass. However, it remains unknown whether such brief periods of disuse also induce impairments in skeletal muscle metabolic function. We investigated the effects of a five day period of muscle disuse on intramyocellular triacylglycerol (IMTG) content, the maximal activity of selected mitochondrial enzymes and the mRNA expression of genes associated with mitochondrial metabolism/biogenesis in healthy young and elderly men. Muscle biopsies were collected from young (n=12; 23±1 y) and elderly (n=12; 70±1 y) healthy men prior to and immediately after a five day period of one-legged knee immobilization by way of a full leg cast. At baseline, elderly men had a greater IMTG content when compared with the young (56.3±6.8 and 34.8±7.3 μmol.g⁻¹, respectively; P<0.05) but no changes were observed following 5 days of immobilization. In line, 5 days of disuse did not reduce citrate synthase, β-HAD or cytochrome C oxidase activity in skeletal muscle tissue. The muscle activation status of the pyruvate dehydrogenase increased following immobilization in the older subjects only, from 0.39±0.06 to 0.55±0.05 μmol.g⁻¹.min⁻¹ (71±33 %; P<0.01). The skeletal muscle mRNA expression of PGC1α and citrate synthase both declined following immobilization in both the young and elderly subjects. We conclude that five days of muscle disuse is not accompanied by net increase in muscle lipid deposition or a concomitant decline in muscle oxidative capacity in young or elderly men.

INCREASED METABOLIC POWER IN PLANTARIS AFTER COMBINED PEAK POWER AND ENDURANCE TRAINING

Furrer, R., ten Harkel, B., Kos, D., van der Laarse, W., Jaspers, R.

**Laboratory for Myology, MOVE Research Institute Amsterdam, VU University Amsterdam, The Netherlands; # Institute for Cardiovascular Research VU, VU Medical Center Amsterdam, The Netherlands*

Introduction Over a wide range of species, size and oxidative capacity of different types of muscle fibers are inversely related [1]. This inverse relationship suggests that within a muscle fiber, an increase in oxidative capacity and muscle fiber size are mutually exclusive [2]. According to a Hill-type diffusion model, it is suggested that the extracellular oxygen tension (PO₂) imposes a size constraint. However, in several sports, high maximal force as well as metabolic power is required. The aim of this study was to investigate whether metabolic power can be increased with combined peak power and endurance training and whether skeletal muscle, cardiac muscle and diaphragm adapt differently. Methods 24 rats were assigned to peak power training (PT, n = 6), endurance training (ET, n = 6), combined peak power and endurance training (PET, n = 6), or no-training (controls, n = 6). Trainings were progressive and performed on a treadmill 5 days per week for 6 weeks (PET performed both training sessions each day with 8 hours rest in between). After 6 weeks, fiber cross-sectional area (FCSA) and succinate dehydrogenase (SDH) activity were assessed for the plantaris, cardiac muscle and diaphragm. For the plantaris, also myoglobin concentration and capillary density were determined. Results After PT, muscle FCSA of myocytes in the left- and right-sided myocardium was increased. In plantaris, FCSA of type IIA fibers increased after PET. Training had no effect on fiber size or oxidative capacity of diaphragm. Metabolic power, which was calculated as the product of FCSA and SDH, was only increased in type IIA and IIX/B fibers of the plantaris in response to PET. In plantaris, myoglobin concentration and capillary density did not change after training. Discussion This study showed that skeletal muscle, cardiac muscle and diaphragm show different adaptive responses to PT, ET and PET. For plantaris muscle, combined training induced an increase in metabolic power and thereby critical PO₂ of muscle fibers even without compensation in oxygen supply systems (i.e. increase in myoglobin concentration or capillary density). These results show that the combined peak power and endurance training performed in this study is a useful training strategy to increase metabolic power in plantaris muscle. References 1. ECCENTRIC VS. CONCENTRIC EXERCISE TRAINING IN HUMANS: RELATIONSHIPS BETWEEN CONTRACTION-SPECIFIC MUSCLE STRUCTURAL REMODELLING AND CHRONIC MUSCLE PROTEIN SYNTHESIS

Franchi, M.V., Wilkinson, D.J., Mitchell, W.K., Quinlan, J.I., Smith, K., Atherton, P.J., Narici, M.V.

University of Nottingham

Introduction We previously showed similar muscle hypertrophy occurs in response to concentric (CON) and eccentric (ECC) loading, despite spatially distinct remodelling i.e. ECC loading being associated with addition of sarcomeres in series vs. in parallel for CON loading (1). We explored links between protein synthesis and architectural responses to CON and ECC. **Methods** Eight men carried out unilateral CON and ECC exercise training i.e. each leg performing distinct exercises for 4-wks (2) (3xwk, 4x8-10 reps at 80% CON or ECC 1-RM). Ultrasound was used to quantify muscle architecture (fascicle length, Lf; pennation angle, PA; muscle thickness, MT). Maximum voluntary contraction (MVC) was quantified using isokinetic dynamometer. D2O tracer (3) was used to evaluate myofibrillar protein synthesis (MPS) in biopsies collected from both legs at mid-belly and distal (~4cm from the myotendinous junction, MTJ) sites of the VL, at baseline and after 4-wk CON/ECC training. **Results** After 4-wks training, increases in MVC (+14 CON vs. +12.5% ECC) and MT (+10 CON vs. +8 % ECC) were similar in response to both loading regimens. However, Lf increased significantly after ECC but not after CON (+4.5 vs. +2%) while PA only increased markedly after CON (+9 vs. +3.5%). In spite of these distinct remodelling patterns, no statistically significant differences were found, either between muscle sites or loading modalities, in terms of chronic (measured over 0-4-wk) rates of MPS over the training period i.e. VL mid-belly: CON 1.48%/d vs. ECC 1.46%/d; VL MTJ: CON 1.37%/d vs. ECC 1.45%/d). **Discussion** In line with our previous work (1), despite the ~1.3 fold greater training load of the ECC group, muscle hypertrophy responses were similar to those observed after CON (this was also matched by similar increases in MVC). Such divergent architectural adaptations to CON and ECC point to contraction-specific muscle growth being controlled by different responses of muscle anabolism (i.e. MPS responses) and activation of distinct signalling pathways (1). However, these distinct architectural adaptations were not reflected in equally specific responses for MPS, which was similar after both ECC and CON training. It was also noteworthy that increases in MPS were not muscle site-specific. Thus, contrary to prevailing views, similar hypertrophy occurs in response to ECC vs. CON; a facet reflected by similar increases in MPS occurring after ECC and CON training. Nonetheless, the mechanisms underpinning divergent architectural adaptations remain to be sought. 1. Franchi et al. *ACTA Physiol* 2014 2. Seynnes et al. *JAP* 2007 3. MOLECULAR SIGNALLING RESPONSE TO SHORT DURATION HIGH INTENSITY/LOW VOLUME RESISTANCE TRAINING IN HUMAN SKELETAL MUSCLE.

Moro, T., Paoli, A., Bianco, A., Toniolo, L., Monaco, L., Naro, F., Reggiani, C.

University of Padova

Introduction Resistance training (RT) is one of the most important stimuli for muscle hypertrophy, but it may play also an important role on weight loss and fat acid (FA) oxidation increase. It has been largely demonstrated that RT affects anabolic signalling molecule phosphorylation but, considering the numerous variables of RT, the differences between training modalities has been till now poorly investigated. The aim of this study was to assess Akt, 4EBP1, S6 and AMPK, ACC signalling after a single bout of high-intensity resistance training (HIRT) and of traditional resistance training (TRT). **Methods** 12 healthy subjects performed in two different moments and with different legs HIRT and TRT protocol. HIRT consisted in 2 sets of 6/2/2 reps with incomplete rest between (20") sets while TRT consisted of 4 sets x15 reps with 1'15" of rest between sets. Biopsies from the vastus lateralis were taken one week before training sessions (pre), immediately after (T0), 6 hours after (T6) and 24 hours after (T24) training. **Results** No significant differences were found at any of time points after exercise in AKT and 4EBP1 phosphorylation. There was a significant increase in S6 phosphorylation at T6 both in HIRT and TRT. S6-P remained at higher level even at T24. Exercise intensity does not seem to influence the response of AMPK: AMPK-P decreased after both kind of RT, with a greater decrease at T6 during TRT. On the other hand, pACC activity increased immediately after HIRT and decrease after TRT, no significant differences were measured at T6 and T24. mRNA analysis showed that HIRT seems to be more related to mechanical deformation (MGF), while the TRT seems to act on IGF-1 pathway. **Discussion** Our findings suggest that a less time commitment resistance training technique is, at least, equally effective to induce an increase of S6-P. The increase of the S6-P without a concomitant increase of AKT-P could be explained by an AKT-independent S6 phosphorylation. The increase of the phosphorylated form of ACC in HIRT, but not in TRT, may suggests a greater FA oxidation with high intensity/low volume resistance training compared to traditional technique. This data seems confirm that the manipulation of different variables of RT induces different molecular and metabolic responses related to the activation of specific muscle signaling pathways. **References** Andersen JL, Aagaard P. ACUTE EFFECTS OF VITAMIN D3 SUPPLEMENTATION ON MUSCLE FUNCTION

Wyon, M.

University of Wolverhampton

Introduction Serum vitamin D insufficiency has been defined when values are between 10-30 ng/mL-1 and deficiency for levels below 10 ng/mL-1(4-6). Hollick and Chen(2008) highlighted in their review the increases in worldwide vitamin D (1,25(OH)D3) deficiency is due to the use of sunblock and skin coverings to reduce the risk of skin cancer; this is exacerbated for indoor athletes (Lovell 2008) that have been shown to be at risk of deficiency mainly due to decreased sunlight exposure (Angeline et al. 2013). The aim of the study was to examine the acute effects of vitamin D supplementation on muscle function using isokinetic dynamometry. **Methods** The study used a randomised placebo-controlled, double-blind design. Eligible participants were male Caucasian national level judoka athletes (n=22) who were involved in full-time training. Exclusion criteria included vitamin supplementation, overseas travel to sunny climes and/or an injury incurred during the last 3 months prior to testing. An independent researcher, using a random number generator, allocated the participants to the treatment (150,000IU vitamin D3) or placebo and dispensed the blinded supplements to all participants. Participants were tested twice, 8 days apart, on a Monday morning prior to the commencement of judo training and after two days of rest. Post a standardised warm up, a 5-7ml blood sample was collected followed by isokinetic concentric quadriceps and hamstring muscle function assessments on the right leg at 30°sec-1 and 200°sec-1. **Results** The treatment group demonstrated a significant increase (34%) in serum 25(OH)D levels between days 1 and 8 (p<0.001). This was accompanied by a muscle strength increase of 13% (p=0.01). No significant differences were found for the placebo group for the same time period. **Discussion** Previous studies have highlighted the direct effect serum 1,25(OH)D3 had on metabolic muscle activity, strength and decreased injury incidence (Wyon et al. 2013). The present study has

demonstrated for the first time that a single bolus of 150,000IU vitamin D3 had a significant positive effect on serum 25(OH)D levels and muscle function within 1 week of vitamin D3 ingestion. These data highlight the short-term benefits of supplementation on muscle strength of deficient elite sportsmen that not only could have an indirect effect on injury occurrence but also a possible direct effect on their sport performance. EXPLAINING THE CONSTANCY OF ADULT MUSCLE FRACTIONAL SYNTHETIC RATES , THE BASIS OF ANABOLIC RESISTANCE AND THE FUTILITY OF TRYING TO OVERCOME IT BY EXCESS INTAKE OF EAA/PROTEIN

Rennie, M.

School of Life Sciences, University of Nottingham, University Park, Nottingham, NG7 2RD

Introduction One puzzling feature of muscle protein FSR values between young and older people is their constancy despite a muscle loss of $\approx 2\%$ p.a. > 50 y. Furthermore, when the sensitivity and responsiveness of MPS to EAA are examined, both are blunted, with the dose response curve of FSR vs. [EAA] or resultant plasma [LEU] being right-shifted/depressed; sedentary older people seem incapable, even at high [EAA], of the full "young" MPS response. (Cuthbertson et al. FASEB J. 2005). I noticed that with methacholine-induced increased microvascular perfusion (Phillips et al. AJP E&M. 2014) or post Resistance Exercise Training (Rennie, Exp Biol, 2014) increases in leg AA balance occurred on feeding, with more metabolically active muscle, via vessel recruitment or hypertrophy, despite constant FSRs. Aim To test if (i) the maintenance rate of MPS (turnover/unit muscle protein) is constant and (ii) that the absolute synthetic rate (ASR, i.e. FSR \times (protein mass) is the key variable (just as a building's maintenance rate is constant whereas total maintenance work (analogous to ASR) increases if the building is extended. Methods I re-analyzed data in 11-20, 28(4) y olds (Y) and 20-24 70(6) y olds (O) for muscle mass, [total alkali-soluble], [myofibrillar and sarcoplasmic] proteins, [RNA], [DNA] as well as myofibrillar and sarcoplasmic FSR, and normalized the data to protein mass and [RNA]/[protein] for 2.5-40 g of EAA given and the basal state. Results Whole body skeletal muscle protein mass was greater in Y than O (2874(442) vs. 2346(351); $P < 0.001$). Mixed (myo+sarc) ASR over 2.5-40 g EAA was significantly greater in Y than O (2.06(1.01) vs. 1.38(0.04), g Prot/h, (mean(SE)), O values being $\approx 67\%$ of those in Y (all $P < 0.001$). However, when FSR was normalized to protein mass, the values were identical (0.306(0.08) vs. 0.276(0.034) $\text{gx}105/\text{g Prot}$ for all values; for Δ increases by going 0-10 or 0-20 g EAA, O/Y ratios of Δ FSR were 62(8)% and 77(10)% respectively; and over the whole range the ratio was 50(6)% ($P < 0.001$). Thus, anabolic resistance is a property of a smaller muscle protein mass of O than Y and cannot be driven by increasing EAA delivery. The major determinants of MPS appear to be RNA/Protein and RNA/DNA which set capacity of MPS and which were 84(24)% and 76(11)% of Y values in O, and mixed protein FSR/RNA (the translational efficiency of ribosomes which was only 55(13)% of Y value in O (values different, $P = 0.05-0.01$). Graphs of MPS vs. dose of EAA or Δ MPS per plasma [LEU] were super-positionable on normalization. Discussion Basal FSR appears to be fixed at a maintenance value/muscle unit unalterable between normal and wasted tissue; that EAA-stimulation depends on the protein mass to be maintained, the ribosomal capacity (RNA/DNA) and translational efficiency, these factors only being improvable by increasing RNA synthesis/effectiveness, e.g. RET or anabolic steroids. Increasing [EAA] is doomed without RNA enhancement *pari passu*. Contact michael.rennie@nottingham.ac.uk.

JUMP TEST CAN DETECT CHANGES IN POWER DURING TRAINING IN JUNIOR BMX RIDERS

Bosse, C.1,2, Beeloo, D.C.M.3, Castelijns, L.C.E.3, De Ruiter, C.J.3, Van Den Wildenberg, R.4

National Olympic Committee The Netherlands

Introduction The purpose of this study was to detect indicators of neuromuscular fatigue which may predict overtraining is important, as the ability to monitor acute changes in performance could help in the prevention of overtraining. As several studies have shown, jump tests can detect neuromuscular fatigue (Andersson et al., 2008; Ronglan et al., 2006). **Methods** Eight male BMX riders of the national junior selection performed three countermovement jumps (CMJ) and drop jumps (DJ) twice weekly for twelve weeks using a Ballistic Measurement System. To reduce the amount of data, only CMJ and performance variable peak power were incorporated in the analysis. On each testing day, athletes completed Profile of Mood States questionnaire (POMS). POMS energy index, the ratio of vigor to fatigue, was calculated. After each training session, data of training load (RPE) were collected. Bivariate correlations between peak power and POMS and RPE scores were conducted for each athlete. Paired samples t-tests compared data at different times during measurements. **Results** Peak power increased (2-25%) for seven out of eight subjects. Subject 8 showed a decrease in peak power (19%) and POMS energy index (69%); he turned out to be injured. POMS energy index was highly variable; however, there was a significant increase from week 1 to week 12 ($t = -2.46$; $p < 0.05$). For three relative unloading weeks, training load was respectively 69%, 48% and 39% compared with the other weeks. There was a significant increase in energy index between before and after the first unloading week ($t = -2.24$; $p < 0.05$), but not for the other unloading weeks. Discussion Performance on the CMJ and DJ was constant, suggesting that only functional overreaching (FO) occurred; FO enables athletes to fully recover with only short-term performance decrements (Kuipers, 1998; Nederhof et al., 2006). Large variances in POMS scores indicate that healthy athletes are able to cope with fluctuations in mood. The jump test was sensitive enough to detect changes in performance over time and may serve as a potential measure of fitness in athletes. However, it cannot be concluded that changes in subjective variables were related to changes in performance, since only few significant relations were found. In additional research, the present study may serve as a baseline and performance can be related to this baseline. References Andersson H, Raastad T, Nilsson J, Paulsen G, Garthe I, Kadi F. (2008). POWER-FORCE-VELOCITY PROFILE IN COUNTERMOVEMENT JUMP

Jimenez Reyes, P.1, Samozino, P.2, Conceição, F.3, González Badillo, J.J.4, Cuadrado Peñafiel, V., Morin, J.B.2

Catholic University of San Antonio, Murcia, España

POWER-FORCE-VELOCITY PROFILE IN COUNTERMOVEMENT JUMP Jiménez-Reyes, P.1, Samozino, P.2, Conceição, F.3, González-Badillo, J.J.4, Morin, J.B.2 1Catholic University San Antonio - UCAM, Murcia, Spain 2Laboratory of Exercise Physiology, Universities of Savoie and Lyon, France 3LABIOME, Porto Biomechanics Laboratory, University of Porto, Portugal 4Faculty of Sports, University Pablo de Olavide, Seville, Spain Explosive performances directly depend on lower limb maximal power (Pmax) (Yamauchi et al 2007). Recently, Samozino et al showed that squat jump (SJ) performance was determined by both Pmax and mechanical force-velocity (FV) profile describing the ratio between force and velocity capabilities (Samozino et al 2012, 2013). However, SJ does not represent natural explosive movements due to the absence of the typical countermovement just before the jump (Markström 2013). The aims of this study were (i) to analyse the effect of countermovement on lower limb F-v relationship and (ii) to experimentally test the theoretical influence of FV profile on countermovement jumping (CMJ) performance, independently from the effect of Pmax. 54 high-level athletes performed maximal CMJ and SJ against additional loads. From vertical ground reaction force and displacement data, individual linear FV relationships were determined using the best trial for each condition. Individual mechanical FV imbalance (FVimb) was determined as the difference between actual and optimal FV profiles. FV relationships in CMJ were linear and shifted towards both greater force and velocity compared to SJ. A multiple regression analysis showed ($r^2=0.952$, $P<0.001$, $SEE=0.011$ m) that both Pmax and FVimb explained a significant part of the interindividual differences in CMJ performance ($P<0.001$) with positive regression coefficients for Pmax and a negative for FVimb. Compared to SJ, CMJ FV relationships were shifted to the right, with higher Pmax, maximal theoretical force and velocity (+35.8, 20.6 and 13.3%, respectively). CMJ performance depends on FVimb, independently from the effect of Pmax, with the existence of an individually optimal F-v profile. The lower the FVimb, the greater the CMJ performance, which is of interest since it is a more specific physical test, and it has been related to performance in many sports (e.g. Comfort et al 2014). Coaches should quantify and consider individual FVimb to orient and individualize training loads and exercises to optimize the FV profile while increasing Pmax, and in turn performances. Moreover, a simple method has been recently validated to determine the individual Pmax, FV profile and FVimb of athletes using loaded CMJ in field conditions (in progress). EFFECTS OF SPECIFIC HIP MUSCLE ACTIVATION EXERCISES USING REAL-TIME BIOFEEDBACK ON DYNAMIC KNEE CONTROL IN JUMPING PERFORMANCE IN FEMALE ATHLETES: RESULTS OF A PILOT STUDY

Hajduk, K.1, Rebschinski, J.1, Schlumberger, A.2, Schmidtbleicher, D.1

1: Institute of Sports Science (Frankfurt am Main) 2: Borussia Dortmund (Dortmund)

Introduction Increasing evidence in the literature indicates that improved triplanar neuromuscular control of the hip and knee muscles may have a positive influence on dynamic frontal plane knee joint control and knee-joint loading, especially in female athletes (Clairborne et al., 2006). Based on this assumption the purpose of the study was to investigate the effects of a specifically arranged training program of hip and knee muscle activation exercises on dynamic control adjustments of the knee joint in the frontal plane and jumping performance in a CMJ. Methods Participants (n 23, age 22.1 ± 1.6) were evaluated for (a) standing frontal plane knee joint angle (FPKJA, i.e. varus/valgus) in anatomical position and (b) for dynamic FPKJA during the eccentric and concentric movement phases of the CMJ, using a 2D video analysis system (Simi Aktysis, 100 fps). Changes in the amount of dynamic excursion of FPKJAs are defined by the difference between peak FPKJA during standing and peak dynamic displacement of FPKJA during both eccentric and concentric movement phases, termed peak range of motion (PROM). Two pretests were examined prior to the study to determine approximate jumping performance FPKJA. Training exercises included two types of miniband exercises and two more complex exercises guided by a visual and acoustic 2D biofeedback device (Simi Aktysis). Subjects trained for 4 weeks, 3 days per weeks. Results Vertical jump height improved significantly by 1.1 ± 1.5 cm ($3.7 \pm 9.9\%$; $p < 0.01$). Post-testing data indicates that dynamic PROM of FPKJA significantly moved toward more varus displacement during the eccentric ($-6.1 \pm 10.4^\circ$; $62 \pm 9.2\%$) as well as concentric phase ($-5.8 \pm 15.1^\circ$; $549 \pm 21.6\%$) before take-off ($p \leq 0.05$ for both phases). Discussion Major findings demonstrate that the training program had a positive influence on muscle power development during a stretch-shortening-cycle. Although the relative contribution of single exercises is speculative, the combination of those exercises focusing on improving intra- and inter-muscular coordination of hip and knee muscles might be responsible for an improved synergistic control mechanism within the kinetic chain of the lumbopelvic hip complex and the lower extremities. However, improvements in jumping performance seem to correlate negatively with an increased amount of frontal plane knee varus (PROM) during the eccentric ($r -0.32$) as well as in the concentric movement phase ($r -0.303$) when preparing for take-off in CMJ. FORCE-VELOCITY RELATIONSHIP OF LEG EXTENSORS OBTAINED FROM LOADED AND UNLOADED VERTICAL JUMPS

Nedeljkovic, A.1, Cuk, I.1, Markovic, M.1, Ugarkovic, D.1, Kukolj, M.1, Jaric, S.2,3

1: UB-FSV (Belgrade, Serbia), 2: DKAP (Newark, Delaware, USA), 3: BMS-GPB (Newark, Delaware, USA)

Introduction Recent research has suggested that loaded multi-joint movements could reveal a linear force-velocity (F-V) relationship (Bobbitt 2012; Yamauchi and Ishii 2007). Our first aim was to evaluate the strength and reliability of the F-V relationship of leg extensors. Our second aim was to compare those outcomes both across the different types of vertical jumps and different types of F and V variables. Our third aim was to evaluate the concurrent validity of F0 and Pmax observed from the linear F-V relationships with the directly measured muscle strength and power output. Methods Ten healthy subjects performed 3 different types of maximum vertical jumps: squat jump (SJ), countermovement jump without arm swing (CMJ), countermovement jump with arm swing (CMJa). Maximum vertical jumps were either loaded or unloaded by constant external forces of up to 30% of their body weight providing 7 different loading magnitudes. F-V relationships were assessed from the recorded F and V variables (separately for their maximum and averaged values). The linear regressions were extrapolated to determine the F- (F0; F at zero V) and V-intercepts (V0; the velocity at zero F), as well as the regression slopes ($a = F0/V0$). Finally, the maximum power output was calculated from the linear regression parameters as $P_{max} = (F0 V0)/4$. Results The observed F-V relationships proved to be strong (median correlation coefficients ranged 0.78 - 0.93) and approximately linear. The regression parameters (i.e., F- and V-intercepts corresponding respectively to maximum F and V, regression slopes, and the calculated maximum power; P) were highly reliable ($0.85 < ICC < 0.98$). The concurrent validity of the regression parameters corresponding to the

maximum F and P with respect to their directly measured values was on average moderate-to-large. Discussion The obtained F-V relationships revealed that (1) the assessment of maximum F and P could be somewhat more reliable and valid than the assessment of maximum V, (2) natural countermovement jumps should be employed rather than the jumps performed from a fixed squat position, while (3) both maximum and averaged F and V variables could be used despite revealing markedly different regression parameters. Taken together, the data generally reveal a strong and linear F-V relationship and therefore suggest that the loaded vertical jumps could be developed into a routine method for testing the force, velocity, and power generating capacity of leg extensors. RUN-UP PARAMETERS AND PERFORMANCE PREDICTION IN ELITE F20 LONG JUMPERS

García Fresneda, A.1, Theodorou, A.S.2, Padullés, J.M.1, Torralba, M.A.3, Padullés, X.1, Olsson, H.J.3, De Fuentes, M.L.2, López, J.L.4

1: INEFC-UB (Barcelona, Spain), 2: SEFAA-NKUA (Athens, Greece), 3: UB (Barcelona, Spain), 4: GREAF-Uv (Vic, Spain).

Introduction Run-up is a key component skill for successful performance in long jumping. Run-up success depends mainly upon the consistency of the stride length, number of strides, and pattern of speed development across all attempts (Hay, 1986). The intellectually disabled population (class F20) was represented in the London 2012 Paralympic Games. The aim of the present study was to identify the biomechanical parameters of the final strides of the approach run in class F20 long jumpers predicting performance. **Methods** The long jump, class F20, finalists participating in the 2012 London Paralympic Games (males=9, females=6) were recorded during the competition. White markers were placed at 1m intervals parallel to the runway's lines. The approach phase of each jump was recorded using a Casio EX-FI video camera operating at 300Hz (Theodorou et al., 2013). Videos were digitized using APAS 2010. **Results** Mean best official distance (m), (males: 6.40 ± 0.82 ; females: 5.06 ± 0.60). Mean length (m) of three last strides, (males: 2.19, 2.34, 2.05; females: 1.91, 1.84, 1.94). Average horizontal velocity of three last strides (m/s), (males: 9.16, 9.32, 10.02; females: 8.24, 8.01, 9.13). Mean duration of take-off phase (s), (males: 0.124; females: 0.135). Mean frequency (Hz) of three last strides, (males: 4.22, 4.00, 4.83; females: 4.49, 4.15, 4.89). Performance was significantly correlated with average stride velocity at 3rd to last and 2nd to last strides in males ($r = 0.88$, $p = 0.002$; $r = 0.83$, $p = 0.005$ and $r = 0.66$, $p = 0.053$) and all the last 3 strides in females ($r = 0.87$, $p = 0.023$; $r = 0.85$, $p = 0.029$ and $r = 0.84$, $p = 0.035$). **Discussion** In men, stride length values and technique were comparable to non-disabled elite athletes (Bae et al., 2011). In women, strides were about 15% shorter compared to elite and lacked technique (2nd stride shorter, last stride longest) (Hay 1986). Both in males and females, stride frequency and take-off duration was comparable to elite athletes but horizontal velocity was 10-15% less. The data of the present study demonstrate that the approach run characteristics of class F20 long jumpers are comparable to elite level athletes and best performance is highly correlated with horizontal velocity at the last three strides. **References** Bae YS, Park Y, Park J, Lee J, Chae W, Park S. ANALYSING THE DETERMINING VARIABLES IN THE LONG JUMP EVENT PERFORMANCE IN DIFFERENT AGE CATEGORIES WHILE COMPETING

López, J.L., Padullés, J.M., Arribas, V., Padullés, X., Portas, A., Rovira, N., Álamo, J.M., Tugores, F., Peña, X., Baiget, E.

University of Vic, University of Barcelona (INEFC)

ANALYSING THE DETERMINING VARIABLES IN THE LONG JUMP EVENT PERFORMANCE IN DIFFERENT AGE CATEGORIES WHILE COMPETING
Introduction During the past few years, numerous biomechanical studies have been conducted on the long jump event, some of them at international competitions. However, there are very few studies analysing and comparing athletes in other age categories during a competition. The purpose of this study is to find out if the determining variables in the long jump event are the same in the different age categories. **Methods** The finals of 12 indoor long jump 2013 championships were analysed in cadet (14-15 y/o), youth (16-17), junior (18-19), under 23 (20-22) and absolute categories in Catalonia, as well as the absolute category in Spain. The study sample was made up of 103 athletes (56 men and 57 women), analysing only their best jump in each competition. The space (runway and sandpit) was calibrated and 3 Casio EXFI cameras were used, recording at 300 fps, another camera recording at 30 fps in HD, 3 Microgate Polifemo Radio photocells placed at a distance of 1, 6 and 11 metres from the take-off board and a Stalker ATS II radar. 54 quantitative variables related to distance, time, speed and angle during the approach run, take-off, flight and landing were extracted from every jump. **Results** On the sample as a whole, the linear discriminant analysis shows a significant relation between the official jumping distance (dependant variable) and the speed on the antepenultimate, penultimate and last stride ($p < 0.01$; $p < 0.000$; $p < 0.001$), time of board contact ($p < 0.036$) and the height of the centre of mass on the flight phase ($p < 0.000$). Using this data, a linear regression model is built for the group of athletes: Official jumping distance (m) = $-0.761 + 0.158 \cdot Vp3$ (m/s) + $0.257 \cdot Vp2$ (m/s) + $0.133 \cdot Vp1$ (m/s) - $3.866 \cdot Tc0$ (s) + $0.036 \cdot h0$ (cm). However, when analysing each championship separately, other variables were found showing a relation between the official jumping distance and the age category, thus obtaining different models of linear regression for each age category. **Discussion** The variables that better explain the performance in the long jump event during a competition vary depending on the athletes' training level and age category. This could be used as a reference in training programmes for the different age groups. Despite the fact that no championship has got the same determining variables, there is however a common characteristic among all of them: they all have variables related to velocity. Additionally, in every championship, at least one of the variables was related to the take-off. We can thus confirm the importance of reaching a higher speed in the final phase of the approach run as well as the importance of the take-off.

Wahl, P.1,2,3, Hein, M.1, Achtzehn, S.1, Bloch, W.2,3, Mester, J.1,3

German Sport University Cologne

Introduction High intensity training (HIT) has been shown to be an effective and time saving strategy to improve endurance performance. Therefore, it seems to be promising to look for methods that allow an intensification of endurance training. Electromyostimulation (EMS) is a training method mainly performed in strength training and is used for its intensification. Up to now, only one study (Wahl et al. 2012) investigated the applicability and metabolic effects of superimposed EMS during endurance exercise. No other data are available. Therefore, the aim of the present study was to quantify the effects of local EMS during cycling on the hormonal system, the acid-base balance, the muscular demand, and the perceived exertion. **Methods** Subjects participated in three experimental trials each lasting 60 min in a randomized order. 1) Cycling (C), 2) Cycling with superimposed EMS (C+E) and 3) EMS (E). Human growth hormone (hGH), testosterone, cortisol, interleukin-6 (IL-6), myoglobin and creatine kinase were determined before (pre) and 0', 30', 60', 240', 24 h after each intervention. Metabolic perturbations were characterized by lactate and blood gas analysis (pH, BE, HCO₃⁻, pO₂, PCO₂). Furthermore, changes of the person's perceived physical state were determined. **Results** C+E caused the highest increases in cortisol, hGH, IL-6, CK and myoglobin, followed by C and E. Testosterone levels showed no significant differences between C+E and C. CK and myoglobine only increased after the C+E intervention. Metabolic stress was highest during C+E, followed by C and E. C+E was also the most demanding intervention from an athlete's point of view. **Discussion** As metabolic changes and acute hormonal responses are important for the induction of cellular signaling cascades and adaptations, the present results indicate that adding EMS to cycling may be an enhancing stimulus for aerobic training. As cortisol, hGH and IL-6 are known to react in an intensity dependent manner and partly depend on the muscle mass involved, the present study showed that superimposed EMS is a useful method to intensify endurance training. The levels of CK and myoglobin showed that superimposed EMS induces a high local stimulus to skeletal muscle, which might be caused by the concomitant stimulation of agonist and antagonist, causing eccentric contractions. In contrast, EMS alone showed no major changes on any of the parameters. **References** Wahl P, Schaerk J, Achtzehn S, Kleinöder H, Bloch W, Mester J. (2012). J Strength Cond Res, 26(9), 2383-2388. FACTORS CONTRIBUTING TO LOWER OXYGEN CONSUMPTION DURING ECCENTRIC THAN CONCENTRIC CYCLING

Penailillo, L., Blazevich A., Nosaka, K.

Universidad Finis Terrae

Introduction We have recently reported that oxygen consumption (VO₂) is 50% lower and vastus lateralis (VL) muscle activity is 38% smaller during eccentric cycling when compared with concentric cycling for the same workload (1). However, the muscle activity difference does not appear to fully explain the difference in metabolic demand between the two. To better understand the low VO₂ for eccentric cycling, the present study compared the muscle-tendon behaviour, muscle oxygenation and muscle activity of synergist and antagonist muscles of VL between eccentric and concentric cycling. **Methods** Eleven untrained men (27.1 ± 7.0 y) performed concentric cycling (CONC) followed 2 weeks later by eccentric cycling (ECC) for 10 min (60 rpm) at 65% of the maximal concentric cycling power output (CONC=188.6 ± 40.8 W; ECC=189.7 ± 43.2 W). During cycling, VO₂ and heart rate (HR) were recorded, and near-infrared spectroscopy measuring total haemoglobin (tHb) and oxygenation index (TOI) of VL were collected. B-mode ultrasound probe was attached to the middle portion of the left VL to measure muscle fascicle length changes, and muscle-tendon unit (MTU) and tendinous tissue (TT) length changes were estimated (2). Surface electromyogram (EMG) was obtained from VL, vastus medialis (VM), rectus femoris (RF) and biceps femoris (BF) muscles, and cycling torque and knee joint angle during each revolution were recorded. Changes in these variables (average in 10 min) were compared between CONC and ECC by paired t-tests. **Results** VO₂ and HR were 55% and 25%, respectively smaller (P<0.001) during ECC (1.3 ± 0.4 L·min⁻¹; 123.3 ± 23.5 bpm) than CONC (2.8 ± 0.5 L·min⁻¹; 163.5 ± 15.4 bpm). tHb was not different between bouts, but TOI was 16% greater (P<0.001) during ECC than CONC. Positive cycling torque was 29% greater during ECC (69.2 ± 15.4 Nm) than CONC (50.1 ± 10.6 Nm), and negative cycling torque was 68% greater during ECC (-22.6 ± 7.4 Nm) than CONC (-7.3 ± 3.7 Nm). The magnitude of MTU, fascicle and TT length changes were similar between CONC and ECC. Peak EMG activities of VL, VM, RF and BF were smaller (23%, 17%, 14% and 17%, respectively) during ECC than CONC (P<0.05). **Discussion** These results suggest that the lower metabolic cost of ECC is mainly due to the smaller muscle activation of not only knee extensors but also BF, and the total muscle activation of the four muscles was approximately 58% smaller during ECC than CONC, which appears to explain the difference in VO₂ between the two (55%). It may be that greater store and recoil of elastic energy from the tendinous tissue account for the greater negative and positive torque during ECC. **References** 1) Peñailillo et al. EFFECT OF THE RATE OF TORQUE DEVELOPMENT ON ISOMETRIC PLANTAR FLEXION TORQUE-EMG RELATIONSHIP: FASCICLE BEHAVIOR MATTERS

Kawakami, Y.1, Hatano, J.1, Wakahara, T.2

1: Waseda University, 2: Doshisha University

Introduction The relationship between torque and electromyographic amplitude (EMG) determined for submaximal to maximal isometric contractions, is known by experience to be affected by how fast a subject exerts torque. In fact, a ballistic contraction often involves a disproportionate burst in EMG amplitude even at a low torque level (Angel 1974). In this study we investigated the effect of difference in the rate of torque development during isometric plantar flexion on the torque-EMG relationship. We also studied internal shortening of gastrocnemius fascicles during isometric contraction to ascertain its dependence on the rate of torque development. **Methods** The sub-

ject ($n=9$ men, 22.3 ± 1.9 yr, mean \pm SD) performed a graded (ramp) isometric unilateral plantar flexion on a myometer from the rest up to his voluntary maximum (MVC), in three conditions: 1) as fast as possible (ballistic), 2) in 5 s (slow ramp), and 3) in 1 s (fast ramp). Surface EMG was recorded from the medial (MG) and lateral (LG) gastrocnemii, soleus (Sol), and tibialis anterior (TA), and the root mean square values (EMGrms) were determined every 10% MVC, from 0 to 90% MVC for each muscle. Fascicle length was determined with B-mode ultrasonography for MG. Two-way analysis of variance (%MVC \times conditions or %MVC \times muscles) with a Tukey post-hoc test was used to detect statistical significance. Results There was no significant interaction among MG, LG, and Sol in the relationship between relative EMGrms and %MVC. Each muscle showed significantly higher EMGrms at low to middle torque levels (10 - 50%MVC) for the ballistic compared to slow and fast ramp conditions whereas no difference was noted between slow and fast ramp conditions. The MG fascicle shortened during ramp contraction, and its velocity in the ballistic condition was higher than slow and fast ramp conditions at 10 - 50 %MVC, and between the slow and fast ramp conditions there were significant differences in fascicle velocity at 10 - 30%MVC. The fascicle length as a function of %MVC did not differ across conditions. Discussion Rapid shortening of MG fascicles after the onset of torque development in the ballistic condition clearly shows a situation for this muscle being subjected to a reduction in force-producing potential. The muscle is thus compelled to activate more to compensate for this and to reach the required torque level. This can be the reason for the unique torque-EMG relationship in this condition with higher EMGrms at low levels. Similar situations are expected for the other agonists considering the lack of significant difference in relative EMGrms at each %MVC levels. HOW STRONG AND LONG-LASTING IS THE CONTRALATERAL REPEATED BOUT EFFECT?

Nosaka, K.I, Chen, T.C.2, Yu, H.I.3, Chen, H.L.4

1. Edith Cowan University (Australia), 2. NTNU (Taiwan), 3. CYCH (Taiwan), 4. NCYU (Taiwan)

Introduction Muscle damage is attenuated after the second eccentric exercise bout, known as the repeated bout effect (RBE). This is observed even when the limb used for the exercise is different between bouts, referring to as the contralateral RBE (1,2). It was evident when maximal elbow flexor eccentric exercise was repeated in 2 weeks, and the magnitude of the effect was similar to that of the effect found for the same arm (1). The contralateral RBE was also found when the two elbow flexor eccentric exercise bouts were separated by 4 weeks (2). Although the ipsilateral RBE was shown to last more than 6 months (3), no previous study has examined how long the contralateral RBE lasts. The present study investigated the effect of the time interval between bouts on the magnitude of the contralateral RBE. Methods Untrained young men were randomly placed ($n=13$ /group) into one of four contralateral repeated bout groups based on the interval between bouts; 30 minutes (0d), 1 day (1d), 1 week (1wk), 4 weeks (4wk), and 8 weeks (8wk), or a control (CON) group. CON performed two bouts (separated by 2 weeks) of 5 sets of 6 maximal elbow flexor eccentric contractions with the non-dominant arm. Other groups performed the 30 maximal eccentric contractions with one arm followed 30 minutes, 1 day, 1, 4 and 8 weeks, respectively, by the exercise with the opposite arm. Changes in several indirect muscle damage markers before and for 5 days after exercise were compared between bouts, and among the groups by two-way repeated measures ANOVA. Results Changes in maximal voluntary concentric contraction torque, optimum angle, range of motion, upper arm circumference, muscle soreness, plasma creatine kinase activity and myoglobin concentration, and ultrasound echo intensity after the first bout were similar among the groups. The changes after the second bout were attenuated for CON, 1d, 1wk, and 4wk groups (the difference between bouts was greater in this order), but not for 0d and 8wk groups. The differences between bouts were smaller for the contralateral groups than CON ($P<0.05$). For example, peak muscle soreness was reduced by 74% for CON, 66% for 1d, 57% for 1wk and 40% for 4 wk from the first bout (average: 65/100 mm). Discussion The contralateral RBE lasts 4 weeks, but the effect appears to diminish earlier than that of the ipsilateral RBE. Importantly, when the two bouts were performed on the same day, the contralateral RBE was not evident. It seems that neural factors are involved in the effect, but the mechanisms warrant further studies. References 1) Starbuck & Eston (2012) *Eur J Appl Physiol*, 112, 1005-13. 2) Newton et al. THE EFFECT OF INTERMITTENT VS. CONTINUOUS PASSIVE MUSCLE STRETCH ON PLANTARFLEXOR RAPID FORCE PRODUCTION.

Trajano, G.S., Seitz, L.B., Nosaka, K., Blazevich, A.J.

Edith Cowan University

Introduction: It has been proposed that muscle stretch can increase electromechanical delay (EMD) and decrease the rate of muscular force development (RFD), which could reduce rapid force production. Recent data from our lab suggests that intermittent muscle stretch affects peak force and neural drive more than constant stretch. However, it is still not clear whether it also has a greater effect on rapid force production. Also, by comparing the RFD during a voluntary contraction vs. an involuntary contraction it is possible to gain some understanding about the influence of central command on rapid force production. Therefore, the purpose of this study was to compare the effects of intermittent and continuous plantarflexor stretch protocols on voluntary (vRFD) and electrically-elicited (involuntary) rates of force development and electromechanical delay (iRFD and EMD). Methods: Eighteen men randomly performed three conditions: 1) one 5-min stretch (constant stretch; CS); 2) five 1-min stretches (intermittent stretch, IS) with a 15-s inter-stretch rest interval; and 3) 5-min of rest (control), on three separate days. The stretch interventions were performed as a constant-torque ankle stretch on an isokinetic dynamometer. An electrical stimulator delivered a supramaximal 1-ms square-wave pulse to the tibial nerve, producing a single twitch to assess involuntary parameters. Isometric maximal voluntary contractions were used to assess vRFD (0-200 ms). Measures of plantarflexor vRFD, iRFD and soleus EMD were taken before and 0, 15 and 30 min after each condition. Results: There was a significant time \times group interaction effect for vRFD and EMD ($p<0.05$), but not for iRFD. Similar vRFD reductions were observed immediately after continuous (26.7%) and intermittent (28.7%) stretches. EMD increased after both stretch protocols (continuous = 4.2%, intermittent = 4.9%) and remained increased at 30 min. Discussion: Prolonged, acute continuous and intermittent muscle stretching can similarly affect vRFD and EMD without influencing iRFD. These results suggest that both types of stretch can be detrimental to rapid force production with a possible influence of a reduced central command, but also suggest that electrically-elicited RFD measurements may be problematic in the assessment functional rapid force production as they may not reflect changes in vRFD. SIX WEEKS OF MAXIMAL ECCENTRIC KNEE EXTENSOR TRAINING AFFECTS MUSCLE-TENDON MECHANICS AND MUSCLE DAMAGE

Kay, A.D.1, Rubley, B.1, Talbot, C.1, Mina, M.2, Blazeovich, A.J.3

1: UoN (Northampton, UK), 2: UoD (Derby, UK), 3: ECU (Perth, WA)

Introduction Strength training can influence muscle-tendon mechanics and architecture, and provide a protective effect from exercise-induced muscle damage; however more data are required describing the specific influence of eccentric training. Therefore, the aims of the present study were to examine the effect of 6 weeks of maximal eccentric knee extensor training on these properties. **Methods** Thirteen recreationally active participants (age = 28.3 ± 1.7 yr, mass = 73.5 ± 14.6 kg, height = 1.7 ± 0.1 m) volunteered for the study after giving written informed consent; ethical approval was granted from the University of Northampton. Training was performed twice weekly and consisted of 5 sets of 12 repetitions of 3-s maximal knee extensor isokinetic eccentric contractions at $30^\circ \cdot s^{-1}$ from 180° to 90° knee extension. Maximal isometric and eccentric knee extensor moment, range of motion (ROM), stretch tolerance, VL thickness and fascicle angle, and tendon and muscle-tendon unit (MTU) stiffness were measured using isokinetic dynamometry and real-time ultrasonography before and after the training. Creatine kinase (CK) concentration and delayed onset muscle soreness (DOMS) were also measured before and 24 h after a 20-min downhill run (16° decline). **Results** A significant increase in isometric (21.6%; $p < 0.05$) and eccentric (28.1%; $p < 0.01$) strength, ROM (6.6%; $p < 0.01$), stretch tolerance (83.6%; $p < 0.01$), VL thickness (7.8%; $p < 0.01$) and fascicle angle (9.2%; $p < 0.01$) was found after training; changes in VL thickness and fascicle angle were strongly correlated ($r = 0.96$; $p < 0.01$). While no change was found in MTU stiffness (slope of the passive moment curve) using dynamometry (-5.8%; $p = 0.45$), ultrasound data revealed a significant increase in VL tendon stiffness (8.7%; $p < 0.01$). Although CK concentration after downhill running increased significantly before (103.2%; $p < 0.01$) and after (42.1%; $p < 0.05$) training, the increase in CK was significantly lower following the training ($p < 0.05$), with subjects also reporting minimal DOMS within the knee extensors. **Discussion** The substantial increases in strength were accompanied by increases in both muscle size and pennation. Moreover, significant increases in ROM and stretch tolerance were observed, indicating a dual benefit to the eccentric training. An increase in tendon stiffness was observed, which will likely impact muscle-skeleton force transfer, and ultimately influence movement capacity. However, importantly this was not accompanied by a change in whole MTU stiffness, suggesting that MTU measurements may miss tissue-specific adaptations. Finally, the attenuated CK and DOMS response after training has clear implications for both muscular performance and injury risk. Contact tony.kay@northampton.ac.uk

OP-SH07 Attention & Sport Performance

THE INFLUENCE OF SELF-CONTROL ON GAZE BEHAVIOR AND PERFORMANCE UNDER PRESSURE

Englert, C.1, Oudejans, R.R.D.2, Bertrams, A.2

1 University of Heidelberg, 2 VU Amsterdam, 3 University of Mannheim

Introduction Under pressure athletes are not always capable of controlling their attention leading to possible performance impairments (e.g., Oudejans & Pijpers, 2010). According to the strength model of self-control attention regulating is a self-control act that is energized by a limited metaphorical strength. This resource can deplete after a primary act of self-control and is not immediately replenished which can negatively impact subsequent self-control (e.g., Baumeister, Gailliot, DeWall, & Oaten, 2006). In a series of studies by Englert and Bertrams (2012) the anxiety-performance relationship was moderated by self-control, as athletes with sufficient self-control strength were able to counteract the negative anxiety effects on attention and performance. In the current study we wanted to expand these findings by applying eye tracking technology to analyze attention regulation under pressure. **Methods** In a mixed between (depletion: yes vs. no)-within (anxiety: yes vs. no) design ($N = 28$), we assumed that self-control strength moderates the relationship between anxiety and dart performance. Furthermore we tested whether self-control negatively affects attention with an eye tracking device. Participants were randomly assigned to a depletion or non-depletion condition and we manipulated self-control strength (e.g., Englert & Bertrams, 2012). We manipulated anxiety by asking participants to perform a series of dart throws low and high (order counterbalanced) on a climbing wall (e.g., Nibbeling et al., 2012). **Results** In the anxiety condition depleted participants performed significantly worse than participants from the non-depletion condition while there were no group differences low on the climbing wall. Depleted participants high on the climbing wall displayed a significantly shorter quiet eye period compared to participants from the non-depletion condition. There were no group differences in gaze behavior low on the climbing wall. **Discussion** Developing interventions to foster self-control strength could enable athletes to perform at a high level under pressure (e.g., Baumeister et al., 2006). **References** Baumeister, R. ANXIETY, GAZE BEHAVIOUR AND PERFORMANCE EXECUTION; GOLF PUTTING WITH THREAT-RELATED DISTRACTORS

Paridon, K.N., Turner, K., Nevison, C.M., Bristow, M., Timmis, M.A.

Anglia Ruskin University

Introduction One of the central tenets of the Attentional Control Theory is that anxiety increases the influence of the stimulus-driven attentional system. This suggests that attention is diverted from task-relevant to threat-related stimuli under anxiety conditions which can be detrimental to performance. This study examined whether anxiety influenced performance and visual attention in a golf putting task with threat-related distractors. **Method** 13 male participants with no golf experience completed 20 putts of 3.5m under counterbalanced low (LA) and high anxiety (HA) conditions. In each anxiety condition, participants completed randomly 5 putts with no, small, medium or large

blocks on both sides of the green creating a passage. Anxiety was manipulated with financial incentives, performance comparisons and a negative evaluative audience. Execution was analysed with a 3-D motion analysis system (Codamotion). Gaze was recorded using SMI Eye tracking glasses. Variables measured were end location of the ball, SD in putter-head velocity, bivariate variable error (BVE) of impact angle and movement time. The dwell times on the areas of interest (AOIs) ball, blocks, hole and quiet eye period (QE) were analysed frame-by-frame. Coping style (CSAI) and anxiety (CSAI-2) were measured and analysed with Wilcoxon signed ranks tests. Other data was analysed with a 2x4 repeated measures ANOVA with Bonferroni corrected t-tests as follow up. Results Cognitive (C) and somatic (S) anxiety were significantly greater in the HA compared to the LA condition (C:17.3±4.8 vs.14.7±3.3 $p=0.020$; S:14.9±4.2 vs.12.3±2.6 $p=0.037$). Avoidance coping was significantly greater in the HA compared to the LA condition ($p=0.048$). End location of the ball was significantly closer to the hole in the HA compared to LA condition ($p=0.014$ $\eta^2=0.41$). This relates to the significant reduction in the BVE of the impact angle ($p=0.017$ $\eta^2=0.42$) and SD in the forward-velocity of the downswing ($p=0.041$ $\eta^2=0.33$) in the HA compared to the LA condition. Movement time of the putter was significantly shorter in the HA compared to the LA condition ($p=0.014$ $\eta^2=0.44$). Relative dwell time at the blocks was significantly reduced in the HA compared to LA condition (1.70%±1.46 vs.2.5%±1.97 $p=0.003$ $\eta^2=0.53$). No significant differences were identified in QE or other AOIs. Conclusion Under HA conditions participants improved performance; they also executed the task faster, with less movement variability, looked less at the distractors and used an avoidance coping style. These results contradict the ideas of the ACT. They suggest that participants adopted an active coping strategy to inhibit stimulus-driven attentional control towards threat-related distractors under HA conditions. SPATIAL ABILITY PREDICTS DOMAIN-SPECIFIC RECOGNITION SKILL BETTER THAN ANTICIPATION SKILL IN RECREATIONAL-LEVEL SOCCER PLAYERS

Belling, P.K.1, Ward, P.2

1: Michigan Technological University, MI, USA, 2: University of Greenwich, UK

Introduction Measures of domain-specific memory have been shown to be correlated with anticipation skill in sport (North et al., 2011). However, the cognitive processes supporting recognition appear to be simpler than those supporting anticipation (North et al., 2011) and may be underpinned by general cognitive abilities, especially in low-skilled performers (Ackerman, 1988). In this paper we hypothesized that domain-general ability would predict domain-specific recognition skill in soccer in a low-skilled sample but that anticipation skill would explain additional unique variance. Methods 58 recreational-level soccer players completed two domain-general tests (i.e., Mental Rotations Test [MRT-A], Peters, et al., 1995; Berlin Numeracy Test [BNT], Cokely et al., 2012), a test of anticipation skill (Online Assessment of Strategic Skill In Soccer [OASSIS], Belling, Suss, & Ward, 2014), and a soccer recognition test. Results The MRT-A ($\beta = .42$, $p < .01$) and BNT ($\beta = .06$, $p = .67$) predicted recognition skill ($R^2 = .20$, $F = 6.72$, $p < .01$). However, the OASSIS did not explain more variance (R^2 change = .01, $F = .78$, $p = .38$). Discussion Only spatial ability significantly predicted recognition performance suggesting that domain-general abilities may be more relevant than anticipation skill at this level. The data partially support Ackerman's (1988) model—domain-general ability predicted performance but a more central measure of general cognitive ability (i.e., BNT) did not, despite the complexity of the recognition task. Further research should explore the benefit of recognition versus anticipation training for improving perceptual skill. References Ackerman, P. L. (1988). PATTERN RECALL OF SOCCER PLAYERS

van Maarseveen, M.J.J., Oudejans, R.R.D., Savelsbergh, G.J.P.

VU University

Introduction In sport research, it has been well established that expert players are better able to recall structured patterns of play than their less-skilled counterparts (Gorman et al., 2012). Gorman et al. (2012, 2013) showed that expert basketball players intuitively predict the movement of the elements of the pattern further in time. The objective of the current study was to apply a similar method in soccer, including both a traditional and an anticipatory recall paradigm. Methods Talented youth soccer players watched video clips of small sided soccer games and after occlusion had to recall the positions of the players by dragging Xs and Os onto a blank field. Recall accuracy was calculated by comparing the participants' response with the actual positions of the players at the moment of occlusion (i.e., traditional recall) and at 60 consecutive 33 ms increments thereafter (i.e., anticipatory recall). The percentage of screen size was used as measurement unit and separate scores for the attacking and defensive pattern structures were calculated. Results Analyses showed that anticipatory recall accuracy (M attack = .0447, M defence = .0305, M overall = .0379) was significantly better than traditional recall accuracy (M attack = .0462, M defence = .0310, M overall = .0386), all $p < .05$, and that the participants anticipated the pattern on average 171 ms in advance, which is significantly different from zero, $p < .001$. The pattern of defensive structures was easier to recall than that of attacking structures, $p < .001$. Discussion The results showed that skilled soccer players intuitively apply an anticipatory encoding process, as was found in previous research of Gorman et al. (2012, 2013). Furthermore, the analyses revealed that the defensive pattern was recalled more accurately than the attacking pattern. Additional analyses in real-world coordinates may help to determine whether this is due to the perspective in the (video) images and by analyzing features of the patterns, instead of isolated player positions, more knowledge can be gained on how one memorizes patterns. In conclusion, this study showed that soccer players apply a similar anticipatory encoding process as basketball players (Gorman et al., 2012, 2013). References Gorman, A. RE-EXAMINING THE EFFECTIVENESS OF SEMANTIC PRIMING ON MOTOR SKILL PERFORMANCE UNDER PRESSURE

Holmes, D., Ashford, K.J., Kinrade, N.P., Jackson, R.C.

Brunel University

Introduction The detrimental effect of pressure on performance is well established (Hill et al., 2010). Priming has been earmarked as a potential intervention that may make performance more robust under pressure. Research has demonstrated that priming can promote concepts such as fluency (Ashford & Jackson, 2010) and activate cortical regions related to automaticity (Beckmann et al., 2012), which appear to lead to superior performance. Following recommendations to replicate priming studies (Kahneman, 2012), the aim was to replicate the study of Ashford and Jackson adding an in-depth cover story for the priming task and a double-blind testing protocol. **Methods** 24 skilled male soccer players dribbled a ball as quickly and accurately as possible through a series of 6 cones spaced across 10.5m. Completion time, lateral displacement and probe-reaction time (PRT) were recorded. Utilising a counter-balanced design, individuals completed a semantic priming sentence task exposing them to target words associated with fluent performance (positive condition) or neutral target words (neutral condition) prior to blocks of five trials. Participants performed under low- and high-pressure conditions, both of which included a control condition with no priming. Results A repeated measures MANOVA revealed non-significant findings for the pressure \times condition interaction and main effect of pressure; the main effect of condition was significant ($p = .01$). Follow-up tests revealed significantly faster task completion times ($p = .02$) and a tendency towards improved accuracy ($p = .06$) in the positive prime condition relative to the control. **Discussion** Present findings support previous work indicating that semantic priming has a significant effect on skilled performance, even when the researcher and participant are blind to the research expectations and the latter unaware of a priming paradigm. However, the benefits of positive priming were not as pronounced as originally suggested; the difference in time was smaller in magnitude, with no significant change in displacement or PRT. The employment of double blind procedures and measures to prevent conscious association between tasks is warranted to truly establish the efficacy of priming on motor skills. Further research should look to investigate cortical activity to enhance our understanding of priming effectiveness and performance under pressure. **References** Ashford KJ, Jackson RC. SELF-SUSTAINED DISSOCIATION CAN REDUCE SENSATIONS OF FATIGUE IN A MAXIMAL RUNNING TIME TRIAL

Nieuwenhuys, A.I., Klaus, L.I., Euwens, F.I., Davis, P.A.2

1: Radboud University Nijmegen (Nijmegen, The Netherlands), 2: Northumbria University (Newcastle, United Kingdom)

Introduction When physical activity becomes more intense, attentional focus is increasingly drawn inward as one starts to monitor internal bodily processes and strive to maintain on-task effort. However, actively focusing on internal processes may also increase awareness of sensations of fatigue and reduce performance when it counts the most. The present study tested whether it is possible to maintain a more external (dissociative) focus of attention under a high intensity workload and examined the extent to which this may reduce sensations of fatigue and improve performance in a maximal running time trial. **Methods** Twenty one runners (7 male, 15 female) of varying experience completed a 15 minute maximal running time trial under different (within-subject) attentional focus instructions, including: 'association' (e.g., breathing, running movement); 'dissociation' (e.g., surroundings); and control (no instruction). During the time trial, an innovative smartphone running application called 'PsyqRun' was used to provide an ambulatory (online) assessment of: (i) runners' thoughts and attentional focus (i.e., % associative statements vs. % dissociative statements); (ii) perceived level of fatigue (0-10); and (iii) running performance (distance in meters, based on GPS recordings). To analyze effects of exercise intensity (low vs. high) a comparison was made between the first and second half of the time trial. **Results** The percentage of dissociative statements differed significantly between each of the attentional instruction conditions (i.e., association: 19%, dissociation: 89%, control: 55%; $F(2,40) = 61.62$, $p < .001$) and did not change significantly over time (i.e., first half compared to second half), indicating that the manipulation of attention was successful and could be maintained throughout the duration of the run. Finally, although no significant differences were observed regarding performance, it appeared that sensations of fatigue were significantly lower in the dissociation condition (5.2) than in the association (5.8) and control conditions (6.0), with $F(2,40) = 3.80$, $p = .037$. **Discussion** In sum, results show that a dissociative focus of attention can be maintained under high levels of exercise intensity, and may significantly reduce sensations of fatigue. Future studies should examine how specific attentional instructions may differentially impact fatigue and performance in runners with different levels of experience and motives (e.g. recreational vs. competitive). Future research using innovative measurement techniques may elucidate potential relations between attention, fatigue and variations in running technique. 18:00 - 19:30**Oral presentations****OP-SH08 Sport Psychological Interventions****THE EFFECT OF PETTLEP IMAGERY AND OSERVATION ON MOVEMENT IMAGERY ABILITY**

Anuar, N.A., Cumming, J., Catton, M., Edge, S., Parry, B., Williams, S.E.

University of Birmingham

Introduction Effective imagery enables athletes to achieve desired outcomes, such as performance improvements, will depend on the ability to image easily and vividly. Techniques for improving imagery ability can be developed based on the neural and behavioural similarities found between movement imagery, observation and execution (Cumming & Williams, 2012). Movement observation has been shown to increase ease of imaging whereas it has been suggested that incorporating PETTLEP elements during imagery can increase the vividness of the imagery experience. However research has yet to directly compare these different approaches. Therefore, the present study investigated the effect of PETTLEP imagery and movement observation on the ability to image visually and kinaesthetically. It was hypothesised that techniques would result higher ratings of ease and vividness compared with traditional imagery. **Method** Participants

(N = 52, males = 24, females = 28; Mage = 18.60, SD = 1.59) completed a modified Vividness of Movement Imagery Questionnaire-2 (VMIQ-2; Roberts et al., 2008) on three separate occasions in random order: (1) Traditional Imagery (TI; e.g., imaging sat down at a table), (2) PETTLEP Imagery actively incorporating all 7 PETTLEP elements (PETTLEP; e.g., wearing sports attire and imaging the item 'kicking a ball' while holding a ball), and (3) Movement Observation (MO; observing video recordings of the 12 movements of the VMIQ-2 from an external perspective). Regardless of the condition, participants imaged each movement using external visual imagery (EVI), internal visual imagery (IVI) and kinaesthetic imagery (KI). Ratings of vividness (1 = no image at all you only know that you are thinking of the image, 5 = perfectly clear and as vivid as if actually experiencing the scenario) and ease of imaging (1 = very hard, 5 = very easy) were given for each image. Results Repeated measure MANOVAs revealed that participants displayed significantly higher ease and vividness of IVI and KI imagery in the PETTLEP condition compared with MO and TI ($p < .05$) and higher ease and vividness of EVI compared with TI ($p < .05$). No differences were found between PETTLEP and MO during EVI. Discussion Findings suggest that PETTLEP imagery can improve the ability to image both VI and KI. MO is just as effective as TI for IVI and KI, but might be helpful for improving EVI of general movements. References Cumming, J., & Williams, S. E. (2012). THE COMPOSITE OF MENTAL AND PHYSICAL RESILIENCE

Hackfort, G.

Universität der Bundeswehr München

Introduction Psychological disorders, chronic fatigue and emotional syndromes such as burn-out and depression overtook cardiovascular diseases in the German statistics of absenteeism and are responsible for huge costs in the German health care system. Factors of physical and psychological resilience, as well as the interrelation between them are of vital importance for the health and well-being of employees. The objective of this study was to find indices to what extent people with different individual physical fitness levels differ with regard to the personality factor of resilience. Methods The endurance performance on a total of 145 participants (the major part were students and employees at the University AF Munich; 26 female and 119 male) with an average age of 25,6 years (SD: 6,2 years) were investigated in a cross-sectional study using a spirometry and two different methods to detect the endurance capacity of the test persons. In addition to the assessment of the fitness level a scale composed by two subscales (emotional stability and mental toughness) of a standardized German personality inventory (BIP) was presented to assess mental resilience by self report. The data analysis proceeded in two stages, firstly correlation analyses were conducted and secondly variance analyses were run to detect differences between various performance groups. Results The findings of the correlation analyses revealed low to middle and highly significant correlations between the measured physical endurance capacity, operationalized by the performance indicators like maximum oxygen uptake (VO2max/VO2peak), maximum time and the maximum absolute power in watt performance, and the subjective assessed mental resilience scale. The analyses of variance indicated very clear evidence that there are high significant differences in self-assessed mental resilience between the performance groups. Discussion In terms of psycho-physical interdependencies the study provides proof for high significant interrelations between physical fitness and mental resilience. A comparison of several physical fitness groups differences in mental resilience can be detected especially between persons very high and very low in endurance performance. The results demonstrate further hints for the influence of an active life-style not only on physical fitness but also on emotional stability and mental toughness. By such an assessment-strategy the opportunity is given for a screening of psycho-physiological resilience as it could be relevant for various purposes of health related issues and employee acquisition or personnel development.

MINDFULNESS AND THE RELATION WITH STRESS, AFFECT AND BURNOUT IN ELITE JUNIOR ATHLETES

Davis, P.1, Gustafsson, H.2, Skoog, T.3, Kenttä, G.4, Harbel, P.5

1: Northumbria University (United Kingdom) 2: Karlstad University (Sweden) 3: Örebro University (Sweden) 4: The Swedish School of Sport and Health Sciences (Sweden) 5: United States Olympic Committee

Introduction Burnout in sport has been considered as a maladaptive consequence of chronic stress and suggested to be associated with ill-health, poor performance, and ultimately dropout. A prospective treatment that has been forwarded as a preventative method to effectively manage the everyday stress of ambitious athletes is mindfulness. Therefore, the aim of the present study is to examine the relationship between mindfulness and burnout and whether this relationship is mediated by stress, negative affect and positive affect in elite junior athletes. Methods Two hundred thirty six (136 males and 100 females) competitive elite junior athletes, (Mage = 17.4 years; SD = 1.08) completed the Mindful Attention Awareness Scale (Hansen et al., 2009), Athlete Burnout Questionnaire (Raedeke & Smith, 2001), Perceived Stress Scale (Cohen, et al., 1983), and Positive and Negative Affect Scale (Watson, et al., 1988). Results The results revealed that mindfulness had a significant negative relationship with both stress and burnout. Mediation analyses indicated that positive affect fully mediated the links between mindfulness and sport devaluation, and that positive affect and negative affect partially mediated the relationship with physical/emotional exhaustion and reduced sense of accomplishment. Discussion The results support mindfulness as negatively related to burnout in athletes and the influential role of positive affect. Future research should further investigate the unique variance in the relationship between mindfulness and burnout not explained by negative affect and perceived stress. Strategies to enhance athletes' mindfulness may be useful to prevent burnout and enhance performance. References Cohen, S., Kamarck, T., & Mermelstein, R. (1983). EXERCISE MOTIVATION AND BEHAVIOUR: A BRIEF THEORY-BASED INTERVENTION

Weman Josefsson, K., Lindwall, M., Fröberg, K., Karlsson, S.

School of Social and health sciences

Introduction The need for adequately designed and well-delivered interventions successfully increasing physical activity and exercise has long been highlighted [1]. Furthermore, interventions based on adequate theory and examined by proper analyses enable researchers to identify central mechanisms of change [2], important for successful intervention design [3]. **Methods** The present study examined potential effects of a short theory based intervention on exercise motivation and behaviour in a randomized controlled trial design. Self-Determination Theory, Cognitive Behavioural Therapy, Motivational Interviewing and Relapse-Prevention Model were used as guiding frameworks. The research questions concerned whether the intervention would influence (a) exercise level and intensity, (b) motivation quality, (c) autonomy and competence need satisfaction, and (d) potential indirect effects of self-determined motivation on exercise were also examined. The participants (N=64) completed self-reported measures of exercise level and intensity (Leisure Time Exercise Questionnaire; LTEQ), of motivational quality (Behavioral Regulations in Exercise Questionnaire-2; BREQ-2) and of autonomy and competence need satisfaction (Psychological Needs in Exercise Scale; PNSE) at baseline and after the six weeks of intervention. **Results** The results showed significant intervention effects for both exercise level and intensity, as well as in motivation quality. Furthermore, the effect of the intervention on exercise was mediated by motivational profile, in particular identified regulation. **Discussion** Despite the short-term and small scale nature of the intervention, effects were found on exercise behaviour and this effect was mediated by self-determined motivation. The results are generally in line with theoretical expectations from an SDT perspective. Furthermore, the study adds interesting findings of potential mechanisms behind exercise behaviour and motivation. Future research should further explore the theoretical mechanisms of behaviour change in order to facilitate tailoring of effective exercise interventions and enhancing motivation. **References** 1. THE EFFECTS OF DIFFERENTIATED MUSIC EXPOSURE ON 10-KM CYCLING TIME TRIAL

Lim, H., Karageorghis, C.I., Bishop, D.T.

Singapore Sports School

Introduction Researchers investigating the effects of asynchronous music in sport and exercise typically employ music for the entire duration of the activity. The few studies that had manipulated the exposure of asynchronous music in-task have reported improvements in psychological state and work output (e.g., Lim et al., 2009, Lima-Silva et al., 2012). The aim of the present study was to investigate the effects of differentiated asynchronous music exposure on a 10-km cycling time trial. **Methods** After completing a familiarization trial, 24 Caucasian males were administered four 10-km time trials in a counterbalanced order: No-music control (C); music throughout the trial (M1); music played from 0-5 km (M2); and music played from 5-10 km (M3). A repeated measures ANOVA was carried out to analyse time to completion, speed, cadence, heart rate, RPE, affect and arousal. **Results** Significant interactions ($p < .05$) were observed for all dependent variables with the exception of time to completion and RPE, while significant main effects ($p < .05$) were reported for time to completion, speed, heart rate and arousal. There were also significant distance effects for all dependent variables ($p < .05$). Follow-up pairwise comparisons indicated that trials were significantly faster under M1 (Mtime to completion = -43.42, Mspeed = 1.13, Mheart rate = 7.82) and M3 (Mtime to completion = -26.54, Mspeed = .64, Mheart rate = 4.56) when compared to control, while M2 did not significantly differ ($p > .05$) when compared against the other three conditions. **Discussion** Participants generally cycled faster with asynchronous music compared to a no-music control, suggesting the presence of energy reserves (Crewe et al., 2004). These faster times with associated with higher heart rates, though the increase in physiological demand did not correspond with an increase in RPE. This indicates that cycling to asynchronous music enabled participants to achieve superior physical performance without a concomitant increase in conscious effort, in line with the parallel processing theory (Rejeski, 1985). Affective valence was positively influenced only when music was presented in the second half of the time trial, suggesting that the point of exposure is a critical factor to consider in the application of music. Further research is required to investigate the reasons behind this phenomenon. **References** Lim HBT, Atkinson G, Karageorghis CI, Eubank MR. (2009). *Int J Sports Med*, 30, 435-442. 18:00 - 19:30**Oral presentations****OP-PM40 Teamsport Soccer & Rugby****MEASURING DECEPTIVE ACTIONS IN SOCCER MATCH PLAY: INFLUENCES OF POSSESSION, PLAYING LEVEL AND MATCH OUTCOME**

Smeeton, N.J., Defreitas, R.

University of Brighton

Previous research into deceptive actions in sport has focused on how these actions are perceived and outcomes are anticipated. Whilst this research has been useful, there has been no investigation into how frequently deceptive actions are displayed in their naturally occurring environments. Also, the factors associated with the expression of deceptive actions have not been investigated. To address this limitation, the aim of this study was to measure deceptive actions in elite and sub-elite soccer players, and to examine the association of these actions with skill level, possession and match outcome. Ten English Premier League (elite playing level group) and ten lower national league division (sub-elite playing level group) games were analyzed and deceptive actions displayed by players with the ball were

recorded under two categories. Actions classified under the Ball Retention category were step overs and uncompleted actions. Actions classified under the Ball Striking category were uncompleted actions, passing outside of the typical angle and atypical techniques. Pitch location was recorded for each action and possession was calculated by recording the time spent with the ball relative to the total time both teams spent in possession. Inter and intra observer agreement for deceptive actions was 91.2% and 97.2% respectively. Results showed that elite players displayed more deceptive actions than sub-elite players ($p < 0.01$). Furthermore, there was a playing level by pitch location interaction ($p < 0.01$), demonstrating that most deceptive actions were displayed in the midfield, followed by the attacking third for elite players, whilst the sub-elite players displayed the most deceptive actions in both the midfield and attacking third. Differences in frequencies of deceptive actions were found between elite and sub-elite players in all but uncompleted actions to retain the ball. Passes outside of the typical angle was the only significant predictor of playing level ($p < 0.05$). No significant differences in deceptive actions were found as a result of match outcome or amount of possession. Nor were deceptive actions significant predictors of match outcome or amount of possession. These results show that deception is displayed more frequent in soccer players playing at an elite level than those playing in lower divisions. Differences in the location of the pitch that deceptive actions are displayed between playing levels may reflect tactical differences. Potential explanations are discussed as to why passes outside the typical angle is a significant predictor of playing level. The value of increasing motor variability during practice to improve an ability to produce deceptive actions is also discussed alongside the implications for elite player development.

STANDARDIZED SMALL-SIDED GAMES EVOKE DIFFERENT PHYSIOLOGICAL RESPONSES IN ELITE-STANDARD YOUTH SOCCER PLAYERS OF DIFFERENT AGES

Olthof, S.1, Frencken, W.2,3, Lemmink, K.1,2

UMCG/RUG

1: Center for Human Movement Sciences, UMCG/UMCG (Groningen, the Netherlands), 2: School of Sports Studies, Hanze University of Applied Sciences (Groningen, the Netherlands), 3: Football Club Groningen (Groningen, the Netherlands) Introduction Small-sided games (SSGs) are suggested as an excellent training tool to improve physiological capacities and simulate the high physiological demands of full-sized matches (Abrantes et al., 2012). However, it is unclear if the physiological response to playing SSGs differs between age categories leading to differences in physiological adaptations. Therefore, the aim of this study is to determine the physiological response in standardized SSGs of elite-standard youth soccer players of different age categories. Methods Thirty-nine elite-standard male youth soccer players were assigned to four teams (under-16, under-17, under-18 and under-19) and played six SSGs. Each SSG's duration was 6 minutes, with a 1.5-minute rest in between. Pitch size was 40x30m. Positional data (LPM) and heart rate data (Polar) were collected during the SSGs to calculate (mean \pm sd) covered distance (m), number of sprints and heart rate (bpm) per team. Team differences were statistically evaluated (MANOVA). Results Under-19 covered less distance and performed a lower number of sprints than under-18 and under-17 during the small-sided games (respectively 685.6 ± 51.8 m, 770.5 ± 31.2 m and 760.9 ± 20.2 m; 11.1 ± 1.1 , 14.1 ± 2.0 and 14.4 ± 1.4 ; $p < 0.05$). Additionally, mean heart rate was lower for under-19 team compared to under-18 and under-17 (respectively 171.6 ± 8.1 bpm, 181.4 ± 1.8 bpm and 181.7 ± 3.7 bpm; $p < 0.05$). Under-16 did not differ from the older teams ($p > 0.05$). Discussion Results indicate an age-related difference in the physiological response during SSGs. Although similar duration and pitch sizes were used, the physiological demands were lower for the under-19 team. Comparable results were observed in regular soccer practices of elite Portuguese soccer players (Abade et al., 2013). This illustrates the need for age-specific designs for SSGs to evoke adequate physiological responses in elite-standard youth soccer players. References Abade E., Gonçalves B., Leite N. & Sampaio J. (in press). Int J Sports Physiol Perform Abrantes C., Nunes M., Maças V., Leite N. & Sampaio J. (2012). J Strength Cond Res, 26, 976-981 Contact s.b.h.olthof@umcg.nl

EVALUATION OF THE 365-SOCCER SHOOTING TEST

Radman, I.1, Wessner, B.1, Markovic, G.2, Hackl, M.1, Ruzic, L.2, Bachl, N.1

1: University of Vienna, Institute of Sport Science (Vienna, Austria), 2: University of Zagreb, School of Kinesiology (Zagreb, Croatia)

Introduction Limitations of existing methods for evaluation of kicking success in soccer brought to establishing a new protocol: 365 Soccer Shooting Test (365-SST). The aim of the study was to examine inter-session reliability and discriminative ability of the 365-SST on male soccer players. Methods Sixty-six soccer players of different playing standard (amateur - AP, young elite - YEP and experienced semi-professional - SPP) were recruited to perform 2 bouts of 10 shots using preferable foot on 2 separated days. Ball velocity (BV) was measured with the radar gun. In addition, we calculated shooting quality (SQ) as ratio of shooting accuracy (SA; mean distance of ball-hit scoring zones from the goal-centre) and time by hitting the ball to the point of goal-entry. Reliability of BV, SQ, and SA was evaluated using systematic bias (SB), within-individual variation (CV) and retest correlation, while the sensitivity was assessed with one-way ANOVA. Results No changes in performance outcome in SQ, SA and BV (0.3-1.4%, all $P > 0.6$) was evident in the second test. CVs for shooting performance measures were 5.3% for BV, 14% for SQ and 15.4% for SA. All performance measures had high inter-session correlation ($r = 0.7-0.88$). The tested groups differed considerably from each other in SQ ($F = 56.8$; $P < 0.001$), SA ($F = 55.8$; $P < 0.001$) and BV ($F = 8.7$; $P < 0.001$). Post-hoc analyses showed differences in SA and SQ among all qualitative groups, while significant difference in BV was observed only between the AP and YP players. Discussion The main findings of this study are good reliability and discriminative ability of a newly developed 365-SST. Indeed, previous soccer-specific shooting tests had considerably higher within-individual variation for velocity and accuracy scores, and lower retest correlations (Ali et al., 2007; Russell et al., 2010, respectively). Furthermore, SA and SQ proved to be sensitive measures of shooting performance of soccer players of different experience and proficiency level. These results generally support the use of the 365-SST in soccer practice. References Ali, A., Williams, C., Hulse, M., Strudwick, A., Reddin, J., Howarth, L., Eldred, J., Hirst, M. & McGregor, S. RELATIVE AGE EFFECT IN PROFESSIONAL AND YOUTH SOCCER LEAGUES IN MEXICO

Fritzler, W.

University of Football and Sport Sciences

RELATIVE AGE EFFECT IN PROFESSIONAL AND YOUTH SOCCER LEAGUES IN MEXICO Introduction. Youth soccer players are grouped in teams by the same year of birth. The Relative Age Effect (RAE) refers to the more advanced maturity of those children born close to the cutoff date of 1st of January (5), and has been studied in youth soccer in many countries (3). In Mexico, the U15, U17 and U20 youth soccer

leagues consist of the same clubs as the First Division. This assumes a similar talent selection process throughout the corresponding leagues. The aim of this study is the comparison of the size and other characteristics of the RAE between Mexicans' youth and First Division teams. Methods. The months of birth, positions and minutes played per game of the Mexican players of the 18 First Division ($n=383$), U20 ($n=417$), U17 ($n=469$), and U15 ($n=318$) teams were collected from the official Internet site of the Mexican Soccer Federation. The distributions of months in each league were tested for uniformity by the Kolmogorov-Smirnov test (2). The size of the RAE was determined by proportion of births in the first half (4) of the year. Results. All leagues showed a significant RAE ($p<0.01$), but its size was bigger for the U15 (73.0%) and U17 players (68.9%), while the U20 (57.8%) and the professional players (59.5%) showed smaller sizes. According to player positions, only the U20 and professional goalkeepers, and the professional defenders showed no significant RAE. The sizes of RAE were similar to the sizes of all players, with the exception of the midfielders who presented a bigger size (69%) in the professional league. The correlations between the size of RAE and points obtained in the corresponding league were bigger in U17 ($r=0.57$) and U15 ($r=0.41$), and lower in the First Division ($r=-0.07$) and U20 ($r=0.18$) teams. The correlation between the months of birth and the minutes played per game was insignificant and only for U17 ($r=0.07$) above 0.02. Discussion. According to the results of (2), the size of RAE got smaller as the age increased and was correlated with the team level, defined by the game-points obtained. The RAE already disappeared in players with 20 years of age. The main conclusion is that the Mexican soccer clubs should inspect their criteria of talent selection because of favoring the players born early in the year due to their maturity (1), while this bias disappears in the professional and U20 teams, independently of the players' position. CREATIVE BEHAVIOUR AND TACTICAL AND TECHNICAL SKILLS WHEN VARYING THE NUMBER OF OPPONENTS DURING SMALL-SIDED FOOTBALL GAMES

Ric Diez, Á.

INEFC Lleida

Introduction In collective sports, under different constraints, some movement configurations or skills are more likely to occur and some are unlikely, breaking system's replica symmetry (Hristovski et al. 2011). The aim of this study was to determine how the number of opponents (3, 5, 6 and 7) affects the emergence of tactical and technical skills and the softly-assembled dynamics when four professional footballers play small-sided games. **Methods** Four professional football players (age: 29.0 ± 3.6 years; height: 180.3 ± 7.4 cm; weight: 74.8 ± 7.9 kg) participated in a cross-sectional study. Eight small-sided games were played by a team of four players, against an opposition of 3, 5, 6 and 7 players (two times for each constraint) and video-recorded. The games were played randomly on a 40x30 metre pitch each for 3 min. Resulting trials were sequentially observed using an observational instrument with 63 categories. The data obtained was then analysed using a soft-assembled hierarchy model by means of two statistical analyses: a Principal Components Analysis (PCA) and the calculation of dynamic overlap order parameter q to determine the structure of the potential landscape of the team. **Results** PCA revealed 13 primary PCs for the games against 3 and 5 opponents, 10 primary PCs for the game against 6 and 11 for the game against 7 accounting for more than 80% of the total variance. The increase in the number of opponents resulted in a decrease in the number of offensive actions and an increase in the actions focused on the space control. In defense, playing with a numerical advantage constrained the players to perform more tactical skills focused on the player with the ball. In offense, players more frequently used skills of ball transmission when playing with numerical advantage, while they used more frequently skills of ball retention when playing with numerical disadvantage. The dynamic overlap formed statistically different plateaus for each condition, being 0.165 for the game with three opponents, 0.154 against five, 0.147 against six and 0.152 against seven. **Conclusions** The plateau values show a higher exploratory behaviour playing against three opponents. Constraining the game can also force the players to use specific technical or tactical skills. Coaches should be aware of these stimuli variability responses when planning the training tasks. **References** Hristovski R, Davids K, Araujo D, & Passos P (2011). *Nonlinear Dynamics, Psychology & Life Sciences*, 15, 2, 175-206.

OP-PM41 Exercise in the Heat

WARM WATER IMMERSION TRAINING INDUCES SIMILAR THERMOREGULATORY AND CEREBROVASCULAR RESPONSES TO EXERCISE TRAINING IN YOUNG FEMALES

Bailey, T.G., Cable, N.T., Miller, G., Sprung, V.S., Low, D., Jones, H.

Liverpool John Moores University, Liverpool University, Aspire Academy

Introduction: Exercise training enhances thermoregulatory efficiency via an earlier core temperature onset for sweating and cutaneous vasodilation. Exercise may be contraindicated in some individuals therefore alternative interventions to enhance thermoregulatory efficiency are warranted. Our aim was to directly compare the effects of exercise training with warm water immersion on thermoregulatory, cardiovascular and cerebral function. **Methods:** Eighteen healthy young females (age 25 ± 5 y) were assigned to either 8 weeks of cycling exercise (70% HRmax, $n=9$) or warm water immersion (42°C , $n=9$) for 30 min three times per week. Brachial artery flow-mediated dilation (FMD) and cardiorespiratory fitness were measured prior to and following the interventions. Passive heat stress in a water-perfused suit ($\sim 48^\circ\text{C}$) was employed to obtain temperature thresholds and sensitivities for sweat rate and skin blood flow. Middle cerebral artery velocity (MCAv) was measured throughout the heat stress. **Results:** Following both interventions FMD ($P=0.003$) and $\text{VO}_{2\text{peak}}$ ($P<0.001$) improved. Sweat rate occurred 0.10°C (95% CI = -0.14, 0.33, $P<0.001$) lower at the chest and 0.19°C (95% CI = 0.12, 0.23, $P<0.001$) lower at the forearm. Sweating sensitivity was $0.47 \text{ mg}\cdot\text{min}^{-1}\cdot\text{cm}^{-2}\cdot^\circ\text{C}^{-1}$ (95% CI = 0.24 to 0.71) higher at the chest and $0.43 \text{ mg}\cdot\text{min}^{-1}\cdot\text{cm}^{-2}\cdot^\circ\text{C}^{-1}$ (95% CI = 0.24, 0.64) higher at the forearm ($P<0.001$). Cutaneous vasodilation occurred 0.20°C (95% CI = 0.14, 0.26, $P<0.001$) lower at the chest and 0.19°C (95% CI = 0.12, 0.25, $P<0.001$) lower at forearm. MCAv was 6.38 cm/s (95% CI 5.50, 7.26, $P<0.001$) higher and CBVC was $0.04 \text{ cm}\cdot\text{s}^{-1}\cdot\text{mmHg}^{-1}$ (95% CI = 0.03, 0.06, $P<0.001$) higher following both interventions. **Conclusion:** These findings demonstrate

that short-term warm water immersion training elicits similar favourable thermoregulatory, conduit- and cerebrovascular adaptations to a period of moderate intensity exercise training in young females.

THE SEPARATE AND SYNERGISTIC EFFECTS OF HYDRATION AND THIRST ON EXERCISE PERFORMANCE IN THE HEAT

Wallace, P.J., McGarr, G.W., Mallette, M.M., Kim, I.M., Greenway, M.J., Cheung, S.S.

Brock University

Introduction: Current scientific recommendations emphasize maintaining fluid balance within 2% of baseline body weight to optimize performance in both temperate and hot environments. However, this idea is largely based on studies manipulating hydration through oral fluid ingestion, which alters the internal physiology but also the perceptual sensations of thirst, and thus potentially the voluntary drive to exercise. To isolate the direct physiological impact of hydration status on aerobic exercise performance, we separated the physiological consequences of 3% dehydration from the conscious awareness of fluid replacement. **Methods:** 11 trained cyclists performed four double-blinded, counter-balanced trials in a hot-dry (35°C, 10% RH, wind speed: 3.0 m/s) environmental chamber. Subjects performed 90 min of steady state (50% $\dot{V}O_{2peak}$) cycling followed by a self-paced 20 km time trial (TT). The four conditions were: Euhydrated-Not Thirsty (EU-NT), Euhydrated-Thirsty (EU-T), Hypohydrated-Not Thirsty (HY-NT), and Hypohydrated-Thirsty (HY-T). Blinding of hydration status was achieved using continuous intravenous infusion (EU) or sham IV (HY). Thirst was manipulated by providing (NT) or withholding (T) ad libitum oral rinse of 35°C water. **Results:** Distinct hydration states were successfully achieved, with $0.42 \pm 0.46\%$ dehydration following the 20 km TT (EU) compared to $3.19 \pm 0.56\%$ in HY ($p < 0.001$). Subject blinding was successful, with 27 out of 44 correct guesses on hydration state but only 54% mean confidence. Thirst manipulation was also successful, with greater perceived thirst in T (7.4 ± 1.7 on a 1-9 rating scale) than NT (4.3 ± 2.4 , $p < 0.001$) after the TT. There were no significant differences in power output during the TT between hydration (EU $202.9 \pm 36.5W$ vs. HY $207.0 \pm 35.9W$, $p = 0.362$) and thirst condition (NT $203.3 \pm 35.6W$ vs. $206.6 \pm 36.8W$, $p = 0.548$) or across all four conditions ($p = 0.886$). No significant differences in completion time ($p = 0.832$), or pacing profile ($p > 0.05$) was evident amongst any of the 4 experimental conditions. HY had non-significant trends towards higher rectal temperature and heart rate throughout the TT compared to EU, but no trials were terminated due to reaching the 40.0°C ethical threshold. **Discussion:** Within the range of up to 3% dehydration, neither the physiological effects from lowered hydration status nor the perception of thirst, in isolation or combined, had an effect on sustained submaximal exercise performance in the heat. Furthermore, this dehydration did not significantly increase thermophysiological strain compared to euhydration, with no premature termination or heat illness present in any of the conditions. This contrasts with the American College of Sports Medicine's 2007 position stand that promotes maintaining $<2\%$ body mass loss to sustain exercise performance. We conclude that this fluid replacement policy may be overly conservative for a healthy and fit population.

THERMOREGULATION AND FLUID BALANCE DURING EXERCISE IN 60 VERSUS 80-YEAR OLD SUBJECTS

Bongers, C.C.W.G.1, Eijssvogels, T.M.H.1,2, Nyakayiru, J.I, Veltmeijer, M.T.W.1, Thijssen, D.H.J.1,3, Hopman, M.T.E.1

Radboud university medical center

1Department of Physiology, Radboud university medical center, Nijmegen, The Netherlands; 2Henry Low Heart Centre, Department of Cardiology, Hartford Hospital, Hartford, Connecticut; 3Liverpool John Moores University, Liverpool, United Kingdom. **Introduction.** The presence of impaired thermoregulatory and fluid balance responses to exercise in older humans is well established. However, it is unknown whether thermoregulation and fluid balance during exercise in older humans continue to decline with further increases in age. Therefore, the aim of this study was to compare thermoregulatory and fluid balance responses between sexagenarians and octogenarians during prolonged exercise. **Methods:** 40 sexagenarians (60 ± 1 year) and 36 octogenarians (81 ± 2 year) volunteered to participate in a 30 km march at a self-selected pace, starting at 7.30 AM. Core body temperature (T_c) and heart rate were recorded every 5 km. Subjects reported fluid intake, whilst urine output and body mass were measured and sweat rate was calculated. **Results:** Wet bulb globe temperature increased from 12 to 24°C during the experiment. Exercise duration ($7h34min \pm 0h58min$) and exercise intensity ($70 \pm 9\%$ of predicted maximal heart rate) were comparable between groups ($p > 0.05$). Octogenarians demonstrated a lower baseline T_c ($37.2 \pm 0.3^\circ C$ versus $37.5 \pm 0.4^\circ C$, $p < 0.01$) and a larger exercise-induced increase in T_c compared to sexagenarians ($1.2 \pm 0.5^\circ C$ versus $0.7 \pm 0.4^\circ C$, $p < 0.01$), whilst maximum T_c was comparable between groups ($38.2 \pm 0.3^\circ C$ versus $38.4 \pm 0.4^\circ C$, $p = 0.09$). Octogenarians demonstrated lower fluid intake ($207 \pm 139 mL/h$ versus $314 \pm 129 mL/h$, $p < 0.01$), urine output ($27.6 \pm 22.0 mL/h$ versus $51.8 \pm 40.1 mL/h$, $p < 0.01$) and sweat rate ($317 \pm 151 mL/h$ versus $401 \pm 144 mL/h$, $p = 0.03$), whilst relative body mass loss was larger in octogenarians ($1.2 \pm 1.0\%$ versus $0.7 \pm 0.9\%$, $p = 0.04$) compared to sexagenarians. **Conclusion:** Under temperate ambient conditions, octogenarians demonstrate a larger increase in T_c and a higher fluid loss compared to sexagenarians during prolonged exercise. Our findings suggest that thermoregulatory and fluid balance responses to exercise are progressively impaired as age increases.

INSIDE THE 'HURT LOCKER': PHYSIOLOGICAL TOLERANCE TIMES WHILE WEARING EXPLOSIVE ORDNANCE DISPOSAL AND CHEMICAL PERSONAL PROTECTIVE EQUIPMENT

Stewart, I.B., Costello, J.T.

Queensland University of Technology

Introduction Explosive ordnance disposal (EOD) personnel wear protective clothing which provides a high level of insulation in the event of a blast. In some circumstances it may also be necessary for the EOD technician to don chemical protection in conjunction with the bomb suit. Unfortunately, the combination of this encapsulating protective clothing may impair heat loss and place the technician at risk of heat injury (Stewart et al., 2013). Therefore, the aim of this study was to evaluate the physiological tolerance times while wearing an EOD bomb and a chemical protective undergarment, in simulated environmental extremes across a range of work intensities. **Methods** Twelve healthy males undertook nine trials while wearing an explosive ordnance disposal bomb suit, respirator and air-permeable, charcoal impregnated chemical protective undergarment (total weight ~35kg). The trials involved walking on a treadmill at 2.5, 4 and 5.5 km.h⁻¹ at 1% grade for each of the following environmental conditions, 21, 30 and 37°C wet bulb globe temperature (WBGT) in a randomized controlled crossover design. The trials were ceased if the participants' core temperature reached 39°C, if heart rate exceeded 90% of maximum, if walking time reached 60 minutes or due to fatigue/nausea. Tolerance times were analyzed using a two-way (environment x intensity) repeated measures analyses of variance. **Results** Significant main effects ($p < 0.01$) were observed in environment, intensity, and their interaction. Post hoc analysis showed tolerance times in WBGT 21°C (mean \pm sd; 54.2 ± 10.4 , 36.5 ± 7.3 and 23.0 ± 6.4 min in the 2.5, 4 and 5.5 km.h⁻¹ trials respectively) were greater ($p < 0.05$) than those in WBGT 30°C (46.2 ± 8.6 , 30.8 ± 5.6 , 18.2 ± 7.0 min) and WBGT 37°C (37.8 ± 7.2 , 28.4 ± 7.9 and 15.9 ± 5.2 min). A significant difference between WBGT 30°C and WBGT 37°C was also observed ($p < 0.05$). Similar-

ly, tolerance times were significantly ($p < 0.05$) reduce in the 5.5 km.h⁻¹ trials compared to the 2.5 and 4 km.h⁻¹ trials. Furthermore, the tolerance times were shorter in the 5.5 trials compared to the 4 km.h⁻¹ trials ($p < 0.05$). Discussion The study has provided a comprehensive evaluation of the physiological tolerance times while wearing an EOD bomb suit, respirator and an air-permeable, charcoal impregnated chemical protective undergarment. This was undertaken in simulated environmental extremes across a range of work intensities using a systematic approach. In conclusion, physiological tolerance times are significantly reduced in higher WBGT's and work intensities. References Stewart IB, Townshend A, Rojek AM, Costello JT. THE IMPACT OF A 37 KM FOOT RACE IN HOT AMBIENT CONDITIONS UPON CARDIAC FUNCTION

Hankey, J.1,2, Gill, S.1, Costa, R.J.S.3, Gregson, W.2, Whyte, G.2, George, K.2

1: CU (Coventry, UK), 2: LHMU (Liverpool, UK), 3: MU (Australia).

Introduction: It is well known that regular exercise has beneficial effects on the cardiovascular (CV) system. However, prolonged strenuous exercise has been associated with a decline in cardiac function during a range of exercise modes, durations and intensities (Middleton et al., 2006). Limited attention has been given to the CV consequences of prolonged exercise combined with environmental stress. Methods: Fifteen trained endurance runners (mean \pm s: age 43 ± 9 yr, height 1.8 ± 0.1 m, mass 71.4 ± 8.8 kg) were assessed before (PRE) and immediately after (POST) a 37 km foot race completed at an average temperature of 32°C. Heart rate (HR), blood pressure and echocardiographic measures of left ventricular (LV) systolic and diastolic function were completed at both assessment points. Results: Mean finish time was 277 ± 36 min. HR was increased PRE-POST exercise (60 ± 11 to 83 ± 12 beats.min⁻¹; $p < 0.001$). LV end-diastolic volume, an estimate of preload was not altered POST whilst blood pressure, an estimate of afterload, was reduced from PRE ($141/81 \pm 13/7$ mmHg) to POST ($115/71 \pm 12/6$ mmHg; $p < .001$). LV end-systolic volume was increased at POST which contributed to a reduction in ejection fraction from PRE-POST exercise (55 ± 7 to $47 \pm 7\%$; $p < .001$). Despite this systolic tissue velocities were unchanged POST exercise. Peak early (E) trans-mitral flow was significantly reduced from PRE-POST exercise (73 ± 11 to 54 ± 11 cm.s⁻¹; $p < 0.001$) as was the E to atrial (A) diastolic filling ratio (1.48 ± 0.29 to 1.07 ± 0.31 ; $p < 0.001$). Early diastolic tissue velocity was reduced PRE-POST exercise (11.7 ± 2.7 to 10.0 ± 2.7 cm.s⁻¹; $p = .046$). Discussion: Whilst previous research on the effect of near marathon distance exercise upon cardiac function have been inconsistent. The present study indicated evidence of both systolic and diastolic functional change (cardiac fatigue) after 37 km running in hot ambient conditions. Therefore exercise of this nature may place increased physiological stress upon the human heart. References: Middleton, N., Shave, R., George, K., Whyte, G., Hart, E. and Atkinson, G. (2006). *Med Sci Sports Exerc*, 38, 681-687. Contact: joanne.hankey@coventry.ac.uk

HAZARDOUS THERMAL AND FLUID BURDENS DURING SCUBA FINNING IN 29 °C WATER

Castagna, O., Desruelle, A.V., Blatteau, J.E., Vallée, N., Schmid, B., Dumoulin, G., Regnard, J.

Military biomedical research institute (IRBA)

Occupational diving combines effects on hydromineral balance, hemodynamic status and thermal balance, which may result in physiological hazards. The study analyzed how the combined strains of occupational diving alter thermal and hydro-mineral balances in fit subjects during a two hour shallow dive. This study is justify since lately, the scientific community started to point the attention on the hazards of hot water during long and physical activity. 12 subjects underwent two dive bouts (3 m depth) in 29°C fresh water. They wore a 2.5 mm integral neoprene suit and breathed pure oxygen through a closed-circuit rebreather. During Quiet session they gently floated above pool's bottom. They continuously fin swam during Fin. Deep and skin temperatures, urine flow and sodium content were assessed, as well as hemoglobin (Hb), hematocrit (Ht), plasma sodium, potassium, aldosterone and active renin. During Fin oxygen consumption and heart rate were twice higher than during Quiet. Deep and skin temperatures reached higher values (respectively 38.5 °C and 36.2 °C ; $p < 0.05$). In Fin the average 2-hour mass loss was 989 g vs 720 in Quiet ($p < 0.05$). Urine volume was 610 mL during Quiet vs 385 in Fin ($p < 0.05$). During Quiet plasma volume decreased by an average 210 mL leaving 66 % of urine volume provided by interstitial and intracellular fluids. Plasma renin and aldosterone were lower than baseline ($p < 0.001$). During Fin, mean plasma volume decreased by 352 mL and plasma renin and aldosterone were not altered. Quiet diving changed body fluid balance similarly to open-circuit diving. Continuous finning caused body heat gain and increased fluid loss through sweat. Sustained exercising in warm water caused whole body fluids and hemodynamic alterations likely to increase health hazards.

OP-PM42 Supplementation & Performance

REHYDRATION WITH A CASEIN OR CARBOHYDRATE DRINK FOLLOWING A 2% DEHYDRATING EXERCISE SESSION.

Black, K.I, Rehrer, N.2, Chung, T.1, Robinson, C.1, Love, T.D.3

1. Department of Human Nutrition, University of Otago, 2. School of Physical Education, Sport and Exercise Sciences, University of Otago, 3. College of Engineering, Swansea University

Introduction Research has shown milk to be a more effective rehydration beverage than a sports drinks (1) which has been attributed to the protein content of milk. Recent research suggests that whey protein does not influence hydration status anymore than a sports drink (2), but milk proteins are 20% whey and 80% casein and no study has investigated the effects of casein protein on rehydration. Methods Ten healthy males provided written informed consent to participate. Participants arrived at the laboratory at 17:30h, provided a urine sample, and were weighed in minimal clothing before entering the heat chamber (35.2±0.3°C, 62±5%). Participants cycled for 10 minute blocks separated by 5 minutes rest during which they were weighed. This continued until participants lost ~2% of their initial body mass. Fifteen minutes following the cessation of exercise participants were provided with 540 mL of fluid containing 20 g casein or a sports drink (5.9% carbohydrate) matched for energy and sodium content. At 30, 45 and 60 mins participants were provided with water in equal volumes so the total fluid consumed was 150% of body mass lost during the exercise session. At 60 minutes a meal of spaghetti on toast was consumed. At 60 and 120 mins a urine sample was collected. A cereal bar was consumed before bed. All overnight urine produced was collected. A first void urine sample was also taken the following morning. Statistical analysis Mixed model regression analysis was undertaken to compare conditions across time. Residuals were plotted to test for normality. Normality of variable distributions was also checked for using a Shapiro-Wilk test. A repeated measures ANOVA analysis was conducted to test for significance. Results There were no significant differences in urine volume between sports drink (1465±605ml) and casein (1449±417ml). Urine osmolality the following morning indicated participants were in a similar state of hydration on sports drink (770±248mosmol/kg) and casein (736±103mosmol/kg; p>0.05). Conclusion When energy and sodium content are matched, casein protein has no effect on rehydration compared to a sports drink. References 1. Watson P, Love TD, Maughan RJ, et al. EFFECT OF BETA-ALANINE SUPPLEMENTATION ON 20 KM CYCLING TIME TRIAL PERFORMANCE AND COGNITIVE FUNCTION

Martin, D.1, Hobson, R.M.1, Cooper, S.B.1, Robertson, J.1, Harris, R.2, Sale, C.1

1: Sport, Health and Performance Enhancement (SHAPE) Research Group, Nottingham Trent University, NG11 8NS, UK; 2: Junipa Ltd., Newmarket, Suffolk, UK.

Introduction Carnosine, a dipeptide of the amino acids beta-alanine and histidine, has several physiological roles that might explain enhanced exercise performance. Studies have demonstrated a beneficial effect of beta alanine supplementation on high intensity exercise performance (Hobson et al, 2012). However, no study to date has examined the effects on longer duration cycling performance. Furthermore, although carnosine has been suggested to have a number of effects within the brain (Sale et al, 2013), the effects of beta-alanine supplementation on cognitive function in athletes has not previously been examined. Method Nineteen UK category 1 male cyclists completed four 20 km cycling time trials (on their own racing bikes attached to a Cyclus 2 ergometer), two before and two after 4 weeks of supplementation with either 6.4 g/d beta-alanine (n=10; BA) or a matched placebo (n=9; P). Performance time for the 20 km time trial was recorded, as were the split times for every 1 km. Capillary blood samples were taken at baseline, immediately following the time trial and again after completing the cognitive function tests for determination of blood lactate. Heart rate was recorded after every 1 km and RPE after every 5 km. A battery of cognitive function tests (Stroop test, Sternberg paradigm and RVP task) was completed before, and immediately following, the time trial. Results There was no significant effect of beta-alanine supplementation on 20 km time trial performance (BA pre 1943±129 s; BA post 1950±147 s; P pre 1989±106 s; P post 1986±115 s; supplement by time interaction, p=0.624) or on the performance of each 1 km split (all p>0.05). The effect of beta-alanine on 20 km time trial performance was deemed unclear as determined by magnitude based inferences. Similarly, there were no effects of beta-alanine supplementation on blood lactate concentrations, heart rate or RPE (all p>0.05). Furthermore, beta-alanine supplementation did not affect cognitive function at rest, or mediate the effects of exercise on any component of cognitive function examined (all p>0.05). Discussion Supplementation with 6.4 g/d of beta-alanine for 4 weeks did not affect 20 km cycling time trial performance in well trained male cyclists. Furthermore, beta-alanine supplementation did not affect any aspect of cognitive function at rest, or mediate the effects of exercise on cognitive function. CAFFEINATED ENERGY DRINKS ENHANCE PHYSICAL PERFORMANCE IN ELITE JUNIOR TENNIS PLAYERS

Gallo Salazar, C.1, Areces, F.1, Abián Vicén, J.1, Lara, B.1, Salinero, J.J.1, Gonzalez Millán, C.1, Portillo, J.2, Muñoz, V.2, Juárez, D.2, Del Coso, J.1

Camilo Jose Cela University Exercise Physiology Laboratory, Madrid, Spain. 2 University of Castilla La Mancha, Toledo, Spain.

Introduction The aim of this study was to investigate the effectiveness of a caffeinated energy drink to enhance physical performance in elite junior tennis players. **Methods** A double-blind, placebo controlled and randomized experimental design was used in this experiment. In two different sessions separated by one week, 14 young (16 ± 1 years) elite level tennis players ingested 3 mg of caffeine per kg of body mass in the form of an energy drink or the same drink without caffeine (placebo). After 60-min for caffeine absorption, participants performed a maximal handgrip strength test, a maximal velocity serving test, an 8x15 m sprint test and then played a simulated singles match (best of 3 sets) against an equally ranked opponent. Body mass was measured before and after the matches and the instantaneous running speed was assessed using global positioning system (GPS) devices. Due to the differences in matches' duration, data on running distance were calculated per hour of play. Heart rate was individually recorded and the matches were video-taped and notated afterwards. **Results** In comparison to the placebo, the ingestion of the caffeinated energy drink increased handgrip force by $\sim 4.2 \pm 7.2\%$ ($P = 0.03$), the running pace over 18 km•h⁻¹ (46.7 ± 28.5 vs 63.3 ± 27.7 m•h⁻¹; $P = 0.02$) and the number of sprints (12.1 ± 1.7 vs 13.2 ± 1.7 bouts•h⁻¹; $P = 0.05$) during the simulated match. Besides, the caffeinated energy drink slightly increased the sweat rate (0.5 ± 0.3 vs 0.7 ± 0.3 L•h⁻¹; $P = 0.04$) during the match although it minimally affected the dehydration level attained (0.1 ± 0.5 vs $0.2 \pm 0.4\%$; $P = 0.04$). There was a tendency for increased maximal velocity during the 8x15m sprint test (22.3 ± 2.0 vs 22.9 ± 2.1 km•h⁻¹; $P = 0.07$) and higher percentage of points won on service with the caffeinated energy drink (49.7 ± 9.8 vs $56.4 \pm 10.0\%$; $P = 0.07$). The energy drink neither improved ball velocity during the serving test (42.6 ± 4.8 vs 42.7 ± 5.0 m•s⁻¹; $P = 0.49$) nor affected mean heart rate (143 ± 3 vs 144 ± 4 bpm; $P = 0.35$) or maximal heart rate (181 ± 3 vs 178 ± 4 bpm; $P = 0.44$) during the match. **Discussion** The present investigation offers new information about the ergogenicity of caffeinated energy drinks. A dose equivalent to 3 mg of caffeine•kg⁻¹, in a form of an energy drink was effective to enhance the physical performance of elite junior tennis players by increasing handgrip force, high-intensity running and tending to increase the percentage of points won on service during a simulated tennis match. **Contact:** cgallo@ucjc.edu

DIETARY FISH OIL DELAYS HYPOXIC SKELETAL MUSCLE FATIGUE AND ENHANCES CAFFEINE STIMULATED CONTRACTILE RECOVERY IN THE RAT IN VIVO HINDLIMB

Peoples, G., McLennan, P.L.

University of Wollongong

Introduction Dietary fish oil, modulates long chain (LC) n-3 polyunsaturated fatty acid (PUFA) docosahexaenoic acid (DHA) composition of skeletal muscle membrane fatty acid (Peoples et al., 2010) and improves oxygen (O₂) efficiency thus enabling sustained contractile force (Peoples et al., 2014). During hypoxia O₂ efficiency is a key determinant of force production in mammalian skeletal muscle. Reduced calcium handling has been identified as key contributor to depressed contractile force (Allen et al., 2008) when fatigue is established. Therefore we examined the protective effects of a fish oil diet on skeletal muscle fatigue under the stress of hypoxia in the rat in vivo autologous perfused hindlimb. **Methods** Male Wistar rats were fed a diet rich in either: saturated fat (SF); n-6PUFA; or LCn-3PUFA DHA from fish oil (FO) for 8 weeks. In anaesthetised, mechanically ventilated rat (normoxia 21% O₂ and hypoxia 14% O₂) with the hindlimb perfused with arterial blood at a constant flow the gastrocnemius-plantaris-soleus (GPS) muscle bundle was stimulated via sciatic nerve (2Hz, 6-12V, 0.05ms, 30min) to established fatigue. In recovery caffeine (2.5, 5, 10mM) was supplied to the GPS muscle bundle via the arterial cannula to assess contractile force recovery. **Results** Hypoxia reduced PaO₂ to <70 mmHg ($P < 0.01$ v normoxia) and attenuated peak twitch tension (normoxia: 82 ± 8 ; hypoxia 41 ± 2 g/g tissue w.w.). However, under hypoxic stress, rats fed fish oil sustained higher maximum twitch tension compared to the SF and n-6 PUFA groups ($P < 0.05$) and completed more contractions before decline to 50% of maximum twitch tension (SF; 546 ± 58 , n-6PUFA; 522 ± 58 , FO; 792 ± 96 seconds; $P < 0.05$). In addition, dietary fish oil enhanced relative skeletal muscle contractile recovery in the GPS muscle bundle at 10mM caffeine concentration (SF; 41 ± 3 , n-6PUFA; 40 ± 4 , FO; $52 \pm 7\%$; $P < 0.05$). **Discussion** Following fish oil supplementation, incorporated DHA in skeletal muscle membranes contributes to improved muscle function under stressful conditions of hypoxia. Enhanced caffeine stimulated recovery strongly suggests that improved calcium handling is an underpinning mechanism. Improved calcium handling following dietary fish oil is also seen in heart where it is protective against ischemic arrhythmia (Pepe et al., 2002). Therefore, these results support the requirement of muscle DHA (from dietary fish consumption) for optimising skeletal muscle function. **References** Allen DG et al., (2008) *Physiol Rev* 88: 287-332. ENDURANCE TRAINING COMBINED WITH IGF-1 SUPPLEMENTATION ATTENUATE AGING-INDUCED APOPTOSIS IN RAT SKELETAL MUSCLE

Mosaferi Ziaaldini, M., Ferenc, T., Radak, Z.

Research institute of sport science

Introduction: Skeletal muscle atrophy contribute to Sarcopenia. Although the exact mechanisms underlying sarcopenia are far to be unveiled, accumulating preclinical evidence suggests that an age-related acceleration of myocytes loss via apoptosis might represent a key mechanism driving the onset and progression of muscle loss [1]. While some studies have reported the Deterrent effects of aerobic exercise training on the apoptosis [2], it has been also suggested an inhibitory role of IGF-1 on apoptosis in vitro via its signaling pathways [3]. Therefore the aim of this study was to Inquiry of 6 weeks exercise training combined with 2 weeks IGF-1 administration on the skeletal muscle apoptosis markers in aged rats. **Methods:** Fifteen young (three mo) and fifteen old (26 mo) male Wistar rats were grouped into young control (YC), young exercised (YE), young exercised and IGF-1 (YEI), old control (OC), old exercised (OC) and old exercised IGF-1 (OEI). The running speed and duration of the exercise were gradually increased, so that, by the last week of the six weeks training program, young animals ran at 22 m/min, on a 10% incline, for 60 min, whereas old animals ran at 13 m/min, and a 10% incline for 60 min. In the final two weeks IGF-1 treated animals received five microgram/kg/day. In order to detection of selected proteins and genes involved in apoptosis Western Blot was applied. Statistical significance were assessed by the SPSS 17 program. After normality control the parametric data were analyzed by one-way ANOVA, followed by Tukey's post hoc test. The significance level was set at $p < 0.05$. **Result:** IGF-1 plasma levels of OC group was significantly lower than YC ($p < 0.01$) while it was higher OEI ($p < 0.05$). Expression of p53, Bcl-2 and ratio of Bax/Bcl-2 as an apoptosis index in OC was significantly higher than YC ($p = 0.00$). Whereas exercise training resulted to a de-

crease in the expression of p53 and an increasing in Cytochrome C in OE versus OC But combination of exercise and IGF-1 supplementation led to a sound decrease in TNF-alpha, p53, Bax/Bcl-2 and an increase in Bcl-2 expression in OE in compare to OC ($p=0.00$, $p<0.05$, $p<0.05$ and $p=0.00$ respectively). Discussion: Based on the present results, it can be inferred that endurance exercise combined with IGF-1 treatment can provide a protective effect on aging-induced apoptosis through the enhancement of Bcl-2 and diminution of TNF-alpha and p53 expression in the rat skeletal muscle. Thus, regular aerobic exercise and IGF-1 Supplementation may be a useful strategy for preventing muscle wasting induced by Sarcopenia problems in the elderly. 1. Marzetti, E. and C. OP-BN12 Muscle Biomechanics

CAN INFRARED THERMOGRAPHY IMAGING BE USED TO ASSESS TEMPERATURE CHANGES INDUCED BY ACHILLES TENDON HYSTERESIS?

Peltonen, J., Toivonen, J., Cronin, N.J., Finni, T., Avela, J.

University of Jyväskylä

INTRODUCTION Hysteresis represents the proportion of elastic energy that is lost to heat during each stretching and shortening cycle of a muscle-tendon unit. Farris et al. (2011) reported 17 % Achilles tendon (AT) hysteresis and estimated that during 30-min running AT core temperatures may reach 41 degrees which could be sufficient for tendon hyperthermia and a potential cause of tendon injury. Thermography cameras detect radiation in the infrared range of the electromagnetic spectrum. Because infrared radiation is emitted by all objects above absolute zero, thermography makes it possible to see how object's temperature changes over time. Thus, the purpose of the current study was to measure relationship between AT hysteresis and AT skin temperature changes during voluntary contractions. **METHODS** 19 males volunteered for the study. Their AT hysteresis was calculated from AT force-length data, which was obtained during 15 voluntary contractions (80% of isometric maximal voluntary contraction) in an ankle dynamometer. AT length changes were measured using motion capture assisted ultrasonography and AT skin temperature changes were measured with infrared thermography imaging. **RESULTS** AT stored energy on average 13 ± 4 joules when it was stretched and returned 11 ± 4 joules when it was shortened. Thus the calculated mean AT hysteresis was 11 ± 10 %. AT skin temperature increase was $0.025^{\circ}\text{C} \pm 0.014^{\circ}\text{C}$ per voluntary contraction or $0.375^{\circ}\text{C} \pm 0.212^{\circ}\text{C}$ after the 15 repeated contractions. Measured AT skin temperature change per cycle correlated positively with hysteresis ($N = 19$, $r = 0.471$, $p = 0.042$). **DISCUSSION** The current data showed positive correlation between AT hysteresis and AT skin temperature change after low number of stretching and shortening cycles. Thus, it is possible that individuals with higher AT hysteresis may be more prone to tendon hyperthermia during physical activity than others. This requires further investigation as hyperthermia was not shown in the current study. The finding that infrared thermography was able to detect subtle changes in AT skin temperatures indicates that thermal cameras are potentially useful tool to investigate AT hysteresis and thermoregulation during physical activity. **REFERENCES** Farris DJ, Trewartha G, Polly McGuigan M. MECHANICAL INTERACTIONS BETWEEN SYNERGISTIC MUSCLES FOLLOWING ALTERATIONS IN MUSCLE CONNECTIVITY IN THE RAT

Bernabei, M.1, van Dieën, J.1,2, Maas, H.1

MOVE Research Institute Amsterdam

1:MOVE Research Institute Amsterdam, Faculty of Human Movement Sciences, VU University Amsterdam, The Netherlands. 2:King Abdulaziz University (Jeddah, Saudi Arabia) **Introduction** Epimuscular myofascial pathways may play an important role in pathological conditions of the musculoskeletal system [1]. Scar tissue formation in response to muscle and tendon injuries can alter muscular force transmission by changing intermuscular connectivity. A reduction of the range for muscle tissue displacement and a localized increase of tissue strain has been associated with the presence of scar tissue following hamstring injury in humans [2-3]. The aim of this study was to quantify the effects of changes in intermuscular connectivity on the mechanical interaction between rat ankle plantar flexors. **Methods** In 8 deeply anesthetized Wistar rats (300±20g), the connective tissue linkages between the dorsal side of the soleus (SO) and the ventral side of the lateral gastrocnemius and plantaris complex (LG+PL) were disrupted and either an adhesion barrier (n=4) or a tissue-integrating mesh (n=4) were implanted at the interface. Two weeks post-surgery, the proximal and distal LG+PL tendons and the distal SO tendon were severed and connected to different force transducers to measure isometric forces at physiological muscle lengths and relative positions. Changes in SO force and proximo-distal LG+PL force difference in response to lengthening LG+PL proximally were assessed. These two measures of intermuscular connectivity were compared to those of non-operated muscle compartments of a control group (n=9). **Results** A significant interaction effect ($p<0.05$) was found between group (increased/decreased connectivity and control) and LG+PL length. When the tissue-integrating mesh was implanted, changes in SO force and the proximal-distal LG+PL force difference were significantly higher (3.2 and 1.9 times, respectively) compared to the control group. However, implantation of the adhesion barrier did not result in changes of mechanical interaction between SO and LG+PL. **Discussion** Our results show that the force transmitted between synergistic muscles can be substantially altered by increasing their connectivity. Changes in mechanical interaction indicate that the manipulation applied resulted in a different stiffness of the intermuscular linkages. As similar responses following muscle-tendon injuries can be expected, this may explain localized increases in muscle strain and reduction of muscle-tissue displacement observed in humans. **References** 1. MEDIAL GASTROCNEMIUS MUSCLE GROWTH DURING ADOLESCENCE IS MEDIATED BY AN INCREASE OF FASCICLE DIAMETER RATHER THAN BY LONGITUDINAL FASCICLE GROWTH.

Weide, G., Huijling, P.A.1, Maas, J.C.2, Becher, J.G.2, Harlaar, J.1,2, Jaspers, R.T.1

1; FBW and MOVE, VU University, Amsterdam, NETHERLANDS, 2; VUMC and MOVE, VU University Medical Center, Amsterdam, NETHERLANDS

Introduction During the process of maturation, skeletal muscles need to adapt size and length-force characteristics to meet functional demands in daily life. Longitudinal growth of pennate muscles can be achieved by either an increase in fascicle length, an increase in fascicle diameter or by a contribution of both. Recent assessments of the pennate medial gastrocnemius muscle (GM) during childhood (5-12y) has yielded that growth occurs by uniform scaling: both fascicle diameter and length increases without changes in pennation angle (Bénard et al., 2011). However, it is not well known how morphological determinants of length-force characteristics change during adolescence. Based on the assumption that during human adolescence a notable increase in force generation capacity is needed, we hypothesized that longitudinal GM growth is predominantly mediated by an increase in fascicle diameter. **Methods** Sixteen healthy Caucasian adolescent males with age ranging from 10-19 years participated in this study. Geometry of the GM was measured within the mid-longitudinal plane derived from a 3D voxel-array composed of transversal ultrasound images tracked by an Optotrak system. Images were taken at standardized externally applied footplate moments while resulting footplate angles were recorded. Muscle activity, expressed as percentage of maximal voluntary contraction (%MVC) was recorded with surface electromyography (EMG). Maximal recorded muscle activity for all subjects averaged 1.2 ± 1.1 %MVC \pm SD ranging between 0.3 and 7.9%MVC. **Results** During adolescence, footplate angles corresponding to externally applied 0Nm and -4Nm (plantar-flexion) moments did not change with age. In contrast, footplate angles corresponding to externally applied dorsal-moments (at 4Nm and 6Nm) decreased with age (by 10° in the age range studied). Regression analysis showed that during adolescence GM muscle belly length increased by 0.5cm/year due to an increase in length component of cross-sectional area of 0.3cm/year. However, no increase in fascicle length was shown. Muscle aponeurosis length and pennation angle increased by 0.5cm/year and 0.5degree/year, respectively, to provide space for the fascicle diameter to increase. **Conclusion** In adolescents pennate GM, longitudinal muscle growth is mediated by an increase in fascicle diameter which evidently decreases the stimulus for longitudinal fascicle growth. EVALUATION OF HILL AND HUXLEY MUSCLE MODELS USING EXPERIMENTAL DATA OBTAINED FROM RAT M. SOLEUS IN SITU

Lemaire, K.K., Jaspers, R.T., Baan, G.C., van-Soest, A.J.

MOVE research institute Amsterdam

The relationship between mechanical behavior and metabolic cost in the widely used Hill muscle tendon complex (MTC) model is not straightforward, while this is an integral part of the Huxley model. In this study we assess to what extent Huxley and Hill type MTC models yield adequate predictions of mechanical muscle behavior during stretch-shortening cycles. In fully anesthetized male Wistar rats (N=3), Soleus muscle was dissected completely from its surroundings, except for the insertion. Cuff electrodes were placed over the n. Ischiadicus. The distal end of the Soleus tendon was connected to a servo motor via a force transducer. The setup allowed for full control over efferent muscle stimulation and muscle length, while muscle force was measured. First, quick release and isovelocity contractions were imposed on the muscle. Hereafter, the muscle was stimulated during quasi-sinusoidal stretch-shortening cycles (SSC). Simulations of SCC were made with both a Hill and a Huxley MTC model, using parameters values determined from the quick release and isovelocity contractions. A modification to the classic two state Huxley model was made to incorporate a tendon. As intended, the period of stimulation resulted in substantial force during shortening only. Experimental results were similar for all muscles investigated. For both models, the fitting procedure of the free parameters to de data of the first part resulted in $R^2 > .90$ for all relations considered. Peak force during the stretch-shortening cycle and maximum rate of force development obtained from experimental data and Hill and Huxley model simulation results were 0.76 (SD .03) N; 0.70 (.03) N; 0.72 (.06) N and 11.2 (.3) N/s; 10.2 (.3) N/s; 9.2 (.4) N/s, respectively. Time averaged squared difference between experimental data and model results were .062 (.004) N for the Hill and .051 (.005) N for the Huxley model. From observation of the force traces and the quantitative measures presented here, it was concluded that force buildup, peak force and the first part of relaxation were predicted accurately for both models in equal measure. However, the force during the second part of relaxation is predicted poorly by both the Hill and the Huxley MTC model, which is surprising, since deactivation was adequately modeled. This issue requires further investigation. Simulation results regarding mechanical behavior during SSC, obtained with the Huxley model, describe the force traces equally well as those obtained with the Hill model. Given the direct relation with metabolic energy expenditure in the Huxley model, this opens up new possibilities to study the relation between mechanical MTC behavior and the associated metabolic cost.

THE USE OF A MUSCULOTENDINOUS STRETCH-SHORTENING CYCLE: A COMPARISON BETWEEN YOUNG AND ELITE SPRINTERS DURING THE FIRST STEP OF THE ACCELERATION PHASE

Aeles, J.1, Jonkers, I.1, Debaere, S.3, Delecluse, C.2, Vanwanseele, B.1

KU Leuven

1KU Leuven Department of Kinesiology, Human Movement Biomechanics Research Group 2KU Leuven Department of Kinesiology, Physical Activity, Sports & Health Research Group 3BLOSO – Flemish Government Sports Administration Centre This study aimed to determine the differences between elite and young sprinters in the use of a stretch-shortening cycle (SSC) at the ankle, knee and hip joint by analysing muscle-tendon (MT) lengths during the first stance after block clearance (start acceleration phase). Sixteen elite athletes (8 male and 8 female) and twenty-six young athletes (16 male and 10 female) performed an explosive start action. Twelve MX3 cameras (250Hz) and two Kistler force plates (1000 Hz) were used to collect 3D marker and ground reaction forces (Nexus, Vicon). A musculoskeletal model (Hamner, Seth, & Delp; 2010) was scaled to each subject's individual anthropometry. An inverse kinematics procedure was conducted to obtain joint angles and individual MT lengths of ankle plantar flexors, knee extensors, glutei and hamstring muscles were computed. These results were normalised by subtracting MT lengths during the static pose (I0). For each muscle, stance phase was divided into a MT lengthening and a shortening phase. MT length change, the time interval (Δt) and the rate of deformation ($(l_{max}-l_{min})/\Delta t$) were calculated per phase. The use of a stretch-shortening cycle during stance was seen in the gastrocnemius, soleus and rectus femoris muscle. MT shortening was higher in the elite group compared to the youth athletes in both gastrocnemius' heads ($33.2 \text{ mm} \pm 4.5$ (med); $34.0 \text{ mm} \pm$

4.5 (lat) vs. 26.7 mm \pm 7.6; 27.3 mm \pm 7.7 respectively) and the soleus muscle (45.4 mm \pm 5.1 vs. 37.9 mm \pm 7.7 respectively). Shortening rate was 23.2% larger in the elite group for the soleus muscle. During MT elongation in the rectus femoris, Δt was less in the elite group (85 ms \pm 24 vs. 105 ms \pm 32) while MT shortening was larger in the elite group (19.2 mm \pm 3.8) compared to the youth athletes (14.9 mm \pm 6.7). These results give strong evidence that the presence of SSC mechanisms during the first stance in the acceleration phase is dependent on individual muscles. In a future project we will look at the contribution of the tendon to joint power and performance in sprinters. Arampatzis, A., Karamanidis, K., Morey-Klapsing, G., De Monte, G., & Stafilidis, S. ASSOCIATIONS OF DIFFERENT TYPES OF SITTING WITH CARDIOMETABOLIC RISK FACTORS

Borodulin, K., Jousilahti, P., Männistö, S.

National Institute for Health and Welfare

Objectives To study the associations of five types of sitting and total amount of sitting with cardiometabolic risk factors in a large representative sample. **Methods** The sample comprised 2561 men and 2822 women, aged 25–74 years, who participated in the National FINRISK 2012 Health Study including a health examination and questionnaires. Sitting was self-reported in daily hours and minutes (min/d): during work day in the office or similar, at home watching TV, at home in front of computer, in a vehicle, and elsewhere. Total sitting was a sum of these five types. Cardiometabolic risk factors were body mass index (BMI), waist circumference (WC), serum total cholesterol (T-CHOL) and HDL cholesterol (HDL-C), glycated hemoglobin (HbA1c) and systolic and diastolic blood pressure (BP). Linear regression analysis, adjusted for age, region, education, smoking status, leisure time physical activity, perceived health status, and BMI (except BMI/WC models) was used. All types of sitting were included in the same model and total sitting in a separate model. **Results** Men and women (respectively) reported sitting 142/155 min/d at office, 136/129 min/d for TV viewing, 62/49 min/d for computer, 58/31 min/d in vehicle, 28/28 min/d elsewhere, totaling to 425/391 min/d. In multivariate models, TV viewing associated with WC in both genders, with BMI and T-CHOL in women, and with HDL-C in men. Computer time associated with BMI, WC and T-CHOL in women. Vehicle time associated with WC and BMI in both genders, and with T-CHOL and diastolic BP in women. Office time associated with HDL-C and HbA1c in men and with diastolic BP in women. Sitting elsewhere associated inversely with BMI in women and with HDL-C in men and women. **Conclusions** Based on the large population-based data, TV viewing and sitting in a vehicle appeared the most detrimental to cardiometabolic health, while other types of sitting and total sitting showed less systematic associations. Cardiometabolic health outcomes may vary by type of sitting, gender, and socioeconomic position. The etiology of sitting on health requires more research to be understood in detail. EARLY SPORT PRACTICE AND THE PREVENTION OF ARTERIOSCLEROSIS IN ADULTHOOD

Fernandes, R.I., Lima, M.2

1: Sao Paulo State University (Presidente Prudente, Brazil), 2: Sao Paulo State University (Rio Claro, Brazil) (FAPESP, 2012/18001-0)

Introduction In adults, higher physical activity level has been associated with lower carotid intima-media thickness (CIMT). However, it is documented that early sport practice (its maintenance during childhood and adolescence) seems to prevent cardiovascular and metabolic outcomes at adulthood. The purpose of this study was to analyze if the possible relationship between early sport practice and CIMT is independently of the current physical activity level among adults. **Methods** The sample was composed of 122 adults of both sexes (69 men and 53 women) and age ranging from 30 to 50 years-old. Current physical activity level was assessed through the use of pedometer (Digi-Walker Yamax, SW200). Early sport practice was assessed through two questions related to organized sport practice outside school during childhood (7–10 years-old) and adolescence (11–17 years-old) (Fernandes and Zanesco, 2010). To measure the CIMT (in mm) was used a Doppler ultrasound device (Toshiba Xario, SSA-660A). Body fatness was estimated by a Dual-Energy X-ray Absorptiometry scanner (Lunar DPX-NT; General Electric Healthcare). **Results** CIMT was negatively related to early sport practice ($\rho = -0.18$; p -value = 0.047), but it was not to current physical activity ($\rho = -0.11$; p -value = 0.202). Body fatness was negatively related to both early and current physical activity ($\rho = -0.63$ and $\rho = -0.43$, respectively [both p -value = 0.001]). Linear regression identified that early sport practice was related to CIMT independently of current physical activity and body fatness ($\beta = -0.10$ mm [95%CI = -0.18; -0.02]). **Discussion** Although obesity plays central role in the development of atherosclerosis due its pro-inflammatory action (Van Gaal et al. 2006), our findings identify that early sport practice prevents atherosclerosis, independently of obesity status. Apparently this protective effect could be attributed to the anti-inflammatory effect of the physical exercise, which can counteract the inflammatory action, independently of body composition modifications (Teixeira-Lemos et al. 2011). However, it is noteworthy that early sport practice affected CIMT independently of current physical activity, this relationship could be supported by the epigenetic. For example, since early age people with polymorphisms related to hypertension are more exposed to the development of the disease only when they have lower physical activity level (Xi et al. 2012). **References** Fernandes R, Zanesco A. COMPARISON BETWEEN REAL AND ESTIMATED CARBOHYDRATE SUPPLEMENTS IN TYPE 1 DIABETIC PATIENTS DURING 1-H RUNS

Buoite Stella, A.1, Manca, E.2, Francescato, M.P.1

1: University of Udine, 2: Sweet Team FVG (Trieste)

Introduction Physical activity helps maintaining a better metabolic control and enhances self-esteem in patients with type 1 diabetes (T1DM). Voluntary exercise is, however, limited by the risk of exercise-induced hypoglycemia (i.e. <3.9 mmol/L; Dubé et al., 2006), which is usually minimized by the ingestion of a carbohydrates supplement (CHO-s), even after reduction of the insulin dose (Grimm, 2004). The recently proposed ECRES algorithm (Francescato et al., 2011) estimates, on a patient and situation specific basis, the CHO-s required to keep a safe glycemia. The real CHO-s during the Telethon 2013 24x1 hour Marathon run were compared with the CHO-s estimated by ECRES. **Methods** Nineteen T1DM patients were studied (8F; 9 with insulin pump; 36 ± 10 yrs, 68 ± 11 kg, HbA1c $7.5 \pm 0.9\%$), with continuous medical assistance during the event. Patient's usual therapy and any specific adjustment, glycemia before, at the middle, and at the end, and heart rate during the run were recorded. ECRES algorithm was adjusted on patient's specific data and the estimated amounts of CHO-s were compared to the real ones. **Results** Patients run on average 10.4 ± 2.8 km, showing an average heart rate of 157 ± 21 bpm. Glycemia at the start ranged from 4.5 to 20.6 mmol/L (average 10.5 ± 4.3 mmol/L); in 8/19 cases glycemia was > 10 mmol/L. Glycemia decreased significantly ($p < 0.01$) to 7.4 ± 3.1 mmol/L at the end of the runs. At the middle of the run, 3 patients showed a moderate hypoglycemia (> 3.3 mmol/L) quickly compensated consuming a few sugar drops, and 1 patient showed a glycemia of 2 mmol/L that was difficult to be fully compensated by the end of the run. In 3 patients glycemia increased by the end of the run. Average consumed CHO-s amounted to 42 ± 42 g. The CHO-s estimated by the ECRES algorithm were significantly related to the actual values ($R = 0.65$, $n = 19$, $p < 0.005$) and would allow 63% of patients to conclude their 1-h run with glycemia in the optimal range. **Discussion** Results show that patients frequently prefer minimizing the risk of exercise-induced hypoglycemia with a very high glycemia at the start of the activity. The ECRES algorithm would have suggested appropriate amounts in a high percentage of cases also for the challenging physical activity constituted by the 24x1-h Marathon. This suggests that the ECRES algorithm can indeed become a useful tool for T1DM patients to help them keeping more constant glycemic levels on each exercise occasion. **References** Dubé MC, Valois P, et al. STRENGTH TRAINING WITH INSTABILITY IS MORE EFFECTIVE THAN CONVENTIONAL STRENGTH TRAINING FOR PATIENTS WITH PARKINSON'S DISEASE.

Silva Batista, C.1, Tricoli, V.1, Roschel, H.1, Mattos, E.1, Mello, M.T.2, Piemonte, M.E.P.3, Ugrinowitsch, C.1

1: EEF- USP (São Paulo, Brazil), 2: CEPE-UNIFESP (São Paulo, Brazil), 3: FM-USP (São Paulo, Brazil).

Introduction: Parkinson's disease (PD) is characterized mainly by motor dysfunction. This motor dysfunction affects functionality and it is produced by changes in neuromuscular parameters. Conventional strength training (ST) is a usual strategy to counteract the decline in neuromuscular parameters. However, the addition of instability to ST (IST) may enhance not only neuromuscular gains but also improve motor control and the functionality, thus alleviating the PD-related effects. Therefore, the aim of this study was to compare the effects of ST and IST in some neuromuscular and functional variables of patients with PD (pPD). **Methods:** Thirty pPD (67.2 ± 8.3 years, 8.9 ± 0.5 disease duration, and 19.5 ± 5.7 motor severity) in stages 2 and 3 of the disease (tested and trained in the clinically "on" state) were divided equally into three groups: control group (CG), ST group (STG), and IST group (ISTG). Experimental groups underwent 12 weeks of ST and IST. STG performed strength-hypertrophy training twice week, ISTG performed strength-hypertrophy training with instability devices (i.e., bosu, dyna disk, balance disk, Swiss ball) twice week. Presynaptic inhibition (PI) and disinhibitory reciprocal inhibition (DRI) of the soleus muscle of the leg most affected, leg press one repetition maximum (1RM), quadriceps cross sectional area (CSA) of the leg most affected, timed up and go (TUG) and balance evaluation systems test (BEST) were obtained and compared before and after the training period. **Significance level** was set at $p \leq 0.05$. **Results:** PI, DRI, 1RM and CSA were significantly increased after ST ($9.9 \pm 18.8\%$ - $26.1 \pm 16.5\%$, $6.2 \pm 7.4\%$ - $17.0 \pm 7.5\%$, 96.5 ± 22.2 kg - 120.9 ± 24.4 kg and 5618.4 ± 599.9 mm² - 6184.1 ± 614.2 mm², $p < 0.05$ respectively) and IST ($9.6 \pm 23.8\%$ - $55.6 \pm 24.3\%$, $6.1 \pm 6.7\%$ - $37.1 \pm 12.7\%$, 93.8 ± 27.2 kg - 118.6 ± 28.4 kg and 5456.5 ± 606.4 mm² - 5641.4 ± 634.4 mm², $p \leq 0.05$ respectively). The values posttest of the PI and DRI were significantly greater in the STG than in the ISTG ($p < 0.05$). TUG and BEST were significantly improved only after IST (10.0 ± 2.4 s - 8.0 ± 1.4 s and 79.4 ± 8.9 score - 92.7 ± 10.0 score, $p < 0.05$). **Discussion:** ST and IST are effective to cause force-production capacity (i.e., strength and muscle mass) adaptations of pPD. However, IST seems to be more effective than ST to improve spinal inhibitory mechanism and functionality of pPD. Thus, IST's results may be very important for this population, once changes in the motor control and functionality are apparently indicative of an abnormal supraspinal influence on spinal mechanisms due to disease. **Financial support:** FAPESP: 2013/04970-4. KINESIOPHOBIA AND PHYSICAL ACTIVITY AFTER SPINAL FUSION SURGERY AND POSTOPERATIVE EXERCISE INTERVENTION

Ilves, O.1, Hakkinen, A.1,2, Dekker, J.3, Wahlman, M.4, Tarnanen, S.1, Marttinen, I.4, Pekkanen, L.2, Ylinen, J.2, Kautiainen, H.5, Neva, M.4

1: JYU (Jyväskylä Finland), 2: KSSHP (Jyväskylä Finland), 3: VUMC (Amsterdam, Netherlands), 4: TAYS (Tampere, Finland)

Introduction High degree of kinesiophobia has been reported after spinal surgery. Kinesiophobia is associated with intensive pain, disability and lower physical activity. Aim of this research was to study kinesiophobia and physical activity before, and three months after lumbar spinal fusion surgery (LSF) and to evaluate the effectiveness of 12 months postoperative exercise intervention in these outcomes. **Methods** Altogether, 98 patients who underwent LSF, attended to the study (mean age 59 y, 73% females). After the surgery all patients received similar postoperative exercise instructions. Three months after LSF, patients were randomized to the exercise group (EG) ($n = 48$) and control group (CG) ($n = 50$). EG started progressive back specific exercise program and was encouraged to increase their physical activity. Fear of movement was individually worked out by physiotherapist in the booster sessions every second month. CG was given only the oral and written instructions of exercises in one session by physiotherapist. Outcome measures were 17-item Tampa Scale for Kinesiophobia (TSK) and short form of the International Physical Activity Questionnaire (IPAQ, total MET-min/week). **Results** Preoperative mean (SD) TSK was 38.8 (7.6) points and it decreased by 7.2 (6.8) points ($p = 0.001$, ES 1.02) in the whole sample 3 months after LSF. During the 12 months intervention, TSK of EG improved by 1.6 points (ES 0.23), while in CG increase of 0.2 points (ES -0.02) was not significant (ns. between groups). In the whole sample, preoperative median IPAQ was 1709 METs and 3 months after the surgery it was 2079 METs (ns.).

During the exercise intervention median (IQR) IPAQ increased from 1863 (1040 , 3042) to 3190 (1150 , 6384) METs in EG and from 2569 (1501 , 4075) to 3590 (1634 , 6485) METs in CG ($p < 0.01$ in both groups, ns. between groups). Conclusions Although exercise group had some improvement in fear of movement during the intervention, the main outcome measure showed equal improvement in kinesiophobia and physical activity in LSF patients randomized to progressive exercise program and usual care program. Study is funded by Academy of Finland, and by Medical Research Funds of Central Finland Central Hospital and Tampere University Hospital. Contact ou-ti.ilves@jyu.fi

OP-PM44 Central & Peripheral Fatigue

EFFECT OF A NORADRENALINE REUPTAKE INHIBITOR ON CENTRAL AND PERIPHERAL FATIGUE DURING INTERMITTENT SUBMAXIMAL CONTRACTIONS PERFORMED TILL EXHAUSTION

Klass, M.1, Roelands, B.2, Rabec, S.1, Meeusen, R.2, Duchateau, J.1

Université Libre de Bruxelles

1 : Université Libre de Bruxelles (Brussels, Belgium), 2 : Vrije Universiteit Brussel (Brussels, Belgium) Introduction Reboxetine (Rebox), a noradrenaline reuptake inhibitor has been shown to alter the cycling performance during time trials (TT) in well-trained subjects (1, 2). This was associated with a greater decrease in average power output during the TT and maximal voluntary contraction (MVC) torque tended to be lower after the completion of the TT. The effect of Rebox appeared to be mainly supraspinal (1). However, to our knowledge, no study has reported the impact of Rebox during fatiguing contractions of a single muscle group performed till exhaustion. Therefore, the aim of the present study was to investigate the difference in endurance time, MVC torque and central and peripheral fatigue during intermittent isometric contractions performed in Rebox and placebo (Pla) conditions. Methods The fatiguing task consisted in submaximal intermittent contractions of the knee extensors repeated till task failure (inability to attain target torque). Changes in endurance time and MVC torque decrease were randomly tested after oral administration of Pla or Rebox in 6 moderately active male subjects. Changes in voluntary activation and muscle contractile properties were tested in the knee extensors using transcranial magnetic stimulation and motor nerve electrical stimulation before and at the end of the exercise (1). Core temperature (Core T) and heart rate (HR) were also measured. Results Based on the results of 6 subjects already tested, endurance time was slightly but not significantly shorter for Rebox (30.9 ± 10.6 min) compared with Pla condition (33.8 ± 10.0 min; $P > 0.05$). The MVC torque declined similarly at the end of the task in both conditions (~35%). At task failure, voluntary activation was similarly ($P > 0.05$) reduced in both conditions when tested by ES (17 and 15% under Rebox and Pla, respectively) and TMS (16 and 10% under Rebox and Pla, respectively). The peak torque and contraction time of the twitch recorded at rest were also reduced to a similar extent (~40 and 13%, respectively) in both conditions. As compared to Pla, Tcore was similar and HR was greater under Rebox at task failure ($P < 0.05$). Discussion In contrast to the cycling TT performance (1, 2), these preliminary data do not show a significant effect of Rebox either on endurance time or on MVC torque decrease after submaximal intermittent contractions performed till exhaustion. A difference in HR was, however, present. Our results suggest that the effect of Rebox appears to depend on the modalities of the fatiguing task. References 1. Klass et al. CHILDREN EXPERIENCE MORE CENTRAL AND LESS PERIPHERAL FATIGUE THAN ADULTS DURING REPEATED MAXIMAL CONTRACTIONS

Ratel, S., Kluka, V., Garcia Vicencio, S., Jegu, A.G., Cardenoux, C., Morio, C., Coudeyre, E., Martin, V.

University of Blaise Pascal

Introduction Although it is well acknowledged that prepubertal children are less fatigable than their adult counterparts when performing repeated maximal isometric or isokinetic contractions (Ratel et al. 2006), the exact causative factors have not been fully elucidated. More specifically, it is still unclear whether the respective contributions of central and peripheral factors to the development of exercise-induced fatigue change throughout growth. Therefore, the aim of the present study was to investigate the respective contributions of central and peripheral mechanisms of neuromuscular fatigue induced by maximal contractions in children and adults. Methods Fifteen healthy boys (10.1 ± 1.4 y) and thirteen male adults (24.1 ± 3.4 y) completed a fatigue protocol consisting in a series of isometric 5-s maximal voluntary contractions (MVC) of the knee extensors interspersed with 5-s passive recovery periods until the generated torque reached 60% of its initial value. Single magnetic stimulations were delivered to the femoral nerve every five MVCs to calculate the maximal level of voluntary activation (VA) by means of the twitch interpolation technique. The amplitudes of the potentiated twitch (Pt) and concomitant vastus lateralis (VL) and rectus femoris (RF) maximal compound action potentials (Mmax) were also used as indicators of peripheral fatigue. Results Torque reached 60% of its initial value after 53.9 ± 17.2 and 34.1 ± 18.8 repetitions in boys and men, respectively, and this difference was statistically significant ($P < 0.01$). Furthermore, men showed a significantly higher decline of MVC torque than boys between 70 and 90% of total repetitions ($P < 0.05$). Interestingly, VA remained unchanged in men whereas it decreased significantly in boys over the second half of the fatigue protocol ($P < 0.05$). In contrast, men displayed a significantly higher Pt decrement compared to boys ($P < 0.001$). However, no significant change of Mmax was observed on VL and RF muscles in boys and men. Discussion The results of the present study reveal that children experience greater central fatigue than adults during repeated maximal contractions. In contrast, the extent of peripheral fatigue, as indicated by the decline of peak twitch torque, is clearly lower in children. On that basis, it could be suggested that children experience more central fatigue than adults in order to prevent the development of extensive peripheral fatigue, and the potential resulting biological harm. Further studies are however required to confirm or infirm this assumption. References Ratel S, Duché P, Williams CA. (2006). Sports Med, 36, 1031-1065.

CAFFEINE EXTENDS CAPACITY FOR REPEATED HIGH INTENSITY KNEE EXTENSOR EXERCISE WITH INCREASED PERIPHERAL EXCITABILITY AND VOLUNTARY DRIVE TO THE KNEE EXTENSORS

Bowtell, J.1, Mohr, M.1, Jackman, S.R.1, Fulford, J.1, Ermidis, G.2, Krstrup, P.1,3, Mileva, K.N.4

1Exeter University, 2Democritus University of Thrace (Greece); 3University of Copenhagen (Denmark); 4London South Bank University (UK).

Introduction We investigated whether caffeine supplementation improved repeated high intensity knee extensor exercise performance via changes in peripheral and corticospinal excitatory output and voluntary activation. **Methods** On 4 occasions each separated by 2 weeks, 9 healthy active young men performed 5 bouts of intense leg kicking exercise to failure with 5 min rest intervals, 1h after consuming either a placebo (P) or caffeine (C, 6mg/kg) pill. On two occasions (P and C trials) quadriceps 31P-MRS scans were performed to quantify pH pre, during and post exercise. On the two other occasions (P and C trials), electrical stimulation of the femoral nerve and transcranial magnetic stimulation of the quadriceps cortical motor area were applied during knee extension maximum voluntary contractions (MVC) pre and post leg kicking exercise to quantify voluntary activation (VA) and peripheral (M-wave) and cortical (MEP) evoked responses in m. vastus medialis (VM) as well as contractility (relaxation rate, RR, and time to peak twitch, CT). **Results** Time taken to reach task failure was 29.0 ± 5.5 % longer in the caffeine trial ($p < 0.001$), and MVC declined to a similar extent in both trials (-13.7 ± 3.0 %, P vs -14.4 ± 5.2 %, C). The resulting decline in intramuscular pH was greater (-0.047 ± 0.103 , P vs -0.144 ± 0.114 , C; $p = 0.028$) in the caffeine trial. The fall in VM M-wave peak-to-peak amplitude during MVC that occurred post-exercise in the placebo trial (-22.2 ± 9.8 %) was reversed in the caffeine trial (13.6 ± 54.7 %, $p = 0.039$). Normalised MEP amplitude during MVC increased after fatiguing knee extensor exercise during placebo (17.0 ± 12.8 %) but declined in the caffeine trial (-20.1 ± 8.4 %, $p = 0.002$), such that MEP amplitude was similar after fatiguing exercise (0.42 ± 0.04 , P vs 0.41 ± 0.04 , C). Voluntary activation of the maximally contracting knee extensors evaluated with peripheral nerve stimulation was significantly enhanced by caffeine supplementation (89.2 ± 6.5 vs 84.2 ± 9.4 %, $p = 0.007$). In addition, RR was enhanced by caffeine supplementation (-11.8 ± 1.2 vs -13.7 ± 0.9 1/s, $p = 0.003$), and caffeine reduced the time to peak twitch (29.6 ± 10.3 , P vs 24.2 ± 7.7 , C; all ms; $p = 0.011$). **Discussion** Capacity for repeated high intensity knee extensor exercise was enhanced by caffeine supplementation despite the greater decline in intramuscular pH. This was achieved through increased peripheral contractility and excitability as well as increased neural drive to the knee extensors.

WIDE-PULSE, HIGH-FREQUENCY NEUROMUSCULAR ELECTRICAL STIMULATION INDUCES LOWER METABOLIC DEMAND THAN CONVENTIONALLY USED PARAMETERS

Gondin, J.1, Foure, A.1, Maffiuletti, N.A.2, Vilmen, C.1, Mattei, J.P.1, Place, N.3, Bendahan, D.1, Wegrzyk, J.1

1 Aix Marseille Université; 2 Schulthess Clinic; 3 UNIL

Introduction Conventional (CONV) neuromuscular electrical stimulation (NMES) is delivered using narrow stimulus pulses (50-400 μ s) and low frequencies (15-40 Hz). Using these current characteristics, motor axons are directly stimulated while slow and fast motor units are recruited in a random order (1). Contrary to voluntary (VOL) contractions, the size principle is violated by CONV NMES, which leads to an exaggerated metabolic demand and consequently to a rapid onset of muscle fatigue (2). NMES combining wide pulses (WP, 1 ms) and high frequencies (100 Hz) is supposed to recruit, at least in part, motor units according to the size principle (3). We therefore hypothesized that, similar to VOL, WP-NMES would result in a lower metabolic demand than CONV-NMES, as assessed by magnetic resonance spectroscopy (MRS). **Methods** 16 healthy subjects (24 ± 2 yrs) completed VOL, WP- and CONV-NMES contractions inside a 1.5T MR scanner. For all conditions, 20 isometric plantar flexions were completed at 10% of the maximal voluntary force with an on-off ratio of 20s. WP and CONV-NMES were delivered through surface electrodes placed on the triceps surae muscle, at 100 Hz (1 ms pulse duration) and 25 Hz (0.05 ms), respectively. For VOL, a visual feedback allowed to maintain the required force level. Force production was constantly recorded and force time integral (FTI) quantified for each protocol. Metabolic changes were recorded at rest and exercise using 31P-MRS. Phosphocreatine (PCr) depletion and intracellular pH were quantified using an in-house processing software (4). **Results** FTI was not significantly different between the three protocols (CONV: 1697 ± 422 Ns, VOL: 1834 ± 500 Ns, WP: 2374 ± 2324 Ns). On the other side, end-of-exercise PCr depletion was significantly larger for CONV (21 ± 8 %) as compared to WP-NMES (13 ± 7 %) and VOL (9 ± 3 %). No significant difference was found between VOL and WP-NMES. End-of-exercise intracellular pH values were similar for the three exercises. **Discussion:** Our results show that CONV-NMES leads to a higher metabolic demand than both WP-NMES and VOL, whereas WP-NMES and VOL result in similar metabolic variations thereby supporting the hypothesis that motor units are recruited similarly between the two exercise modes. Energetically less demanding protocols like WP-NMES might be of particular interest when applied to hypoactive patients who are typically highly vulnerable to fatigue. **References:** 1) Bickel et al. MUSCLE FATIGUE INDUCED BY REPEATED SQUAT JUMPS REALIZED WITH OR WITHOUT NEUROMUSCULAR ELECTRICAL STIMULATION

Place, N., Samararatne, J., Malatesta, D.

University of Lausanne

Introduction Neuromuscular electrical stimulation (NMES) has been shown to be an effective training stimulus to enhance muscle force, although concomitant improvement in sporting abilities (sprint, jump) is not always found (1). Recently, a wireless stimulator has been developed, which facilitates the use of NMES during dynamic exercise. The present study was designed to test the hypothesis that the superimposition of NMES to repeated squat jumps (SJ) would induce a higher level of muscle fatigue in comparison to the same task performed without NMES. **Methods** Nine healthy men (24 ± 2 yrs) volunteered to participate to two experimental sessions (NMES-S vs. nonNMES-S, respectively with and without NMES) presented in a counterbalanced order and separated by 11 ± 3 days. Participants were asked to perform a fatiguing exercise consisting of 50 SJ (5 sets of 10 SJ with 6s recovery between each SJ and 18s recovery between each set) realized on a force plate. NMES (frequency: 104 Hz, pulse duration: 300 μ s, maximal tolerable intensity) of the quadriceps muscle was superimposed to each SJ during NMES-S only. Neuromuscular fatigue of the dominant quadriceps was evaluated before and immediately after exercise. The main outcomes were SJ height, maximal voluntary contraction (MVC) force, voluntary activation (twitch interpolation), M-wave amplitude and 100Hz doublet peak force (PS100). **Results** SJ height was on average 16.3 ± 2.1 % lower ($p < 0.05$) for NMES-S; in addition, a significant decrease in SJ height (-5.9 ± 4.2 %, $p < 0.05$) was found for the last set of NMES-S only. MVC force was more reduced for NMES-S in comparison to nonNMES-S (-24.8 ± 12.1 % vs. -11 ± 11.2 %). Voluntary activation was not affected in either condition. M-wave amplitude was decreased (~ 20 %, $p < 0.05$) for vastii muscles after NMES-S only. The reduction in PS100 was larger ($p < 0.05$)

for NMES-S ($-25.4 \pm 12.7\%$) than for nonNMES-S ($-13.6 \pm 11.3\%$). The decrease in PS100 was significantly correlated to the reduction in MVC force for both sessions (NMES-S: $r=0.75$, $p<0.05$; nonNMES-S: $r=0.88$, $p<0.05$). Discussion The extent of muscle fatigue (MVC force loss) was ~2 fold higher for NMES-S. Muscle fatigue was of peripheral origin for both sessions, and the higher decrease in PS100 for NMES-S can be explained by altered muscle excitability, as shown by M-wave amplitude alteration. The decrease in SJ height in NMES-S suggests altered coordination in comparison to non-NMES-S, probably caused by the synchronous, non-selective stimulation of superficial muscle heads of quadriceps muscle with NMES. In conclusion, NMES superimposed to repeated jumps is effective to further fatigue the quadriceps muscle, which can be valuable for training purposes. (1) Gondin J et al. INFLUENCE OF CAFFEINE CONSUMPTION ON STEADY STATE CONTRACTIONS AND MOTOR UNIT ACTIVITY

Jakobi, J.M., Brown, R.E., Harwood, B.H., Lizu, A.

University of British Columbia

Caffeine (1,3,7-trimethylxanthine) is the most widely consumed stimulant drug in the world due to its purported ergogenic effects. At the cellular level caffeine inhibits phosphodiesterase which increases the level of CAMP and in-turn Ca^{2+} which should effect the excitability of the cell. The objective of this study was to determine whether orally ingested caffeine influences force steadiness (FS) and motor unit activity. Seven young healthy men (25 ± 4 years) participated in a double-blind, repeated-measures experimental design. Each participant refrained from consuming caffeine 48 hours prior to experimentation. Experimental trials of Maximal Voluntary Contraction (MVC) and force steadiness were performed before and after oral ingestion of caffeine (6mg/kg) and placebo (flour). The submaximal isometric elbow flexion force steadiness tasks consisted of a 5-second ramp, 7.5-second steady state and a 5-second decline. Force was produced in the neutral wrist position and steadiness was expressed as the coefficient of variation of force (CV) for target forces of 5%, 10% and 25% MVC. Surface EMG and single motor units were recorded from the short head (SH) and long head (LH) of the biceps brachii (BB) of the left, non-dominant arm. Elbow flexion MVC was (269 ± 42 N) and did not differ between the caffeine and placebo condition prior to and following supplementation. There was a significant interaction of condition (caffeine, placebo) \times time (pre, post) \times force level (5, 10, 25) ($p=0.008$) for the CV of steadiness. Force steadiness was less following caffeine consumption at 5% but irrespective of condition became better as the submaximal force level increased. There were ~61 and 59 motor unit spike trains analysed prior to and following caffeine consumption, while there were ~41 and 44 in the placebo condition. As the submaximal target force increased (5%, 10%, 25% MVC) motor unit discharge rates increased (12.0 ± 1.9 ; 13.4 ± 2.2 ; 16.5 ± 2.8). Caffeine did not influence the average steady state motor unit discharge rates. Following caffeine consumption at 5% and 25% there was a decrease in the CV of motor unit discharge rate variability by approximately 4%. Albeit preliminary in analysis, caffeine consumption reduces the ability to maintain submaximal steady contractions, and this is in-part due to the initial discharge activity of motor units. However, it seems that as the duration of the submaximal task increases the effect of caffeine on force steadiness and motor unit activity is lessened.

OP-BN13 Motor Learning

EFFECTS OF DISTRIBUTED DIFFERENTIAL LEARNING ON SKILL ACQUISITION IN NOVICES

Beckmann, H., Schöllhorn, W.I.

Johannes Gutenberg-University Mainz

Introduction The differential learning (DL) approach (Schöllhorn, 2000) uses self induced stochastic variations in order to initiate a self organized learning process. In motor learning these variations cover changes in geometry, velocity, acceleration, and rhythm at each joint as well as changes in environmental circumstances. Previous studies (e.g. Wagner et al., 2008) showed benefits for this approach in learning and optimizing motor skills. Beside supporting the individual strength of a learner the increase of fluctuations around the to-be-learned movement in DL intends to cope with a constantly changing (living) system in order to improve situation specific behavior (Schöllhorn et al., 2009). The aim of this study was to look for the influence of the variance which is caused by interceptions of different length between the intervention sessions on the learning process. Methods The hockey dribbling performance of 23 novices (physical education students, mean age: 25.5 years, sd: 4.6) was assessed by a slalom sprint and dribble test in a 15 m slalom parcour (modified from Lemmink et al., 2004). After the pretest participants were separated into three groups. Each group performed five practice sessions according to the DL approach with the same variations of the indian dribbling. Only the duration of the interception (24 h, 48 h, and 72 h) between the practice sessions was different for each group. After the third practice session all participants completed an intermediate test and at the end of the last session the posttest. One week after the posttest all participants returned for a retention test. Results The results of the ANOVA show significant ($p < .05$) group and time effects. Post-hoc analysis reveals significant benefit in the posttest for medium and longer interception groups (48 h, $p=.01$; 72 h, $p=.04$) in comparison to the short interception group (24 h). The results of the retention test provide significant differences only between the group with a 48 h interception and the shorter (24 h) as well as to the longer (72 h) one (in each case $p=.01$). Discussion It seems that the learning process can not only be optimized by movement and environmental variations in DL (see Schöllhorn et al., 2006). In fact, also the interception between practice sessions according to DL is an additional parameter to customize motor learning schedules to the changes of the learning system. References Lemmink, K. DIFFERENCES IN VISUAL SEARCH BEHAVIOUR BETWEEN NATIONAL AND DEVELOPMENTAL SKI-CROSS RACERS

Panchuk, D.

Victoria University

Introduction There is surprisingly little known about the relationship between gaze and steering in competitive environments. In complex steering tasks, like those found in ski-cross, an individual needs to account for their current position as well as other individuals (Wilkie et al., 2010). This additional complexity requires the ability to develop adaptive gaze control strategies to sample the direction of travel and other individuals in the environment. **Methods** Eight ski-cross racers (5 National Team, 3 Developmental) had their visual search behaviour recorded while viewing footage from 6 training runs using a mobile eye tracking device (ASL Mobile Eye). Footage was recorded from the skier's perspective using a head-mounted camera (GoPro Hero3+) and included 5 different tracks (one track was repeated with and without a competitor) with each clip containing: a start section, 2-4 jumps, and 3-4 turns. Data was coded using observational coding methods and search rate (fixations/s), fixation duration (ms), and relative viewing time (% of time spent viewing environmental features as a function of total trial time) were compared between National team and Developmental skiers. **Results** There were differences in search rate (2.05 ± 0.35 fix/s vs. 2.28 ± 0.31 fix/s) and fixation duration (376.0 ± 91.9 ms vs. 347.8 ± 49.2 ms) between the National team and Developmental skiers. National team skiers also spent a greater proportion of time viewing the competitor ahead of them ($13.3 \pm 9.4\%$ vs. $11.5 \pm 8.4\%$). While Developmental athletes spent a greater proportion of time viewing the inside of the turn ($2.7 \pm 2.6\%$ vs. $0.6 \pm 1.1\%$) and the track immediately in front of them ($26.4 \pm 8.7\%$ vs. $24.5 \pm 13.6\%$). **Discussion** Like other complex sporting environments (Roca et al., 2011), these findings highlight differences in visual search behaviour as a function of expertise. There were also differences in the relative importance that each group placed on areas within the environment. National team skiers spent greater time fixating the other skier and less time viewing the track immediately in front of them compared to Developmental athletes. This strategy may be relevant for monitoring the behaviour of other skiers in close quarters. **References** Roca, A, Ford, PR, McRobert, AP, & Williams, AM (2011). TRAINING ANTICIPATION WITH FUNCTIONAL VS. DYSFUNCTIONAL COLOUR CUES IN BEACH-VOLLEYBALL

Vater, C., Klostermann, A., Hossner, E.J.

University of Bern

Introduction Evidence suggests that guiding visual attention to information-rich areas using the colour-cue method accelerates learning in anticipation tasks (e.g., Cañal-Bruland, 2009). However, findings are inconsistent so that it has been questioned whether highlighting relevant kinematic cues actually affect learners' gaze behaviour (Abernethy et al., 2012). Therefore, in an intervention study, colour cues were experimentally manipulated by presenting functional (i.e., highlighting the gaze path of volleyball experts) vs. dysfunctional (i.e., highlighting the ball path) colour cues in a beach-volleyball anticipation task. It was expected to find better learning for the functional compared to the dysfunctional and a control group. **Methods** 3 groups of 10 participants each (14 male, 16 female) watched beach-volleyball attacks that were displayed on a life-size screen. The task was to predict the type of attack (cut shot, line shot, smash). In the intervention (12 blocks of 12 trials each), scenes were presented either with functional, dysfunctional or without colour cues (control group). Participants were instructed either to learn the (alleged) expert-like gaze behaviour (colour-cue groups) or to focus on the different attack techniques (control group). Performance was tested in pre-, post- and retention tests (3 blocks of 12 trials each, occluded either at 40 ms or 200 ms before ball-hand contact). As dependent measure, decision accuracy was assessed and analysed with 3 (intervention) x 3 (test) x 2 (occlusion) x 3 (shot type) ANOVAs with repeated measures on the last three factors. **Results** Significant main effects for test, $F(2,25) = 43.94$, $p < .01$, $f = 0.98$, and shot type, $F(2,25) = 7.46$, $p < .05$, $f = 0.55$, were found indicating that participants improved from pre- to post- and retention test and reaching higher accuracies for line shots and smashes compared to cut shots. Furthermore, a main effect for occlusion was revealed, $F(1,25) = 65.97$, $p < .01$, $f = 1.64$, with higher accuracies in scenes with late occlusions. A trend for an interaction for block x group, $F(4,25) = 1.90$, $p = .13$, $f = 0.39$, suggests better results of the control group in post- and retention test. **Discussion** The results show that participants were able to improve decision making independent of intervention type. Interestingly, no advantage of the functional colour-cue group was found. Instead, by tendency, the control group outperformed both experimental groups. Consequently, it might be suggested that gainful information could not be extracted from colour cues (Abernethy et al., 2012). **References** Abernethy, B, Schorer, J, Jackson, RC, Hagemann, N (2012). *J. GAIT RETRAINING TO REDUCE LOADING: WHAT IS THE IDEAL LOCATION FOR PROVISION OF VISUAL ACCELEROMETER BIOFEEDBACK?

ÓCatháin, C., Moran, K.

Dublin City University

Health and Human Performance Department, Dublin City University, Dublin, Ireland O'Hare Scholarship fund, DCU **Introduction:** Research has demonstrated that provision of visual biofeedback from a tibial accelerometer during running can alter running mechanics and reduce the magnitude of tibial impact accelerations by up to 60%, potentially reducing the risk of injury development (Crowell et al. 2010). However, it has not yet been investigated if other anatomical locations (sacrum) or off-body locations (treadmill) can be used to provide biofeedback. This study aims to compare the use of tibial, sacral, and treadmill acceleration biofeedback to examine which location is most effective at decreasing load experienced by the body during running, and thus decrease the risk of injury development. **Methodology:** 26 male subjects were split into three groups. Each group was provided biofeedback from an accelerometer attached at a different location: tibia, sacrum, or treadmill. Subjects ran continuously over three phases: six minutes of "normal" running to collect baseline data, 10 minutes of running where continuous visual biofeedback was provided (location of feedback dependent on group), and then a further 6 minutes without biofeedback. Accelerometer data was collected for 15-second windows at the end of each of the three phases. While receiving biofeedback subjects were instructed reduce the magnitude of the acceleration peaks displayed on a screen in front of the treadmill, and asked to maintain these reductions during the final 6 minutes of no feedback. **Results:** Statistical analysis revealed a significant main effect of time but not of group. Impact accelerations were significantly less than baseline measures at both post biofeedback and post no biofeedback, at the tibia ($p < 0.001$) and the sacrum ($p < 0.001$). Although insignificant, there was variance in % difference between each group, from baseline to post biofeedback measures for the tibia (Treadmill=-29% versus Tibial=-22.6% versus Sacral=-

12.8%) and the sacrum (Sacral=-34.3% versus Treadmill=-20% versus tibial=-13.3%). Discussion: Results indicate that visual accelerometer biofeedback appears to dramatically alter tibial and sacral loading. Given the ease of use and relative cheapness of such a system this may have numerous practical applications as an injury preventative or rehabilitative tool. Although no statistical difference between groups was observed, the repetitive nature of running may place importance in percentage differences observed. THE EFFECT OF ACUTE EXERCISE AND PSYCHOSOCIAL STRESS ON FINE MOTOR SKILLS AND TESTOSTERONE CONCENTRATION OF HIGH SCHOOL STUDENTS

Budde, H., Koutsandréou, F., Koedijker, J.M., Wegner, M.

Medical School Hamburg

INTRODUCTION Little is known about the influence of different stressors on fine motor skills, the concentration of testosterone (T), and their interaction in adolescents. To our knowledge, no study exists which investigated the influence of different stressors on testosterone concentration and fine motor skills in adolescents. Therefore, as a preliminary effort, the aim of the present study was to analyze whether changes in fine motor performances due to acute physical and psychological stress could be related to changes in testosterone levels (Wegner et al., under review). **METHODS** Therefore, 62 high school students aged 14-15 years were randomly assigned to two experimental groups (exercise, psychosocial stress) and a control group. Exercise stress was induced at 65-75% of the maximum heart rate by running for 15 minutes (n = 24). Psychosocial stress was generated by an intelligence test (HAWIK-IV), which was uncontrollable and characterized by social-evaluative-threat to the students (n = 21). The control group followed was part of a regular school lesson with the same duration (n = 28). Saliva was collected after a normal school lesson (pre-test) as well as after the intervention/ control period (post-test) and was analyzed for testosterone. Fine motor skills were assessed pre- and post-intervention using a manual dexterity test (Flower Trail) from the Movement Assessment Battery for Children-2. **RESULTS** A repeated measure ANCOVA including gender as a covariate revealed a significant group by test interaction, indicating an increase in manual dexterity only for the psychosocial stress group. Correlation analysis of all students shows that the change of testosterone from pre to post test was directly linked ($r = -.31$, $p = .01$) to the changes in manual dexterity performance. **DISCUSSION** Participants showing high increases in testosterone from pre to post-test made less mistakes in the fine motor skill task. Findings suggest that manual dexterity increases when psychosocial stress is induced and that improvement of manual dexterity performance corresponds with the increase of testosterone. OP-PM45 Metabolic Adaptation to Exercise

MECHANISM FOR EXERCISE INDUCED PGC-1 α TRANSCRIPTION IN SKELETAL MUSCLE

Kim, K.I, Ahn, N.I, Kim, H.2, Chang, I.3, Kim, S.I, Koh, J.I, Jung, S.I

1: *KMU (Daegu, Korea)*, 2: *KMC (Daegu, Korea)*, 3: *CUD (Daegu, Korea)*

Introduction An exercise-induced increase in muscle mitochondria plays a major role in the increase of endurance capacity with training. These mechanism were suggested by Nuclear respiratory factors 1 and 2 (Scarpulla, 2002) and PGC-1 α (Puigserver et al., 1998). Activation of PGC-1 α may mediate the initial phase of the exercise-induced adaptive increase in muscle mitochondria, whereas the subsequent increase in PGC-1 α protein sustains and enhances the increase in mitochondrial biogenesis (Wright et al., 2007). Mechanism for exercise induced PGC-1 α transcription in skeletal muscle is not well understood. This study determine which transcriptional factors, activating transcription factor 2 (ATF2) and/or cAMP responsive element binding protein (CREB), bind to and activate cAMP response element (CRE) transcriptional binding site of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1 α) promoter during exercise. **Methods** Twelve rats were randomly assigned into 2 groups (Sedentary and Exercise). Exercise groups were trained by using a 30min swimming with tail load equivalent to 2% of animal's own body weight. Muscle samples were harvested immediately after exercise. C2C12 cells were treated clenbuterol (β 2-adrenergic agonist) and anisomycin (p38 MAPK activator) to determine whether p-CREB and/or p-ATF2 can activate PGC-1 α promoter transcriptional activities using luciferase reporter system. Results Clenbuterol and anisomycin increased phosphorylation of CREB and ATF2 respectively in C2C12. The ATF2 phosphorylation was increased in the exercise group compared with sedentary group, but CREB phosphorylation was not changed after exercise. PGC-1 α transcription activities were enhanced by ATF2 activation, but not in CREB activated condition. Induction of DN-ATF2 completely blocked PGC-1 α promoter activity by p-ATF2. **Discussion** Mitochondrial biogenesis by activation of β -adrenergic receptor with catecholamine in skeletal muscle was the object of interest for several decades. Several recent studies argue that because catecholamine formation is increased during exercise, mitochondrial biogenesis is also increased by catecholamine action in skeletal muscle. As measurement of PGC-1 α and mitochondrial electron transport enzymes to evaluate the mitochondrial biogenesis by β -adrenergic stimulates in rat skeletal muscle, norepinephrine and clenbuterol increased PGC-1 α mRNA and protein expression in BAT, but they had no effect on PGC-1 α and mitochondrial electron transport enzymes in skeletal muscle (Kim & Kim, 2012). These findings suggest that ATF2 phosphorylation by p38 MAPK system induce PGC-1 α transcription in exercised muscle. References Scarpulla RC. (2002). *Gene*, 286, 81-89. TWO WEEKS OF IMMOBILISATION INCREASES SKELETAL MUSCLE ROS PRODUCTION AND DECREASES COUPLING EFFICIENCY IN ELDERLY HEALTHY MEN - AN EFFECT WHICH IS REVERSED BY AEROBIC TRAINING

Gram, M., Vigelsoe, A., Yokota, T., Nørregaard, J., Wiuff, C., Kuhlman, A.B., Helge, J.W., Dela, F., Hey Mogensen, M.
University of Copenhagen

Introduction The purpose of this study was to investigate the effect of physical inactivity and subsequent aerobic training on mitochondrial reactive oxygen species (ROS) production and respiratory capacity determined at a clamped submaximal membrane potential. This study was conducted in elderly, a growing segment of the population, under the hypothesis that elderly are sensitive to inactivity but retain the capacity to respond to subsequent retraining. **Methods** 15 elderly healthy male subjects (68 ± 1 yr; 33 ± 2 ml O₂/min/kg (mean \pm SEM)) had one leg immobilised for two weeks using a DonJoy cast. This was followed by six weeks (20 sessions) of supervised cycle ergometer training ($86 \pm 1\%$ of maximal heart rate). Muscle biopsies (v. lateralis) were obtained before (PRE) and after immobilisation (IM) and training (TR). Mitochondrial respiratory rate, ROS production and membrane potential were determined simultaneously in isolated mitochondria using pyruvate and malate as substrates. In the basal state (substrate only) 3 submaximal ADP infusion steps was followed by a bolus to achieve state 3 (ADP varied condition). State 4 respiration was achieved by addition of oligomycin followed by 3 submaximal rotenone titration steps until a bolus was added to induce full inhibition of complex I (rotenone varied condition). Respiration and ROS production was evaluated at a clamped membrane potential equal to 50% of the ADP varied membrane potential range. Coupling efficiency was calculated as the percentage of ATP generating respiration JATP relative to leak respiration JLEAK. Statistical differences were tested using a linear mixed model. **Results** Immobilisation decreased the coupling efficiency (PRE: $92.7 \pm 0.9\%$ vs. IM: $88.2 \pm 1.4\%$ vs. TR: $92.3 \pm 0.9\%$) caused by a decrease in JATP (PRE: 101 ± 8 vs. IM: 84 ± 7 vs. TR: 110 ± 7 nmol/min/mg prot.) and a parallel increase in JLEAK (NS) (PRE: 7.3 ± 0.9 vs. IM: 9.8 ± 1 vs. TR: 8.3 ± 0.9 nmol/min/mg prot.), which was reversed by training. Immobilisation increased ROS production, in both the ADP and rotenone varied condition, which was also reversed with training: (ADP varied condition: PRE: 109 ± 9 vs. IM: 150 ± 17 vs. TR: 94 ± 12 and rotenone varied condition: PRE: 1051 ± 87 vs. IM: 1295 ± 109 vs. TR: 997 ± 67 pmol H₂O₂/min/mg prot.) **Conclusions** Two weeks of immobilisation decreased the mitochondrial coupling efficiency through decreased JATP and increased JLEAK and increased the ROS production evaluated at a clamped submaximal membrane potential revealing intrinsic changes to the mitochondria. These effects were reversed after 6 weeks of aerobic training, thus elderly retain the capacity to respond to inactivity and subsequent retraining. **Contact:** mgram@sund.ku.dk

EFFECTS OF INDUCED CHANGES IN ACID-BASE BALANCE ON MITOCHONDRIAL ADAPTATION TO TRAINING

Hawke, E.1, Hammarström, D.1, Sahlin, K.2, Tonkonogi, M.1
1 Dalarna University, 2 GIH

Introduction Endurance training leads to an improved ability of muscle to utilize oxygen. This is related to an increased density and function of mitochondria. The biogenesis and adaptation of mitochondria is a complex process mediated by various signalling pathways and seems to be highly sensitive to the type of exercise and the local environment in the muscle. Changes in the muscle environment in terms of altered metabolism and substrate accumulation are affected by changes in acid/base balance in response to exercise. Recent studies have shown that changes in acid/base balance may affect the regulation of mitochondrial adaptation to acute exercise; however, how this responds to training and relates to performance adaptations in humans is unclear. Similarly, the effect of acid/base balance on mechanisms underlying mitochondrial biogenesis is unclear. The objectives of this study were to examine the relationship between acid/base balance, mitochondrial biogenesis and adaptation. **Methods** Nineteen recreationally active men undertook a six-week periodised high-intensity interval training programme, a protocol known to produce increases in mitochondrial biogenesis. Participants were matched for aerobic fitness and randomly assigned to one of two different training groups. One group ingested sodium bicarbonate (alkaline) and the other group ingested a placebo prior to each training session. Performance test results, blood samples and muscle biopsies were collected before and after the six week training period and assessed for changes in aerobic fitness, blood metabolites and muscle markers of mitochondrial function and biogenesis. Changes in gene expression associated with mitochondrial biogenesis were also examined. **Results** After the training period, there were significant ($P < 0.05$) improvements in TTF, Wmax and LT in both groups, citrate synthase activity in the alkaline group and VO₂peak in the placebo group. Improvements were also seen in citrate synthase activity in the placebo group and VO₂peak in the alkaline group, however these did not reach significance ($P = 0.089$ and 0.066 respectively). Despite these significant changes within groups in response to training, there were no significant differences between groups. **Discussion** Both training groups showed substantial changes in performance and physiological measures following the training period, however, suppressing exercise-induced acidosis during training did not significantly improve mitochondrial adaptations or performance in comparison to the placebo condition. However, there was a large degree of individual variation in the response and there were trends towards greater adaptations when exercise-induced acidosis was attenuated.

PLATELET-RICH PLASMA COMBINED WITH TGF-BETA ANTAGONIST FOR IMPROVED MUSCLE HEALING AND REINJURY PREVENTION

Kelc, R., Trapecar, M., Vogrin, M.
University Medical Center Marior

Platelet-rich plasma combined with TGF-beta antagonist for improved muscle healing and reinjury prevention **Background:** Muscle reinjury is often in sports medicine and as such an important target of reinjury prevention. Growth factors from platelet-rich plasma (PRP) with proven effects in tendinous and ligamentous healing have not yet been studied in skeletal muscles mainly due to the concern that exogenous TGF- β application could lead to even greater fibrosis development in an injured muscle. Therefore, only some TGF- β antagonists like decorin have shown their positive role in muscle repair so far. In our study, we investigated the effects of PRP in combination with TGF- β antagonist decorin in skeletal muscle regeneration. **Objective:** This study proves so far unknown positive effects of platelet-rich plasma in muscle healing, especially when combined with a TGF- β antagonist. **Methodology:** A novel human myoblast cell culture, defined as CD56 (NCAM)+ developed in our laboratory, was used for evaluation of potential bioactivity of PRP and decorin. The influence on the cells mitochondrial activity, expression of TGF- β was studied in parallel with cell proliferation. Further we have studied the ability of the therapeutic agents to influence the differential cascade of dormant myoblasts towards fully differentiated myotubes by monitoring step wise activation of single nuclear factors like MyoD and Myogenin via multicolor flow cytometry. **Results:** Our results clearly showed that PrP and decorin treated myoblasts have a significant increase in the mitochondrial activity and in the cell proliferation rate as compared to non-treated control cells. At the same time lower expression of TGF- β and MSTN was evident in PrP treated myoblasts, although

PRP itself contains some amount of TGF- β . Conclusion: PRP can be a highly potential therapeutic agent for skeletal muscle regeneration and repair, especially if in combination with a TGF- β antagonist. In such way not only better healing but also lower reinjury rate could potentially be achieved.

EFFECTS OF 6 MONTH AIT ON INSULIN SENSITIVITY AND SKELETAL MUSCLE GLUCOSE METABOLISM IN METABOLIC SYNDROME PATIENTS.

Guadalupe, G.A.1, Fernández, E.V.E.2, Ortega, J.F.2, Dela, F.1, Helge, J.W.1, Mora Rodríguez, R.2

1 Xlab. University of Copenhagen (Denmark). 2 Exercise Physiology Laboratory. University of Castilla-La Mancha. Toledo (Spain).

Aerobic interval training (AIT) increases glucose transport and utilization to a greater extent than aerobic continuous training in metabolic syndrome patients [1], and this could be mediated by the higher calcium transients in the muscle with AIT. Intramuscular calmodulin mediated kinase II (CaMKII) plays a critical role in the regulation of contraction-induced glucose uptake in skeletal muscle [2]. However, long term effects of AIT on insulin sensitivity, CaMKII phosphorylation level (pCaMKII), and intramuscular glucose metabolism has not been investigated. Purpose: To assess the effects of AIT on body composition, cardiovascular fitness, insulin sensitivity and muscle glucose metabolism in metabolic syndrome patients. Methods: Eleven metabolic syndrome patients (54.5 ± 0.7 yrs old) underwent 6 month of 3 days a week supervised AIT program in a cycle-ergometer. Body composition and cardio-metabolic health were assessed using gold-standard procedures. Insulin sensitivity was assessed by a short intravenous glucose tolerance test (CSI), glycosylated hemoglobin (HbA1c), and HOMA index. Muscle biopsies were collected from the vastus lateralis prior and at the end of the AIT program to measure the glucose transporter GLUT 4, hexokinase II enzymatic activity (HKII), pCaMKII levels and glycogen content. Results: Body weight, muscle mass and VO2peak remained unchanged after the intervention, whereas body fat mass and waist circumference were reduced by 4 % and 2 % respectively ($p < 0.05$). Arterial blood pressure was reduced by 9% after 6 month of AIT ($p < 0.05$). No changes were observed in blood cholesterol, triglycerides, and HDL. Fasting insulin, glucose, HbA1c, HOMA and CSI remained unchanged after the intervention. Muscle HKII activity, pCaMKII and glycogen content were similar, whereas the total protein expression of GLUT4 was increased by x % with AIT ($p < 0.05$). Conclusion: Overall, insulin sensitivity and glucose utilization is not significantly improved with 6 months of AIT despite discrete improvements of the total amount of its transporter GLUT4. The lack of enhanced carbohydrate metabolism could be due to the absence of reduced circulating lipids, a factor that affects glucose transport [3]. References: 1. Tjonna, A.E., et al. THIOL-BASED SUPPLEMENTATION ALTERS CYTOKINE AND ADHESION MOLECULE RESPONSES FOLLOWING TWO EXERCISE MODELS

Fatouros, I.1, Sakeliou, A.2, Tsoukas, D.2, Mitrakou, A.2, Chatzinikolaou, A.1, Draganidis, D.1, Jamurtas, A.Z.4, Mandalidis, D.5, Michailidis, Y.1, Avloniti, A.1, Pontidis, T.1, Kambas, A.1

DEMOCRITUS UNIVERSITY OF THRACE, 1: DPSS-DUTH (Komotini, Greece), 2: MS-UOA (Athens, Greece), 3: DPSS-UTH (Trikala, Greece), 4: DPSS-UOA (Athens, Greece)

Introduction Aseptic inflammation induced by muscle damaging exercise is associated with reactive oxygen species (ROS) generation (Michailidis et al., 2013) that may mediate muscle's inflammatory responses (Ji, 2008; Michailidis et al., 2013) which include immune cell recruitment through the action of pro-inflammatory cytokines and adhesion molecules. The aim of this study was to investigate if cytokine and adhesion molecule responses during the inflammatory phase following muscle damage induced by two different exercise models are redox-sensitive. Methods In the first study, 12 trained males received either placebo or n-acetylcysteine (NAC) or placebo (PLA) for three days following eccentric exercise (300 repetitions, 30 deg/s) in double-blind, cross-over, repeated-measures design. In the second study, 20 football players received either NAC (N=10) or PLA (N=10) for three days following a football match. Blood was collected, muscle strength (peak torque at 60 deg/s) was measured and muscle soreness was determined at baseline, immediately post-exercise and daily for three days post-exercise. Blood was analyzed for creatine kinase activity (CK), leukocyte count (WBC), C-reactive protein (CRP), reduced (GSH) and oxidized (GSSG) glutathione, protein carbonyls (PC), adhesion molecules (sVCAM-1, sP-Selectin) and cytokine (IL-1 α , IL-4, IL-6, IL-10) concentrations. Results Both exercise models increased CK, soreness, WBC, CRP, adhesion molecule and cytokine levels with eccentric exercise inducing a more pronounced response. NAC attenuated the GSH/GSSG ratio decline and PC rise in both studies suggesting that NAC altered blood redox status. Adhesion molecule and cytokine concentrations increased in both studies with eccentric exercise inducing a greater elevation. NAC administration resulted in an attenuation of WBC, CRP, adhesion molecule and cytokine rise in both studies. Muscle performance was reduced ($p < 0.05$) in both studies but it was better maintained in NAC trials 24-48h post-exercise. Discussion Results of this study suggest that muscle's inflammatory response following exercise-induced aseptic muscle damage may be redox-sensitive by mediating adhesion molecule and pro-inflammatory cytokine responses and thus immune adaptations. 08:30 - 10:00**Oral presentations****OP-SH09 Education & Pedagogics****CHARACTERIZATION OF PARENTS WITH DIFFERENT PERCEPTIONS ABOUT PHYSICAL EDUCATION STATUS IN THE CURRICULUM**

Carreiro da Costa, F.1,2, Marques, A.1,3, Martins, J.3

1 CIPER (Portugal), 2 ULHT (Lisbon, Portugal), 3 FMH-UL (Lisbon, Portugal)

Introduction School interventions aiming to promote physical activity (PA) needs to be implemented based on knowledge about subjects and processes involved. Considering that parents play health-related roles for their children as models of appropriate behaviours, as gatekeepers to opportunities and barriers, and as a major source of reinforcement in most children's lives, the purpose of this study was to characterize parents' perceptions about Physical Education (PE) status. **Methods** 1056 fathers and 1406 mothers have participated in the study. Parents' opinions about both the status and aims of PE in school were measured using questions from Carreiro da Costa et al's (1998) questionnaire; self-perception of PA was measured by the question: How do you classify your own lifestyle? The item concerning past experience in PE was: Taking into account your past experience in PE in the schools you have attended, how do you classify it? Responses were given using a 5-point scale. Educational level was derived from a closed question. A cluster analysis distinguishes four groups of parents with distinct PE views: compulsory and examinable; compulsory but non-examinable; optional; should not exist in the curriculum. **Results** A past positive experience characterizes parents in favour of PE as an examinable subject. A negative or indifferent past experience characterize parents stating that PE should be non-examinable. An indifferent attitude characterizes parents responding "optional". As for PE aims, learning characterizes the parents who share that PE must be examinable, while enjoyment characterizes parents who say that PE must be non-examinable. Parents' level of education does not characterize the four groups of parents. **Discussion** These findings indicated the importance of past experiences in PE for the development of habits, knowledge, and attitudes that valorise PA. The results also suggest that a dominant socio-cultural view of PE as a peripheral subject remains among the Portuguese parents. In addition to the need to ensure the quality of PE in Schools, it is necessary to revise the expectations and roles that PE teachers must play, assuming that teaching is not the only function of a PE teacher. It is important to recognize the need for preparing PE teachers able to functioning in the school with other subject teachers, to interact with parents, and with structures outside of the school. **References** Carreiro da Costa, F., Carvalho, L., Diniz, J., Onofre, M. PARTICIPATION STYLES IN ELEMENTARY PHYSICAL EDUCATION

Romar, J.E., Nygård, J., Smedman, T.

Åbo Akademi University

INTRODUCTION Both observational data and direct measurement of student activity seem to indicate a large variation in student activity during physical education lessons depending on student variables and context. Similarly, there is a large variation between students in the same lesson. Therefore, researchers and physical education teachers need to attend to student voice in physical education and Griffin (1984, 1985) was the first to reveal the impact of participation styles in physical education. There is a need to extend this line of research by using quantitative data of student activity. Therefore, the aim of this study was to identify participation styles during elementary physical education lessons by using multiple data source. **METHODS** Seventeen fifth grade students and 14 sixth grade students were taught by a physical education specialist for three lessons each. Both classes had coed physical education lessons and all students were systematically analyzed by using heart rate measurement, systematic observation and perceived exertion. Average heart rate, maximal heart rate and MVPA were calculated from the heart rate measurement. System for Observing Fitness Instruction Time (SOFIT) was used to systematically observe students' level of MVPA and the Borg rate of perceived exertion scale was used to measure perceived exertion during the lessons. Each lesson was videotaped for further analysis. Finally, 10 high and low skilled students were formally interviewed after the last lesson about their experiences in physical education. **RESULTS** The results indicated four different participation styles among the students in these physical education elementary classes. These were low skilled fighters, low skilled avoiders, high skilled fighters and high skilled avoiders. A low skilled fighter tries to be physical active despite a limited ability. A low skilled avoider does not use more effort than necessary. A high skilled fighter attempts to and is active while a high skilled avoider does not show more effort than necessary despite the high physical fitness level. **DISCUSSION** Several contextual factors are contributors to these participation styles. The main reason for this appears to be differences in students' fitness levels, physical activity behavior and interest in physical education. This large variation between individual students shows that each student should be treated separately. **REFERENCES** Griffin, P. (1984). JTPE, 4(1), 30-38. Griffin, P. S. (1985). ASSESSMENT CRISES OR OPPORTUNITY? THE ROLE OF ASSESSMENT FOR LEARNING IN NORWEGIAN PHYSICAL EDUCATION

Leirhaug, P.E.1, Annerstedt, C.2

1. Norwegian School of Sport Sciences (Norway), 2. University of Gothenburg (Sweden)

BACKGROUND Stiggins (2002) referred to the absence of assessment for Learning (AfL) on the political level an 'assessment crisis'. This appears to be no longer the case, as many countries have "embarked on an education reform with a highly emphasised Assessment for Learning agenda" (Berry & Adamson, 2011, p. 99), with the 2006 Norwegian reform 'Kunnskapsløftet' as one example. However, while there is evidence that the political landscape has somewhat embraced AfL, Georgakis and Wilson (2012) believe that there an 'assessment crisis' remains in school physical education (PE), with a concern on the associated hidden and negative consequences for students. Where Stiggins (2002) aimed at the political level, the purpose of this paper is to present an empirical study of the realization of AfL in PE at six upper secondary schools in Norway. Educational literature interprets AfL in several ways, but seems to agree on some key princi-

ples that can be used to characterize Afl (Gardner, 2012). The analytical approach of this study is guided by five key principles of Afl and the following research question: How do the students and teachers report of assessment practices in PE reflect the Afl key principles? METHODS A mixed method design has been applied in this study. Data is collected through a survey of 1486 students at six upper secondary schools in Norway (841 girls, 645 boys; response rate 72,6 %), and focus groups of a total of 23 PE teachers at the same schools. FINDINGS Key principles of Afl, such as engaging student in self-assessment and sharing the assessment criteria, are to a large extent absent in the students' perceptions of assessment in PE. In addition most of the PE teachers seem not to be familiar with the Afl key principles. DISCUSSION Rather than stating an 'assessment crises' in Norwegian PE, this paper argues that the findings should mainly be interpreted as opportunities for PE teacher and subject development. To rethink assessment from ground in PE, which probably is the case, teachers need substantial knowledge, as well as motivation, and an understanding that integrating Afl is part of their professional development. PERFORMING ARTS TEACHERS' CONCEPTIONS OF MOTOR CREATIVITY

Torrents, C., Casals, M., Castañer, M.

INEFC- University of Lleida

Introduction Creativity has been described in many ways and teachers' conceptions of creativity seem to be confusing in different curricular areas. The aim of this study is to compare the objective quantitative observations of the variety of motor behaviour using systematic observational methodology with the subjective performing arts teachers' conceptions of motor creativity. Methods One group of 7 Physical Activity and Sports Science students (A) and another group of 7 amateur dancers (B) were video-recorded whilst improvising for 5 min in a space of 10 m x 10 m. A mixed methods approach (Camerino et al. 2012) was used to analyse the data. Both trials were sequentially observed by three dance experts using the observational instrument OSMOS (Castañer et al. 2009), with the movements of each dancer being analysed separately with LINCE software. The data obtained was then analysed with THEME software. In addition, 15 performing arts teachers were asked to complete a questionnaire about the creative behaviour of the students and of the amateurs as well as about the repetition of motor actions after observing the videos. The answers were subjected to a content analysis using Nvivo-v8 Software. Results Observational results of group A showed 10 significant T-patterns, while group B did not repeat any sequence of actions. Group A performed a greater number of actions, but the variety of these actions was similar in both groups. The teachers differed in their subjective comments about the motor creativity of the participants. Some of them considered that the participants' creativity was related to the beauty of the movement or its technical quality, while others related it to the exploration and the originality. The teachers did not use the quantitative criteria to evaluate the creativity and no teacher detected the repetition of sequences of movements by group A. Improvisation was associated with creativity by some teachers, while others believed an improvised dance could not be creative. Conclusions This study shows that performing arts teachers have different creativity conceptions and that two approaches can be identified: the appreciation of the novelty or originality and the appreciation of beauty. These differences can explain why improvisation is considered by some as something related to creativity, while other teachers consider it as the opposite. Motor creativity is a concept that needs more clarification, even among performing arts professionals. References Camerino, O. Castañer, M & Anguera, M.T. (Eds.) OP-SH10 Sport & Cognition

THINKING FAST AND SLOW: TESTING COGNITIVE EXPERTISE IN HIGH DIVISION AND LOWER DIVISION FIELD HOCKEY PLAYERS.

de Vries, S.

Saxion University of Applied Sciences

Introduction A number of studies showed that expert athletes outperform less experienced athletes on a number of cognitive domains (Mann, Williams, Ward, & Janelle, 2007). Although most of this work was initially aimed at studying the relationship between sport expertise and performance on game specific cognition recent studies also explored the relationship between expertise and executive functioning (Alves et al., 2013). Positive results of expert athletes on executive functioning could also be explained by the fact that executive functioning tests rely on psychomotor speed and expert athletes often have fast response times. With this study we wanted to answer the question whether differences would exist between high and lower division field hockey athletes and whether these differences would be independent of psychomotor speed. Method 30 high division field hockey players (16.5 years; 15 male, national main division) and 30 lower division field hockey players (16.8 years; 15 male, national first division) participated in the study. All athletes completed two executive functioning tests: the Figure Fluency Test (FFT) and a digital version of the Trail Making Test (TMT part A and B). A Finger Tapping Task (FTT) was used to measure psychomotor speed. Both, the TMT and the FTT were administered with a digital tablet. Differences between high and lower division and male and female athletes were tested with an ANOVA. The influence of psychomotor speed on cognitive test performance was tested with an ANCOVA with FTT as a covariate. Results High division athletes were significantly better than lower division athletes on the TMT A with $F(1,59) = 23,13$, and TMT B with $F(1,59) = 7,33$ and FFT with $F(1,59) = 5,99$ (all $p < .05$). Performance on the difference score between TMT A and TMT B (TMT B-A) did not differ significantly with $F(1,59) = 0,11$, $p = .74$. When corrected for psychomotor speed only performance on the FFT differed significantly between high and low division athletes with $F(1,57) = 4,22$, $p < .05$. Discussion Our research shows that psychomotor speed influences performance on cognitive measures in high and low division field hockey players. After taking psychomotor speed into account high division athletes performed significantly better on the FFT while performance

on the TMT did not differ significantly. This research shows that also within the game of field hockey cognitive skills could play an important role in expertise development. Our results suggest performance on cognitive functioning should be assessed independent from psychomotor speed. References Alves, H., Voss, M. W., Boot, W. R., Deslandes, A., Cossich, V., Salles, J. A COMPARISON OF ERROR PROCESSING DURING TASK SWITCH BETWEEN CLOSED-SKILL AND OPEN-SKILL ELDERLY EXERCISERS

Lan Ya, C.

National Taiwan Normal University

Introduction Successful aging has been related to better executive function. The task switching paradigm allows investigation of cognitive flexibility. Studies have shown that participation in physical activity can reduce switch cost in adults (Hillman, Kramer, Belopolsky, & Smith, 2006) and recent studies have further examined the moderating effect of exercise mode on task switch (Dai, Chang, Huang, & Hung, 2013) and go/nogo task (Di Russo et al., 2010). However, these studies have exclusively focused on the “correct process” while left the error processes unexamined. Therefore, the present study intended to fill this knowledge gap by investigating the differences on error processes between open-skill and closed-skill elderly exercisers. **Methods** Twenty-seven older adults aged 64–76 were categorized into either an open-skill (N= 9, age= 68.67± 3.46 yrs), a closed-skill (N= 9, age= 71.10± 2.92 yrs), or a sedentary group (N= 9, age= 67.44± 2.24 yrs). Task-switching paradigm was administered in forms of 2 homogeneous blocks of 64 trials and four heterogeneous blocks of 128 trials that consisted of 64 switch and nonswitch trials each. Behavioral data (mixing cost / local cost / inter-trial SD / accuracy rate) and ERP data (ERN / Pe) were examined by ANOVAs. Results Both open-skill (p=.006) and closed-skill (p= .016) groups reacted faster than that of the sedentary group. Moreover, the open-skill group exhibited less RT variation (p = .014) in mixing cost setting and shorter ERN (p=.043) than the sedentary lifestyle group. **Discussion** Replicating previous work (Dai et al., 2013), behavioral results indicate less mixing cost for elders in open-skill and closed-skill groups. Moreover, less inter-trial variability in open-skill group suggests that enriched exercising environment is more beneficial to reduce cognitive decline associated with aging. In addition, the shorter ERN latency observed in open-skill group suggests that open-skill exercise may accelerate the detection of the conflict between correct and incorrect responses in the elderly. This study concludes that participation in exercise is associated with reduction in switching cost in the elderly and participation in open-skill exercise can provide extra benefit beyond that of closed-skill exercise. **Reference** Dai C, Chang Y, Huang C, Hung T. COGNITIVE FUNCTIONING AFTER AN ACUTE BOUT OF EXERCISE IN OLDER ADULTS: MODE AND DURATION EFFECTS

Polman, R.I, Selva Raj, I.2, Addamo, P., Borkoles, E.I

1 Victoria University, 2 RMIT

Introduction Given the multitude of factors involved (duration, intensity, mode) it is not surprising that the influence of exercise on cognitive functioning has been equivocal. In addition, relatively little research has been conducted on acute effects and its time course. It is still unclear how acute exercise responses attenuates cognitive decline. It is therefore important for research to examine the parameters of exercise which optimally facilitate cognition in the growing elderly population to decrease cognitive decline in a non-pharmacological way. We therefore examined the acute and intermediate effects of exercise mode (Aerobic-Resistance) and duration (10 vs. 30 min) on cognitive performance in elderly individuals. **Methods** Thirty-one community dwelling older adults (10 males and 21 females; mean age, 71.7 ± 1.5 years) participated in the study. Following 2 familiarisation sessions in which VO₂peak and 1RM for 5 different strength exercise was determined, participants were randomised to aerobic (n = 17; VO₂ peak = 19.58 ± 8.54; mini-mental = 29.06 SD = 1.19) or resistance (n = 14; VO₂peak = 17.55 ± 6.47; mini-mental = 29.36 SD = 0.74) training condition. In 2 further sessions participants engaged in either 10 or 30 minutes of aerobic or resistance exercise. The Stroop task was performed prior to the exercise bout, immediately after and 30 and 60 minutes following the bout. The workload for the exercise session was set at 13-14 RPE (somewhat hard or sweaty, still able to talk). **Results** Repeated measures ANCOVA showed that immediate post exercise all 4 conditions showed a significant improvement in performance (5.1%) in the Stroop interference task (p < .001; eta = .39). Also, a significant improvement (±3%) was observed for the Stroop control condition for the 4 conditions (p = .05; eta = .12). These improvements were accompanied by self-rated increases in felt arousal and significant increase in HR. Improvements lasted up to 30 minutes although at this point both felt arousal and heart rate returned to pre-exercise levels. At 60 minutes performance on the Stroop task was not different from baseline. Interestingly, the 10 minutes sessions resulted in higher rating of positive feelings 60 minutes following exercise which was not the case for the 30 minute exercise sessions. **Conclusion** No statistical differences were found between mode or duration of exercise on immediate or delayed cognitive performance in elderly participants. This suggests that even 10 minutes of moderate exercise, independent of mode, can have significant effects on cognitive functioning lasting for up to 30 minutes. It might be more beneficial for ageing individuals to engage in short multiple exercise bouts during the day rather than one long session. Contact Remco.Polman@vu.edu.au

THE IMMEDIATE AND DELAYED EFFECTS OF A SINGLE AEROBIC SESSION ON EXECUTIVE FUNCTIONS AND ATTENTION IN HEALTHY ACTIVE ADULTS

Netz, Y.

Wingate College

Introduction The acute effect of aerobic training on cognition in healthy adults has rarely been studied. Studies on the length of the effect are scarce and the findings are equivocal. The purpose of this study was to examine the immediate and delayed effect (following 30 minutes of rest) of a single session of aerobic training (60% of heart rate reserve – HRR) on executive functions and attention in healthy adults. **Methods** Forty (30 men) physically active adults (age 51.88±8.46) attended three individualized sessions, with a week to two-week interval. Executive functions and attention were calculated based on three cognitive tests: Go-Nogo, Stroop and Catch Game, assessed by Mindstreams – novel computerized software assessing multidomain cognitive functioning. In the baseline session participants per-

formed cognitive tests and a graded, progressive, maximal exercise test for establishing their maximum predicted HRR. In the two remaining sessions they either performed the aerobic session or watched a TV show. In both sessions their cognition was examined before, immediately after, and after 30 minutes of rest. Results The executive function scores for the aerobic session were $108.82(\pm 9.24)$, $112.88(\pm 8.00)$ and $110.88(\pm 7.34)$ for the pre, post and delayed testing respectively, and for the TV session $110.80(\pm 9.33)$, $111.70(\pm 8.33)$ and $111.08(\pm 8.73)$. The attention scores for the aerobic session were $104.09(\pm 13.78)$, $107.54(\pm 7.29)$ and $105.99(\pm 6.90)$ for the pre, post and delayed testing respectively, and for the TV session $106.86(\pm 6.61)$, $106.21(\pm 7.72)$ and $105.88(\pm 7.99)$. A 2-way ANOVA indicated improvement immediately after the aerobic session on attention - $F(1,38)=4.23$, $p<.05$, and marginally significant improvement for executive functions - $F(1,38)=3.37$, $p=.07$. The scores on the delayed tests did not differ from the pretest. Discussion The improvement in executive functions and attention immediately following a moderate intensity aerobic session supports previous studies (Tomprowski, 2003). The fact that the improvement did not last 30 minutes after the termination of the exercise corresponds to the results of Giorno et al. (2010), but differs than the findings of Joyee et al. (2009). More studies are needed to explore the mechanisms mediating between aerobic exercise and cognition. References Joyce J, Graydon J, McMorris, T. & Davranche, K. (2009). Brain Cogn, 71, 14-19. EFFECT OF MODERATE-TO-VIGOROUS PHYSICALLY ACTIVE ACADEMIC LESSONS ON TIME-ON-TASK IN THE CLASS-ROOM

Hartman, E., Mullender Wijnsma, M.J., De Greeff, J.W., Visscher, C.

Center for Human Movement Sciences

Introduction Academic engagement can be seen as a major predictor of academic success (Greenwood et al., 2002). Combining physical activity with academic lessons can contribute positively to academic engagement, which can be measured by the time spent focusing on academic tasks, i.e. Time on Task (ToT; Grieco et al., 2009). This could be especially effective in socially disadvantaged children (SDC), as these children are more likely to have poor academic outcomes (Downer and Pianta, 2006). The aim of the present study was to examine the effect of physically active academic lessons on ToT in SDC and their peers (non-SDC) as well as the effect of physical load on ToT. Methods The study is part of the randomized-controlled trial 'Fit and Academically Skilled at school' (F&S). In F&S an in-class physical activity program is implemented. A subsample of 86 experimental children (mean age: 8.2 ± 0.65 years; 41 girls; 45 boys) of four schools were recruited to participate in the current study. Twenty-three children had parents who completed less than three years of secondary school; they were classified as SDC. During the 22 weeks of F&S, ToT of the children was determined by classroom observations after paired intervention and control lessons. Results of a 20-m-shuttle run test during the gym in combination with heart rate monitors during the F&S-lessons provided a physical load measure as percentage of the maximum heart rate (% HR-max). Physical activity of 60-90% HRmax was considered as moderate-vigorous (MVPA; ACSM, 1998). Results ToT of SDC was significantly lower than that of non-SDC during the post-control lessons ($t=3.57$; $p<.05$). ToT of all children was significantly higher during post-intervention than during post-control lessons ($t=4.37$; $p<.05$, $d=.58$). There were no significant differences between SDC and non-SDC. Mean percentages of MVPA during F&S lessons ranged from 53-65% in SDC and 51-68% in non-SDC. In both groups there were no significant correlations between the percentage of MVPA during the F&S lessons and ToT in the regular classroom lessons that immediately followed the F&S lessons. Discussion Physically active academic lessons positively influenced ToT in SDC and their peers, which might contribute positively to academic success in the long term. More research is needed on the relationship between physical load and ToT in children. References American College of Sports Medicine (ACSM). (1998). Med Sci Sport Exerc, 30(6), 975-991. SIZE BIAS IN SOCCER REFEREES AND THE IMPACT OF RUMINATIVE THOUGHTS

Kinrade, N.P., Howard, J., Glover, C.

Brunel University

Introduction Several factors have been suggested to influence decision-making, including past experiences (Jullissson et al., 2005) and cognitive biases (Stanovich & West, 2008). Soccer referees make important decisions carrying significant consequences under temporal pressure (Lane et al., 2006). The aim of this study was to establish previous evidence suggesting referees and observers exhibit a size bias (Van Quaquebeke & Giessner, 2010) in ambiguous foul situations; and whether their decision-making is influenced by a tendency to engage in ruminative thoughts (Poolton et al., 2011). Methods 43 participants, including referees (13), coaches (16) and players (14) completed the decision-specific reinvestment scale (DSRS; Kinrade et al., 2010). Participants viewed 88 video clips depicting two footballers (one approx. 30% larger than opposition); one dribbling towards the other (size of dribbler/tackler was counterbalanced), a grey screen appeared one frame prior to the tackle for 500ms followed by a scene showing a player on the floor. Participants then responded as to whether the player was fouled, tackled or dived. Results Data was categorised into decisions favouring the taller, smaller or neither player. Non-significant differences between referees, coaches and players decision preferences ($p>.05$) allowed collapsing of data. Median splits categorised participants for each factor of the DSRS. Separate Group (high/low reinvestment/rumination) x Response (Tall bias, Small bias, No bias) mixed design ANOVA's identified a significant main effect for decision preference, reflected in participants favouring the tall player less compared to the smaller player ($p<.001$) and no player favoured ($p<.001$). A significant interaction effect was found for the rumination factor only ($p<.05$) reflected in a magnified size bias in high ruminators. Discussion The findings support Van Quaquebeke & Giessner (2010) findings of a size bias occurring in ambiguous foul scenarios. Embodied cognitions, abstracted cognitive derivations of "real-life" patterns, are used to make sense of situations. Referees may associate the smaller player as the foul perpetrator less often because of embodied cognitions showing smaller people as weaker than tall people. Training programmes aimed to improve referees decision-making should consider the importance of not ruminating over past bad decisions in order to avoid biases. OP-PM46 ACL Reconstruction & Exercise

QUADRICEPS/HAMSTRINGS EXPLOSIVE STRENGTH IN ALPINE SKI RACERS WITH ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Jordan, M., Aagaard, P., Herzog, W.

University of Calgary

Introduction There is a high incidence of anterior cruciate ligament (ACL) injury in elite ski racing, and unique mechanisms of injury involving high forces [1, 2, 6]. Following ACL reconstruction (ACLR) restoring hamstrings (Ham) and quadriceps (Quad) muscle strength is critical, yet long-term strength deficits often persist [5]. As Ham/Quad maximal and explosive strength is important for ACL injury prevention [7, 8] and for performance in ski racing [3, 4] the effects of ACLR on Ham/Quad maximal strength and explosive strength was evaluated in healthy male, healthy female and ACLR elite ski racers. **Methods** Healthy (n=13 males; n=8 females) and ACLR (n=8; 25.0±11.3 months post-op) ski racers performed explosive maximal voluntary isometric Ham/Quad contractions to obtain maximal torque (MVC), initial rate of torque development (initial RTD: 0-50, 0-100 ms), and late rate of torque development (late RTD: 0-150, 0-200 ms) [8]. Between-limb comparisons were made and a limb average for MVC and RTD (per kg body mass) was calculated for the control group to compare between sexes, and to compare the control group with the affected and unaffected limbs of the ACLR skiers [7]. Ham/Quad MVC and RTD strength-ratios were also compared [8]. **Results** The ACLR limb demonstrated significant Ham/Quad deficits compared to the contralateral limb for MVC and late RTD ($P<0.05$). Healthy male skiers also displayed a limb difference for Ham MVC and RTD at 150 ms ($P<0.05$). Significant Quad explosive strength and MVC deficits were found in the affected limb of ACLR skiers compared to the control group ($P<0.05$). Compared to males, healthy females displayed an elevated strength-ratio and Ham initial RTD (50 ms) ($P<0.05$). **Discussion** The primary finding was evidence of significant Ham/Quad maximal strength and explosive-strength deficits in the affected limb of actively competing ACLR skiers despite full return to sport. Healthy males displayed between-limb hamstring strength deficits, which differs from other reports [4]. Healthy females displayed elevated Ham/Quad strength-ratio (50 ms) suggesting enhanced ACL protection [8]. As Ham/Quad strength deficits are associated with ACL injury [7, 8] and are important for ski performance [3, 4] future research is required to assess the relationship between Ham/Quad strength deficits and ACL injury/re-injury risk. **References** [1] Bere et al, *Am J Sports Med* 39, 2011; [2] Flørenes et al, *Br J Sports Med* 43, 2009; [3] Hintermeister et al, *Med Sci Sports Exerc* 27, 1995; [4] Neumayr et al, *Int J Sports Med* 24, 2003; [5] Palmieri-Smith et al, *Clin J Sports Med* 27, 2008; [6] Pujol et al, *Am J Sports Med* 35, 2007; [7] Thorlund et al, *Arth Care Res* 62, 2008; [8] Zebis et al, *J Strength Cond Res* 25, 2011

THE EFFECTS OF SOCCER MATCH SIMULATION ON FUNCTIONAL HAMSTRING TO QUADRICEPS RATIO AND PEAK KNEE ABDUCTION MOMENTS IN SIDE CUTTING

Raja Azidin, R.M.F., Pykett, J., Scanlon, E., Bradburn, H., Robinson, M.A., Vanrenterghem, J.

Liverpool John Moores University

Introduction The reduction in eccentric hamstrings (Hecc) and concentric quadriceps (Qcon) strength and improper mechanics in side cutting manoeuvres during soccer match fatigue have been shown to be a potential predisposing factor for anterior cruciate ligament (ACL) injury (Delextrat et al., 2011; Sanna et al., 2008). This study focused on how the fatiguing effects of a treadmill (TM) versus an over-ground (OG) match simulation affected hamstring and quadriceps ratio and peak knee abduction moments during side cutting. **Methods** In a single-group repeated measures design, 15 healthy female participants completed 45 min TM and OG soccer match simulations with similar running velocity profiles. Prior to exercise (time 0 min), at half time (time 45 min) and 15 min post exercise (time 60 min) participants performed either five maximal dominant limb isokinetic contractions at 120 deg/s for Qcon and Hecc or five trials of anticipated 45° side cutting manoeuvres. Heart rate (HR) and rate of perceived exertion (RPE) were recorded every 5 min throughout the simulation. **Results** The HR and RPE were significantly greater during the OG than during the TM simulation ($P<0.01$). A significant time dependent reduction in Hecc at time 45 min (9.3%), time 60 min (12%) and functional Hecc:Qcon ratio at time 45 min (8.5%) was observed in the OG simulation only ($P<0.05$). There were no significant changes in Qcon and peak knee abduction moments during both simulations ($P>0.05$). **Discussion** The greater physiological changes imposed in the OG than the TM simulation may be due to high accelerations, decelerations and a broad range of utility movements. The close similarities observed during the present study with physiological values reported from actual match-play support the accuracy of the OG simulation at replicating the demands of soccer. The reduction in Hecc peak torques and functional Hecc:Qcon ratio may help explain the reported increased predisposition to ACL injury during the last 15 min of first halves of match play (Hawkins et al., 2001). Unchanged peak knee abduction moments indicate that these females had an appropriate strategy for performing anticipated side cuts and avoiding excessive knee loading after 45 min of match-play. These results suggest a greater risk of ACL injury in females at the end of the first half due to muscular imbalance rather than an adverse frontal plane knee loading mechanism. **References** Delextrat A, Baker J, Cohen DD, Clarke ND (2011). *Scan J Med Sci Sport*, 23, 1-9 Hawkins RD, Hulse MA, Wilkinson C, Hodson A, Gibson M (2001). *Brit J Sport Med*, 35, 43-47 Sanna G, and O'Connor, KM (2008). *Clin Biomech*, 23, 946-954 Contact R.M.Raja-Azidin@2011.ljmu.ac.uk

ANTICIPATORY POSTURAL ADJUSTMENTS TO PREDICTABLE PERTURBATIONS IN INDIVIDUALS WHO UNDERWENT ACL RECONSTRUCTION

Labanca, L.1, Laudani, L.1, Casabona, A.2, Menotti, F.1, Mariani, P.P.1, Macaluso, A.1

1: *University of Rome "Foro Italico" (Rome, Italy)*, 2: *University of Catania (Catania, Italy)*

Introduction Anticipatory postural adjustments (APAs) help to actively stabilize limb segments in response to expected perturbations during voluntary movement (Massion et al., 1999). It has been shown that APAs of the lower limb muscles acting around the knee joint are altered for years after surgical reconstruction of the anterior cruciate ligament (ACLR) with patellar tendon (Gokeler et al., 2010). Early identification of abnormal APAs following ACLR is paramount in order to design appropriate rehabilitation protocols and prevent re-injury.

The aim of the study was to investigate APAs to predictable perturbations of the knee joint during the early phase of rehabilitation two months after ACLR. Methods Ten predictable perturbation trials were administered to the operated knee of 9 patients with ACLR and to the dominant knee of 10 healthy volunteers. During each trial, participants were sitting on a table with the leg fully extended, which was supported by the contralateral limb. After a verbal signal of the experimenter, participants were asked to quickly move away the supporting limb, while maintaining the involved limb in full extension. Surface electromyography was recorded in the vastus lateralis (VL), rectus femoris (RF) and biceps femoris (BF) muscles of both limbs. Amplitude and latency of anticipatory activations of the VL, RF and BF of the involved limb were measured with respect to the onset of movement, which was identified as the offset of the VL in the supporting limb. Results There were no significant differences in the amplitude of anticipatory muscle activations between patients with ACLR and healthy participants. Latencies of anticipatory muscle activations were significantly higher in patients with ACLR than in healthy participants for the VL (83.5 ± 45.1 vs 25.8 ± 21.2 ms; $P < 0.05$), RF (59.2 ± 48.6 vs 10.4 ± 13.5 ms; $P < 0.05$) and BF (71.6 ± 42.4 vs 12.5 ± 14.1 ms; $P < 0.05$). Discussion Two months after surgery patients with ACLR showed abnormal APAs of the knee extensor and flexor muscles to predictable postural perturbations. The higher latency of anticipatory muscle activations in patients with ACLR than in healthy individuals may be a strategy to minimize postural disturbances and preserve functional stability prior to a forthcoming self-initiated movement. Further studies are needed to evaluate whether appropriate rehabilitation protocols may help to reverse the early abnormalities in APAs of the lower limb muscles. EFFECT OF THE USE OF A PATELLAR STRAP OR SPORTS TAPE ON PATELLAR TENDINOPATHY SYMPTOMS

de Vries, A.J., van den Akker Scheek, I., Tak, I., van Cingel, R., Diercks, R.L., van der Worp, H., Zwerver, J.

University of Groningen, University Medical Center Groningen

Introduction Numerous athletes with patellar tendinopathy (PT) use a patellar strap or sports tape during sports to reduce their pain. To our knowledge there is no scientific evidence supporting the use of these orthoses in this common overuse injury. The aim of this study was to investigate the effect of wearing a patellar strap or sports tape on pain in athletes with PT during functional tests. Methods In a randomized controlled crossover experiment, active volleyball and basketball players with symptomatic PT were included. All participants performed three functional patellar loading tests (single leg decline squat, counter movement jump, and triple hop test) under four different conditions: control, patellar strap, sports tape, and placebo (kinesiotape administered in a non-functional way). The order of the conditions was randomized and balanced between subjects. The visual analogue scale (VAS, 0-100 mm) for pain was used to quantify the amount of pain experienced by the subjects during the tests. A difference of 12 mm was considered clinically relevant (Kelly 2001). Results A total of 35 basketball and volleyball players (60% male, age 26.1 (SD 6.8), VISA-P 58.3 (SD 11.9)) were analyzed. The largest effect of orthoses on pain was found when athletes performed 10 single leg decline squats. We found an average reduction of 8.5 (95% CI 2.7 – 14.2) and 5.0 (95% CI 0.7 – 10.8) mm on the VAS pain score in the patellar strap and sports tape condition, compared to control during this test and a reduction of 5.6 (95% CI -0.5 – 11.4) and 2.3 (95% CI -3.4 – 8.1) mm compared to placebo. Only the difference between the patellar strap and the control condition was statistically significant. Twelve of the 35 subjects showed a reduction in VAS pain score of 12 mm or more in the patellar strap condition compared to control on the single leg decline squat test. Discussion This study shows that in athletes with PT the use of a patellar strap during patellar tendon loading results in significant lower VAS pain scores. However, despite our finding that one third of the athletes experienced a clinically relevant reduction of pain, it should be concluded that on average the orthoses cause no noticeable decrease in pain. The fact that the placebo intervention led to a small reduction in pain scores also questions the effectiveness of these orthoses. Further research should focus on which athletes might benefit from wearing a strap/tape. References Kelly, A. (2001) The minimum clinically significant difference in visual analogue scale pain score does not differ with severity of pain. Emergency Medicine Journal 18: 205-207 Contact a.j.de.vries02@umcg.nl

RETURN TO SOCCER AFTER ACL RECONSTRUCTION – CONSENSUS FINDING PROCESS OF A MULTIFACETED TEST BATTERY

Bloch, H.

German Social Accident Insurance Institution for the administrative sector, Hamburg (Germany)

INTRODUCTION: Especially before huge sport events, like the FIFA World Cup, time based forecasts about the return of important players after a serious injury appear in sports media. As a result of this, team physicians often are confronted with internal and public pressure asking for an early return of the player to the pitch (Best 2011). When analyzing injuries in professional soccer injuries of thighs and knees are most frequent (Faude 2009, Klein 2013), but especially ACL ruptures are accompanied by high medical costs and days of disability. This is aggravated by the fact that a previous ACL injury represents the greatest risk factor of a recurrence injury. Until now standardized and practical progressive test methods for an optimal return to training and competition are missing. AIM: This consensus finding process intends to determine the best-practice of return to professional soccer after an ACL reconstruction. METHOD: With a systematic literature review different approaches giving return to soccer (further keywords: sport, activity, competition, play) recommendations were compared. Via PubMed and Google Scholar articles with one of the following inclusion criteria were searched: a) report about risk factors which predict a non-successful return to sport after ACL-reconstruction b) report of a return to sport measurement c) analyzes of the relationship between the measurement and a successful return to sport. Additionally, an internet research was used to identify already implemented examples in professional soccer. RESULTS: Hop tests were the most commonly used functional tests (Abrams et al. 2014). Consensus exists about using a combination of different types of hop tests and the important role of side cutting measurements (Kristianslund & Krosshaug 2013, Werner 2013). Furthermore additional testing under fatigued conditions is suggested to identify limb and biomechanical asymmetries (Di Stasi 2013, Werner 2013). Nevertheless, a consensus for a suitable limb symmetry index is still missing. Principally protocols of test batteries should identify deficits in both lower limbs (Di Stasi 2013). In addition to that, strength and flexibility measurements are recommended (Petersen 2012, White 2013, Gomes 2014). Moreover psychological factors are predictive of ACL reconstruction outcomes (Arden 2013, Everhart 2013). Therefore a psychological screening should be included into the test battery. Gait patterns show significant correlations to success of current return to sports criteria (Ziogas 2011, Di Stasi 2013, Gokeler 2013), thus movement analysis as an outcome measurement is recommended. CONCLUSION: Progressive and assessment based criteria within a multifaceted test battery will help to reduce pressure on medical teams and athletes. A consensus workshop with stakeholders consisting of team physicians, physiotherapists, sport psychologists and research groups may help to combine the best elements of the reviewed tests, questionnaires and algorithms.

OP-PM47 Exercise & Cooling

EFFECT OF REGULAR POST-EXERCISE COOLING ON MUSCLE AEROBIC ADAPTATIONS TO ENDURANCE TRAINING.

Ihsan, M.1, Watson, G.2, Hui, C.C.1, Govus, A.1, Pham, T.3, Hickey, A.3, Markworth, J.3, Cameron Smith, D.3, Abbiss, C.R.1
1: ECU (Perth, Australia), 2: UTAS (Tasmania, Australia) 3: UA (Auckland, New Zealand)

Introduction Cold water immersion (CWI) is a popular technique used to enhance post-exercise recovery (Ihsan et al. 2013). Recently, it was shown that a single CWI intervention enhanced the post-exercise mRNA expression of PGC-1 α (Ihsan et al. 2014), a master regulator of muscle oxidative adaptations to endurance training. However, effect of regular CWI interventions on longer term oxidative adaptations to training are yet to be elucidated. The purpose of this study was to investigate the effect of repeated post-exercise CWI on muscle aerobic adaptations to endurance training. **Methods** Ten males performed 3 sessions/week of endurance training for 4 weeks. Following each session, subjects immersed one leg in a cold water bath (10°C; CWI) to the level of their gluteal fold for 15 min while the contralateral leg served as control (CON). Prior to, and following the training intervention, subjects performed a graded running test to exhaustion to determine their maximal oxygen uptake (VO₂max) and aerobic speed (MAS). Muscle biopsies were obtained from vastus lateralis of both CON and CWI legs prior to training and 48 h following the last training session and analysed for markers associated with aerobic adaptations. Significance was accepted at $p < 0.05$. **Results** VO₂max was improved by 5.4% and MAS was improved by 6.4% following training. Repeated CWI resulted in higher content of phosphorylated AMPK, phosphorylated ACC and the protein expression of respiratory chain complex 3 when compared with CON. However, no training effects were observed in the protein expressions of PGC-1 α and respiratory chain complexes 1, 2, 4 and 5. Additionally, no training effects were observed in the enzyme activities of citrate synthase, succinate dehydrogenase and carnitine palmitoyltransferase. **Discussion** This is the first study to demonstrate enhanced AMPK activity following regular post-training CWI treatment. However, its effect on mitochondrial biogenesis is unclear, as only complex 3 protein expression was significantly enhanced in the CWI leg. While further research is needed to elucidate the mechanisms by which post-exercise CWI activates AMPK, it is plausible that cold induced adrenergic activation was responsible for the increased AMPK activity (Tadaishi et al. 2011). **References** Ihsan M, Watson G, Lipski M, Abbiss C R. A DURATION-DEPENDENT RESPONSE TO ISOLATED LEG COOLING EXISTS FOR INTERMITTENT-SPRINT EXERCISE IN THE HEAT

Smith, D., Ross, E., Watt, P., Maxwell, N.

University of Brighton

Introduction: Leg precooling has been used as an effective ergogenic aid to reduce the negative effects of heat stress that are exacerbated during intermittent sprint exercise. An assumption exists that longer cooling durations may elicit greater benefits through creation of a larger heat sink. The aim of this study was to determine the optimal duration of a single bout of precooling on intermittent sprint performance in the heat. **Methods:** Twelve males, free from any heat or cold exposure (age 22 \pm 2 yrs, height 178.1 \pm 3.9 cm, body weight 76.7 \pm 7.5 kg, sum of four skinfolds 40.4 \pm 3.9 mm, peak oxygen consumption 44.9 \pm 6.1 mL/kg/min) completed five cycling intermittent sprint protocols (CISP) in a randomised order on separate days. The CISP comprised of 20 sets of 10s passive rest, 5s max sprint against 7.5% body weight and 105s active recovery against 35% peak oxygen uptake. Each CISP was preceded by a cooling period of 10, 15, 20, 25 min and a no-cooling control. Peak power output (PPO) and work done (WD) were measured throughout each CISP, alongside the measurement of skin (T_{sk}) and core (T_c) temperature. Muscle temperature (T_{mu}) was measured pre cooling and post exercise. **Results:** Average PPO and WD improved in the 15 and 20 min conditions only ($P < 0.05$). 15 min saw the largest improvements (3.8% and 6.7%, respectively) compared to the Control ($P < 0.05$) but was lowest after 25 min of cooling. T_c during precooling remained unchanged in all trials, but 15 min displayed the slowest rate of T_c rise during the CISP compared to the Control (Control, 0.07 \pm 0.01 degrees/sprint; 15min, 0.05 \pm 0.0 degrees/sprint, $P < 0.05$). Mean T_{sk} was unchanged during all precooling trials yet thigh T_{sk} was lower than the Control in all conditions ($P < 0.05$). 15 and 20 min cooling reduced thigh T_{sk} more than 10 min ($P < 0.05$) yet further cooling provided no additional reduction (Control, 30.7 \pm 1.3; 10min, 13.6 \pm 6.3; 15min, 9.4 \pm 3.3; 20min, 9.2 \pm 3.2; 25min, 11.4 \pm 3.9 degrees C). T_{mu} reduced the most for longer durations. Post CISP T_{mu} was only lower than the Control after 15 min cooling with additional periods of time not reducing T_{mu} further (Control, 38.5 \pm 1.2; 10min, 37.9 \pm 1.4; 15min, 37.5 \pm 1.8, 20min, 37.6 \pm 1.8; 25min, 38.2 \pm 1.4 degrees C, $P < 0.05$). **Discussion:** Findings from this study suggest that 15 min was the optimal duration of localised cooling for improvements in PPO and WD during intermittent sprint exercise in the heat. Cooling for shorter durations may not offer sufficient suppression of thermo-physiological responses before exercise in the heat, while longer durations of cooling may result in too great a thermo-physiological offset to optimise intermittent sprint performance.

SYMPATHETIC RESPONSES TO COMBINED COLD STRESS AND ISOMETRIC EXERCISE IN HEALTHY AGED HUMANS

Greaney, J.L., Kenney, W.L., Alexander, L.M.

Pennsylvania State University

Cardiovascular-related morbidity/mortality increase in cold weather, and physical activity in the cold may increase cardiovascular risk more than cold exposure alone. Healthy human aging is associated with altered neurovascular responses to whole-body cooling; however, the influence of age on sympathetic nerve activity (SNA) during combined cold stress and isometric exercise is not well understood. We hypothesized that cold stress would (1) increase SNA at rest and (2) augment the SNA response to exercise in older, but not young, adults. Whole-body cooling using a water-perfused suit induced reflex vasoconstriction in 8 young (24 \pm 1 yr; resting blood pressure (BP) 111 \pm 2/71 \pm 2 mmHg) and 8 healthy older adults (63 \pm 2 yr; resting BP 118 \pm 3/73 \pm 4 mmHg) by lowering mean skin temperature (T_{sk}) from

34°C to 30.5°C. BP (Finometer) and muscle SNA (MSNA; peroneal microneurography) were measured continuously throughout cooling and during isometric handgrip at 30% maximal voluntary contraction performed at Tsk=34°C and 30.5°C. Neither mean BP at Tsk=34°C (87 ± 2 young v. 90 ± 3 older mmHg; $P=0.56$), nor the increase in mean BP during cooling ($\Delta 5 \pm 1$ young v. $\Delta 7 \pm 1$ older mmHg; $P=0.35$), were different between age groups. MSNA at rest was greater in older adults at Tsk=34°C (14 ± 3 young v. 25 ± 3 older burst/min; $P<0.05$). Additionally, MSNA increased during cold stress in older, but not young, adults ($\Delta 0 \pm 1$ young v. $\Delta 11 \pm 2$ older burst/min; $P<0.05$). During static handgrip, the increases in mean BP and MSNA were not different between groups at Tsk=34°C ($\Delta 22 \pm 3$ young v. $\Delta 21 \pm 3$ older mmHg; $\Delta 14 \pm 3$ young v. $\Delta 12 \pm 2$ older burst/min; both $P>0.05$) or 30.5°C ($\Delta 20 \pm 4$ young v. $\Delta 18 \pm 3$ older mmHg; $\Delta 12 \pm 2$ young v. $\Delta 9 \pm 2$ older burst/min; both $P>0.05$). Contrary to our hypothesis, concomitant cold stress did not alter the sympathetic responses to static handgrip in either age group. These data indicate that although the MSNA response to cold stress alone is augmented in older adults, the sympathetic response to handgrip during cold stress is not exaggerated, which suggests preserved sympathetic regulation during exercise in the cold in healthy aging. SKIN TEMPERATURE DISTRIBUTION AND CORE TEMPERATURE IN PASSIVE COOLING AND EXERCISE: THE INFLUENCE OF BODY FAT

Fournet, D.1, Griggs, K.3, Redortier, B.1, Havenith, G.2

1: Oxyane Research (Villeneuve d'Ascq, France), 2: Environmental Ergonomics Research Centre (Loughborough University, UK), 3: Peter Harrison Centre for Disability Sport (Loughborough University, UK)

Introduction Few studies have investigated the local influence of body fat and its distribution on body temperatures, at rest (Livingstone et al., 1987) or in exercise over a wide body fat range (Fournet et al. 2013). It has been suggested that heat dissipation strategies vary locally between obese and lean people during exercise in a thermoneutral environment (Savastano et al. 2009). The aim of the study was to evaluate the role of body fat in a cold environment where its contribution to thermoregulation is more determinant. **Methods** Twenty healthy and semi-nude males sat still for 60-min on a stool followed by 30-min of cycle ergometry (100W). Both phases were performed in a 10°C, 50%rh climatic chamber. Three groups of body fat%, but similar fitness level, were created (Low Fat (LF) 5-10%, Medium Fat (MF) 10-15% and High Fat (HF)>15%) with a total range varying from 7 to 40 %BF. Skinfold thickness was assessed at 24 regions over the body. Skin temperature (Tsk) was measured by infrared thermography and thermal whole-body maps were created (Fournet et al., 2013). Rectal temperature (Tre) and metabolic heat production (W/m², from VO₂) were assessed throughout the protocol. **Results** Thermal maps revealed consistent patterns of Tsk distribution between groups, though shifted to colder Tsk the higher the body fat%. Trunk regions were consistently warmer than limbs (>8°C Tsk difference). A V-shape isotherm was observed over the anterior torso. Within a body map, Tsk distribution was not correlated with the distribution of skinfold thickness. Exercise-induced rewarming over the active quadriceps was more pronounced in LF (+2.0°C, $p<0.05$). A significant effect of body fat was observed on mean Tsk and Tre dynamics, especially during exercise. Notably for HF, mean Tsk dropped by an additional 1°C (constant for LF and MF) and Tre increased immediately up to 37.5°C (unlike LF and MF) during cycling while heat production was similar between groups ($p>0.05$). **Discussion** Our results indicate that body fat influences absolute body temperatures and their dynamics in the cold. Locally, fat thickness is a predictor of Tsk (between individuals), however the bodymapping approach revealed that a thermal map does not rely on the variations of fat thickness within the person as hypothesized by LeBlanc (1954). Insulation provided by unperfused muscles and circulatory adjustments are strong contributors to the Tsk pattern. Excessive body heat was dissipated through the hands for obese (Savastano et al. 2009) even in the cold whereas heat production and dissipation was facilitated in lean people through active muscles. **References** LeBlanc J. THE EFFECT OF PRECOOLING IN DYNAMIC BALANCE ABILITY

Gkrilias, P.1, Geladas, N.1, Nassis, G.1, Koskolou, M.1, Manolaki, N.1, Athanasopoulos, S.1

National and Kapodistrian University of Athens

Introduction Precooling is used as a method for increasing performance in athletes competing in an environment with high thermal load (Marino 2002, Quod et al. 2006). However, the effect of pre-cooling on dynamic balance ability has not been adequately studied. The purpose of this study was to examine whether whole body immersion in cool water can affect short-term dynamic balance ability. **Method** Ten healthy male volunteers (age: 23.2 ± 2 years, body mass: 77.6 ± 6.4 kg, body fat: 12 ± 2.7 %) participated in the present study. Dynamic balance ability was assessed by performing the multiple single leg hop test (Riemann et al. 1999) on two occasions: without (Contr) or with pre-cooling (Pcool) maneuver. Pre-cooling involved 30 minutes immersion of the whole body, except one forearm, in water (16-18 °C). Dynamic balance ability (Test 1) was evaluated in thermo-neutral environment (19-22°C) before each condition (Pcool or Contr). Subsequently subjects warmed-up on a cycle ergometer (60 Watts) for 5 min in an environmental chamber (temperature: 31-33 °C, humidity: 40-50% rh) and immediately after they performed again the dynamic balance ability test (Test 2) in the chamber. The dynamic balance ability was evaluated by recording the landing and balance errors, as well as the total errors during the test. Body rectal temperature (Tre), temperature of the finger (Tfin) and thermal sensation (Tsen) were recorded throughout the experiment. **Results** Tfin and Tsen were lower in the Pcool than in the Contr condition (24.3 ± 0.94 vs. 32.83 ± 2.59 °C, and 3 ± 0.5 vs. 5 ± 0.35 , respectively), whereas Tre was not different (0.03 ± 0.25 vs. 0.12 ± 0.11 °C drop, respectively). In test 2, higher landing errors ($p=0.051$), balance errors ($p=0.036$) and total errors ($p=0.018$), were observed in Pcool compared with the Contr condition. **Discussion** Low finger temperature and low score in cold sensation, probably affecting neuromuscular function, resulted in high balance errors observed in the present study. Such deficits in balance may increase the risk for musculoskeletal injuries. Therefore, application of this specific pre-cooling method should be cautiously used. **References** Marino FE. (2002). THE INFLUENCE OF LOCAL CRYOTHERAPY AND MANUAL LYMPHATIC DRAINAGE ON RECOVERY PARAMETERS AND MUSCLE ENZYMES AFTER EXHAUSTING ECCENTRIC EXERCISES

Jedlicka, D., Behringer, M., McCourt, M., Mester, J.

Institute of training science and sport informatics

Introduction Enhanced recovery processes particularly after intensive exercises combined with short resting periods influence athletes' performance positively and have thus been a major aim in sports medicine. Although numerous regeneration modalities are applied in

practice, only few of them are based on good scientific investigations (Bleakley et al., 2012; Lubkowska, 2012). The objective of this study was to investigate, if two well-known and widely-used physical therapies, manual lymphatic drainage and local hypothermia enhance the rate of recovery and reduce symptoms of delayed onset of muscle soreness compared. Methods 4 x 20 single leg eccentric contractions were performed by 30 subjects. Afterwards they randomly received either 30min manual lymphatic drainage (MLD), local hypothermia (CRY) or rest (RST). Maximal voluntary contractions (MVC) and electrically induced tetani (EIT) at low (20Hz) and high (100Hz) frequencies, impulse widths (150µs vs. 400µs) as well as specific muscle enzymes and pain sensations were tested pre, post, 1h, 4h and 24h post exercise (Behringer et al. (in preparation 2014)). Results Neither MLD nor CRY improved recovery processes, measured as MVC, EIT and pain sensations and did thus not show differences to RST. Likewise, these outcomes resulted for the parameters pain, CK, h-FABP, urea, LDH and neutrophil granulocytes. Discussion The present data do not support the use of MLD or CRY during recovery from damaging exercises when applied for 30 min. However, other case and pilot studies showed positive effects of CRY (Nemet et al., 2009) and MLD (Schillinger et al., 2006) when applied in conjunction with other intervention treatments. Different results could derive due to varying treatment periods and post intervention measurement time points. IS-PM15 Ultra endurance exercise; physiological limitations and performance

THE TEFR-PROJECT: ADAPTATION AND TOLERANCE TO EXTREME ULTRA ENDURANCE EXERCISE

Schütz, U.

University Hospital of Ulm

Purpose: In the TEFR-project 44 participants were accompanied during the ultramarathon TransEurope FootRace (TEFR) by a mobile 1.5 T MRI mounted on a 40-tonnes truck when running 4,500 km in 64 days without any day rest. They got differentiated MR-measurements regarding body composition, brain lesions and volume distribution and the cartilage of lower extremity. Methods and Materials: During the TEFR the got repeated MRI in regular intervals with specific protocols: A T1w TSE-sequence was used for whole body MRI. For topographic tissue segmentation and mapping a modified fuzzy c-means algorithm was used. A semiautomatic postprocessing allowed reliable analysis of: Total, somatic and visceral adipose (TAT,SAST,VAT) and lean (TLT,SLT,VL) tissue volumes. A volumetric 3D dataset on brain volume was performed using a MP-RAGE sequence. For detection of brain lesions MRI data consisting of DWI-EPI and FLAIR sequences were acquired. For the quantitative biochemical evaluation of lower extremity joint cartilage a T2* GRE-sequence was used. T2*-relaxation times were obtained from online reconstructed T2*-maps by using a pixelwise, monoexponential nonnegative least squares fit analysis. For detection of osteochondral lesions an additional TIRM and fat saturated PD sequence were done. Results: Adipose tissue showed a significant decrease for TAT, SAST and VAT. Lean tissues decreased until the end of the race, but not significantly. The mean relative volume changes were: TAT-41.3%, SAST-48.7%, VAT-64.5%, intraabdominal adipose tissue -67.3%, mediastinal adipose tissue -41.5%, TLT-1.2%, SLT-1.4%. Grey matter volume before the run had a mean of 641 ml. After 2,500 km the grey matter volume had decreased 26 ml and after 4,000 km 38 ml. After 6 months, the follow up showed restored grey matter volume. There was no brain edema and there were no lesions in the DWI. The amount of brain lesions and lesion volume showed no significant change. There were significant increases of mean T2*-values detectable in all cartilage layers of all evaluated joints during the TEFR. We found relevant decreasing of mean T2*-values in the cartilages of joints with axial loading after 2,000 km distance run. No relevant morphological changes were seen for any of the investigated joints. Conclusion: Even lean tissue volume (mainly skeletal muscle) decreased due to the unpreventable chronic negative energy balance during TEFR. VAT has the fastest and highest decrease compared to SAST and lean tissue compartments during the race and seems to be the most sensitive morphometric parameter regarding the risk of non-finishing a transcontinental ultramarathon. The measured brain volume loss was 100 fold compared to the expected natural decline. The brain volume reduction was not uniform but took place mainly in secondary optical areas. It could be shown for the first time in vivo that after early degradation human cartilage matrix is able to develop anabolic changes with recovery of GAG and collagen under ongoing multistage ultramarathon burden in axial loaded lower extremity joints.

ENVIRONMENTAL INFLUENCES ON ULTRA-ENDURANCE ATHLETES

Cotter, J.D.

University Of Otago

As if the extreme stress of ultra-endurance exercise, sometimes with severe sleep deprivation, isn't enough of a challenge, such exercise is often performed in extreme environments (e.g., Marathon des Sables, Hawaii ironman, transcontinental polar expeditions). The importance of environmental influences on human performance and health is apparent from how readily they can cause impairment or termination of exercise; e.g., via bacteria-induced illness, hypoxia-induced pace reduction or acute mountain sickness, severe hypohydration from lack of water, or trench foot or hypothermia from excessive water. The increasingly popular ultra-endurance sport of open-water swimming, with races up to 25 km, may take place in water of 16°C through to 32°C and thereby cause high physiological and psychophysical strain and impair performance. While absolute performance is typically impaired by environmental stress, relative performance (placing) may be markedly improved for those who are prepared genetically, habitually or technologically – all of these being important but not always possible. Most environments impose multiple stressors, which can have additive effects on human physiology,

welfare and success, e.g., the Antarctic plateau, at ~3000 m, imposes cold, mild hypoxia, and lack of water and food, which may act collectively to reduce muscle function. Both exercise and sleep deprivation can impair the regulatory systems that act against environmental stressors, such as thermoregulation against both heat and cold stress, but the functional effects are surprisingly small given the number of processes that are impacted on. An environmental influence, perhaps seldom considered, that has several marked effects on ultra-endurance athletes is gravity. Its muscle-damaging effects caused by prolonged eccentric exercise are intuitively recognisable, but also likely to be modest and self-limiting. The prolonged orthostatic stress of gravity may be less intuitive; it leads to lower-limb oedema and rapid expansion of plasma volume, by a surprisingly consistent and substantial 20-25% in many settings. Yet, orthostatic tolerance is greatly reduced because of diminished baroreflex sensitivity and hyperventilation-induced hypocapnia. Thus, environmental influences are integral to ultra-endurance exercise, and may not all be obvious. They exert a wide variety of substantial effects that can impair performance or health in absolute terms, but also enhance the experience for those who are prepared.

FACTORS DETERMINING ULTRA-ENDURANCE EXERCISE PERFORMANCE

Mattsson, C.M.

Åstrand Laboratory of Work Physiology, The Swedish School of Sport and Health Sciences

Introduction This talk will focus on the major nutritional and physiological factors that influence ultra-endurance exercise performance in both recreational and elite athletes. Empirical observations show that athletes who have been engaged in ultra-endurance sports for several years have a large advantage compared to novices in the sport. It depends of course in part on the fact that they are more experienced, but even athletes from traditional endurance sports with a documented higher aerobic capacity (i.e., higher VO₂max) have difficulties to keep up with ultra-endurance specialists when exercise duration exceeds three or four hours. This indicates that fatigue and performance in ultra-endurance exercise is determined by (in part) other factors compared to traditional endurance sports. Ultra-endurance sports vary in form and duration, such as running or adventure racing (AR) from 6 h to more than 6 days, but are no matter the nature of the specific competition still in many aspects extreme sports. The athletes do not generally need to perform at high maximum speeds, but the energy expenditure is extremely high. The total energy expenditure for a 24-h AR is approximately 18-20 000 kcal, which is almost 10 times more than normal basal metabolism (Enqvist et al. 2010). One reason for fatigue is that the energy deficit is substantial, also the profile of amino acids in blood and muscle change during races (Borgenvik et al. 2012), indicating that specific supplementations may be needed. As for the physiological factors, our research group and collaborators have investigated many aspects of the versatile physiological adaptation to ultra-endurance exercise, such as circulatory adaptations and cardiac fatigue (Mattsson 2011, Mattsson et al. 2010, 2011) muscular damage (Wichardt et al 2011, Marklund et al 2013), hormonal status (Berg et al 2008), and immunological response (Wallberg et al 2011), which all in various ways can contribute to fatigue and decreased performance. The effect of sleep deprivation on both mental and physiological functions during the races must also be included in the total complex of factors limiting performance. References Berg U et al. IS-BN10 What do we know about intermuscular force transmission?

IMPORTANCE OF INTERMUSCULAR CONNECTIVITY FOR IN VIVO MUSCLE FUNCTION AND NEUROMUSCULAR CONTROL

Maas, H.

VU University Amsterdam

The physiological significance of epimuscular myofascial force transmission is still subject to considerable debate. Invasive animal studies have shown that skeletal muscles are linked to each other and to non-muscular surrounding structures by connective tissues that are capable of transmitting muscle fiber force. This link suggests that the different muscles involved in a particular movement cannot be considered as independent functional entities. The functional relevance of this newly discovered phenomenon is dependent on the magnitude of the effects found during normal movements. However, many experimental conditions in the above mentioned studies were supra-physiological, i.e. different from the conditions under which muscles function in vivo. In the last few years, we have investigated the effects of muscle connectivity for the transmission of triceps surae muscle forces onto the skeleton in the rat. In addition, we have assessed the effects of muscle connectivity on feedback from muscle receptors and the consequences for neuromuscular control. Triceps surae consists of three muscles (m. gastrocnemius medialis and lateralis, and m. soleus) with different independent origins but inserting together as the Achilles tendon into the calcaneus. Even though three fascicles can be distinguished, dissection of each tendon fascicle in rat becomes progressively more difficult towards the calcaneus, suggesting that these fascicles unite in one tendon. Besides this shared distal tendon, the triceps surae are mechanically linked via connective tissues at their shared muscle belly interface (i.e., epimuscular myofascial linkages). Both structures link the action of one muscle to its adjacent synergists. Via epimuscular linkages, muscle fiber force can be transmitted to the tendon of a neighboring muscle. Via a common tendon, force exerted by one muscle affects the length at which muscle fibers in the adjacent muscle are contracting. An update of recent results that indicate the importance of muscle connectivity for the mechanical and sensory function of rat triceps surae muscles will be presented. Supported by NWO-ALW Grant 864-10-011.

THE EXTENT OF INTERMUSCULAR FORCE TRANSMISSION IS MUSCLE AND ACTIVITY DEPENDENT

Finni, T.

University of Jyväskylä

Few *in vivo* human studies have investigated myofascial force transmission between synergistic muscles using ultrasound imaging techniques. Focusing on the plantar flexor muscles, (Bojsen-Moller et al, 2010) selectively stimulated the medial gastrocnemius (MG) muscle and measured, using ultrasound, the relative muscle motion between the synergistic soleus (SOL), MG and flexor hallucis longus muscles. The results suggested that forces can be transmitted between SOL and MG. However, the results were not clear if there could be force transmission between SOL and deeper plantarflexor muscles. The role and importance of this force-transmission was further examined by (Tian et al, 2012) who estimated that the magnitude of force that is transmitted between passive muscles only a few Newtons (<5N). They suggested that this low level of force is unlikely to have much functional relevance. However, when muscles are activated the magnitude of myofascial force transmission may be greater because of the increased stiffness of the structures. Specifically, (Lieber et al, 2000) showed that activation can increase aponeuroses stiffness *in vitro*, which then likely influence force transmission at the muscle interface. More recently, (Azizi and Roberts, 2009) showed in an *in situ* preparation that aponeurosis strain is different between active and passive conditions. *In vivo*, the aponeurosis has connections to the surrounding tissues and upon activation the stiffer aponeurosis can act as significant force transmitting medium (cf. Huijing, 2009; Brown and McGill, 2009). In a recent study we examined the effect of activation per se on myofascial force transmission in humans *in vivo*. The results showed that the inter-aponeurosis shear between SOL and lateral gastrocnemius (LG) was decreased when stretch was applied in a condition where LG was selectively activated as compared to a passive stretch. This result supports the concept that muscle activation itself can stiffen the connective tissue between muscles. This activity-induced stiffening may enhance force transmission between muscles but can also magnify myotendinous force transmission (Kinugasa et al. 2013). Understanding the functionality of myofascial force transmission helps to shed light on the mechanical complexity of force transmission which cannot be captured precisely by simple models. VARIOUS HUMAN AND ANIMAL EXPERIMENTS SHOW SUBSTANTIAL INTERMUSCULAR FORCE TRANSMISSION EFFECTS, EXCEPT AMONG MUSCLES EXPOSED TO BOTULINUM TOXIN

Yucesoy, C.

Boğaziçi University

Animal experiments served our understanding of intermuscular force transmission effects (Yucesoy 2010). Bi-articular muscle tested in an intact compartment showed the characteristic and now classic effect of unequal proximal and distal muscle forces. Remarkable other effects were shown: muscle length-force characteristics are not unique properties of a muscle, but they can change due to intermuscular interactions. This implies that a muscle can produce a different amount of force at the same joint position depending on the mechanics of other muscles. Similarly, a muscle can exert force for a wider/narrower range of joint angles. This appears quite relevant for an athlete or for patients with movement disorders because in most cases the issue is to control the amount of muscle force available at certain joint positions. Modeled muscle mechanics indicates that intermuscular interaction is not solely part of force of one muscle being integrated in the force of another. Instead, myofascial loads of muscular and connective tissue origins take action and manipulate force production capacity of a muscle, locally, at the sarcomere level (Yucesoy & Huijing 2007). Magnetic resonance imaging analyses confirm such theoretically posed expectations, *in vivo*. Length changes of human m. gastrocnemius due to knee movement at fixed ankle angle cause variable magnitudes of local lengthening and shortening to co-exist within different locations of the muscle (Yaman et al. 2013). Moreover, this occurs also in other lower leg muscles despite being globally isometric. These findings suggest that even for conditions in which the net effect of intermuscular force transmission on forces exerted at the tendon would be small, local heterogeneous effects of myofascial loads may still be substantial. Recent imaging analyses indicate a heterogeneous deformation along the muscle fiber direction as well. Human muscle force measurements are rare. Yet, our intraoperative tests in physiologically attained knee angles show that spastic muscle's active force differs if an antagonist is co-stimulated whereas, if the spastic muscle is activated alone, its mechanics are not abnormal. Therefore, intermuscular force transmission is indicated as a key determinant of the movement disorder. BTX-A is common in treating spastic muscle. Animal experiments show that among muscles exposed to BTX-A intermuscular force transmission becomes diminished. This implying an unconsidered therapeutic effect is notable, but also as a unique exception for effectiveness of intermuscular interactions. References Yucesoy CA. 10:20 - 11:50**Invited symposia****IS-PM09 Cardiovascular Adaptation in Athletes: What's New? *****THE ATHLETE'S HEART: NEW TOOLS PROVIDE NEW INSIGHT INTO UPPER LIMITS OF CARDIAC ADAPTATION**

George, K.

Liverpool John Moores University

Knowledge of the upper limit of cardiac adaptation to physical training has interested sport and exercise clinicians and scientists for centuries. This data is important to: understand the cardiovascular contribution to elite athletic performance and to aid the differentiation of the athletic heart from cardiac diseases that increase the risk of sudden cardiac death. This latter issue has come into stark contrast recently with several high profile cases of (aborted) sudden cardiac death in athletes. As we have developed our understanding of the cardiac diseases that can result in SCD we now recognize that cardiomyopathies are of significant concern. Hypertrophic cardiomyopathy

presents with left ventricular hypertrophy (often regional and asymmetric) as well as functional changes and marked ECG variants. Arrhythmogenic right ventricular cardiomyopathy presents with changes to right ventricular structure and function as well as abnormal ECG patterns. Our ability to differentiate those with these diseases from the phenotypical expression of the athletic heart has required new and large data sets documenting indices of left ventricular, right ventricular and left atrial morphology. Further, novel developments in imaging technology (MRI and 2D myocardial speckle tracking) have allowed close interrogation of regional and global function in all heart chambers to aid differential diagnosis. This presentation provides a historical reflection on athletic heart research from the initial studies of Morganroth and colleagues and then details new technologies that are being used to assess and describe the athletic heart that may aid the differentiation of physiological adaptation from pathological changes, in the heart of athletes.

IS THERE AN "ATHLETE'S ARTERY"?

Green, D.J.

Liverpool John Moores University

For several decades the notion that athletes of different types (endurance versus strength) possess morphologically distinct hearts has held sway in the scientific literature. This notion owes much to the Law of Laplace and the idea that different forms of persistent and intermittent ventricular loading (volume vs pressure) may induce physiologically distinct types of cardiac hypertrophy (eccentric vs concentric). Anatomically, the peripheral vasculature and heart are contiguous and lined by similar cells (endothelium/epicardium), which are known to respond similarly to haemodynamic stimuli. This suggests the intriguing hypothesis that different types of athletes may exhibit fundamentally different forms of adaptation in conduit, resistance and microvessels. In this presentation, data regarding characteristics of the vasculature in different types of athletes will be reviewed, along with a critical appraisal of different methodologies used to assess arterial function and structure in humans. The potential relevance, in terms of performance and long term health, of different types of arterial adaptation will also be addressed.

THERMOREGULATION IN ATHLETES

Narihiko, K., Amano, T.

Kobe University

It is well known that heat loss responses associated with sweating and skin blood flow are improved by exercise training. The magnitude of the improvement of heat loss response is associated with 1) the level of maximal oxygen uptake ($\text{Vo}_{2\text{max}}$), 2) the degree of body temperature elevation and 3) the degree of activation of heat loss responses during exercise training. There are many types of exercise training for improving sports performance and it has been suggested that various types of exercise training may induce differential adaptations in thermoregulatory responses. For example, sprinters and distance runners exhibit different sweating responses. In addition, heat loss responses during exercise are controlled by thermal factors such as body temperature and non-thermal factors (central command, afferent signal from active muscle and so on). Thus, it is needed to evaluate the heat loss responses based on the both factors. In this presentation, the effect of different types of exercise training on heat loss responses associated with thermal and non-thermal factors will be reviewed.

ACTIVEARTH: THE AMERICAN PERSPECTIVE

Rankin, J.

Virginia Tech

Global carbon emissions, at a record high, are predicted to have profound negative effects on global health and economics. Physical inactivity is associated with chronic diseases that bloat the cost of health care. The challenges of exploding medical costs and climate change are not always recognized as being connected to transportation and physical activity. However, about one-third of greenhouse gas emissions in the US are from motorized transportation and individuals who use active transportation (AT) tend to be leaner and healthier than nonusers. Currently only about 3.4% of US commuters use AT with much higher participation in many European countries. Partly as a result, the average US household contributes ~22 metric tons of greenhouse gas while a European household emits about half of this. Clearly, access to infrastructure such as sidewalks and bike lanes has an impact on use of AT but even when adequate infrastructure is available, use is limited. In the US, 28% of all car trips are < 1.6 km (1 mile). Most individuals understand that AT is healthful but perceive that AT is too time consuming, difficult, and unsafe. Modeling research estimates benefits of AT on health, the environment and the economy. For example, assuming that 50% of trips < 2.4 km were replaced with walking and 50% of 2.4-8 km trips replaced by cycling in the San Francisco Bay area demonstrated a 14% reduction in burden of cardiovascular disease and diabetes and the same proportional reduction in greenhouse gas emissions (Maizlish et al. 2013). A similar simulation substituting 50% of car trips of < 4 km with cycling in cities in the mid-western US (31.3 M people) estimated a total savings of \$8.7 B per year and an annual reduction of almost 1300 fewer deaths due to improved air quality and improved physical fitness and health (Grabow et al. 2012). There is evidence that some attitudes and behaviors are changing to provide an opportunity to make these simulations a reality. For example, there has been a reduction in licensed drivers and fewer per capita miles driven in the US. Some research demonstrates that one of the highest motivators for use of AT in young people is to have a lower impact on the environment. Economic data shows that walkability has value for local businesses and that house buyers look for a short commute as a priority in home selection. In conclusion, promotion of AT has the potential to increase physical activity and health while reducing our impact on the environment, use of fossil fuels, and health care expenses. Emphasis on these co-benefits may provide additional motivation for use of AT beyond the traditional health message. Refer-

EXCHANGE SYMPOSIA: ACTIVEARTH

DeBourdeaudhuij, I.

Ghent University

This presentation will present results on the application of the ecological perspective that includes physical environmental variables in addition to more traditionally studied demographic and psychosocial variables in explaining physical activity. A more robust model is presented for explaining an increased amount of variance in moderate intensity and total physical activity. Specifically, following topics will be discussed: • Relationships between walkability and physical activity in Europe and comparisons with other continents based on the IPEN adult study network • The need for different definitions of walkability across age groups • The need to specify the relationship between the environment and physical activity across the life span • Results from experiments in which environments are manipulated to get insight into critical factors to encourage walking and cycling for transportation • The development of interventions to change the environment to promote physical activity: macro versus micro environments In summary, this presentation aims to put forward that ActivEarth needs a life course perspective integrating environmental and psycho-social research to enhance physical activity across the world.

OP-BN14 Injury Prevention

INJURY PREVENTION IN RUGBY PLAYERS: KNOWLEDGE AND EDUCATION STRONGER DETERMINANTS OF CORRECT BEHAVIOUR THAN PERCEPTIONS

Brown, J.1,2, Lubbe, S.3, Lambert, M.1, Van Mechelen, W.2, Verhagen, E.2

University of Cape Town; VU University Medical Center Amsterdam

Introduction Rugby union ("rugby") players have an above-average risk of injury compared to participants of other popular team sports (Fuller & Drawer, 2004). The BokSmart programme attempts to educate coaches about injury prevention with the assumption that this translates into behaviours which reduce the players' risk of injury (Viljoen & Patricios, 2012). Therefore, this study investigated whether the correct knowledge, positive perceptions and education are associated with correct injury prevention behaviours in rugby players. Methods Between 2008-2012, a questionnaire was completed annually by 111 (99%, n=2279 players) junior and 81 (96%, n=1642 players) senior rugby teams. Chi-squared analyses and a multiple correspondence analysis (MCA) map investigated associations between 18 self-reported injury prevention behaviours and their corresponding knowledge, perception and education components. Results: The average age of players completing the questionnaire was 21±4 years. There was a significant ($p<0.05$) positive relationship between knowledge/education for all 18 behaviours. In contrast, players' perceptions of the efficacy of injury prevention behaviour did not correspond with their self-reported behaviour. These findings were confirmed visually using an MCA map. Discussion: These findings imply that player's correct behaviour was determined more by their knowledge and through receiving education, rather than by their perceptions of the efficacy of particular injury prevention behaviours. This supports the implementation strategy of BokSmart, which is to improve the knowledge of player's coaches (Gianotti et al., 2009; Viljoen & Patricios, 2012). Thus, to improve injury prevention behaviour, BokSmart should focus on improving the knowledge and education of players. Future 'true' prospective studies should investigate the above relationships, in particular how much influence BokSmart has on player's education/knowledge. A NEW INJURY PREVENTION PROGRAMME FOR CHILDREN'S FOOTBALL IMPROVES MOTOR PERFORMANCE: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Rössler, R.1, Junge, A.2,3, Bizzini, M.2, Dvorak, J.2, Faude, O.1

1Department of Sport, Exercise and Health, University of Basel, Basel, Switzerland 2FIFA-Medical Assessment and Research Centre (F-MARC) and Schulthess Clinic, Zurich, Switzerland 3Medical School Hamb

Introduction The injury prevention programme "FIFA 11+" was designed for players older than 13 years, and has been shown to be effective in reducing football injuries (Soligard et al., 2008). An injury prevention programme for football players under 13 years of age could not be found in the literature (Faude et al., 2013). Therefore, "FIFA 11+" was modified with regard to injury characteristics and physical maturity of children. The present study evaluated the effects of this new programme "FIFA 11+ Kids" on motor performance. Methods Twelve football teams (under-9, -11, and -13 age categories) took part in the 10-week intervention study. Teams were stratified according to the age category into an intervention (INT, N=56) and a control group (CON, N=67). INT conducted the 15-min warm-up programme "FIFA 11+ Kids" twice a week, and CON received a sham treatment. Before and after the intervention players were examined using: Single leg stance (dominant leg); Y-balance test; drop and countermovement jump; standing long jump; 20-m sprint; agility run; slalom dribble; and wall-volley-test. The baseline adjusted percentage difference between INT and CON in the change scores were calculated, and the probability for an effect being practically worthwhile was estimated. Results Likely beneficial effects favouring INT were observed in Y-balance (right leg; +3.2% [90% CI 0.7, 5.8]; standardised mean difference (SMD)=0.34) and agility run (+3.6% [2.0, 5.1]; SMD=0.45). Possibly beneficial effects were present in Y-balance (left leg; +2.6% [0.4, 4.8]; SMD=0.23), drop jump reactivity index (+9.1% [-0.5, 19.7]; SMD=0.21) and height (+4.3% [-3.6, 12.8]; SMD=0.12), countermovement jump height (+3.7% [0.0, 7.6]; SMD=0.22), standing long jump

(+1.9% [-0.5, 4.5]; SMD=0.17), slalom dribble (+2.9% [0.3, 6.0]; SMD=0.18) and wall-volley test (+23.2% [6.7, 41.1]; SMD=0.34). Likely trivial effects were found for single leg stance (-0.5% [-5.0, 6.3]; SMD=0.02) and 20-m sprint (-0.1% [-0.9, 1.1]; SMD=0.02). Discussion At least possibly beneficial improvements were observed in nearly all performance tests. Although most effects were small, such slight improvements in motor performance may contribute to a reduction of injury risk. This programme will be evaluated with regard to its potential to reduce injuries in a RCT in near future. References Faude O, Rößler R, Junge A. (2013). *Sports Med*, 43, 819-837. MORE RUNNING SHOES, LOWER INJURY RISK?

Malisoux, L.1, Ramesh, J.1, Mann, R.1, Seil, R.1,2, Urhausen, A.1,2, Theisen, D.1

1: *Sports Medicine Research Laboratory, CRP-Santé, Luxembourg*; 2: *Sports Clinic, Centre Hospitalier de Luxembourg*. Introduction

INTRODUCTION Because running is a repetitive activity with very few movement variations, most running-related injuries (RRI) are cumulative micro-trauma injuries, usually defined as overuse injuries. Previous studies have shown that shoe characteristics influence the type and the magnitude of impact forces applied to the body. Therefore, regular alternation between different shoes might cause variation of repetitive external loads. The purpose of this study was to determine if runners who use concomitantly different pairs of running shoes are at a lower risk of RRI. **METHODS** Recreational runners (n=264) participated in this 22-week prospective follow-up and reported all information about running training characteristics, other sport participation and injuries on a dedicated internet platform, the TIPPS (Training and Injury Prevention Platform for Sports). Multiple shoe users were identified as those who reported a minimum of 2 different pairs of running shoes in the system and who alternated a minimum of 2 times between them over the observation period. A RRI was defined as a physical pain or complaint, located at the lower limb or lower back region, sustained during or as a result of running practice and impeding planned running activity for at least 1 day. A Cox regression analysis was used to identify injury risk factors amongst participants' characteristics and sport participation characteristics over the period of interest. Firstly, unadjusted analyses were performed to identify potential risk factors ($p < 0.250$). Next, these variables were introduced in the final model (Forward Likelihood Ratio method). Significance was accepted for $p < 0.05$. **RESULTS** A total of 148 runners were classified as multiple shoe users and reported having used an average of 3.6 ± 1.6 different pairs of shoes during the observation period. One third of all the participants (n=87) experienced at least one RRI during the observation period. The adjusted Cox regression analysis revealed that the parallel use of more than one pair of running shoes was a protective factor (HR=0.614; 95%CI=0.389-0.969). Additionally, increased weekly volume of other sports (h.week⁻¹; HR=0.848; 95%CI=0.732-0.982) and increased mean session distance (km; HR=0.795; 95%CI=0.725-0.872) were also associated with lower RRI risk while previous injury was a risk factor (HR=1.722; 95%CI=1.114-2.661). **DISCUSSION** Runners are advised to alternate between different pairs of running shoes and to practice other sporting activities, since these strategies have a beneficial effect on RRIs. The underlying mechanism could be that such a strategy may lead to a variation of external and internal forces applied to the body. **CONTACT** laurent.malisoux@crp-sante.lu

IMPLEMENTATION EFFECTIVENESS OF AN EVIDENCE BASED APP TO PREVENT ANKLE SPRAINS

Vriend, I.1, Coehoorn, I.1, Verhagen, E.2

1: *VeiligheidNL*, 2: *EMGO+, VUmc (Amsterdam, The Netherlands)*

Introduction Ankle sprains are the most common athletic injury with a high recurrence risk and may result in long-term symptoms. As such, these injuries pose a significant burden to the individual athlete and society as a whole. External applied supports and neuromuscular training programs are successful in preventing recurrent cases of ankle sprains. However, the uptake of effective preventive measures is lagging behind. Contemporary electronic media is regarded as a practical tool in the dissemination of preventive measures. For this purpose a freely available App was developed including a neuromuscular training program that was shown to be effective in a previous randomized controlled trial. We evaluated the implementation effectiveness of this "Versterk je Enkel" App. **Methods** The App was evaluated within its practical context using the RE-AIM Framework. The App contains an 8-week neuromuscular training program with 6 exercises and has been linked to a 50% reduction in ankle sprain recurrence risk. The App was launched in September 2011 with a press release, banners and advertisements in offline and online media. Data for the evaluation of the App were objectively registered through online analytical tools, and were obtained in February 2013 based on 25,781 users in follow-ups of 18 months (iOS) and 15 months (Android). User questionnaires provided a qualitative view of the objectively assessed measures (n=82). **Results** The App reached 2.6% of the projected target population of Dutch sport participants sustaining an ankle sprain. This can be regarded as a low percentage in light of the attention given to the App. The App was rated with a mean score of 8.1 of 10. User ratings for the App's relevancy, clarity, usefulness, appeal, information and reliability were high. Google Analytics showed a mean of 3.3 App sessions per user. Of all questionnaire respondents 38% did not actively use the App, whereas 33% used the App multiple times per week. Only 32% of all questionnaire respondents indicated to have followed the entire program, and 59% stated to have followed part of the program. As such, there is a large share of users that do not actively use the App and compliance to the embedded program is low. **Discussion** Although the App was well received by users, reach and implementation within the target population were low, likely due to the broad and unfocused dissemination of the App. Targeted efforts are required to deliver the App to the target population, e.g. through coaches or therapists, and ensure proper uptake and usage of the program. The current evaluation has resulted in modifications of the App to improve compliance to the program and to increase use through therapists. A new version will be released this summer and evaluation is ongoing. **Contact** i.vriend@veiligheid.nl

EXPECTING ANKLE TILTS AND WEARING A BRACE REDUCE ANKLE INVERSION IN THE SPRAIN MECHANISM

Gehring, D., Wissler, S., Lohrer, H., Nauck, T., Gollhofer, A.

University of Freiburg

Introduction Ankle sprains belong to the most frequent sport injuries and thus they pose a significant burden to the athlete's health (Swenson et al., 2013). Aiming to develop effective injury prevention it is essential to understand how 'active' neuromuscular control mechanisms and 'passive' mechanical constraints are able to stabilize the ankle joint during injury-related situations (Gutierrez et al., 2009). Therefore, the aim of the present study was to determine how (a) expecting ankle tilts and (b) the application of an ankle brace influence ankle joint control when imitating the ankle sprain mechanism during walking. **Methods** Three-dimensional ankle kinematics and muscle activity of the m. peroneus longus, m. tibialis anterior and m. soleus were assessed in 17 healthy men. Rapid ankle perturbation

tions were applied during gait using a trapdoor (tilting with 24° inversion and 15° plantarflexion). The subjects either knew that a perturbation would definitely occur (expected tilts) or there was only the possibility that a perturbation would occur (potential tilts). Both conditions were conducted with and without a semi-rigid ankle brace. Results Expecting ankle tilts led to an increased ankle eversion at foot contact ($P = 0.03$), which was mediated by an altered preactivation of the m. tibialis anterior (-10%, $P = 0.04$) and the m. soleus (+6%, $P < 0.001$). Moreover, the maximal inversion angle and velocity (-7% and -4%, $P < 0.003$), as well as the reactive response of all muscles (-9% to -37%, $P < 0.005$) were significantly reduced when the perturbation was expected. While wearing an ankle brace did not influence muscle preactivation nor ankle kinematics before ground contact, it significantly reduced maximal ankle inversion angle and velocity (-14% and -11%, $P < 0.01$) as well as reactive neuromuscular responses of all muscles (-11% to -14%, $P < 0.02$). Discussion The present findings reveal that expecting an ankle tilt modifies neuromuscular joint control and reduces injury-related ankle joint inversion (Fong et al., 2012). Although such motor control strategies are weaker in their magnitude compared with braces, they seem to assist ankle joint stabilization in a close-to-injury situation (Gutierrez et al., 2009). In consequence, being aware of potentially harmful situations can be considered as an integral part of the athlete's strategy to prevent ankle sprains and might therefore be incorporated in prevention programs. RELATIVE AGE EFFECT AND INJURIES IN ELITE SCHOOLBOY CRICKETERS

Stretch, R.

Nelson Mandela Metropolitan University

Introduction The relative age effect (RAE) has been widely observed in a number of sports as a result of annual age-grouping policies, while there is a paucity of literature on injuries to young cricketers. This study aimed to identify the existence of RAE among elite South African schoolboy cricketers and whether RAE was evident in those players who sustained injuries. **Methods** Ethics approval for this study was obtained. Injury data was collected on elite schoolboy cricketers (Under 15, Under 17 and Under 18 age-groups) over a five-year period. Biographical data included the birth-date distribution (January to March (Q1), April to June (Q2), July to September (Q3), October to December (Q4)) The Sample Statistical Analysis System (SAS) was used to compute univariate statistics and frequency distributions with RAE tested using chi-squared analyses. **Results** Injury patterns for 1 554 young cricketers, who sustained 2 050 injuries, were spread between the age-groups (U15 - 36%, U17 - 35%, U18 - 29%). These injuries were predominantly to the lower limbs (38%), back and trunk (33%) and upper (26%) limbs with 3% occurring to the head and neck region. The primary mechanism of injury was bowling (44%) and fielding, including running to field the ball (22%). Eighty-six lumbar muscle strains, 30 hamstring strains, 23 groin strains, 21 spondylolysis and 18 ankle sprains occurred. The injuries were acute (49%), chronic (41%) and acute-on-chronic (10%), with 26% and 47% being recurrent injuries from the previous and current seasons, respectively. A significant ($p < 0.005$) RAE for the cricketers as a group (Q1 = 37%, Q2 = 28%, Q3 = 19%, Q4 = 16%), as well as for their age-groups (U15: Q1 = 43%, Q2 = 29%, Q3 = 16%, Q4 = 12%; U17: Q1 = 37%, Q2 = 28%, Q3 = 20%, Q4 = 15%; U18: Q1 = 33%, Q2 = 26%, Q3 = 20%, Q4 = 21%) was found. Similarly, when the players were grouped into their role in the team, the all-rounders, batsman and fast bowlers showed a significant ($p < 0.005$) RAE (All-rounders: Q1 = 39%, Q2 = 28%, Q3 = 20%, Q4 = 17%; Batsmen: Q1 = 35%, Q2 = 28%, Q3 = 20%, Q4 = 17%; Fast Bowlers: Q1 = 37%, Q2 = 26%, Q3 = 21%, Q4 = 16%). RAE was not evident in the players who had sustained ($n = 1 073$) and/or not sustained an injury ($n = 481$), nor between the players who had sustained a single injury ($n = 380$) and those who had sustained more than one injury ($n = 101$). **Discussions** The young cricketers showed similar injury patterns to those reported for adult cricketers, while the RAE effect was evident in the whole group of elite schoolboy cricketers, as well as in some of the specific roles they played in the team. There was no RAE with regards to those who sustained an injury and those who had not sustained an injury or those who sustained one or more injuries. Contact richard.stretch@nmmu.ac.za

OP-PM48 Training & Adaptation

TAPERING IN MIDDLE-DISTANCE RUNNERS: THE EFFECT OF A FINAL HIGH INTENSITY TRAINING BOUT ON 1,500 M PERFORMANCE

Spilsbury, K.S.1,2,3, Faulkner, S.H.2, Fudge, B.W.1,3, Pringle, J.S.1, Nimmo, M.A.2

1: English Institute of Sport, 2: School of Sport, Exercise and Health Sciences, Loughborough University, 3: British Athletics

Introduction The maintenance of training intensity during tapering is crucial to prevent a decline in performance (McConnell et al., 1993). However, an increase in training intensity in the final days of a taper may have a positive impact on performance (Thomas et al., 2009). The aim was to investigate 1,500 m performance after a 7-day taper where intensity of the final interval session was above race speed. **Methods** Ten well-trained male middle-distance runners; (mean \pm SD) age 22 ± 3 years, height 182.9 ± 7.0 cm, body mass 73.4 ± 6.8 kg, performed two trials, each consisting of a 7-day regular training period (control week) followed by a 7-day taper period (taper). Training during the taper was based on the practices of elite British middle-distance runners. The final interval session during the taper was performed on the fifth day at; 1,500 m race speed in the race speed trial (RS) and at 115% of race speed in the high intensity trial (HI) and consisted of 300 m intervals with 90 s recovery. Number of repetitions was individualised and dependent upon interval volume during the control period. Trials were balanced and separated by three weeks of training. In each trial, following a standardised warm up, 1,500 m performance was measured on a treadmill at baseline, after the control week and after the taper week. Participants were blind to pace and elapsed time. A one-way repeated measures ANOVA examined differences in performance time between baseline, control and taper time trials for RS and HI, with Bonferroni post-hoc analysis. **Results** Performance time improved by 4% after the taper period compared to control in RS (288 s vs. 300 s, $P < 0.05$) and by 3% compared to baseline in RS (288 s vs. 296 s, $P < 0.05$). Performance after the taper in HI was not different to control (+2%, 292 s vs. 298 s) or to baseline (+1%, 292 s vs. 295 s). Performance time was not different at baseline or control between RS and HI. No difference in training load was evident between RS and HI for the control and taper periods (excluding the intensity of the final interval session during the HI taper). **Discussion** The results suggest that the current tapering strategy of

elite British middle-distance runners leads to a greater improvement in 1,500 m performance. HI may be less effective at improving performance due to insufficient recovery from the increase in intensity during the final session. To facilitate peak performance, a greater reduction in training volume during the taper in HI might be necessary. References McConell, et al. (1993). *Int J Sports Med*, 14(1), 33-7. Thomas, et al. THE IMPACT OF 8-MONTH TRAINING PREPARATION FOR AN IRONMAN DISTANCE TRIATHLON ON FITNESS AND IMMUNE RESPONSE IN RECREATIONAL ATHLETES.

Tanner, A.V.I, Roberts, J.D.I, Lancaster, R.2

1: University of Hertfordshire (Hatfield, United Kingdom) 2: University of Bedfordshire (Bedford, United Kingdom)

Introduction The popularity of extreme endurance events has grown over the past decade and recreationally trained athletes are more commonly undertaking extreme events, such as long distance triathlons. Few studies have investigated the effect of high volume triathlon training on illness risk; however, a high training load has been indicated as a predictor of increased risk of URTI symptoms in athletes (Gleeson et al, 2013). The aims of the current study were to examine the immune response and training adaptations to 8-months training for an ironman triathlon. **Methods** 12 recreational athletes (following an 8-month training plan to prepare for an Iron-distance triathlon) (IMM) and 12 recreationally active controls (CON) completed the study. At months 0, 2, 4, 6, and 8, participants completed a treadmill incremental exercise test to assess of maximal oxygen consumption (VO₂max). Prior to the exercise test, a passive timed collection of saliva was undertaken, for subsequent analysis of secretory IgA (s-IgA) and salivary lysozyme using ELISA. Throughout the 8-month study period, participants completed bi-weekly nutrition diaries and weekly illness symptom and training diaries. **Results** There was a significant increase in VO₂max in IMM between 0 and 2 months (48.1 ± 5.6 mL·kg⁻¹·min⁻¹, $p=0.030$); however, no subsequent changes. VO₂max did not change in CON, although there was a significantly higher VO₂max in IMM compared to CON at months 2, 4, 6 and 8. There was no significant difference in incidence of URTI or symptom score between months 0 and 8 in IMM. There was no difference in incidence of URTI between IMM and CON, except a significantly higher symptom score in IMM at month 6 ($p=0.018$). **Discussion** The increase in VO₂max during the first two months of initiating triathlon training, indicates that adaptations occurred quickly; however after month 2 increasing training load did not affect VO₂max. There was little difference in illness episodes scores, or incidence of URTI between time points or groups, this may have reflected the moderate and progressive training load undertaken by IMM; which did not increase the risk of URTI, predicted in elite athletes (Nieman, 1994). Analysis of s-IgA and s-lysozyme is required to examine the concomitant physiological response of the immune system and individual difference will be considered. However, it appears that 8 months of training for a long distance triathlon may not have a detrimental effect on the immune response in recreational athletes. **References** Gleeson, M., Bishop, N., Oliveira, M. and Tauler, P. DISTURBANCES TO SLEEP ARCHITECTURE IN ATHLETES DURING RAMADAN

Chamari, K., Farooq, A., Belfekih, T., Herrera, C.P.

Aspetar

Sleep is a fundamental component of post-exercise recovery given the relationship between DEEP and REM sleep with physical and psychological restoration. Current evidence suggests that sleep disturbances among athletes are minimized in a training camp setting during Ramadan. However, these data are from subjective questionnaires and there are no available objective data to describe the sleep behavior of athletes during Ramadan. **PURPOSE:** To determine the influence of Ramadan on EEG based sleep in athletes living in a training camp environment. **METHODS:** Qatar national cyclists ($n=11$, 23.6 ± 5 years, range 17-35) lived in a residential training camp setting for three months (July-September); Ramadan was observed between 7 July and 8 August. EEG sleep measurements were recorded using a commercially available ambulatory EEG device (ZEO Sleep Manager, Zeo Inc, Newtown, MA) before Ramadan (BR), during the first (R1) and fourth (R4) week of Ramadan, and after Ramadan (AR). A repeated measures ANOVA was applied to detect differences between measurements. **RESULTS:** Bed- and Wake-times were significantly delayed during Ramadan (+3 hours) but duration of sleep was not affected. REM and DEEP sleep percentages decreased whereas LIGHT sleep percentage increased during and after Ramadan ($P<0.05$) compared to BR. The time spent in DEEP sleep AR (49 ± 22 min) was significantly lower than BR (75 ± 22 , $P=0.05$). The number of awakenings during sleep tended to be higher during R1 (4.3 ± 2.6) and R4 (3.9 ± 3.6) compared to BR (1.9 ± 1.7) and AR (2.4 ± 1.7 ; $P=0.06$). **CONCLUSION:** The results demonstrate clear disturbances in sleep architecture suggesting a plausible negative influence on post-exercise recovery during Ramadan. Further studies into the nap behaviors of athletes are needed to determine whether 24hr sleep loss is present in athletes during Ramadan

THE EFFECT OF REPEATED BOUTS OF DOWNHILL TRAINING ON 30-KM RUNNING PERFORMANCE AND RECOVERY

Lambert, M., Schutte, L.

University of Cape Town

Purpose This study examined the effect of repeated bouts of either downhill or level running on running performance in, and recovery after, an undulating 30-km run. **Methods** Sixteen male subjects with a mean (\pm SD) age of 34 ± 6 years, body mass of 72.0 ± 7.3 kg and a stature of 176.6 ± 4.5 cm were randomly allocated to either a downhill (DG) ($n = 9$) or a level group (LG) ($n = 7$). The protocol consisted of a 5-week training phase, followed by a 30-km run and then a recovery phase for 3 weeks. During the training phase participants had 9 sessions where they ran for 40 minutes on a treadmill at 70% of peak treadmill running speed (PTRS), either downhill at a -10% grade (DG) or at a 0% grade (LG). Thereafter they participated in a 30-km run on the treadmill (70% of PTRS, with downhill and level gradients), where heart rate (HR) and rate of perceived exertion (RPE) were recorded, followed by four 15 minute submaximal recovery runs (4, 7, 14 and 21 days later). HR and RPE were recorded during these 15 minute runs. Plasma creatine kinase (CK) activity and muscular soreness were assessed for the duration of the study. **Results** HR decreased in the downhill group during the training phase, suggesting a training effect. Muscle pain and plasma CK activity in DG increased after the first 40 minute downhill training run (12-fold and 2.2 fold respectively), but then did not change after the remaining training sessions, suggesting a "repeat bout effect". Towards the end of the 30-km time trial LG had a greater heart rate drift (18% vs. 12%; LG vs. DG) and an increased RPE (14.6 ± 3.8 vs. 12.3 ± 2.8 units; LG vs. DG), suggesting that they were not able to resist fatigue to the same extent as DG. HR during the recovery phase showed that the DG had a better recovery after the 30-km time trial (143 vs.130 beats/min; LG vs. DG). During the recovery phase DG experienced no increase in muscle pain after performing the 30-km time trial, in contrast to LG who experienced muscle pain for five days after the 30-km time trial. Plasma CK

activity, was blunted after the 30-km time trial in DG in contrast to the LG in which it increased almost 10-fold. Conclusion The inclusion of downhill training causes the repeat bout effect that is associated with better performance in an endurance event and in the recovery after the event. NO EFFECT OF INTENSIVE TRAINING ON PLASMA BDNF AND CORTISOL CONCENTRATIONS IN HIGHLY TRAINED CYCLISTS

Piacentini, M.F.1,2, Witard, O.C.3, Tonoli, C.2, Guidotti, F.1, Jackman, S.R.4, Kies, A.K.5, Jeukendrup, A.E.6, Tipton, K.D.3, Meeusen, R.2

Introduction Short-term overload periods are frequently included in training programs in order to increase performance. Psychological mood state often responds rapidly to periods of increased training load and is therefore used as an early warning signal of non-functional overreaching (Meeusen et al. 2013). Recently, the role of brain derived neurotrophic factor (BDNF) in stress related mood disorders has been acknowledged (Duman and Monteggia 2006). Therefore, the purpose of the present study was to evaluate the effects of intensive training and recovery training on baseline plasma cortisol and BDNF concentrations and mood disturbances. **Materials and methods** Eight trained cyclists (VO₂max 64.2±6.5 ml/kg/min) performed 1 week of normal (NT), 1 week of overload (INT) and 1 week of recovery training (REC). Fasted blood samples were collected on day 7 of each training week and were analyzed for BDNF and cortisol. A 24 item Profile Of Mood State questionnaire was administered on day 7 of each week and global mood (GM) was calculated. A repeated measures ANOVA and a Pearson correlation test were used to verify differences due to training and the strength of the relationships between dependent variables in relation to training week. **Results** Baseline cortisol (153±16 ng/ml NT, 130±11 ng/ml INT, 150±14 ng/ml REC) and BDNF (484±122 pg/ml NT, 488±122 pg/ml INT, 383±56 pg/ml REC) concentrations were not different between training conditions. GM increased significantly (21%) during INT and remained elevated during REC (7%) compared with NOR. Cortisol concentrations and GM were significantly correlated in NT ($r=0.766$) and RT ($r=0.833$). **Discussion** These results confirm that changes in psychological parameters precede changes in commonly used biochemical markers and cortisol does not seem to be a useful measurement in monitoring athletes (Meeusen et al. 2013). BDNF has been related to stress induced mood disorders. Both acute and chronic stress paradigms decrease the expression of BDNF in the hippocampus probably caused by the increase in cortisol levels (Duman and Monteggia 2006) and exercise normally can counteract this downregulation. However, no correlation between cortisol, BDNF and GM was found during INT. It is likely that the INT followed immediately by REC prevented dysregulation of both BDNF and cortisol. Funding received from DSM Food Specialties, Delft, The Netherlands. **References** Meeusen R et al (2013) Med Sci Sports Exerc 45:186-205 Duman R and Monteggia L (2006) Biol Psychiatry 59:1116-27 mariafrancesca.piacentini@uniroma4.it

BEHAVIOURAL EPIDEMIOLOGY OF SITTING AND ACTIVITY AT WORK

Brown, W.

University of Queensland

Introduction: Western lifestyles have changed remarkably over the last century, with decreasing levels of physical activity and increased sitting in most working populations. This presentation will consider typical patterns of activity and sitting at work, and the emerging evidence on the health effects of these. **Methods:** Data will be drawn from large population-based prospective cohort studies, observational studies of samples of men and women who work in a range of occupations, and experimental studies. **Results:** Current estimates suggest that working adults spend about half their waking time at work, and those who are in 'seated' occupations spend up to two thirds of this time sitting. Time spent sitting at work appears to increase with age, and with seniority in some occupations. Prospective evidence shows that sitting time is associated with increased risk of all-cause mortality, cardiovascular disease and type 2 diabetes, and there is observational and experimental evidence to explain the possible biological mechanisms underpinning these associations. Relationships are however clouded by potential confounding roles of weight, weight gain and physical inactivity on both health outcomes and sitting. It is also difficult to disentangle the effects of sitting and activity at work on long term health outcomes, from those attributable to sitting and activity outside work. **Discussion:** In many occupations the changing nature of work means that working adults are becoming less active and more sedentary. While there may be detrimental health effects of high sitting and low activity at work, these effects are likely to be moderated by patterns of these and other behaviours outside work.

REDUCING SEDENTARY BEHAVIOUR IN THE WORKPLACE

van der Ploeg, H.P.

VU University Medical Centre

Sedentary behaviour has recently been shown to have detrimental health effects. Sedentary behaviour is defined as any activity done sitting or reclining of less than 1.5 MET. Sedentary behaviour is distinctly different from the lack of moderate to vigorous intensity physical activity. One can easily meet physical activity recommendations and be sedentary at the same time (i.e. getting 30 minutes of moderate to vigorous intensity physical activity per day but sit the majority of the rest of the day). Epidemiological studies suggest prolonged sitting time is associated with higher risks on cardiovascular disease, diabetes and premature mortality, independent of moderate to vigorous intensity physical activity. Sedentary occupations have become more prevalent over the past decades and people with a desk job are likely to sit the majority of their day. Recent innovations in the workplace have seen the integration of strategies aimed at reducing sedentary behaviour at work. The most common strategy is arguably the introduction of sit-stand workstations in the office environment, which

allow workers to alternate sitting and standing throughout the day. This presentation will focus on the health risks of sedentary behaviour, the prevalence of sedentary behaviour and especially on potential solutions for the workplace setting. There will be a specific focus on the feasibility, effectiveness and risks of introducing sit-stand workstations in the workplace. Evidence from epidemiology as well as quantitative and qualitative evaluation of workplace interventions will be presented. Contact: hp.vanderploeg@vumc.nl

NOVEL WORKSITE INTERVENTIONS FROM THE SOUTHERN HEMISPHERE

Kolbe Alexander, T.L.

University of Queensland

Introduction: Recent research in South African (SA) worksites reported that 60% of employees who voluntarily participated in health screening were not meeting public health recommendations for health enhancing physical activity (PA). Similarly, more than half of Australian adults are insufficiently physically active. The aim of this presentation is to provide an overview of worksite health promotion initiatives in SA and Australia. Methods: Data from cross-sectional and intervention studies which focus on promoting physical activity and reducing sedentary behaviour in South African and Australian employees will be presented. Results: Preliminary data from a cross-sectional study comparing physical activity and sedentary behaviour in night and day shift workers show both groups were sedentary for more than 10 hours per day, despite having 12-hour shifts. These nurses may therefore be at increased risk for cardiovascular disease. In another study, Australian office workers with high levels of sitting were 2.7 times more likely to have increased waist circumference and 9 times more likely to be obese than those with lower sitting times. Standing desks have been proposed as an option to reduce sitting time at work. Novel interventions to investigate employees' use of standing hot desks and their impact on sedentary work in an open plan office has been conducted in Australia. Employees spent approximately 75% of their 8-hour working day at their desks, and interventions to promote more standing have had mixed success. Employers may therefore implement policy and environmental strategies to encourage healthy lifestyle behaviours at the workplace. Data from South Africa has shown that employees meeting PA guidelines were based at worksites with more health promotion facilities than those not meeting PA guidelines. However, further research to determine the effect of these ecological interventions are required. Discussion: Employees' health and lifestyle habits are placing them at increased risk for non-communicable diseases. The worksite environment might play a role in increasing employee PA and reducing sedentary behaviour, but larger 'real-world' trials are required to confirm the potential of workplace strategies to change these behaviours. IS-SH11 Sports law: the integrity of sports

THE SPORTS-MONOPOLY: PLAY IT "FAIR"

Olfers, M.

Free University, Amsterdam

The sports-monopoly: play it "fair" Professional sports requires a sufficient number of competitors to produce the product: sport. Although there is no single-club dominance there is (of course?) one dominant league in each sport. There is market power at the top. This dominant monopoly position of the league can lead to abuse of dominance. Is this dominant position still defensible? What are the risks? From a law and policy perspective, Olfers will handle the concept of 'fair play', using case-law and policy examples, reference will be made to doping, discrimination, violence etc.

EVALUATION OF THE CREATION OF A GLOBAL SPORTS ANTI-CORRUPTION BODY

Gardiner, S.

Leeds Metropolitan University

Financial corruption (along with prohibited drug use issues and many other forms of cheating and gamesmanship) is a key area of Competition Governance. It manifests itself with vote rigging and bribery in international sport federations; match fixing and spot fixing (manipulation of an event in a sporting event); fraudulent betting and connected money laundering. All these are a current and very evident challenge to 'Sporting Integrity'. The argument supporting the creation of such a Global Sports Anti-Corruption Body is predicated on the belief that it would be able to adopt a more coherent and wide-ranging approach to this problem than has been evident up to this point with a variety of disparate structures within sports bodies. And as with WADA, the body would be able to be part of a multi-agency approach together with law enforcement bodies such as Interpol. There would also be the opportunity to pool resources and allow the type of forensic investigation that is required to unravel the financial complexities inherent in corrupt financial dealings. Such a body if it came to fruition, would clearly be able to adopt the good exemplars, which have been developed within specific sports such as international cricket and tennis to fight corruption and match fixing. As such it would have a harmonising effect across all sport. However, the efficacy of this approach has been questioned. Is it realistic that such a body could adequately respond to inherent criminality of money laundering and other activities of criminal gangs connected to match fixing? Additionally, unlike WADA that was very much a creation of the IOC and its then existing anti-doping infrastructure, it is not obvious to see where the specific political impetus will come from for the creation of an equivalent anti-corruption organisation such as a Global Sports Anti-Corruption Body. The focus of the paper will be on the position of the Council of Europe and the European Commission on this issue.

INTEGRITY OF SPORTS – GOOD GOVERNANCE IN SPORT ORGANIZATIONS

Schenk, S.

Transparency International

Sochi 2014 and Brazil 2014 have become synonyms for the struggle of international sport with its own ambitions and people's expectations. The development of the Olympics with regard to economic importance, outreach and impact on all parts of the societies around the globe has outpaced the ethical impetus of the Olympic movement. When Pierre de Coubertin founded the modern Olympic Games it was not just about sports and not at all about business. Coubertin's idea was to combine the international event of a multi-sport competition with educational and ethical goals. The Olympic Charter says in its "Fundamental Principles" 1 and 2: "Blending sport with culture and education, Olympism seeks to create a way of life based on the joy of effort, the educational value of good example and respect for universal fundamental ethical principles. The goal of Olympism is to place sport at the service of the harmonious development of man, with a view to promoting a peaceful society concerned with the preservation of human dignity." The European Union in its "Communication on the European Dimension of Sport" from 2011 states: "Autonomy within the limits of the law" is a condition for the autonomy and self-regulation of sport organizations. The following principles for sport organizations are: • Autonomy within the limits of the law • Democracy • Transparency • Accountability in decision-making • Inclusiveness in the representation of interested stakeholders This is nothing really new. It is just transferring Coubertin's idea into the modern globalized and complex world, using a specific, up-to-date approach and adequate instruments to meet today's challenges. So sport organizations have to reform and tackle conflicts of interest, corruption and other unethical behaviour in order to protect integrity. Especially on the international level this needs considerable efforts taking into account the traditionally close relationships between politics, business, media and sports. OP-PM49 Cardiovascular Exercise Physiology 3

DOSE-RESPONSE OF HABITUAL PHYSICAL ACTIVITY AND HEART RATE VARIABILITY IN YOUNG WOMEN

Krause, F., Vogt, L., Banzer, W.

Institute for Exercise & Sport Science

Introduction There is strong evidence for the influence of systematic aerobic training on parameters of heart-rate-variability (HRV). Current studies also provide increasing evidence for a linear dose-response relationship of HRV and physical activity (PA) in adolescents (Henje Blom et al. 2009), younger men (Melanson 2000) and people over 50 years of age (Buchheit et al. 2005). The present study examined the relationship of cardiac autonomic regulation and habitual physical activity in young, healthy women. **Methods** In four consecutive 4 week time intervals 20 healthy female volunteers (20-30 years, BMI 21.2±2.0 kg/m²) documented their everyday habitual physical activity behavior using a standardized questionnaire (IPA-Q). For data analysis total activity (METH) as well as average hours of moderate and vigorous physical activity (MVPA) per week were calculated. At the end of the 16-week observation period, standardized heart rate variability (HRV) recordings (Polar S810®) were carried out in accordance to international guidelines (ESC/NASPE). After supine resting for at least 5 minutes in a quiet room, five minutes of beat-to-beat heart rate data were sampled. From artefact-free RR data, calculations of time and frequency domain parameters were performed (Kubios HRV analysis). **Results** The average volume of activity per week was 71,6±37,2 METH and 7,7±4,4 MVPAh for total and moderate to intense physical activity, respectively. Linear correlation analysis revealed significant relationships between PA in different intensities and mean HR ($r = -.583$ to $-.674$; $p < .05$) as well as MeanRR, SDNN, RMSSD and HF ($r = .517$ to $.859$; $p < .05$). **Discussion** The obtained results point toward a strong linear dose-response relationship between habitual PA and variables of cardiac autonomic regulation in young, healthy women. Activities of moderate to vigorous intensity showed closer relationships with HRV than total activity. The findings are in agreement with other investigations showing reduced resting heart rate and pronounced increases of RMSSD and HF, indicators of enhanced parasympathetic activity, with increasing levels of PA. In conclusion, habitual physical activity could contribute to the cardioprotective effect of increased HRV in a linear dose-response manner. **References** Buchheit M. et al. (2005). WHICH ALLOMETRIC MODEL BEST DESCRIBES THE BODY SIZE/CARDIAC DIMENSION RELATIONSHIP IN AN ETHNICALLY DIVERSE COHORT OF ATHLETES?

Riding, N., George, K., Whyte, G., Wilson, M., Batterham, A.M.

Aspetar, Orthopaedic and Sports Medicine Hospital.

Introduction: Our aim was to determine the best allometric model for describing the body size-cardiac dimension relationship, in an ethnically diverse cohort of athletes. **Methods:** Pre-participation cardiovascular screening with echocardiography was undertaken in 1,329 competitive male athletes, (Arabic: n= 776, Black: 407 and, Caucasian: 147). The primary outcome variables for these analyses were left ventricular (LV) mass, LV volume in diastole, and interventricular septum thickness (IVS). The indexes of body size were body mass, fat-free mass (FFM), body surface area (BSA), and height. Five different allometric models were evaluated: 1. Traditional log-linear allometry of the form $\log(Y) = \log a + b \log(X)$, 2. A simple nonlinear model with normal homoscedastic error ($Y = aX^b$), 3. A simple nonlinear model with normal heteroscedastic error, 4. A full allometric model with normal homoscedastic error ($Y = aX^b + c$), and 5. A full allometric

model with normal heteroscedastic error. These 5 models were applied to each of the 4 body size indexes in the 3 ethnic groups, and compared using a combination of graphical inspection and information-theoretic methods (Akaike's Information Criterion). Results: For LV mass the best model overall was Model 3 with FFM as the body size index. The FFM exponent (95%CI) was 0.62 (0.45 to 0.78) for Whites; 0.89 (0.82 to 0.96) for Arabs; and 0.89 (0.80 to 0.99) for Blacks. Models with other body size indexes had weak or no support apart from Models 2 and 3 using body mass in Whites. For LV volume the best model was again Model 3 using FFM. The FFM exponent was 0.82 (0.66 to 0.98) for Whites; 0.88 (0.81 to 0.95) for Arabs; and 0.76 (0.68 to 0.85) for Blacks. All other models had weak or no support with the exception of Model 3 using body mass in Whites. For IVS Models 2 or 3 using FFM were superior to all other models among Blacks. Model 3 using body mass provided the best fit in Whites and Arabs, with Model 3 using FFM equivalent in Whites and a plausible alternative in Arabs. The FFM exponent for IVS from Model 3 was 0.11 (0.01 to 0.21) for Whites; 0.29 (0.24 to 0.33) for Arabs; and 0.36 (0.29 to 0.42) for Blacks. Models 1, 4 and 5 were dismissed in all scenarios. Discussion: Overall, a nonlinear allometric model allowing for heteroscedasticity provided the best fit, with FFM the most robust index of general body size. In this sample, the relationship between body size and cardiac dimensions is substantially different in Whites vs. Arabs or Blacks. The findings demonstrate that care must be taken when evaluating large heterogeneous cohorts of athletes, highlighting the importance of scaling within clinical practice while providing the most suitable means to do so.

CARDIOPULMONARY FUNCTION IN AMATEURS RUNNERS BEFORE AND AFTER SÃO PAULO INTERNATIONAL MARATHON

Sierra, A., Santos, V.C., Benetti, M., Gorjão, R., Cury Boaventura, M.F., Python Curi, T.C., Ghorayeb, N., Bachi, A., Sierra, C.A., Kiss, M.A.P.D.M.

EEFE-USP, University Nove de Julho, ICB-USP, UNICSUL, IDPC

Introduction The marathon is one of the most demanding sports in relation to muscle and physiological wasting, and sometimes can change some cardiopulmonary variables such as peak oxygen uptake (VO₂). Transient cardiac dysfunction is observed during recovery several days after prolonged exercise, and it is called 'cardiac fatigue'. Respiratory muscle fatigue has also been reported following marathon or ultra-marathon running. The aim of this study was investigate cardiopulmonary function in amateurs runners before and after São Paulo International Marathon. **Methods** 74 male marathoners, aged 19 to 51 years old (34±8.36) were evaluated before and after São Paulo International Marathon. The rest spirometry and treadmill tests with ramp protocol were performed 1-3 weeks before and 3 to 15 days after the marathon. The gas analyser was coupled with the treadmill. Blood samples were collected before and 72 hours after the marathon race. Statistical analyses were performed using Wilcoxon Signed Ranks Test and Spearman Correlation. The results are presented as the mean± standard deviation. **Results** We found significantly differences between the measurements before and after marathon race in relation to: rest Heart Rate (69.50±11.58 to 77.51±11.61), 1st threshold VO₂ (33.54±4.63 to 31.94±3.62), 1st and 2nd threshold PetO₂ (88.97±5.23 to 91.41±4.6 and 97.29±3.39 to 99.22±3.08, respectively), 2nd threshold and Ventilation Peak (VE) (107.77±18.88 to 111.69±18.55 and 132.89±21.92 to 136.95±20.02, respectively) and respiratory frequency peak (RF) (52.6±7.71 to 54.81±9.79). In spirometry parameters we also found significantly differences in relation to forced vital capacity (FVC) (5.04±0.98 to 5.93±0.84) and forced expiratory volume in one second (FEV1) (4.26±0.92 to 5.09±0.72). We also found significantly difference between the blood variables obtained before and 72 hours after marathon: erythrocytes (5.11±0.38 to 4.94±0.38), hemoglobin (14.98±0.39 to 14.44±1.02) and total Iron (97.39±30.77 to 86.38±30.8). **Discussion** We can observe that the cardiopulmonary variables PetO₂, VE and RF increased after the marathon and 1st threshold VO₂ decreased showing that there are physiological difficulties to maintain the same capacity than in the test before the marathon. In addition, we can observe a decrease of blood variables that are responsible for the oxygen transportation after marathon, showing that despite maintaining the same capacity, since there is no difference in the VO₂ peak and stage attained in the test, some variables are deficient in this period. Maybe the increase of the FVC and FEV1 is a compensatory mechanism to maintain the capacity and performance of the athletes that are in a cardiac fatigue.

INFLUENCE OF A CYP1A2 POLYMORPHISM ON HEART RATE VARIABILITY DURING EXERCISE WITH CAFFEINE INGESTION

Carrillo, A.E., Thomas, R.M., Algrain, H.A., Popojas, A., Ryan, E.J.

Chatham University (Pittsburgh, PA, USA)

Introduction Heart rate variability (HRV) is a clinical tool used to assess the risk of cardiac abnormalities. Caffeine ingestion prior to exercise has been shown to stimulate an exaggerated decrease in HRV at post exercise that has been associated with an increased risk of experiencing a cardiac event. A (C/A) single nucleotide polymorphism of the cytochrome P450 (CYP1A2) gene has been shown to slow caffeine clearance as well as amplify the risk of cardiovascular disease when caffeine is ingested. The purpose of this study was to determine the influence of a CYP1A2 polymorphism on HRV at rest, during exercise (with and without caffeine), and immediately following exercise. **Methods** Five C allele carriers (C/A; 3 males and 2 females; Age: 26.6 ± 1.0 years; BMI: 25.7 ± 5.6 kg/m²) and three AA homozygotes (A/A; 3 males; Age: 29.0 ± 1.0 years; BMI: 29.9 ± 5.6 kg/m²) were recruited for participation in a repeated measures, double-blind, placebo controlled trial. Each participant chewed three pieces of gum containing either caffeine (CAF) (100 mg per piece) or placebo (PLA) for 5-min. Thereafter, participants were asked to cycle for 15-min at 75% of their maximal oxygen consumption. HRV indices [low (LF) and high frequency (HF) bands, and their ratio (LF/HF), the square root of the mean of squared differences between successive RR intervals (RMSSD), and the percentage of successive normal-to-normal intervals greater than 50 ms (pNN50)] and respiratory rate were measured for 10-min at baseline, 10-min during exercise, and 10-min immediately post exercise. **Results** For the PLA condition, the change in HRV indices during exercise and post exercise compared to baseline were not significantly different between genotypes (P>0.05). For the CAF condition, however, the change from baseline in RMSSD during exercise was significantly greater in C/A (-57.7 ± 18.0 ms) compared to A/A (-27.4 ± 3.4 ms) (P<0.05). Similarly, the change from baseline in LF/HF during post exercise was significantly lower in C/A (3.8 ± 2.5) compared to A/A (10.6 ± 2.5) (P<0.05). Respiratory rate was similar between genotypes within each condition (i.e. CAF and PLA) at baseline, during exercise, and post exercise (P>0.05). **Discussion** These data indicate that compared to AA homozygotes, C allele carriers may experience an exaggerated suppression of parasympathetic activity during exercise with caffeine ingestion. These findings should be investigated further to elucidate the risk of exercising C allele carriers experiencing a coronary event following caffeine consumption. **References** Womack CJ, Saunders MJ, Bechtel MK, Bolton DJ, Martin M, Luden ND, Dunham W, Hancock M (2012). *J Int Soc Sports Nutr*, 9(1):7. CROSS-SECTIONAL STUDY ON THE RELATION BETWEEN MEDITERRANEAN DIET SCORE AND BLOOD LIPIDS

Mertens, E., Mullie, P., Deforche, B., Lefevre, J., Huybrechts, I., Clarys, P.

Vrije Universiteit Brussel

Background: Blood lipids like blood cholesterol are used as an indicator for cardiovascular health. A high value of low density lipoprotein (LDL) cholesterol and/or a high ratio total cholesterol (TC)/high density lipoprotein (HDL) cholesterol are related with cardiovascular mortality. There is some evidence that a Mediterranean diet, which is characterized by higher intakes of fruit, vegetables, whole grains and fish can reduce the incidence of cardiovascular diseases, however a clear and consistent link between blood lipids and Mediterranean diet has not been found so far. Therefore the aim of this study is to investigate whether there is a relationship between Mediterranean Diet Score (MDS) and blood lipids. Methods: Data were collected by the Flemish Policy Research Centre Sport, Physical Activity and Health. A representative sample of 506 females and 707 males (aged 18-75 years) was recruited through clustered random sampling. Data of a three day diet record was used to calculate MDS. Blood samples of the participants were analyzed for serum TC, LDL cholesterol and HDL cholesterol. To investigate the differences in blood lipids across the tertiles of MDS, ANOVA tests were used. Results: Total energy intake was lowest in tertile 1 ($p=0.040$). There was no significant difference between the three groups in TC and LDL cholesterol. HDL cholesterol increased with increasing MDS tertile ($p=0.027$), while the ratio TC/HDL cholesterol decreased with increasing MDS tertile ($p=0.049$). Conclusions: A higher MDS is associated with a higher value of HDL cholesterol and a lower ratio TC/HDL cholesterol. This can partly explain the cardioprotective effect of a Mediterranean diet. Introduction Sports practice alters athletes' homeostasis. To achieve homeostatic equilibrium, the integrated action of neuroendocrine and immune systems is necessary (Fragala et al., 2011, Sandvik et al., 2013). Here we studied the relation between hormones and cytokines in marathon runners. Methods Twenty male recreational marathon runners (mean age=35.7±9 years) and 20 male sedentary individuals (mean age=35.5±7 years) were recruited. We compared the serum levels of growth hormone, cortisol and interleukins 8 and 10 and the amounts of these two cytokines spontaneously produced by peripheral blood mononuclear cells. Blood samples of sedentary people were collected at rest. Marathon runners' blood was collected at rest (24 hours before the race (PRE)), immediately and 72 hours after (POST) a marathon. Results Our results showed that levels of interleukins 8 and 10 in the supernatant of culture cells and serum concentration of growth hormone were significantly higher in athletes compared to sedentary people, at rest. Immediately after the race all serum parameters analyzed were statistically higher than PRE values. POST-marathon, serum levels of hormones and interleukins returned to values at rest, but the concentrations of interleukins in the supernatant of culture cells showed a significant reduction compared to values at rest. Discussion Our results are in accordance with the literature concerning the behavior of GH after training period (Steinacker et al. 2000). The higher serum levels of growth hormone in athletes at rest and the higher production of cytokines in culture without previous stimulus observed before the race, suggests that marathon runners present mechanisms that may be associated with preparing their body to perform prolonged strenuous exercise, such as a marathon. INDIVIDUAL PATTERNS IN BLOOD-BORN INDICATORS OF FATIGUE - FORTUITY OR TRAIT?

Julian, R., Hecksteden, A., Fullagar, H., Skorski, S., Hammes, D., Meyer, T.

Saarland University

Introduction Blood-born markers of fatigue like creatine kinase (CK) and urea (U) are widely used to fine-tune training recommendations. However, the predictive accuracy of individual indicators is low (Meeusen, 2013). A possible explanation for this dissatisfactory finding is the propensity of athletes to react with different patterns of fatigue indicators (e.g. predominantly muscular (CK) or predominantly metabolic (U)). Thus, it may be of benefit to characterise individual patterns of fatigue indicators amongst athletes and assess whether these patterns are reproducible. This study aims to explore these questions using CK and U as exemplary parameters. Method Twenty-two (16 males, 6 females; 177.6 cm ± 6.5; 67 kg ± 9.3; 18.2 y ± 3.2) junior elite athletes completed five weeks of low-intensity high-volume training. Training load was documented throughout. Preceding training each Monday (following recovery or no training on Sunday) and Friday (following a week of 10-12 training sessions) venous blood samples were extracted from the antecubital vein, prior to training and on the same time of day. Blood was analysed for CK and U and Monday-to-Friday differences were calculated for either parameter (dCK and dU, respectively). To avoid uninterpretable leading signs in the ratio dCK/dU changes were converted into positive natural numbers (1-14) using the respective histogram. Subsequently, dCK/dU was determined. Standard error of measurement expressed as percent of the subject's mean score (coefficient of variation (CV)) with 90% confidence limits (CI) for each week were calculated. Variability was analysed using a random effects model (factors day of measure and participant). Results Overall ratio data of CK and U exhibited a mean CV of 48.9% (CI 36.1-79.4%). The random effects model indicates that the participant factor explains 12.2% of total variation (between subject variability) with a residual variation of 87.8 %. Discussion The current results suggest that the reproducibility of individual patterns in blood-born indicators of fatigue in junior elite athletes is low. Therefore it is suggestive that the relationship of CK and U responses is not

a trait of the individual athlete. However, for future research it would seem pertinent to use a larger panel of parameters to determine individualised patterns. HORMONAL CHANGES DUE TO A 2-BOUT EXERCISE PROTOCOL

de Geus, B., Descamps, F., Bos, I., Buyse, L., Meeusen, R.

Vrije Universiteit Brussel

INTRODUCTION: the 2-bout exercise protocol is used as an objective and immediately available test to make the distinction between well-trained, (non-functional) overreached (NFO) and athletes suffering from the overtraining syndrome (OTS) [1;2]. OTS athletes will have a "overshoot" of e.g. ACTH in the first exercise bout and a complete suppression in the second exercise bout [1], however, until now these values have not been described in healthy, well-trained cyclists. Therefore the purpose of this study was to evaluate hormonal changes due to a 2-bout maximal exercise protocol. **METHODS:** Twenty well-trained (PL4 [3]; 65.1 +/- 6.1 ml/min/kg) cyclists (23.9 +/- 4.2 yrs) participated in this study. All athletes performed two maximal exercise tests until voluntary exhaustion (MT1 and MT2) separated by 4 h. Blood was taken before (PRE) and after (POST) each test and analyzed for cortisol (COR), adrenocorticotrophic hormone (ACTH), human growth hormone (hGH) and prolactin (PRL). Values are presented as % changes, compared to baseline. **RESULTS:** Performance (Wattmax), lactate and heart rate decreased by 1.8%, 13.3% and 0.6% respectively between MT1 and MT2. The within subject difference in hormonal response between PRE to POST changed to the same amount between MT1 and MT2. The between subject difference in hormonal response differs to a great extent, ranging from a minimal decrease between PRE and POST MT1 and MT2 of 28% and 18% respectively for COR to a maximal increase between PRE and POST MT1 and MT2 of 18000% and 13000% respectively for hGH. **CONCLUSION:** although large between subject differences were measured, no within differences were measured in hormonal response. THE REPRODUCIBILITY OF BLOOD-BORN AND PSYCHOLOGICAL MARKERS OF FATIGUE AND RECOVERY IN ELITE ATHLETES

Fullagar, H., Hecksteden, A., Julian, R., Skorski, S., Hammes, D., Meyer, T.

Saarland University

Introduction There is a lack of consensus regarding the best markers to monitor fatigue in athletes (Meeusen et al., 2013), especially since little is known about the intraindividual variability of potential parameters and their responses. From both a practical and theoretical point of view this would be worth knowing to enable interpretation of fatigue markers as a result of changes in fatigue status or random variation. Thus, the aim of this study was to determine the reproducibility of blood and psychological fatigue markers in elite junior athletes during endurance training. **Methods** Twenty-two (16 M, 6 F; 177.6cm±6.5; 67kg±9.3; 18.2y±3.2) tri-athletes and swimmers (regional to national level) completed 5 weeks of low-intensity/high volume endurance training which was constant over the study. Venous blood samples (VBS) and psychological questionnaires (Hitzschke et al., 2013; Acute Stress and Recovery Scale (ASRS) comprising of scales each with 0-6 weighting (6=fully recovered) of perceptual fatigue were collected every Monday (MON; following recovery/no training 24h prior) and Friday (FRI; following a week of 10-12 training sessions) prior to training at the same time of day. VBS were analysed immediately for creatine kinase (CK) and urea (U) using appropriate laboratory procedures. Means, standard deviations and coefficients of variation (CV) were calculated for ASRS and for MON, FRI and difference between MON and FRI (DIFF) for CK and U. **Results** Mean CK for MON was 220.1±154.5 with a CV 40.0%. Mean CK for FRI was 266.0±141.5 with a CV 34.2%. Mean DIFF for CK was 53.9±153.1 (p<0.05) with a CV of 219.7%. Mean U for MON was 32.0±8.7 with a CV 18.5%. Mean U for FRI was 34.3±8.8 with a CV 21.9%. Mean DIFF for U was 2.1± 9.9 (p<0.05) with a CV 73.0%. Mean scores for ASRS ranged from 1.94-4.01 and a CV range on MON of 18.9-51.9% and 17.8-50.2% for FRI. **Discussion** Our results suggest the reproducibility of raw values and training induced changes in these indicators of fatigue is low. This impedes the diagnostic accuracy of detecting changes in the fatigue status of elite athletes. However, training induced changes in the current study were small. It could be speculated that larger changes would result in better reproducibility. Since this study only used two blood markers, this supports current recommendations to use a larger array of parameters in future research (Le Meur et al., 2013). **References** Meeusen R, Duclos M, Foster C, Fry, A, Gleeson, M et al. PS-PL03 Challenges for the Paralympic Games: fairness and identity *

PARALYMPIC SPORT PERFORMANCE: HOW CAN DIVERSITY IN TRAINING, EQUIPMENT, ERGONOMICS AND IMPAIRMENT RESULT IN FAIR COMPETITION?

Vanlandewijck, Y.

KU Leuven

Since the first International Wheelchair Games held in 1948 at Stoke Mandeville Hospital in England major changes have occurred in Paralympic sports. While the events in the early days were more about enhancing the quality of life for people with spinal cord injuries, they have now evolved into elite-level competitive games for athletes with a diversity of impairments. The wheelchairs used have transformed from heavy, bulky, one-size-fits-all hospital chairs used for all events into light-weight, fast, custom-fit chairs specially made for each sports discipline. Analogously, the competitor has transformed from a rather untrained, unfit patient with a disability into a highly

trained, fit, often full-time, professional athlete. This lecture explains how diversity threatens fairness in competition and frames the way the International Paralympic Committee is anticipating.

BRAVE NEW WORLD: ABILITY, TECHNOLOGY AND ETHICS

McNamee, M.

Swansea University

The London 2012 Paralympics was the culmination of impressive developments in training techniques, equipment, and assistive devices that augmented admirable human qualities such as 'determination' and 'courage' which are the first two of the International Paralympic Committee's four "official" values. Perhaps most notable was the progress made by athletes with lower-limb amputations and specialized running blades, which have supported conjectures that in the future "disabled" runners may run faster than their "able-bodied" counterparts. Several other technological innovations, such as robotics, prosthetics, and exoskeletons may further contribute to Paralympic evolution, while potentially undermining considerations of 'equality' and the ability to 'inspire', which are the remaining official Paralympic values. Employing conceptual, ethical and sociological insights, this lecture will explore the concept of "athletic ability" in Paralympic and Olympic sports, evaluate the ethical dimensions of assistive technologies that could undermine the concept of "Paralympism", and consider the extent to which technological developments may threaten the separate but equal-Parallel-conception of the Olympic and Paralympic games.

TABLE TENNIS SPECIFIC TESTS FOR CLASSIFYING INTERNATIONAL PLAYERS WITH INTELLECTUAL DISABILITIES

Wu, S.K., STEFAK, J., CHANG, Y.C.

National Taiwan University of Physical Education and Sport

Background & Purpose: Table tennis (TT) players with intellectual disabilities (ID) have been included in the 2012 London Paralympic Games. However, no study has examined the credibility of the current TT-specific classification system for players with ID. The aim of this exploratory study was to analyze the performance of the TT specific tests for players with ID to clarify whether the TT-specific system is valid to classify TT players with ID. **Methods:** Data from 104 international TT players with ID including 66 male and 38 female players were collected in the major international TT championships from October 2011 to September 2013. Three main parts of TT testing results (i.e., service, return service, and basic table tennis skills and control) in classification and training information of players were analyzed. **Results:** We found that 86 players with ID were clearly classified as eligible players just through the TT specific test using the cut-off points proposed in the current ITTF classification manual. However, 18 players needed to attend the advanced test and further observation during competition in order to confirm their classification status for eligibility in competition. After the confirmation of the advanced test and observation during competition by international senior TT classifiers, 11 players were recognized as borderline and 3 players were not eligible. **Conclusion:** Based on the results of this exploratory investigation, the current TT classification system for most players with ID was generally valid and fair as well as most players with ID can be clearly classified without difficulties. However, the TT-specific test may need slight adjustment in the cut-off points for borderline players with ID. It is essential that the borderline TT players need to be monitored longitudinally and so the TT classification system for players with ID can be evaluated with more scientific evidence and less subjective discussion and decision-making by international TT classifiers.

FACTORS ASSOCIATED WITH PHYSICAL ACTIVITY IN JAPANESE ELDERLY PEOPLE: USING THE PHYSICAL ACTIVITY STANDARD VALUE FOR AGED 65 AND OVER IN THE PHYSICAL ACTIVITY GUIDE FOR HEALTH PROMOTION 2013 IN JAPAN.

Aiko, I.

Seijoh University

Introduction: Previous studies have been described that physical activity of elderly people associated with physical function, mental well-being and support from people around them. In Japan, physical activity standard value of aged 65 and over were published for the first time by Physical Activity Guide for Health Promotion 2013. However, no studies has described that factors associated with their physical activity. No studies has described that related factors of physical activity by this standards. **PURPOSE:** The aim of the present cross-sectional study was to investigate Japanese elderly people using the standards to factors associated with their physical activity. **METHODS:** Participants were 194 elderly people aged 65 and over (mean age 76±6 years). To assess physical activity, ascending and descending stairs, getting up, 15-min continuous walking, fall experience, fear of falling, and daily living function of the Tokyo Metropolitan Institute of Gerontology Index of Competence (TMIG) and the following subordinate items: instrumental activities of daily living (IADL), intellectual activity (IA), social role (SR), depression on the Geriatric Depression Scale (GDS-15), going out, health condition, grip strength, and chair stand (CS). For statistical analyses, we used unpaired sample t-test, Mann-Whitney test, and chi-square test to compare items reported by a group with more than the standard value to those reported by a group with less than the standard value. Then, we performed a multiple logistic regression analysis for which the independent variables were items with $p < .25$ for the comparison of each item. The dependent variables were the amount of physical activity and extracted associated factors ($p < .05$). **RESULTS:** Age, ascending and descending stairs, getting up, 15-min continuous walking, fear of falling, TMIG, IADL, IA, SR, depression, going out, health condition, grip strength, and CS were considered for multivariable model. The multiple logistic regression analysis for which the dependent variable was the amount of physical activity extracted 15-min continuous walking, fear of falling, and IA. The model chi-square test and each variable were significant. The discrimination rate was 74.2%. **CONCLUSION:** 15-min continuous walking, fear of falling, and intellectual activity are associated with the physical activity standard value necessary for elderly people to maintain their health. For preventive care for elderly people, it is important that support be undertaken with particular attention to these factors.

METABOLIC AND CARDIAC STRAIN OF FINNISH AND SWEDISH OPEN-PIT MINERS

Oksa, J., Rissanen, S., Jussila, K., Rintamäki, H.

Finnish Institute of Occupational Health, Oulu

Introduction Mining industry has grown significantly over the past few decades in Finland and Sweden. Though the work has mechanized to a great extent it still contains elements of heavy manual work. The aim of this study was to evaluate the level of metabolic and cardiac strain of mine workers and to compare if there are differences in the strain between Finnish and Swedish open-pit mine workers. **Methods** Ten Finnish (F) and thirteen Swedish (S) voluntary mine workers participated in the study. Their weight was 87±12 and 78±8 kg, height was 178±13 and 176±12 cm and BMI was 27±3 and 25±2 for F and S, respectively. Their maximal oxygen consumption was evaluated by three stage submaximal bicycle ergometer (Monark 818, Ergomedic, Sweden) test by using equations (Liikuntatieteellinen Seura 2004) utilizing the workload and corresponding heart rate (PolarRCX3, Polar Electro, Finland). During their normal working day their heart rate was measured continuously (cardiac strain) and was related to the heart rate – oxygen consumption relationship obtained from the

bicycle ergometer test and expressed as %VO₂max (metabolic strain). Results Estimated maximal oxygen consumption was the same for both groups being 37±3 and 37±2 ml·kg⁻¹·min⁻¹ for F and S, respectively. Their average heart rate during a working day was 101±9 and 94±11 beats·min⁻¹ and oxygen consumption 34±5 and 35±3 %VO₂max for F and S, respectively. Discussion WHO recommends that during a normal 8 hour working day metabolic strain should not exceed the 50 %VO₂max level (Andersen et al 1978). Cardiac and metabolic strain results indicate that modern days mining work can be considered as light and/or moderately heavy work. There was no differences in the strain between Finnish and Swedish mine workers. References Andersen KL, Masironi R, Rutenfranz J, Seliger V. (1978). Habitual physical activity and health. WHO Regional Publications European series No. 6. Liikuntatieteellinen Seura ry. Kuntotestauksen käsikirja. Tammer Paino Oy, Tampere 2004.

EFFECTS OF DIFFERENT MODALITIES OF WARM-UP ON PARALYMPIC 100-M FREESTYLE

Weissland, T.1, Bourdeau, C.2, Westelynck, J.M.2, Lepretre, P.M.1

APERÉ, Université Picardie Jules Verne1, Fédération Française Handisport2

Introduction Warm-up (WU) generally increased swimming performance (Neiva et al. 2014). However, WU procedure appeared complex especially among disable-body swimmers in a warm and humid pool environment. Some athletes were also able to determine the optimal WU intensity (Balilionis et al. 2012) but not for others (Mandengue et al. 2005). Additionally it was observed a greater performance after an intermittent (IWU) compared to continuous (CWU) WU modalities but this effect would depend on WU duration (Balilionis et al. 2012) and intensity (Bishop D. 2003). Hence, the aim of this study was to compare freestyle performance in Paralympic swimmers (PS) after self-select WU (SSWU), IWU and CWU modalities. Methods 17 trained PS (21.6±8.3y, IPC classification: S3-S15) performed 100-m freestyle trials on separate days after 20min of SSWU, CWU or IWU. The critical velocity (CV) was used to determine intensity of CWU and IWU (Wakayoshi et al. 1992). SSWU replicated the swimmers' usual precompetition strategy. Swimming performance, WU covered distance, blood lactate 3min after WU (3Lact) and the difference between peak recovery – 3Lact values (Δ Lact) were assessed. Results The mean VC was 1.013±0.22m.s⁻¹. Individual data indicated that 46.7% of PS swam fastest after SSWU, 33.3% after IWU and 20.0% after CWU. WU covered distances were different between IWU (921±155m), CWU (1182±230m) and SSWU (1234±1342m) (P<0.05). All WU modalities induced a positive Δ Lact (P<0.001) with no WU modalities interaction. Swimming performance was inversely correlated with covered distance (-0.66, P<0.001) and Δ Lact (-0.67, P<0.001). 3Lact was negatively related to Δ Lact (-0.33, P= 0.03). Discussion SSWU strategy could be adapted for swimming fastest but inter-individual variability observed in their regular routine interacted on the performance. Balilionis et al. (2012) and Mandengue et al. (2005) already observed that some able-body athletes needed a controlled WU to optimize their performance. Each mean WU modalities on the present study also induced to swim a moderate distance - between 1,000 and 1,500m - according recent recommendations (Neiva et al. 2013). However, lower is the covered distance during warm-up, shorter was the swimming time. Thus, intermittent sets at CV could be the better strategy compared to self-select or continuous WU modalities to optimize the subsequent performance in Paralympic swimmers. Balilionis et al. University of Padova

Investigations on how exercise and physical activity affects dual-task (DT) performance in the elderly are growing rapidly due to the fact that DT activities are commonplace with activities of daily living. Preliminary evidence has shown the benefit in exercise on DT balance, though it is unclear to what extent the effect exercise has on DT performance in elderly subjects with disease conditions, including subjects with a high risk of falls. Hence, the objective of this study was to critically review the existing evidence of a potential relationship between exercise and improvement of static and dynamic balance during DT conditions as well as secondary outcomes in elderly subjects with different disease conditions. A systematic search using online databases was performed to source documents. Inclusion criteria sourced articles classified as randomized controlled trials (RCT), controlled trials (CT) and uncontrolled trials (UT). Moreover, the studies had to administrate an exercise or physical activity protocol in the intervention. Seventeen studies met the eligibility criteria and were comprised of 12 RCTs, 3 CT, and 2 UTs. Overall, 13 studies supported exercise being effective to improve parameters of static and dynamic balance during single or DT conditions. Despite the heterogeneity of pathologic conditions, exercise showed similar benefits to improve function in two main areas: neurological conditions and frailty conditions. The lack of a common method to assess DT performance limited the ability to compare different interventions directly. Future research is warranted to study the optimal dose and exercise modalities to best reduce the risk of falls in the elderly with multiple disease conditions.

THE INVESTIGATION OF PHYSICAL ACTIVITY LEVELS OF DPU ACADEMICAL PERSONAL'S

EYNUR, A., EYNUR, B.R., ERZEYBEK, M.S., ARABACI, R., TOPSAÇ, M.

DUMULPINAR UNIVERSITY

Introduction Healthy individuals undoubtedly among the vital requirements include physical activity. When considered in this context, which can add value to the lives of academic staff to improve the quality of life and wellness is very important to raise awareness. In this study, physical activity levels of academic staff and examination of attitudes towards physical activity is regarded as important. Methods In this study, physical activity measurement tool that Aerobics Center Longitudinal Study Physical Activity Questionnaire was used (MEMIS, 2007). According to Academic level and BMI index classification, Datas were analyzed with Kruskal Wallis H Test. Significantly level was accepted as $\alpha=0,05$. The research sampling was emerged 180 academical person which ages from 22 to 65. However we were also examined data with descriptive. Results According to MET Scores; At academic level and BMI index classifications, there is no significantly differences between groups (p>0,05). However, at PA Attitude and PA General Skills, according to academic levels there is significantly differences (p<0,05). While according to BMI levels there is no significantly level (p>0,05). At the same time, research results shows that inactive % 6,1, mid-level active %45,6 and high-level active % 48,3 of all academic personal. Discussion When the results examined, according to age raising, PA levels shown that fall (Soyuer & Soyuer, 2008). However, PA levels of all personal are shown that commonly low in this study. Especially this condition shown that placed between research assistants and professors, between research assistants and lecturers, supports our study. At the same time, this condition shows that academic personal's has very low knowledge about PA benefits and must be learned for themselves. In another study, It was founded that academic personal's was commonly in-active (Arslan, Koz,

Gür, & Mendes, 2003). References Arslan, C., Koz, M., Gür, E., & Mendes, B. (2003). Üniversite Öğretim Üyelerinin Fiziksel Aktivite Düzeyleri ve Sağlık Sorunları Arasındaki İlişkinin Araştırılması. THE ROLE OF PHYSICAL ACTIVITY COUNSELING AMONG SEDENTARY ADULTS IN FINLAND

Kivimäki, S., Malvela, M., Komulainen, J.

LIKES – Research Center for Sport and Health Sciences

The role of physical activity counseling among sedentary adults in Finland A government funded Fit for Life program (KKI) promotes physically active lifestyle among sedentary adults in Finland. One goal for KKI is to promote top-down development projects to be established in communities providing physical activity counseling that involves several municipal departments. Communal physical activity counseling involving several authorities of the civic organization is a fairly new type of service. Physical activity counseling as a preventive health care has not been an important part of services provided by health sector. Methods and Results The state of physical activity counseling in Finnish municipalities were evaluated by the questionnaire in year 2013. More than a half of the municipalities that answered the questionnaire reported having physical activity counseling. Under the planning or consideration phase were noticed in 22 % of the municipalities. Physical activity counseling totally lacks in 13 % of municipalities. Physical activity counseling was mainly organized by the sport sector. Patients/customers came to physical activity counseling by guidance/prescription of nurses, physicians, occupational health care or the staff of the sport sector. The content as well as a number of counseling sessions varied a lot. Conclusion and discussion There is a great need to increase physical activity counseling to help and encourage sedentary adult population to involve physical activity to their daily life. The challenges still exist, how 1) to include training on physical activity counseling in medical schools as well as in the contents of health care diplomas and degrees, 2) to offer continuous training to those already involved in practical work, 3) to enhance documentation of physical activity counseling in the patient record system and to enable information sharing with professionals linked to the counselling chain. 4) To develop forums for cross-sectoral and expert collaboration. Cross-sectoral service chain including personal health enhancing physical activity counseling should be a permanent function at community health care system. Also new service provides should be searched for as partners. It is essential to commit health care professionals to promote health enhancing physical activity as a preventive health care. Training seminars and cooperation with sports sector is important. In the future the aim is to combine physical activity counseling to public health stall to provide even more developed counseling. More low-threshold physical activity groups would be established.

CHANGES IN GROSS MOTOR SKILLS AFTER A 4-WEEK BALANCE TRAINING PROGRAMME IN AUTISTIC BOYS: A COLLECTIVE CASE STUDY

Africa, E., Hagemann, C., Welman, K., De Vries, P.

STELLENBOSCH UNIVERSITY

Background: Current studies have brought to attention that clumsiness and gross motor impairments are common in children with Autism Spectrum Disorder (ASD) such as poor balance, laterality, body awareness, low muscle tone, coordination and motor planning. Most of these impairments may be attributed to poor vestibular and proprioception input. The aim of the study was to establish if a 4-week balance training programme will improve sensory-motor functioning in Autistic children. Methods: The case study included two Autistic boys (N=2) aged six and eight years. Both boys demonstrated severe gross motor skills discrepancy, except balance which was rated in the moderate discrepancy category. Psychiatric tests for scientific diagnostic confirmation (ADI-R, ADOS and SCQ) were conducted for each boy. One boy showed higher- (HCF) and the other lower cognitive functioning (LCF). The intervention consisted of a pre-test (1 week), a 4-week balance training program twice a week, a post-test (1 week) followed by a natural retention of two weeks and a final test conducted in 1 week. The Quick Neurological Screening Test (QNST-III) (Mutti et al., 2012) and the Sensory Input Screening Test (SIST, also known as the Pyfer) (Auxter et al., 2010) were used to evaluate the boys' gross motor skills. Results: Both boys showed an improvement in gross motor skills (QNST-III) between 9- and 48% from pre to post-intervention. However, these improvements were not maintained 2 weeks after cessation of the exercises. The SIST only showed a 13% improvement in the HCF boy, with no change in the boy with LCF. Furthermore, no improvement in kinesthetic input was found, but vestibular functioning seemed to react to the 4-week training in the HCF boy. Interestingly, both boys did show an additional 13% improvement in SIST scores after retention. Discussion: Four weeks of balance training improves gross-motor skills in Autistic boys, but was lost as soon as the exercises ceased. In addition there is a need for ASD-specific gross motor test batteries, which are task specific and functional to incorporate perceptual learning. It is recommended that some adjustments need to be made to specific subtests in order for children with ASD to understand instructions, interpret demonstrations correctly and perform the activities. AUXTER, D., PYFER, J., ZITTEL, L. & ROTH, K. (2010). Principals and methods of adapted physical education and recreation. 11th Edition. Singapore: The McGraw-Hill Education. LOCOMOTOR AND OBJECT CONTROL SKILLS OF CHILDREN WITH INTELLECTUAL DISABILITY IN A DEVELOPING COUNTRY

Eguia, K.F.1, Capio, C.M.2, Sit, C.H.P.1, Simons, J.3

1:The Chinese University of Hong Kong, 2:University of Hong Kong, 3:University of Leuven (Belgium)

Introduction The Philippines is one of the developing countries, as reflected in available opportunities for children with disability. Adapted physical activity (APA) programs are not systematically included in special schools' curricula. One of the population-specific characteristics that are relevant in APA program development is proficiency in locomotor and object control skills. This study examined the use of a standardized testing procedure to characterize locomotor and object control skills among children with intellectual disability (ID) in the Philippines. Methods Participants include 70 children with ID, aged 9.29±2.66 years, who were tested on 10 components of the Test of Gross Motor Development-2 (Ulrich, 2000). Locomotor components included run, hop, leap, horizontal jump and slide, while object control components are stationary dribble, catch, kick, overhand throw and underhand roll. Results Reliability analysis showed good internal consistency for locomotor and object control (Cronbach's alpha=.86 and .76 respectively) components. Significant correlations were found for locomotor (r=.42-.69) and object control (r=.22-.63) components. Excellent inter-tester reliability was found for locomotor

(ICC=.99), object control (ICC=.96) skills. Intra-rater reliability was also excellent (ICC=1.0). Age was found to have moderate positive associations with locomotor ($r=0.353$) and object control scores ($r=0.509$). Participants' mean locomotor score of 22.94 ± 10.07 is significantly lower than the full score of 40 ($p<.001$). The mean object control score of 19.87 ± 7.69 is also significantly lower than the full score of 38 ($p<.001$). Discussion Locomotor and object control skills are phylogenetic (Burton and Miller, 1998), thus scores were expected to be positively associated with age. Because children with ID are known to have related motor impairments (Westendorp et al., 2011), participants were also expected to have significantly lower scores. Findings support these propositions, and suggest that the standardized testing procedure used in this study could be used for examining locomotor and object control skills of children with ID in the Philippines. Participants' impaired skills proficiency suggests APA programs in special schools in the Philippines could include supportive training programs for locomotor and object control skills. EFFECTS OF A 12-MONTHS SUPERVISED EXERCISE PROGRAM ON CARDIORESPIRATORY FITNESS, METABOLIC AND OXIDATIVE STRESS MARKERS IN TYPE 2 DIABETIC SUBJECTS

Vinetti, G., Mozzini, C., Desenzani, C., Bulla, L., Lorenzetti, I., Pasini, A., Cominacini, L., Assanelli, D.

University of Brescia

AIM. To evaluate the efficacy of supervised exercise training on metabolic parameters, cardiorespiratory fitness and oxidative stress markers in patients with type 2 diabetes mellitus (T2DM). To prove the role of cardiopulmonary exercise testing (CPX) in the management of physically active diabetic patients. **METHODS.** Twenty male patients with T2DM were randomly assigned to an intervention group, who performed supervised exercise training in a hospital-based setting, and to a control group, who received standard medical care only. The exercise program consisted in 12 months of both aerobic and resistance training. Patients underwent anthropometric examination, biochemical investigation, maximal CPX on cycle ergometer and oxidative stress markers dosage. Oxidative stress markers (1-palmitoyl-2-[5-oxovaleryl]-sn-glycero-3-phosphorylcholine [POVPC]; 1-palmitoyl-2-glutaryl-sn-glycero-3-phosphorylcholine [PGPC]) were measured in plasma and in peripheral blood mononuclear cells (PBMC). All investigations were carried out at baseline and after 12 months. **Results.** In the investigation group we observed a significant modification ($p<0.05$) in the following parameters: maximum oxygen consumption (+14.4%), anaerobic threshold (+23.4%), maximum workload (+13.3%), waist circumference (-1.4%), total cholesterol (-14.6%), LDL-cholesterol (-20.2%), fasting insulinemia (-48.5%), HOMA-IR (-52.5%), plasma concentrations of POVPC and PGPC at T12 (-27.9% and -31.6%, respectively). After 12 months, the control group showed no statistically significant changes and presented a maximum oxygen consumption, a maximum workload and an anaerobic threshold significantly lower ($p<0.05$) than the intervention group. **CONCLUSIONS.** Supervised exercise training was effective in improving cardiorespiratory fitness, the metabolic asset and the oxidative status in subjects with T2DM. The CPX allowed to customize the exercise prescription and to accurately detect improvements in cardiorespiratory fitness.

EVALUATING THE EFFECTS OF SKIN COOLING ON H-REFLEX RECOVERY CURVE USING A DOUBLE STIMULATION METHOD

Yona, M.1, Tadano, C.2, Naito, Y.3, Shimose, R.4, Sugawara, H.5, Sakamoto, M.6, Muro, M.2

1: TUPLS (Japan), 2: Toho Univ. Med (Japan), 3: Kokushikan Univ. (Japan), 4: Sagami Chuo Hospi. (Japan), 5: Tokyo Univ. Tec. (Japan), 6: Kitazato Univ. (Japan)

Introduction We have demonstrated that the decrease in skin temperature with skin cold stimulation more markedly acts on high threshold MUs (HT-MUs) than on low threshold MUs (LT-MUs), resulting in a decrease in the threshold force of HT-MUs. On the other hand, there was no change or a decrease in the threshold force of LT-MUs with skin cooling suggesting there is no clear effect of skin cooling on LT-MUs. H-reflex recovery curve testing via double stimulation has been widely used in the evaluation of spinal motoneuron pool excitability in various motor disorders of central origin. Therefore, the purpose of this study was to investigate the effects of skin cooling on the spinal cord by analyzing the H-reflex recovery curve using a double stimulation method. **Methods** Eight healthy adults volunteered for this study. Isometric contraction force and twitch of the triceps surae were measured with a force transducer attached to a footplate apparatus. Electric signals were picked up by surface electrodes (10mm) on the belly of SOL and MG. This experiment was performed under two conditions that consisted of skin cooling (skin temp. 26 deg.; SC) and control (skin temp. about 33 deg.; NSC). A cooling pad, attached to the skin, was used in the cooling condition. H-reflexes and M-wave were evoked in the SOL and MG muscles by electrical stimulation of the posterior tibial nerve via a cathode ball electrode (5mm in diameter) pressed into the popliteal fossa. H-reflex using double stimulation (conditioning H reflex: H1, test H reflex: H2) was obtained under the two conditions at rest. Time intervals between conditioning and test stimulation ranged between 10 and 800 ms. The data analyzed was H-reflex peak-to-peak amplitude (H2/H1). **Results and Discussion** There was no significant difference in Hmax, Mmax and H/M ratio between CS and NCS. There was no significant difference between the amplitude of control H-reflex and H1-reflex. Regarding the rate of H2/H1, there was an initial complete depression within several tens of milliseconds and an early recovery attaining a peak at 250–300 ms (80%) under both conditions. The initial peak of recovery at around 250–300 ms has been used as an optimal point for measuring spinal motoneuron pool excitability in the double H-reflex test. However, there was a difference in the time it took to attain a peak recovery between CS and NCS (CS:250ms, NCS:300ms). The rate of H2/H1 after peaking was unchanged in NSC in SOL and MG. However, in CS the rate of H2/H1 after peaking decreased to about 60% in SOL. These results suggest that the decrease in H2/H1 with skin cooling is related to elevated motoneuron inhibition. LENGTH/HEIGHT FOR GESTATIONAL AGE IN GIRLS WITH DOWN SYNDROME IN SOUTHEAST BRAZIL

Bertapelli, F.1, Guerra Júnior, G.1

1: Growth and Development Lab, Center for Investigation in Pediatrics (CIPED), School of Medicine, State University of Campinas (UNICAMP)

Introduction Short stature in children born preterm has been reported in several studies. However, no studies were found on the height status in children born preterm with Down syndrome. Thus, we assessed length/height status according to gestational age in girls with Down syndrome in southeast Brazil. **Methods** The study included 1,338 observations of length/height retrospectively in 147 girls with Down syndrome aged 0 to 12 years. Gestational age was characterized as preterm when 28–36 (21 girls/302 observations) and full term

for 37-42 (121/1,036) completed weeks. The data were divided into 8 different age groups. Results Babies born at 28-36 weeks of gestation were lower in comparison with the 37-42 weeks group ($p < 0.01$) in all age group up to 2 years. Children aged 3-5 years, born between 28-36 weeks presented higher values (97.88 ± 9.3 cm) than 37-42 weeks group (95.17 ± 5.71 cm), $p = 0.049$. After 5 years of age, the girls did not show different height according to gestational age. Discussion Our data show that after 2 years of age, the girls born preterm reached height at the age corresponding to full term (37-42 weeks), suggesting that height in girls with Down syndrome tends to normalize after the first two years of life. The postnatal growth in the majority of preterm children is followed by a period of catch-up growth, which start in early infancy and usually stops at 2-3 years of age, but it may continue into adolescence (Euser et al., 2008). Furthermore, some confounders should be analyzed such as height of parents, diseases, nutritional factors and others, in order to explain the results of this study. ELECTROMECHANICAL DELAY DURING BALL'S RELEASE IN BOCCIA PLAYERS WITH CEREBRAL PALSY

Sabido, R., Caballero, C., Reina, R.

Miguel Hernandez University

Introduction Athletes with hypertonia, ataxia and athetosis are classified for Boccia competition according to several functional tests, to check the impact of the impairment in the sport's activity limitation. People with cerebral palsy are difficult to fit into classification systems that are appropriate for other health conditions or disabilities (2). The aim of this study is to show the utility of electromechanical delay (EMD) to classify boccia players. **Methods** Ten boccia players participated as volunteers in this study. They performed 20 trials of ball release in two different conditions. They were required to grasp a boccia ball and to drop it on a target placed on the floor. Later, they performed the same task but reacting to a sound stimulus. Ten trials were performed in each situation, and they were seated in a standard chair with knees at 90° , feet on the floor, back on the backrest, and arm placed on a lateral platform with elbow flexion close to 90° . Electromyography (EMG) was recorded from carpal extensors, and mini-switches were placed on the fingers to capture ball's release. EMD was calculated by time from the onset of EMG activity and the ball release. **Results** Mean EMD were 50.02 ± 12.16 ms in task without sound stimulus, and 46.88 ± 14.68 reacting to sound stimulus. Coefficient of variation (CV) was 24.31% in situation without sound stimulus and 31.31% in situation with sound stimulus. CV calculated for each participant showed a range from 8% to 52%. No significant differences were obtained in related condition comparison. **Discussion** EMD is primarily a measure of series elastic stiffness, and this is an important characteristic in cerebral palsy athletes. The results showed similar EMD values to other studies (1) where EMD was measured in lower body of CP participants. CV is a non-usual variable in EMD analysis but several authors (3) have showed the importance of this variable to describe performance in CP population. Results about CV in each participant suggest EMD variable could be a variable to classify CP athletes to check impact of the impairment in sport. Further research is necessary to quantify EMD values with performance in this population. **References** 1. Granata, K.P., Ikeda, A.J., Abel, M.F. (2000). *Arch Phys Med Rehab*, 81(7): 888-94 2. ROLE OF VISION IN BALANCE AND COMPLEXITY IN SIGHTED AND BLIND FOOTBALL PLAYERS

Reina, R., Campayo, M., Caballero, C., Barbado, D.

Miguel Hernandez University

Introduction The maintenance of upright standing posture is an important motor act, which depends upon the integration of different sensory sources (Manor et al., 2010), and visual impairment has a major impact on motor development and skill acquisition (Hallemans et al., 2011). The hypothesis about the relationship between complexity and performance has been studied with controversial results. To test this hypothesis, linear and nonlinear tools has been used to analyze the center of pressure (COP) structure between different populations, blind and sighted football players. **Methods** Nineteen football players took part in this study (blind = 5 (age: 26.4 ± 6.4 years; height: 1.71 ± 0.02 m; mass: 69.4 ± 2.9 kg; $M \pm SD$) and sighted = 14 (age 25.3 ± 6.4 years; height: 1.77 ± 0.05 m; mass: 73.2 ± 6.0 kg)). They were requested to maintain stability on a force platform (Kistler 9287BA) in absence of vision in one-foot stance on a stable surface (30s) and bipedal stance on an unstable surface (1min). Center of pressure (CoP) fluctuation was recorded in all trials. Balance performance [bivariate variable error (BVE) and magnitude mean velocity (VmeanM)] and complexity of CoP [Fuzzy Entropy (FE) and Detrended Fluctuation Analysis (DFA)] were analyzed. **Results** There are no significant differences in complexity and performance between blind and sighted football players. Pearson bivariate correlations were obtained: $r = .544^*$ for BVE and VmeanM in bipedal test and $r = .805^{**}$ in one-foot stance. Also, there are negative correlations in one-foot stance for FE with BVE ($r = -.593^{**}$) and VmeanM ($r = -.488^*$). Between non-linear tools, a correlation is obtained for DFA and FE ($r = -.629^{**}$) in one-foot stance test. **Discussion** Blind and sighted football players presented a similar behavior in complexity and performance. They performed both tests in absence of vision so in this case a maintained absence of vision had no effects on balance control tasks (Schwesig et al., 2011). In this way, both groups showed greater complexity related with a greater performance (Manor et al., 2010). **References** Barbado D., Sabido R., Vera-García F, Gusi N, & Moreno F (2012). *Hum Mov Sci*, 31: 1224-37. EVALUATION OF SKELETAL MUSCLE OXIDATIVE METABOLISM IN ALZHEIMER DISEASE PATIENTS.

Bellistri, G.1,2, Marzorati, M.1, Sodero, L.1, Zuccarelli, L.1, Bisconti, V.1, Ramaglia, M.1, Porcelli, S.1

Università degli Studi di Milano

1Institute of Bioimaging and Molecular Physiology, Consiglio Nazionale delle Ricerche, Segrate (MI), Italy. 2Department of Biomedical Sciences for health, Università degli Studi di Milano, Milan, Italy. **Introduction** Alzheimer disease (AD) is the most common form of dementia affecting the aging population and its hallmark is a progressive deterioration in cognitive function (1). The pathogenesis of AD is characterized by beta-amyloid (β AP) over production and its deposition in the brain (2). Recently, evidence has been provided that β AP deposits can be also present in skeletal muscles of AD patients (3). Abnormalities of mitochondrial morphology and respiratory chain dysfunction in peripheral tissues of AD patients have been also described (4). **Aim** of this study was to evaluate whether in AD patients skeletal muscle oxidative metabolism is impaired. **Methods** Thirteen AD patients (71.5 ± 5.2 years, mean \pm SD) and twenty-nine healthy sex-matched control subjects (CTRL) (73.8 ± 4.7 years) were investigated. Skeletal muscle oxidative metabolism was evaluated during two

incremental exercises performed up to voluntary exhaustion: a cycloergometer (CE) and a one-leg knee extension (KE) exercise. The following variables were determined: breath-by-breath pulmonary O₂ uptake (VO₂); heart rate (HR) and cardiac output (CO); vastus lateralis muscle fractional O₂ extraction by near-infrared spectroscopy ($\Delta[\text{deoxy(Hb+Mb)}]$); blood lactate concentration ([La-]) at rest and after exercise. Results During CE, peak work-rate (92.9 ± 32.5 vs 128.3 ± 41.8 watt) and VO₂ peak (1.44 ± 0.41 vs 1.86 ± 0.5 L*min⁻¹) were significantly lower in AD patients vs CTRL. CO was similar between AD patients (18.1 ± 2.4 L*min⁻¹) and CTRL (17.9 ± 3.1 L*min⁻¹) whereas $\Delta[\text{deoxy(Hb+Mb)}]$ was significantly lower in AD patients (52.6 ± 3.3 %) vs CTRL (69.0 ± 6.4 %). During KE, VO₂ peak (0.78 ± 0.22 vs 0.99 ± 0.25 L*min⁻¹) and $\Delta[\text{deoxy(Hb+Mb)}]$ (31.2 ± 4.8 vs 58.9 ± 6.6 %) were significantly lower in AD patients vs CTRL. RPE and [La-] were not different in the two groups, both for CE and KE. Conclusions Our findings show that AD patients have a reduced exercise capacity compared to healthy control subjects, likely due to a reduced muscle fractional O₂ extraction capacity. Indeed, the impairment of muscle oxidative function was confirmed even reducing constraints (by KE) to oxidative function deriving from cardiovascular O₂ delivery. If confirmed on a larger number of patients, these observations lead to some interesting prospects, the most striking of which is that AD may be a systemic disease rather than exclusively a disease of the central nervous system. THE ANALYSIS OF MINERAL CRYSTALLINITY IN CORTICAL AREA OF TIBIA USING OVARECTOMIZED RAT

Yuichi, N., Umon, A., Naomi, O.

Universe of Tsukuba

Background Osteoporosis in woman with postmenopausal, regarded as social problem, is well-known that expected bone fracture caused by decreasing bone mass. On the other side, previous study reported that change of bone quality is also one of the factors affecting bone strength. Recent, micro-Raman spectroscopy have been used to evaluate bones, and reported that structure of mineral crystals in cortical bone might be associated with bone mechanical properties. [1] However, the association between crystallinity and reducing bone strength caused by ovariectomy is still unclear. Purpose In this study, characterize of mineral crystals in cortical bone of tibia for ovariectomized rats was analyzed using micro-Raman spectroscopy. Materials and methods Female Sprague-dawley rats ovariectomized in 6 week-old were used in this study. Rats were selected at random and ovariectomized (OVX, n=6). Other rats were sham-operated (Sham, n=6). The animal feed contained 0.6% calcium and 0.6% phosphorus. We allowed them to take feed and drink distilled water. After 8 weeks, all rats were sacrificed, and blood and bone samples were collected. Tibia was used to analyze structure of mineral crystals using micro-Raman spectroscopy after the measure of bone mineral density (BMD). Result Crystallinity of cortical bone at tibia tended to decrease in OVX rats compared to Sham rats ($P=0.1$). Furthermore, BMD of proximal region at tibia and bone breaking energy of femur were remarkably lower in OVX rats than Sham rats. Discussion BMD and bone breaking energy were same results as previously study using OVX rats. Therefore, this study indicates that OVX rats were under the lack of estrogen caused by OVX, and bone resorption was more active than Sham rats. And we observed tendency to reduce crystallinity in OVX rats. Therefore, crystallinity of bone for OVX rats observed decreasing BMD and bone strength tended to reduce, which indicates possibility of association between crystallinity of cortical bone and postmenopausal osteoporosis. ASSESSMENT ON INFLAMMATORY MARKERS BEFORE AND AFTER A RUGBY TRAINING SESSION

Gutierrez, F.

Cruzeiro do Sul University

Introduction Previous studies have shown that rugby athletes have a higher risk of neurodegenerative diseases. Rugby players are subject to high-impact physical contact and therefore are highly exposed to injuries leading to inflammatory processes. Acute and chronic inflammation may be a determining factor for a higher risk of degenerative diseases, but little is known on this subject. The purpose of this study was to assess the inflammatory markers before and after a rugby training session. Methods 11 male players participated in the study (age 25.72 ± 8.13 , weight 78.97 ± 11.14 , height 1.76 ± 0.03 , BMI 25.48 ± 3.63 , fat percentage 17.75 ± 5.738). Venous blood samples were taken before and after the session and plasma and serum were separated and stored at a -20°C temperature. Concentration of IL-12, IL-10, IL-6, TNF, IL-1b, and IL-8 was determined by flow cytometry (Human Inflammatory Cytokines Kit, San Diego, CA). PCR concentration was determined by the immunoturbidimetric method (Kit Bioclin, Minas Gerais, BR). The statistical analyses were made aided by IBM SPSS Statistics 20 software. Results The rugby training session increased IL-10 and IL-2 concentration by 51.02 and 34.83%, respectively ($p<0.05$). TNF, IL-6, IL-8, and IL-1b concentrations did not change during the session. Before the training session, we further noticed that IL-10 had moderate correlation with TNF-alpha ($r = 0.68$) and PCR ($r = 0.71$); TNF-alpha with IL-8 ($r = 0.76$); and IL-1beta with IL-6 ($r = 0.62$). Following the training, high correlation between IL-6 and IL-1b ($r = 0.82$) and IL-8 ($r = 0.90$) was reported. Discussion After the training session, an increase in anti-inflammatory cytokine IL-10 was noticed, which is responsible for inhibiting TNF, IL-1b, IL-6, and IL-8 secretion caused by increased muscle micro injuries (Suzuki, et al., 2006). However, no correlation was found between IL-10 and the other cytokines. We also identified an increase of IL-12 following the training session, which is in accordance with an anaerobic exercise study in which the highest IL-12 concentration occurred right after the session (Takayuki et al., 2000). IL-12 promotes the production of Th1 cells, related to cell immunity and defense against intracellular pathogens. IL-10 and IL-12 are involved in the pathogenesis for neurodegenerative diseases such as the Parkinson's disease (Arnaud LT et al., 2009). We have thus concluded that the rugby training session led to an increase of interleukins with both anti- and pro-inflammatory effects, and an excessive occurrence of chronic inflammation in athletes may promote the development of neurodegenerative diseases.

SIX WEEKS HIT DOES NOT CHANGE THE EXPRESSION OF MUSCLE FATTY ACID TRANSPORTER AND TG HANDLING PROTEINS

Søgaard, D., Vigelsø, A., Dela, F., Helge, J.W., Larsen, S.

Copenhagen University

Introduction In humans, high intensity training (HIT) has been shown to induce similar effects on maximal oxygen uptake (VO₂max) and insulin sensitivity as traditional endurance training. However, the influence of HIT on lipid metabolism is not fully elucidated and therefore the aim of this study was to investigate the effect of HIT on lipid transport and storage capacity in skeletal muscle of overweight untrained

subjects. Our hypothesis was that HIT given the large glycolytic flux and expected glycogen utilization, would not influence lipid transport and TG synthesis capacity. Methods Ten (2 female/8 male, age 38 ± 3 years) overweight (BMI $xx \pm y$), untrained subjects were recruited. The subjects completed 6 weeks of HIT training (one session; 5×1 min at 128 ± 2 % of maximal load 232 ± 15 watt) 3 times a week. Maximal oxygen uptake and DXA (Lunar iDXA, GE Medical Systems Lunar, USA) were measured and skeletal muscle biopsies obtained before and after the HIT period. The content of lipoprotein lipase (LPL), fatty acid binding protein (FABPpm), cluster of differentiation 36 (CD36), diacylglycerol acyl transferase 1 & 2 (DGAT1 & 2), perilipin 5 (PLIN 5), adipose triglyceride lipase (ATGL) and hormone sensitive lipase (HSL) were analyzed by western blotting. Results Body weight, body fat and lean body mass remained unchanged. The maximal oxygen uptake increased ($p < 0.05$) from 2.9 ± 0.2 to 3.1 ± 0.2 L min^{-1} after the training. The protein expression of HSL was increased ($p < 0.05$) in muscle after the training period and a tendency ($p = 0.098$) towards an increase in FABPpm expression was observed. In contrast the expression of CD36, DGAT1, DGAT2, LPL, PLIN5 and ATGL remained unchanged. Discussion In line with our hypothesis the expression of the majority of muscle lipid transport, storage and utilization proteins were not affected by 6 weeks of HIT training. Surprisingly the muscle HSL expression was increased after HIT and further research is required to confirm and explain this adaptation. Overall it is apparent that very high intensity HIT does not lead to major effects on lipid metabolism over shorter training periods.

DEVELOPMENT AND CHARACTERIZATION OF STRENGTH TRAINING BY LADDER FOR RATS WITH A PULLEY SYSTEM

Costa, K.G., Candido, J.P., Brenzikofer, R., Macedo, D.V.

State University of Campinas

Development and characterization of strength training by ladder for rats with a pulley system UNICAMP (CAMPINAS, BRAZIL) Introduction Different animal models of strength training are described in the literature. Between them the strength training in ladder attaches the overload secured to the base of the rats' tails using plastic insulation tape (Hornberger et al, 2004). Our goal was to present strength training in ladder with overload applied with a similar system to the regular weight machines used by humans and to characterize the metabolic, hypertrophy and oxidative stress responses to training. Methods Twenty two Wistar male rats were divided in trained (Tr - $n=12$) and control (C - $n=10$). A 1.1m ladder was built with two sheaves connected and supported in an angle of 80° on the wall. The Tr group trained for eight weeks with three sessions per week, four climbing for session, and overload in grams adjusted every week by a performance test (PT). Blood samples were collected before and after the last session to measure creatine kinase (CK-U/L) and lactate (LAC-mmol/L). Cross-sections ($12\mu\text{m}$) of the muscle Flexor hallucis longus (FHL) were done to determine muscle fiber area (MFA- μm^2). Concentration of Glycogen (mmol/kg tissue) and thiobarbituric acid reactive substance (TBARS-nmolTMP/g ww) in FHL were done by spectrophotometric assays. Also the activities (U/g wet wt) of Citrate Synthase (CS), Lactate Dehydrogenase (LDH), Catalase (CAT), Glutathione Reductase (GR) and Superoxide Dismutase (SOD) were analyzed in FHL by spectrophotometric assays according specific methodology. Results The Tr group relative to C showed a significant increase in PT on 4^o week ($501.3 \pm 44.87\text{g}$ vs $375.4 \pm 31.8\text{g}$) and on 8^o week ($610.5 \pm 30.5\text{g}$ vs $402.5 \pm 27.92\text{g}$). The sessions were glycolytic: LAC (before) 4.8 ± 0.8 vs (after) 9.9 ± 1.7 and lead to muscle traumas: CK (before) 152 ± 130.4 vs (after) 335 ± 187.7 . The MFA shows hypertrophy (4274 ± 1606 vs 3373 ± 1371) and glycogen stores were higher (41.85 ± 7.2 vs 29.76 ± 6.7). The Tr group also exhibited higher CS (1696 ± 292.6 vs 1086 ± 193.1) and LDH (12775 ± 747.1 vs 12196 ± 443) activities. The antioxidant enzymes also were up regulated compared to C: CAT (135.5 ± 31.45 vs 102 ± 57), GR (65.91 ± 8.9 vs 57.33 ± 5.9) and SOD (0.1369 ± 0.056 vs 0.1039 ± 0.033). The Tr group was more protect against oxidative attack: TBARS (1.235 ± 0.3881 vs 1.963 ± 0.9010). Discussion Our system of overload was sufficient to promote adaptations characteristic of strength training such as hypertrophy. Moreover, our results have shown that strength training adapts both metabolism (anaerobic and aerobic) and can protect against oxidative stress. This well characterized training model support further studies about signaling mechanisms involved in muscular strength production. References Hornberger, T.A., Jr, and Farrar, R.P. (2004). Can. J. THE EFFECTS OF LOW-VOLUME HIIT AND AEROBIC EXERCISE ON REDOX STATUS PARAMETERS

Jamurtas, A., Sakellariou, V., Apostolopoulos, A., Deli, C.K., Georgakouli, K., Fatouros, I.G., Koutedakis, Y.

University of Thessaly

Introduction Low volume, high-intensity interval training has been used recently in healthy trained individuals and patient populations. This type of training is characterized by high intensity that results in significant changes in ATP:ADP/AMP ratio and activation of key enzymes involved in metabolism. However, there are only few studies that examined the effects of this type of training on redox status modulation. Therefore, this study aimed to identify possible changes in redox status parameters and compare those to an aerobic exercise session. Methods Twelve healthy young men participated in a randomized, cross-over design in two exercise sessions. In one of those sessions participants performed four 30 second sprints on a cycle ergometer interspersed with 4 min of recovery (HIIT). Resistance on the cycle ergometer was equivalent to 0.075 kg/kg of body mass. The aerobic exercise session consisted of cycling on a cycle ergometer for 30 minutes at an intensity corresponding to 70% of their predetermined VO_2max . Blood was drawn before the exercise, immediately post, 24, 48 and 72 hours post-exercise and was analyzed for thiobarbituric acid reactive substances (TBARS), catalase activity and total antioxidant capacity (TAC). Results A significant group \times time interaction was found for TAC. HIIT resulted in significant ($p < .001$) increases in TAC immediately post and 24 hours post exercise whereas aerobic exercise resulted in significant ($p < .001$) increases in TAC only immediately post exercise. Furthermore, catalase levels were significantly higher immediately post ($p < .05$) and 24 hours ($p < .001$) post exercise in HIIT compared to aerobic exercise. No significant changes ($p > .05$) were observed for TBARS and catalase following neither exercise session. Conclusion HIIT results in significant changes in antioxidant status that lasts for 24 hours post exercise and these changes seem to be higher compared to aerobic exercise. Further research should examine more redox status indices following HIIT as well as attempt to delineate the reasons behind the aforementioned changes. References Bogdanis G.C., Stavrinou P., Fatouros I.G., Philippou A., Chatzinikolaou A., Draganidis D., Ermidis G., Maridakis M. Short-term high-intensity interval exercise training attenuates oxidative stress responses and improves antioxidant status in healthy humans. Food and chemical Toxicology, 61: 171-177, 2013.

THE WINNING OF AN OLYMPIC MEDAL IN MODERN PENTATHLON: NEW BORDERS OF SPORTS SCIENCES USING AN SPORTOMICS APPROACH

Magno França, A.1,2,3, Magalhães Neto, A.M.1,4, Bachini, F.1, Bassini, A.1, Cameron, L.C.1

1:UNIRIO (Brazil), 2:UFU (Brazil), 3: CDE (Brazil), 4:UFMT (Brazil)

Introduction The modern pentathlon (MP) is an Olympic sport comprising the disciplines of fencing, swimming, horseback riding and an event combining running and pistol shooting. It becomes a great tool for studying the relationship between metabolic stress and the

immune and central nervous systems. Our research focused on comparing Sportomics findings during MP training (Bassini and Cameron, 2014), bringing relevant changes in its planning content. The aim of this study is to describe metabolic adaptations of an exercise of various intensities using MP as a model. Methods A female athlete was monitored for over 34 months, from years 2010-2013, during ten different weeks samples (3-6 days each), collected at fasting, pre and post training and after a 90 min recovery period. As result, training, her rest and nutritional behavior were adjusted. We measured ~300 blood and urine parameters. Results We previously used the activity of creatine kinase (CK) to estimate exercise intensity (Bessa et al., 2008). During the first year, most of the training remained below a 300% increase (190-677 U/L in CK levels). In the second year, the increase was near 400% (135-550 U/L), and it reached almost 800% (119-928 U/L) by year three. We were able to establish a pattern that returned the CK level to the near baseline values measured at the beginning of each week. In the last year, evolution in training showed that the increase in neutrophils decreased almost ten-fold with higher intensity exercise. The lymphocyte response was a third smaller than that for the neutrophils. Alanine aminotransferase raise in response to the increase in exercise intensity (peak at 350%), and it was smaller than that for aspartate aminotransferase (peak at 180%). In contrast, no changes in gamma-glutamyltransferase were measured and the modifications in training associated with diet and resting flattened the C-protein response, abolishing its increase even with higher exercise intensities. Discussion Muscle injury markers and inflammatory response indicated the best recovery kinetics for diverse training phases. In addition, we showed that the increase in training intensity was followed by a decrease in inflammatory response without a lack in immunity. By monitoring these analyses, it is possible to adopt a more intense training program decreasing the chance of muscle injury. To our knowledge, this is the first biochemical and signaling analysis of a MP athlete, supported for the winning of an Olympic medal. References Bassini A and Cameron LC. THE LEVEL OF ACTN3 PROTEIN EXPRESSION DOES NOT INFLUENCE KNEE EXTENSOR STRENGTH

Nakamura, T.1, Kakigi, R.1, Ichinoseki Sekine, N.1,2, Kobayashi, H.3, Sakuma, K.1, Machida, S.1, Naito, H.1

1/Juntendo University, 2/The Open University of Japan, 3/Tsukuba University Hospital

Introduction Human skeletal muscle expresses α -actinin (ACTN) 3 and ACTN2 proteins which are encoded by ACTN3 and ACTN2 gene, respectively1). ACTN3 gene includes three polymorphisms, RR, RX and XX genotype. The presence of ACTN3 protein in muscles is shown to generate higher muscle strength. However, it is unclear that ACTN3 genotype affects the level of ACTN3 protein expression, and the level of ACTN3 protein expression influences muscle strength. Therefore, the aim of this study was to examine (1) the effect of ACTN3 genotype on the level of ACTN3 protein expression and (2) the influence of the level of ACTN3 protein expression on muscle strength of the knee extensors. **Methods** Twenty college level male sprinters (20.8 \pm 1.7 years old, 172.4 \pm 5.1 cm, 67.5 \pm 5.0 kg) participated in this study. They were genotyped for ACTN3 R577X using a real-time polymerase chain reaction method. After that, XX subjects were excluded. Subjects performed isometric and isokinetic knee extensions (60, 180, 300 and 400 deg/sec) on a dynamometer. After a week, muscle biopsies were obtained from the vastus lateralis muscle. The level of ACTN3 and 2 protein expression was evaluated by western blot analysis and the muscle fiber composition was determined using ATPase staining. **Results** The ACTN3 genotype distribution was 7 subjects for RR, 9 subjects for RX and 4 subjects for XX. The level of ACTN3 protein expression was significantly higher in RR than RX (RR vs RX: 1.00 \pm 0.06 vs 0.73 \pm 0.15, $p < 0.05$). In contrast, the level of ACTN2 protein expression was significantly higher in RX than RR (RR vs RX: 1.00 \pm 0.02 vs 1.16 \pm 0.13, $p < 0.05$). However, no significant differences were found in knee extensor strength at any speed and the muscle fiber composition between RR and RX. **Discussion** This is the first study to show that ACTN3 genotype affects the level of ACTN3 protein expression, but the level of ACTN3 protein expression does not influence knee extensor muscle strength. In the previous studies, knee extensor strength is strongly related to muscle fiber composition2). In the present study, there was no difference in the muscle fiber composition between RR and RX. Therefore, it is thought that knee extensor strength is greatly influenced by the muscle fiber composition more than the ACTN3 protein expression levels in muscle fibers. These results suggest that ACTN3 genotype affects the level of ACTN3 protein expression, however the level of ACTN3 protein expression does not affect concentric muscle strength in college level male sprinters. **Reference** 1).Beggs AH, et al. ANALYSIS OF THE MITOCHONDRIAL EFFICIENCY IN RATS SUBMITTED TO AN OVERTRAINING MODEL

Ferraresso, R.L.P., Gadelha, F.R., Peloso, E.F., Ferrucci, D., Cartaxo, R.T., Ferreira, C.V., Macedo, D.V.

University of Campinas

Introduction Overtraining is a continuous process of intensified training with possible outcomes of functional-overreaching (FOR), which will eventually lead to an improvement in performance and nonfunctional-overreaching (NFOR) characterized by a decreased performance reversed only by a longer regenerative period. Recently we developed an OT animal model that lead at the end to both performance states (Hohl et al.,2009). The FOR group exhibited increased mitochondrial content. Conversely, the citrate synthase and the mitochondrial complex IV activities in NFOR were lower than that of the control and FOR. This impaired mitochondrial adaptation was associated with increased muscular antioxidant enzyme activities and lipid peroxidation, suggesting that underperformance was related to muscle oxidative stress (Ferraresso et al., 2012). In the current study we addressed this question by investigating the behavior of isolated mitochondria and autophagy proteins expression in skeletal muscle of FOR and NFOR animals. **Methods** Male Wistar rats were submitted to OT protocol and 9 and 8 animals were separated as FOR and NFOR groups, respectively. The mitochondrial O2 consumption was monitored using a computer-interfaced oxygen electrode. Determination of mitochondrial H2O2 release and O2- production was obtained by fluorimetric methods. Autophagy proteins LC3 and P62 were analyzed by western blotting. **Results** The isolated muscle mitochondria of NFOR rats relative to FOR showed lower O2 consumption (12.04 \pm 2.25 vs 21.9 \pm 4.0mM.O2.min-1mg), higher H2O2 release (2715 \pm 168 vs 2056 \pm 272pmoles.min) and O2- production (0.42 \pm 0.08 vs 0.2 \pm 0.06pmol). FOR rats showed increased expression of autophagy proteins. Conversely NFOR showed attenuated increased in LC3 (1.61 \pm 0.53 vs 1.1 \pm 0.35u.a) and P62 (0.88 \pm 0.14vs 0.61 \pm 0.15u.a). **Discussion** Recent evidence suggests that increased autophagy by exercise accounts for exercise benefits and improvement of physical performance. This condition was confirmed in FOR animals that exhibited higher oxidative capacity and performance after an OT period. Maintaining autophagy at normal levels is important to rejuvenate organelles and to prevent accumulation of dysfunctional proteins. Here, we document for the first time that NFOR rats exhibited attenuated autophagy. Probably, the accumulation of dysfunctional mitochondria contributes to higher ROS production responding for both, the loss of previously acquired performance and the delay in performance recovery in NFOR state. **References** Hohl R, Ferraresso RLP, Lucco R. et al. Biomechanics

ASSESSMENT OF KNOWN KINEMATIC PREDICTORS OF FAST BOWLING PERFORMANCE AT BOTH THE START AND END OF A CRICKET SEASON

Olivier, B., Stewart, A., Green, A., McKinnon, W.

Department of Physiotherapy, School of Therapeutic Sciences; and School of Physiology, Faculty of Health Sciences, University of the Witwatersrand Medical School.

Introduction The speed at which a cricket fast bowler releases the cricket ball is key to bowling performance. Various 3D kinematic variables describing body movement during the bowling delivery stride are known to be related to ball release speed including: knee angles [Portus et al, 2004], shoulder angles [Wormgoor et al, 2010], trunk orientation [Roca et al, 2006] and ball release height [Bartlett et al, 1996]. Additionally, in contrast to the large number of cross sectional studies assessing the kinematic predictors of ball release speed, few studies have investigated whether kinematic variables that predict fast bowling performance do so reproducibly over time. The aim of this study was to assess the ability of kinematic variables to predict ball release speed and bowling accuracy, both at the beginning and at the end of a cricket season. **Methods** 31 injury free, premier league (amateur) cricket fast bowlers over the age of 18 years were invited to participate in this study. A standard marker set and established three dimensional kinematic methods were used to measure shoulder and pelvic rotation, angles of spinal vertebrae (L1, T7 and T10), as well as shoulder and knee joint angles at both front foot placement and ball release during the delivery stride, were quantified. All measurements were performed at the beginning of the cricket season and repeated 8 months later (after the season). Pearson's correlation was used to analyse relationships between kinematic data and ball release speed. **Results** Average ball release speed was 124.25km/hr (34.51m/s) and 125.23km/hr (34.79m/s) at the start and end of the season, respectively. A more extended knee angle ($r=0.40$; $p=0.04$), a larger arm to thorax angle ($r=0.50$; $p<0.01$), a more upright global trunk position ($r=-0.37$; $p=0.05$), more global trunk left lateral flexion ($r=0.36$; $p=0.05$), larger L1 ($r=-0.45$; $p=0.01$), T10 ($r=-0.47$; $p=0.01$), T7 ($r=-0.51$; $p<0.01$) segmental spinal lateral flexion and more global trunk left rotation ($r=0.41$; $p=0.02$) were positively correlated with higher ball release speeds at the start of the season. Only arm to thorax angle ($r=0.46$; $p=0.02$) remained a significant predictor of ball release speed after the season. **Discussion** The data presented in this study confirm the important contributory role that a number of known candidate kinematic variables play in the determination of fast bowling performance. Differences found before and after the cricket season may be due to refinement of the action of bowlers, resulting in less variation in the bowling action between bowlers, resulting in fewer positive correlations. It should be noted that many of the variables favouring increased performance identified in this study, have been associated with injury in cricket fast bowlers. **References** Bartlett et al, J Sports Sci, 14: 403-424, 1996. EFFECTS OF EIGHT-WEEK PLYOMETRIC TRAINING ON JUMPING HIGH AND SPECIFIC MOVEMENT PATTERNS IN BADMINTON PLAYERS

Felder, H.1,3, Fröhlich, M.2,3, Reuter, M.2

1:Olympic Training Center, 2:Saarland University, 3:Institute for Prevention and Public Health, University of Applied Sciences

Introduction: Plyometric training is popular among individuals involved in dynamic sports. Plyometric exercises, such as jumping, hopping, skipping and bounding are executed with the goal of increasing dynamic muscular performance, especially jumping [Kannas et al., 2012; Markovic, 2007]. Much less information is available on the effectiveness of plyometric training (PT) in badminton, where jumping high (e.g. forehand overhead jump-smash) is important for success. The aim of the study was to investigate the effects on jumping high, agility and power among male and female junior badminton players of an eight-week periodized PT program using high-impact bilateral plyometric exercises. **Methods:** Starting and finishing with the biomechanical diagnostics of the squat jump (SJ), counter movement jump (CMJ), and drop jump (DJ) on force plates, kinematic analysis of forehand overhead smashes, anthropometric data as well as force data for pre- and posttest were analyzed. Before and after the biomechanical diagnostics, the players underwent an 8-week plyometric training (2 units per week) with a total of 2286 jumps. 8 male and 3 female junior badminton players (age: 16.0 ± 1.6 years, height: 175.5 ± 9.9 cm, mass: 69.3 ± 11.4 kg) were tested for their performance in jumping high and forehand overhead jump-smashes. **Results:** Looking at the plyometric strength parameters and the floor reaction time of the squat jump ($p<0.05$; $d_z=0.8$) and the drop jump ($p<0.05$; $d_z=1.1$), the positive effect of the eight-week plyometric training in junior badminton players is significant. Consequently, this form of training is essential for the development of junior and top-level badminton players. Moreover, the study has shown that the contact of the overhead smash cannot be increased by improving plyometric strength training ($p>0.05$). Therefore, the focus must be on technical training for complex movements, such as the badminton smash. **Discussion:** It is considered to be important to include short-term plyometric programs in in-season preparation in order to improve complex badminton-specific dynamic performance (smash-jumping). The results of this study can directly be applied to specific badminton training. Furthermore, this study provides information on the increase in physical performance in combination with a technical component. The findings can also be used for the prevention of injuries. **References:** Kannas, T., Kellis, E., & Amiridis, I. (2012). A COMPARISON OF THE BADMINTON SPLIT AND CUT MOVEMENT WITH A PLANT AND CUT MOVEMENT

Reeves, J.1,2, Trewartha, G.1, Churchill, S.M.1,3

1:University of Bath (UK), 2:Vrije Universiteit (NL) 3:Sheffield Hallam University (UK)

Introduction The plant and cut is an established mechanism for non-contact anterior cruciate ligament (ACL) injury as it involves multi-planar motion that likely places greater strain on the ACL than sagittal motion alone [Markolf et al, 1995, Cochrane et al, 2007]. Badminton players perform cutting like movements that may place them at a high risk of ACL injury [Kimura et al, 2010]. The aim of this study was to compare knee joint moment patterns of a standard plant and cut with a badminton-specific split and cut movement. **Methods** Eight healthy, experienced, female badminton players (23 ± 6 years) performed badminton movements and cutting movements. Badminton movements started with a split step followed by a cut and a mimicked forehand or backhand shot, while cutting movements were a plant and cut or crossover from a running start. Ground reaction forces and three-dimensional kinematics were combined in order to calculate

internal knee joint moments using inverse dynamic analysis. Results Mean peak extension moment of the lunge leg was 1.21-1.40 N•m/kg/m, mean peak abduction/adduction moment was -0.36--0.41 N•m/kg/m and mean peak internal rotation moment was 0.21-0.41 N•m/kg/m. Mean peak internal rotation moment of the lunge leg in the forehand (0.41 ± 0.06 N•m/kg/m), was significantly greater than the lunge leg of the backhand (0.21 ± 0.03 N•m/kg/m), significantly greater than the propulsive leg of the forehand (0.10 ± 0.18 N•m/kg/m), but not significantly different to the leg that makes the step after the cut in the plant and cut (0.43 ± 0.13 N•m/kg/m). Discussion Knee joint loading in both forehand and backhand movements occurred in multiple planes and was similar to the high risk plant and cut movement. The peak internal rotation moment of the lunge leg during the forehand movement, in combination with loading in other planes, was of a level that could place a considerable load on the knee joint ligaments (Besier et al, 2001). This could partly explain the ACL injuries to the racket-hand side knee during the forehand plant and cut shot reported by Kimura et al, (2010). An important difference between the cutting movements in team sports and badminton may be that the push-off leg is the leg that is typically injured in the plant and cut and crossover (Cochrane et al, 2007), but the lunge leg experiences greater loading in cut movements in badminton. Therefore, findings in the literature regarding planting and cutting may not be directly transferable to badminton movements. References Besier, T. et al. (2001). *Med Sci Sport Exer*, 33, 1168-1175. THE IMMEDIATE EFFECT OF DIFFERENT MANDIBULAR POSITIONS ON MUSCLE FORCE IN THE UPPER AND LOWER LIMBS. A PILOT STUDY IN ASYMPTOMATIC SUBJECTS

Isselée, H.1, Asscherickx, A.2, De Mot, B.2, Dankaerts, W.1, Staes, F.1, Deklerck, J.1, De Neve, J.3, De Laat, A.4

KU Leuven

Introduction It has been suggested that the use of occlusal splints to effect the mandibular position can improve sports performance in professional athletes. However, the scarce research in this area demonstrates conflicting evidence. This pilot study evaluates upper and lower limbs muscle force under three different mandibular positions in asymptomatic subjects. Methods Twenty one healthy subjects (13 males – 9 females) aged 18- 24 years were recruited among students physiotherapy based on strict inclusion/exclusion criteria. They all underwent a dental and orthopaedic screening examination. Included subjects were free of temporomandibular, oral or musculoskeletal disorders. In subjects who met the inclusion criteria, a hard wax bite of 2-4 mm in central relation was individually made to be used in this study. Grip strength was measured by maximal isometric contractions using the Jamar dynamometer. Isometric muscle force of the quadriceps at 60° was measured using a Biodex dynamometer. Eccentric muscle force was measured in shoulder abduction muscles using the break method with also using a dynamometer (MicroFet). Three trials were done in each of 3 mandibular positions: 1) mouth closed without bite 2) mouth open and 3) mouth closed on a wax bite within each session, and in a random order. In 12 of the subjects the procedure was repeated after a period of a week. Using a linear mixed model approach covariance results were controlled for confounding of mandibular position, within-session trials and test day. Results No significant differences were found in muscle force between the three mandibular positions in any of the muscle groups tested ($p > 0.05$). Discussion The results of the present study indicate that in asymptomatic subjects, muscle force in the limbs was not influenced by altered mandibular position. This is in line with previously reported research (Williams et al, 1983, Schubert et al, 1984, Grosdent et al 2014) who failed to demonstrate improved strength as a result of wearing a balanced splint. The latter study, however, reported that artificial imbalanced occlusion could induce alteration of eccentric muscle performance. BACKWARD AND FORWARD HAND MOVEMENT OF EXPERT PIANIST IN CONTROLLING SOUND DYNAMICS

Ishigaki, T.

Aichi University of the Arts

Introduction Controlling the subtle kinematic action of the upper extremities is a very important technique for piano performance (Furuya et al., 2012). However, the keystroke process of actions in the upper extremities for the control of sound dynamics remains poorly understood. Purpose: The aim of this study was to examine how expert pianists move their upper extremities for the control of sound dynamics on the piano. Methods The subjects were eleven graduate students majoring in piano. The piano used for this experiment was a grand piano. The experimental task was to play a C major chord (C5E5G5) eight times in a row, gradually changing the dynamics from pianissimo to fortissimo with the right hand. Sound pressure level (SPL) was input to computer via a soundboard (sampling frequency: SF=50 kHz). Three-dimensional motion analysis (SF=150 Hz) was performed to measure the maximum speed of down stroke (MS), backward and forward (BFD), horizontal (HD) and vertical (VD) displacement of hand (metacarpophalangeal joint). Collected SPL data were root-mean squared. We employed the highest SPL per keystroke for data. Each parameter was analyzed by Spearman's rank correlation. Pearson's correlation coefficient was used for the relationships between SPL and the other parameters. Results The mean Spearman's rank correlation coefficients were 0.954+/-0.028 in SPL, 0.948+/-0.041 in MS, 0.617+/-0.434 in HD, 0.911+/-0.095 in BFD, and 0.647+/-0.462 in VD, respectively. The mean Pearson's correlation coefficients were 0.920+/-0.043 in MS, 0.598+/-0.456 in HD, 0.833+/-0.128 in BFD, and 0.598+/-0.429 in VD, respectively. Discussion: The results of Spearman's and Pearson's correlation coefficient values indicated that hand MS, and backward and forward movement strongly affected the gradually change in sound volume control. These results indicate that pianists move their hands backward and forward to control sound dynamics. References Furuya, S., Aoki, T., Nakahara, H., Kinoshita, H. (2012). *Hum Mov Sci*, 31, 26-39. RELATION BETWEEN KICKING FORCE AND POWER OUTPUT IN TAEKWONDO

Michalski, R.1, Busko, K.1, Staniak, Z.1, Lach, P.1, Mazur Rozycka, J.1, Gajewski, J.1, Gorski, M.2

1: Institute of Sport (Warsaw, Poland), 2: Jozef Pilsudski University of Physical Education (Warsaw, Poland)

Introduction Taekwondo is a combat sport where kicking techniques is essential. Punching and kicking force is rarely measured in athletes. There are few studies which describe the relation between punching force and power output or joint torque in boxers but not in taekwondo athletes. The aim of this study was to investigate the relation between maximal punching/kicking force and maximum power output measured in 10s Wingate test, maximum power output and jumping height of taekwondo athletes. Methods The study involved six taekwondo athletes (age 17.7±0.7 years, body height 179.5±4.1 cm, weight, 62.3±6.0 kg). Measurements of maximal punching and kicking force were carried out on a boxing dynamometer. Each participant performed six punches of rear hand (3 hook and 3 straight

punches) and six kicks (3 apdollyo and 3 dwit-chagi). Maximal power output and jumping height in counter movement jump (CMJ) were measured on a force plate. 10s Wingate anaerobic test (WAnT) was performed on a cycle ergometer connected to a PC. Braking force on pedals was determined by load equal to 0.075 of body weight. Statistical calculations were prepared using STATISTICA software. Results Mean, maximal straight and hook punching forces were 1659.2 ± 254.2 N and 1843.8 ± 453.3 N, respectively. Maximal apdollyo right, apdollyo left and dwit-chagi kicking forces were 3541.3 ± 1130.3 N, 3205.3 ± 965.1 N and 3568.0 ± 1306.0 N respectively. Means (\pm SD) of CMJ height and maximum power were 0.501 ± 0.040 m and 2440.5 ± 731.7 W, respectively. The maximal power output in WAnT was 704.0 ± 66.7 W. Linear correlation coefficients were estimated between force delivered in each punching/kicking technique and the three investigated variables: power output in WAnT; power output and jumping height in CMJ. No significant correlation was found ($\alpha=0.05$). Discussion Punching force depends on the method of measurement, technical skill of athletes and punching type. The peak punching force of boxers ranged from 1990 to 4741 N in study of Waliko et al. [2005]. The values obtained in our study were smaller. Our taekwondo athletes achieved similar CMJ height (0.527 ± 0.111 m) as those described by Noorul et al. [2008]. No relation was found between punching/kicking forces, and power output. Presented results demonstrate that no relations are between maximal punching/kicking force, power output measured in WAnT, and jump height and power measured in CMJ in taekwondo athletes. EFFECTIVENESS OF ELBOW FLEXORS TRAINING ON MACHINE WITH VARIABLE-CAM AND DISC

Karczewska, M., Urbanik, C., Madej, A., Iwańska, D., Staniszewski, M., Mastalerz, A.

Jozef Pilsudski University of Physical Education in Warsaw

Introduction Training of selected muscle groups takes place usually on the training machines, where the external load is transferred from the weights by the link to the lever. Most of these machines have a circle with constant radius, which translates to equal external torque values. Since in human joints only rotatory movements are possible, the muscle length and its strength depends on the muscle's angular position in the joint (Folland 2008). In regard to the above, some incompatibility may be noticed between the constant external load obtained on training machines using circular discs and muscle strength ability, which depends on the angular position of the joint (Ogasawara 2013, Oliveira 2009). The aim of this study was to verify the effectiveness of training on machine that use a variable-cam allows adjustment of external load to muscle work abilities and circle with equal radius. Methods The experiment included subjects divided into 4 groups of 15 people each. Group A and B performed bodybuilding training, group C and D strength training. Training lasted for 8 weeks with training sessions 3 times a week with 3 min rest intervals and was carried out on a machine for training flexor muscles in the elbow joint. The daily workout for group A and B consisted of four sets of 10 elbow flexion. Group C and D performed strength training in 8 series (I: 4x75% max, II: 2x85% max, III-VIII: 1x1RM). Control measurements of muscle torques of elbow flexors under isokinetic conditions at velocity of $60^\circ \cdot s^{-1}$ took place before experiment, after 3 weeks, on the last day of experiment and 3 weeks after (4 measurement sessions). Results The significant increase ($p < 0.05$) of muscle torque as a result of training at the velocity most adequate to the one of the movement while training ($60^\circ \cdot s^{-1}$), was observed only in group A (17.3%). The increase of muscle torque values noted in group B was over 0.6%. In strength training, the grade of muscle torques changes was 3.0% in group C (variable-cam) vs. 6.1% in group D (disc). Discussion On the basis of the results in the present study it may be ascertained that elbow flexors training on machine with variable-cam is more efficient for increase strength than training with the use of circle. The use in training machines of the specially constructed cams determines that the external load is adjusted to the ability of muscle strength through the whole range of motion in the joint, which is important for efficiency, comfort, and safety of the exercises. SPRINT PERFORMANCE OF HIGH LEVEL WHEELCHAIR BASKETBALL PLAYERS REGARDING FUNCTIONAL CLASSIFICATION

Villacieros, J.I., Ferro, A.I., Pérez Tejero, J.I., Graupera, J.I.2

1: Faculty of Physical Activity and Sport Sciences-INEF. Polytechnic University of Madrid. Spain 2: Department of Biomedical Sciences II. Alcalá de Henares University. Spain.

Introduction Wheelchair basketball players (WBP) are classified in four levels according to the disability degree (IWBF, 2010). The players combine repeated short movements, intense exercise bouts and dynamic positions changes (Coutts, 1992). Sprint tests are used by coaches to assess the performance and to make decisions on the distribution of players on-court (Pérez et al., 2010). The purpose was to analyze the relationship between the quality of velocity and the functional classification levels of WBP using a laser system. Methods Eleven men, WBP of the Spanish National Team, took part in a 3 series of a 20 m sprint test. Distances were measured in real time by a laser system Biolasersport® (Ferro, 2012, Ferro & Flórida, 2010) using a LDM301-Jenoptik-type1-laser at 2000 Hz. Average velocities (Vm), maximum velocities (Vmax), relative velocities to Vmax (RVmax) and relative distance in reach Vmax (RDVmax) over sections 0-3, 3-5, 5-10, 10-15, 15-20 m were analyzed. Several one-way ANOVAs were applied. The ICC ranged between 0.96-0.99 for all variables. Results Significant differences were found in Vm and Vmax in all sections between levels 2 and 4, (except Vmax0-3), and between levels 3 and 4 ($P < 0.05$). Additionally, Vmax5-10 was higher in level 2 than 3 (4.83 ± 0.06 m/s, 4.56 ± 0.19 m/s; $P=0.001$). The players reached the 65.18 ± 4.02 % of their Vmax in 0-3 m, 73.71 ± 4.20 % in 3-5 m, 87.01 ± 4.54 % in 5-10 m, 94.44 ± 3.47 % in 10-15 m and 99.99 ± 0.15 % in 15-20m ($P=NS$, among levels). The RDVmax was reached at 90.23 ± 6.74 % of the total distance ($P=NS$, among levels). Discussion The levels 2 and 3 achieved better Vmax than level 4, being the level 2 the fastest. Near 87% of Vmax have been obtained for all the levels in 5-10 m. Although level 2 have more disability than 3 and 4, however their Vmax5-10 were the best where many intense activities succeeded. According to Vanlandewijck et al (1994) the level of disability has little impact in dynamic forces applied to the wheel in levels 2 and 3. This information could be used for coaches to distribute the players on-court with a levels balance. References Coutts, K. D. (1992). J. Med Sci Sports Exerc, 24, 231-234. THE EFFECT OF KINESIO TAPE ON MUSCLE STIFFNESS OF M. RECTUS FEMORIS IN SOCCER PLAYERS

Kirmse, M., Bakenecker, P., Babel, S.

Ruhr-University Bochum

THE EFFECT OF KINESIO TAPE ON MUSCLE STIFFNESS OF M. RECTUS FEMORIS IN SOCCER PLAYERS Kirmse, M., Bakenecker, P., Babel, S. Ruhr-University Bochum, Department of Sports Medicine and Sports Nutrition, Germany Ruhr-University Bochum, Department of Movement Science and Biomechanics, Germany Introduction: Muscle stiffness is an important factor for performance of athletes and for rehabilitation of patients. According to the manufacturer Kinesio Tape (KT) is able to regulate stiffness of muscles. The aim of this study was to analyze the effect of KT on muscle stiffness in soccer players. Methods: 17 healthy soccer players agreed to participate (24.1 ± 2.5 y, 181.7 ± 6.1 cm, 79.8 ± 7.8 kg). Subjects were tested twice in randomized order with one week between tests and with at least one day of no sports prior to test days. On the tape test day, KT was applied to the skin above m. rectus femoris with maximal stretch from distal to proximal (Tape), while no tape was applied on the control day (noTape). After warming up with a standardized program on a bicycle ergometer for 10 minutes subjects performed 3 countermovement jumps (CMJ). Directly after the jumps subjects underwent tensiomyography, and radial muscle displacement (Dm) which is associated with muscle stiffness (Garcia-Manson et al. 2011), time to respond to the voltage shock (Td), time-to-peak contraction (Tc), relaxation time (Tr) and contraction time (Ts) were determined. Results: Height in CMJ did not differ between test conditions (34.4 ± 6.36 cm vs. 33.03 ± 4.23 cm, $p > 0.05$). Dm was significantly reduced with KT (9.2 ± 2.2 mm vs. 8.4 ± 2.1 mm, $p = .005$). Further Td was higher in KT compared to the no-tape condition (22.07 ± 1.61 ms vs. $23.17 \pm$ ms $p = .005$). KT had no influence on Tc or Tr ($p > 0.05$), while there was a trend for lower Ts in KT (104.46 ± 58.05 ms vs. 91.99 ± 59.21 ms, $p = .074$). Discussion: The most important parameter for muscle stiffness is Dm. The reduction in Dm using KT indicates higher muscle stiffness. Performance in CMJ, however, was unaffected by KT, indicating that KT-induced increase in muscle stiffness is not relevant for jump performance. References: 1. García-Manso, J. M., Rodríguez-Ruiz, D., Rodríguez-Matoso, D., Saa, Y. da, Sarmiento, S. & Quiroga, M. (2011). Assessment of muscle fatigue after an ultra-endurance triathlon using tensiomyography (TMG). COMPARISON OF SEGMENT MASSES BETWEEN JAPANESE TOP SENIOR AND JUNIOR MALE GYMNASTS

Hakamada, N.1, Funato, K.2, Hirano, Y.1

1: Japan Institute of Sports Sciences (Tokyo, Japan), 2: Nippon Sport Science University (Tokyo, Japan)

Introduction Several studies have focused on anthropometry characteristics of gymnasts because they have specificity in body shape. Long-year training from childhood possibly may as to demonstrate the cause such a specific anthropometrical developments. In this study, we examined the difference in segment mass distribution between top Japanese senior and junior male gymnasts by means of three dimensional whole body scanning anthropometry. Methods Subjects were Japanese top male gymnasts (TG, age : 23.0 ± 3.0 years, body height: 162.7 ± 4.0 cm, body mass: 55.0 ± 2.4 kg) and Japanese top junior male gymnasts (JTG, age : 13.9 ± 0.7 years, body height: 143.3 ± 9.0 cm, body mass: 39.9 ± 5.8 kg). Whole body volumes were measured by using three dimensional whole body scanner (BLS: Hamamatsu Photonics KK). Scanning data obtained from BLS was divided in 17 parts of each segmental volume based on anatomical landmark point, and each segmental volume was calculated. Definition of each segment were same as C.E. Clauser, 1969. Each segment mass (SM) by multiplying each segment volume and respective segment density was calculated. Relative SM to whole body mass (%SM) was also calculated. Results and discussion TG had a tendency to have significantly heavier SM for all segment except for hand, shank and foot. In relative SM to whole body mass (%SM), TG showed significantly larger values than JTG in neck + shoulder (TG: $10.16 \pm 0.87\%$ vs. JTG: $7.70 \pm 1.04\%$), hip (TG: $19.20 \pm 3.38\%$ vs. JTG: $24.04 \pm 1.66\%$) and upper arm segments (TG: $3.20 \pm 0.07\%$ vs. JTG: $2.84 \pm 0.16\%$). It was suggested that large upper arm might one of the anthropometrics characteristics in gymnast which was clearly different in top and junior gymnasts. Larger trunk in top gymnasts was characterized by neck + shoulder and hip segment volume compared to junior gymnasts. Conclusion It was suggested that top gymnast were anthropometrically characterized as relatively large segmental mass in upper arm and trunk, particular in neck + shoulder and hip segments. EFFECT OF TURNED-OUT ANGLE ON ERECT STANDING POSTURE AND DEMI-PLIE POSTURE IN ADULT AND CHILD BALLET DANCERS

Saito, M.1, Kashiwagi, Y.1, Hakamada, N.2, Sato, H.3, Funato, K.4

1: Graduate school of Health and Sport Science, Nippon Sport Science University, 2: Japan institute sports science, 3: Seibu Gakuen, 4: Nippon Sport Science University, Tokyo, Japan

Introduction The purpose of this study was to investigate the characteristics of erect standing posture and demi-plie posture changes with turn-out angle for professional ballet dancers, child ballet dancers and aged matched sedentary adults. Methods Thirteen professional ballet dancers (age 29.2 ± 6.0 years, height 159.6 ± 5.4 cm, weight 50.6 ± 4.9 kg, dance career 24.1 ± 6.1 years), ten children ballet dancers (age 5.9 ± 1.4 years, height 114.3 ± 8.8 cm, weight 19.4 ± 3.0 kg, dance career 2.2 ± 0.9 years), and thirteen sedentary adults (age 18.8 ± 0.4 years, height 162.2 ± 4.1 cm, weight 51.9 ± 3.0 kg) participated in this study. All subject stood erect and demi-plie postures with three different foot positions on Pedoscoap (Patella, VTS200), which were such as parallel, 90 degree toes turned out, and 180 degree toes turned out (1st position). To calculate posture angles, pelvic angles, and neck angles and horizontal displacement from COP, the digital camera (CASIO, EX25) was used to take pictures in sagittal plane. Results and Discussion Professional ballet dancers had greater neck angles than children ballet dancers and adults during erect posture with parallel and 1st position. Then, professional ballet dancers tended fewer forward tilt move vertical posture when their feet were with the 1st position. In comparison to erect posture with parallel position, professional ballet dancers with 1st position had greater pelvic angles (degree). The posture and pelvic angles for child ballet dancers with 1st position was greater than when they erected with parallel position. Conclusion Extension of cervical vertebrae might be necessary in classic ballet to gain and stabilize the ideal posture line. Professional ballet dancers tended to tilt backward in erect posture with 1st position however, child ballet dancers weren't able to do the same postures as professional ballet dancers did. This is because they may be fall if they had tilted backward. From these results, ideal posture in classic ballet dancers during erect/plie standing with adducting hip joint can be described as well as suggesting training methods of the ideal posture for early child dancers. COMPARISON OF DIFFERENT METHODS TO CHARACTERIZE EXPLOSIVE HAMSTRING TO QUADRICEPS RATIO IN YOUNG MALE FOOTBALL PLAYERS

Péter, A.1, Hegyi, A.1, Schuth, G.1, Cronin, N.2, Tihanyi, J.1

Semmelweis University, Faculty of Physical Education and Sport Sciences

1Department of Biomechanics, Kinesiology and Informatics, Faculty of PE and Sport Sciences, Semmelweis University, Budapest, Hungary
2Department of Biology of Physical Activity, University of Jyväskylä, Finland
Introduction Explosive force capacity of the hamstrings and quadriceps seems to be important in knee stability. However several methods exist to determine the dynamic knee stability, the aim of the study was to compare three of them. Methods Isometric hamstrings and quadriceps explosive force capacity of 60 male football players (10-16 yrs) were measured on a dynamometer (70 deg of knee flexion). Rate of torque development hamstrings to quadriceps ratio (RTD H/Q) was determined 25, 50, 100, 150 and 200 ms after the onset of contraction. The onset of contraction was determined using three different methods: 1) the last trough before the signal deviated from baseline (M1; Hannah et al., 2013) 2) when the torque exceeded the baseline by >7.5 Nm (M2; Greco et al. 2013) 3) when the torque exceeded the baseline by 2.5 % of the peak torque (M3; Zebis et al., 2011). Kruskal-Wallis ANOVA was applied to identify differences in RTD H/Q using different methods; Mann-Whitney U-test was used to identify differences between dominant (D) and non-dominant (ND) leg using the same method. Results M2 (0.89±0.78) resulted in significantly higher RTD H/Q at 25 ms than M1 (0.55±0.50; p<0.001) and M3 (0.57±0.58; p=0.001) in the D leg. M2 RTD H/Q at 25 ms (0.92±0.44) was significantly higher than M3 (0.66±0.51; p=0.001) in the ND leg. RTD H/Q at 25 ms (0.55±0.50) and at 50 ms (0.60±0.59) in the D leg was significantly lower than those in the ND leg: 0.89±0.93 (p=0.011) and 0.96±1.19 (p=0.049), respectively using M1. RTD H/Q at 25 ms (0.57±0.58) was significantly lower in the D leg, than in the ND leg (0.66±0.51) using M3. Discussion M2 seems to overestimate RTD H/Q at 25 ms compared to the other methods, suggesting that may not be advisable to use the same threshold for the H and Q because of their different force capacity. M3 seems to be sensitive to detect differences between the D and ND leg at 25 ms, M1 could detect these differences at 25 and 50 ms as well. The higher value of the ND leg might be a sport-specific adaptation as this leg stabilizes the body while the D kicks the ball. RTD H/Q seems to be applicable to young male football players, but different methods may influence the results. Further studies are needed to determine the relationship between RTD H/Q and knee injury risk. References Greco CC, da Silva WL, Camarda SR, Denadai BS. ANALYSIS OF GROUND REACTION FORCES FOR CHANGE OF DIRECTION ABILITY DURING "505 AGILITY TEST"

Kaneko, K.1, Kashiwagi, Y.2, Ito, T.3, Funato, K.2

1:Tokushima Bunri University (Tokushima, Japan), 2 :Laboratory for Human Movement Sciences, Nippon Sport Science University (Tokyo, Japan), 3 :Osaka Ohtani University (Osaka, Japan)

Introduction "505 agility test" is a relatively simple test that measures the time for acceleration, deceleration and rapid change of direction. Not only sprint ability but also cutting quickness might be one of the important factors for ball game players. 505 agility time might be determined by not simply maximum sprint velocity but some complicated factors such as acceleration/deceleration abilities and cutting movement quickness. Therefore, the purpose of this study was to evaluate ground reaction forces in rapid change of direction during "505 agility test". Methods During "505 agility test" trial, instantaneous velocity was measured by laser measuring instrument system (100Hz, Laveg, Germany) as well as ground reaction force data synchronized by three force platforms (100Hz, Kistler, model Type9287C, Switzerland), VICON motion capture system (100Hz, Oxford Metrics, England) was used for kinematic analysis. All these data were synchronized with photo cell triggering device measured the elapse time taken for 5-meter interval shuttle sprint. Agility and kinematic data were taken from 18 healthy male subjects (age 20.0±4.1 years, body mass 62.0±5.8 kg). From Laveg measurements, following parameters were taken for the analysis distance where maximum sprint velocity attained, maximum sprint velocity, from maximum sprint velocity (Vmax). Data from the force platforms were magnitudes and timing of peak vertical (Fz) and horizontal (Fy) ground reaction forces during acceleration/deceleration phases. Results 505 time (mean±SD) was 2.33±0.07 seconds and high correlation was shown between 505 time measured by photo cell and by Laveg (r=0.956, p<0.001). Maximum instantaneous velocity (mean±SD) was 6.79±0.33m/s which appeared at 1.66±0.56m before approaching 5m interval shuttle run zone. Statistically significant correlation was observed between that peak ground reaction forces of acceleration phase and 505 time (r=0.526, p<0.05). No statistically significant correlation was observed between peak ground reaction forces of deceleration phase and 505 time. Discussion 505 agility time might be determined by not simply maximum sprint velocity but some complicated factors such as acceleration/deceleration abilities and cutting movement quickness. Draper and Lancaster (1985) introduced 505 agility test for the assessment of one of the important physical abilities in ball game players. From the results of this study, to increase horizontal/vertical(Fy/Fz) the ratio during acceleration phase, might be factors to improve the technique will not only reduce the time for changing of direction. References Draper JA, Lancaster MG. (1985). Australian journal of Science and Medicine in Sport17(1),15-18. Michael K. Dayakidis, Konstantinos Boudolos. (2006). Clinical Biomechanics 21, 405-411.

STEP BY STEP VARIABILITY IN 3D GROUND REACTION FORCES DURING TREADMILL WALKING AT DIFFERENT CONSTANT SPEEDS

Hirano, T.1, Yamagishi, M.2, Kashiwagi, Y.1, Hakamada, N.3, Funato, K.2

1: Graduate School of Health and Sport Science, Nippon Sport Science University (Tokyo, Japan), 2: Nippon Sport Science University (Tokyo, Japan), 3: Japan institute of sports science (Tokyo, Japan)

Introduction Human walking is executed by repetitive movement. Development of new technology as instrumented split-belt treadmill enables to analyze continuous recordings of each step during walking. The purpose of this study was to describe the variability of 3D ground reaction forces (GRFs) during treadmill walking at different constant speeds. Methods Six healthy male subjects (age: 24.9±5.0yrs, BH: 170.3±5.1cm, BW: 64.1±4.5kg) walked on a split-belt instrumented treadmill (GRAIL: Gait Real-time Analysis Interactive Lab, Motek Medical BV, the Netherlands). GRF were measured based on force sensors mounted underneath each belts. Self-paced target walking speeds (60-140 m/min) were set by synchronizing with motion capture system. 3D GRFs (Fz: vertical, Fx: medio-lateral, Fy: anterior-posterior) were recorded in order to analyze on the last 15 steps in each walking speed for one minute. After each GRF was superimposed at the onset of foot contact, average GRF curve as well as standard deviation (SD) were calculated. Results and Discussion As walking speed increased, stance time was decreased (from 60 to 140 m/min, 0.74 to 0.46sec). SD of 3D GRFs were increased at double

support in stance phase. In double support, each leg were performed a substantial amount of positive and negative external work simultaneously (Donelan et al., 2002). Also, large variability especially in GRFs were observed at fast walking such as 140 m/min. It was suggested that unstable dynamic balance was indicated especially at the early phase in double support during fast walking. References Donelan JM, Kram R, Kuo AD. Introduction: The first and second trimesters of pregnancy are characterized by a weight increase due to the development of the foetus and changes in the volume of the breast and abdominal region. These changes may lead to an increase in mechanical loads of the lower limb, to support the body. The biomechanical analysis of gait during pregnancy provides more information about the magnitude of the external and internal forces and with the way that musculoskeletal structures compensate the internal forces. **Purposes:** to describe and quantify the biomechanical, spatial and temporal parameters of the lower limb during gait, and compare it between trimesters and with non-pregnant women. **Methods:** A three-dimensional biomechanical analysis was performed in fifteen pregnant women in the end of first and second trimesters of pregnancy and in twelve non-pregnant women (control group). Kinematic data was collected by means of ten infrared high-speed cameras (Qualisys, 200Hz). Kinetic data was collected by means of two Kistler platforms (1000Hz). The Visual 3D (C-Motion) software was used for data analysis. **Results:** The spatiotemporal parameters remain unchanged between trimesters and between pregnant and non-pregnant women. Kinematics changes are related to the hip and pelvis in sagittal plane, suggesting that pregnant women need to maintain greater stability in anterior displacement of the body. The ground reaction forces show a greater need for body stabilization in the medial and lateral component. The internal loading of the lower limbs along the stance phase reveals an increased demand placed on the external rotators of the thigh and on the knee flexors. In the final stages of the stance phase, we verified a reduction in the contribution of the hip flexors and of the foot invertors. **Conclusions:** The results suggest that pregnant women had greater load and more instability of the musculoskeletal structures in the lower limbs during pregnancy.

MINIMUM-TIME TRAJECTORIES DURING THE CURVE IN LONG TRACK SPEED SKATING

Takenaka, S., Fujii, N., Suzuki, Y.

University of Tsukuba

Introduction Athletes skate an oval track in a short period of time as much as possible. However, if skater try to shorten the distance in curve phase, the larger centripetal force is required. Trajectory optimization for a car driving has been presented (Velenis, E. et al., 2005), but it is not clear for speed skating. The aim of this study was to determine minimum-time trajectories during the inner curve in long-track speed skating. **Method** We determined averaged patterns of force during curve stroke from displacement of body center of mass that was analyzed at the official 5000-m race (World single distances championship 2008, Nagano, Japan). In this study, we set one-mass model with eleven variables; point of entry, approach angle, changing rates of pitch and force. The object function was set as a split time of curve phase. These variables were optimized by use genetic algorithm. Initial speed in this model was 12.5m/s. Air frictional force was estimated by use in the previous study (de Koning et al. 1999). **Results and Discussions** The point of entry to curve phase was inside of the course center, and Approach angle was small. Changing rates of force during stroke was increased over the curve phase, and skating speed was also increased. The innermost point of the course in trajectories was near half of the curve phase. These results were similar to measured values. We concluded that Elite athletes already take the optimal line to minimize time at curve phase in accordance with the initial speed. **References** Velenis, E., Tsiotras, P. (2005). *IEEE Int.
