Organisation

Congress President

- Arnold de Haan (NED)

ECSS Executive Board

- Marco Narici - President (GBR)
- Sigmund Loland – Past President (NOR)
- Tim Cable –President Elect (GBR)
- Joan L. Duda (GBR)
- Stephen Seiler (NOR)
- Gisela Sjøgaard (DEN)

ECSS Scientific Board

- Anton Wagenmakers - Chair (GBR)
- Flemming Dela - Co-Chair (DEN)
- Jan Cabri - Secretary (NOR)
- Paul Greenhaff (GBR)
- Martin Halle (GER)
- Susanna Hedenborg (SWE)
- Luc van Loon (NED)
- Jose Antonio Lopez Calbet (ESP)
- Abigail Louise Mackey-Sennels (DEN)
- Erich Müller (AUT)
- Nicole Wenderoth (SUI)

ECSS Scientific Committee

- Natalia Balague (ESP)
- Wilhelm Bloch (GER)
- Annalisa Cogo (ITA)
- Wim Derave (BEL)
- Peter Federolf (NOR)
- Taija Finni (FIN)
- Daniel Green, FECSS (GBR)
- Michael Grey (GBR)
- Markus Gruber (GER)
- Jørn Wulff Helge (DEN)
- Ylva Hellsten (DEN)
- Pierre-Nicolas Lemyre, (NOR)
- Johannes van Lieshout, (NED)
- Mike McNamee, FECSS (GBR)
- Maria Francesca Piacentini (ITA)
- Afroditi Stathi (GBR)
- Cecilie Thøgersen-Ntouman (GBR)
- Janice L. Thompson (GBR)

ECSS Office

- Thomas Delaveaux
- Elias Tsolakidis
- Steffen Neubert
- Tuulia Hokkanen
- Juliane Melber

Local Scientific Committee

- Allard van der Beek
- Peter Beek
- Maarten van Bottenburg
- Maarten Bobbert
- Koen Breedveld
- Hein Daanen
- Jaap van Dieën
- Karin Gerrits
- Arnold de Haan
- Ivo van Hilvoorde
- Thomas Janssen
- Richard Jaspers
- Jos de Koning
- Koen Lemmink
- Willem van Mechelen
- Mireille van Poppel
- Jo de Ruiter
- Geert Savelsbergh
- Knoek van Soest
- Evert Verhagen
- Floris Wardenaar

Additional reviewers

- Cécile Boot
- Gertjan Ettema
- George Havenith
- Han Houdijk
- Vana Hutter
- John van der Kamp
- Willem van der Laarse
- Koen Levels
- Huub Maas
- Dionne Noordhof
- Raoul Oudejans
- Rob Pijpers
- Hidde van der Ploeg
- Karin Proper
- Bart Roelands
- Dick Thijssen
- Yves Vanlandewijck
- Lex Verdijk
- Rob Wüst
- Herman IJzerman

Organizing Committee

- Irene van Baardwijk
- Peter Beek
- Allard van der Beek
- Carien Damen
- Arnold de Haan
- Herman IJzerman
- Thomas Janssen
- Jos de Koning
- Romke Langezaal
- Solveig Lund
- Willem van Mechelen
- Hidde van der Ploeg
- Jo de Ruiter
- Eric van Rossum
- Thom Veeger
- Evert Verhagen

Welcome

On behalf of the European College of Sport Science (ECSS) and VU University Amsterdam we welcome you to Amsterdam for the 19th annual congress of the ECSS.

The two hosting partners, VU University Amsterdam and VU University Medical Center Amsterdam, have a long-standing reputation with excellent research in sport science. We have MOVE research institute amsterdam, which performs fundamental research on human movement with focus on rehabilitation, regenerative medicine and sports.

Besides that there is the Institute for Health & Care Research (EMGO+) with research is on public health, primary care and long-term care. We combine various fields of study and innovative techniques with focus on implementation and use in society.

The Amsterdam congress provides an outstanding scientific programme that emphasizes the current state of knowledge in sport science. The congress will feature four plenary sessions and 36 invited symposia on topical issues in the field. In total more than 2400 abstracts have been submitted from 67 countries. Free communications have been distributed among 74 oral and 106 mini-oral sessions. There are also 500 undebated E-posters, which can be viewed on large screens.

The capital of The Netherlands, host city for this 19th congress, is known for its beauty and historic significance. No-one can visit Amsterdam without having mounted on a boat for a trip on the cosy canals. Viewing the city from the water gives a total different experience.

Enjoy the finest works of art, the fruit of the blossoming 17th century in the Netherlands. In that time Amsterdam was a center where intellectual, artistic and trading activities converged. Rembrandt, Vermeer and other successful painters made the city Europe's leading center of art. Later, freethinkers like the philosopher Baruch de Spinoza found a warm welcome in Amsterdam, where religious tolerance was an important issue. You can learn about it in, amongst others, the Rijksmuseum and the Spinoza House.

Amsterdam will offer you a high-quality scientific programme, we anticipate that the 19th annual congress of the ECSS will be outstanding. On behalf of the ECSS and the local organizers we wish you great stay in Amsterdam. Enjoy sport science around the canals.

Prof. A. de Haan (VU University Amsterdam)

COMBINED LONG-TERM CAFFEINE INTAKE AND EXERCISE IMPROVES DIABETIC NEPHROPATHY IN OTSUKA LONG-EVANS TOKUSHIMA FATTY RATS

Masato, S.

The Jikeikai University School of Medicine

PURPOSE: An exercise regimen has long been considered an important component in the therapy for diabetes, as it has been found to improve insulin sensitivity, increase muscle mass, and assist in weight control. Further, van Dam and Feskens found that moderate coffee consumption helps reduce the risk of type 2 diabetes. Therefore, by using Otsuka Long-Evans Tokushima fatty (OLETF) rats, this study examined the effects of a combined treatment with exercise and caffeine on renal pathophysiological findings and urinary albumin excretion (Ealb) as well as body composition, glucose intolerance (GI), and dyslipidemia associated with diabetes mellitus. **METHODS:** Twenty-four OLETF rats were divided into the following groups: sedentary (Sed), exercise (Ex), caffeine (Caf), and a combination of exercise and caffeine group (Ex & Caf). All treatments were performed from 25 to 29 weeks of age. Rats in the Caf and Ex & Caf groups were fed rat chow containing 0.25% caffeine based on a previous study. Rats in the Ex and Ex & Caf groups were permitted to voluntarily run every day. Body weight (BW) and blood pressure (BP) were measured once every week. Before and after the treatment, 24 h urine samples were collected for measuring the Ealb. Whole-body subcutaneous fat mass (SFM), visceral fat mass (VFM), and lean body mass (LBM) were measured before and after the treatment using a radiographic computed tomography scan. The animals were sacrificed by exsanguination after the completion of treatment. The kidneys were removed for performing renal pathophysiological analysis; blood samples were collected for measuring the fasting blood glucose (FBG), insulin and lipid concentrations. **RESULTS AND DISCUSSION:** The BW, SFM, and VFM reduced significantly in the Ex, Caf, and Ex & Caf groups, whereas these variables increased significantly in the Sed group after treatment. There was no change in systolic BP (SBP) during the treatment period in the Ex, Caf, and Ex & Caf groups, but the Sed group had a significantly higher SBP compared with the pre-treatment level. The Ealb of the Caf and Ex & Caf groups significantly decreased compared with the pre-treatment levels, and the mean mesangial area and glomerular basement membrane thickness were significantly lower in the Caf and Ex & Caf groups than in the Sed and Ex groups. The FBG and dyslipidemia remarkably improved in the Ex and Ex & Caf groups after treatment. **CONCLUSION:** Treatment with caffeine alone inhibited the progression of DN, whereas exercise alone did not inhibit the progression of DN. Our results suggest that a combined treatment with caffeine and exercise is more efficacious than treatment with either caffeine or exercise for improving DN as well as GI and dyslipidemia in OLETF rats.

EFFECTS OF CAFFEINE CONTAINING ENERGY DRINK ON FEMALE VOLLEYBALL PERFORMANCE

Pérez López, A.1, Salinero, J.J.2, Valadés, D.1, Abián Vicén, J.2, Lara, B.2, Hernández, C.3, Areces, F.2, González, C.2, Del Coso, J.2

1. University of Alcalá; 2. Camilo José Cela University; 3. Polytechnic University of Madrid.

Introduction: Ingestion of caffeine containing products has been widely tested in endurance sports (Jenkins et al., 2008). However, the effect of caffeine consumption on team-sport performance remain to be evaluated (Astorino & Roberson, 2010). In volleyball, only one study has tested a caffeine containing beverage on male volleyball players (Pérez-López et al., 2013). Therefore, the aim of this study was to evaluate the effect of caffeine containing energy drinks on female volleyball players' performance. **Methods:** Double-blind, placebo controlled and randomized experimental design was performed. On two different days, 13 semi-professional female volleyball players (25.2 ± 4.8 yrs; 174 ± 9 cm; 64.4 ± 7.6 kg) ingested 3 mg of caffeine per kg of body mass in an energy drink (Fure®, ProEnergetics) or the same drink without caffeine (placebo). After 60-min for caffeine absorption, athletes performed seven tests: a) standing spike; b) spike jump (SPJ); c) block jump (BJ); d) squat jump (SJ); e) counter-movement jump (CMJ); f) jumping spike; g) agility T-test. Later, a simulated volleyball match was played and recorded. Afterward time motion analysis was done. **Results:** In comparison to the placebo drink, the ingestion of caffeinated energy drink improved standing (19.2 ± 2.1 Vs. 19.7 ± 1.9 m•s⁻¹; $P = 0.023$) and jumping spike ball velocity (17.9 ± 2.2 Vs. 18.8 ± 2.2 m•s⁻¹; $P = 0.038$). Also, it enhanced mean jump height of SPJ (43.3 ± 4.7 Vs. 44.4 ± 5.0 cm; $P = 0.024$), BJ (35.2 ± 5.1 Vs. 36.1 ± 5.1 cm; $P = 0.044$), SJ (28.1 ± 3.2 Vs. 29.4 ± 3.6 cm; $P = 0.028$), CMJ (32.0 ± 4.6 Vs. 33.1 ± 4.5 cm; $P = 0.018$) and time to complete T-test was reduced (11.1 ± 0.5 Vs. 10.9 ± 0.3 s; $P = 0.036$). Finally, during the simulated match, when the energy drink was ingested positive game actions were more frequent (34 ± 9 Vs. 45 ± 9 %; $P < 0.001$); whereas negative game actions were diminished (28 ± 7 Vs. 14 ± 9 %; $P < 0.001$). **Discussion:** Pre-exercise ingestion of a caffeinated energy drink improved jump height, spike and displacement velocity as in male volleyball players (Pérez-López et al. 2013). Moreover, in females, higher jump spike velocity, spike and block jump height, and a reduction in frequency of negative actions during the match were also observed. Thus, caffeinated energy drink was effective to improve female volleyball players' performance. **References:** Astorino TA, Roberson DW. (2010). J Strength Cond Res, 24(1), 257-65. COMBINED EFFECTS OF ICE SLURRY AND CAFFEINE INGESTION ON THERMOREGULATION AND EXERCISE CAPACITY IN A WARM ENVIRONMENT

Hasegawa, H.

Hiroshima University

Introduction Caffeine is widely consumed as an ergogenic aid to improve cognitive and physical performance. Endurance performance can be improved when humans are administered with approximately 3 to 9 mg/kg caffeine. Internal cooling such as cold water ingestion has been recently attracted attention. A more aggressive internal pre exercise cooling process appears to occur with the ingestion of an ice slurry mixture (Siegel and Laursen, 2012). The purpose of this study was to investigate the combined effects of ice slurry and caffeine ingestion on thermoregulation and endurance exercise capacity in a warm environment. **Methods** One hour before exercise, nine male subjects ingested either 6 mg/kg caffeine or placebo. Subjects then ingested either 15 g/kg ice slurry (-1°C) or water (37°C) during 60 min of rest. Subjects completed four experimental cycling trials at 60% maximum voluntary exercise to exhaustion at 30°C and 70% relative humidity. Four experimental conditions were set for placebo and water ingestion (CON), caffeine and water ingestion (CAF), placebo and ice slurry ingestion (S), caffeine and ice slurry ingestion (SCAF). Exhaustion was considered to have occurred when the subject was unable to keep pace or rectal temperature reached at 39.5°C . Results In the SCAF, time to exhaustion was significantly longer than that of the CON (SCAF: 67.4 ± 12.3 min, CON: 51.6 ± 11 min). The decrease in rectal temperature during rest in S and SCAF were significantly greater than that of CON and CAF. Rectal temperature, skin temperatures and heart rate were increased during exercise, but these physiological responses were not different between the conditions. In the CAF, S and SCAF, rating of perceived exertion from 10 to 40 min exercise were significantly lower than that for the CON. The rate of attainment of critical temperature in SCAF was higher (CON: 11%, CAF: 22%, S: 0%, SCAF: 44%). **Discussion** Both ice slurry and caffeine ingestion before exercise had a positive effect for the exercise capacity in a warm environment. Combined methods of ice slurry and caffeine ingestion increased endurance exercise due to the increase in heat storage capacity and decrease in subjective responses, and delayed the onset fatigue. The present results were not partly consisted with the results that caffeine induced an additional increase in core temperature (Roelands et al, 2011). Although many subjects in SCAF were able to continue exercise, they had to stop exercise because their core temperature reached at the critical level. It is necessary for attention to be paid if we use combination of ice slurry and caffeine ingestion during exercise in a warm environments. **References** Siegel R, Laursen PB. (2012). *Sports Med* 42, 89-98. Roelands B et al. (2011). *Eur J Appl Physiol* 111: 3089-95.

HEALTH BENEFITS OF CREATINE SUPPLEMENTATION WITH AND WITHOUT ALLFA-LIPOLIC ACID IN OVERWEIGHT SEDENTARY MALES: PILOT STUDY

Polyviou, T.1, Celis Morales, C.1,2, Pitsiladis, Y.3, Malkova, D.1

1; MVLS (Glasgow, UK), 2; HNRC (Newcastle, UK), 3; BCM (Brighton, UK)

Introduction Creatine (Cr) supplementation, used for lean body mass and exercise performance enhancement (Harris et al., 1992) can also improve insulin sensitivity (Eijnde et al., 2001). However, in the absence of exercise uptake of Cr is limited (Harris et al., 1992). The purpose of this study was to determine whether health related benefits of Cr supplementation can be improved when Cr is taken with alpha lipoic acid (Ala), an agent known to enhance Cr uptake by skeletal muscle (Volchegorskii et al., 2011). **Methods** Participants (Cr group (n=7): age 33.6 ± 6.8 y, BMI 28.8 ± 4.7 kg/m 2 ; Cr/Ala group (n=7): age, 37.8 ± 9.6 , BMI 29.4 ± 2.8 kg/m 2) attended the laboratory after a 12-hour fast and performed an oral glucose tolerance test (OGTT) before and after four weeks of supplementation with either Cr (20 g/day for the first week and 5 g/day for 3 weeks) or Cr/Ala (same as Cr group plus 1000 mg/day of Ala). Mean values of glucose and insulin during OGTT and insulin sensitivity index (Matsuda and De Fronzo, 1999) were calculated from fasting and post-glucose plasma glucose and insulin concentrations. Results Mean glucose response during OGTT was improved with Cr (Pre, 5.3 ± 0.8 ; Post, 4.8 ± 0.9 ; $P = 0.04$) but not with Cr/Ala (Pre, 5.9 ± 1.9 ; Post, 5.6 ± 1.9 ; $P = 0.71$) supplementation while mean insulin responses were not significantly different between Cr (Pre, 8.5 ± 4.7 ; Post, 7.3 ± 2.4 ; $P = 0.73$) and Cr/Ala (Pre, 8.4 ± 1.2 ; Post, 8.0 ± 1.2 ; $P = 0.68$) trials. Insulin sensitivity index was not modified by supplementation with either Cr (Pre, 6.1 ± 3.4 ; Post, 7.1 ± 2.1 , $P = 0.78$) or Cr/Ala (Pre, 5.2 ± 1.2 ; Post, 5.6 ± 2.0 , $P = 0.58$). **Discussion** Data obtained in this study suggest that Cr supplementation can improve glucose tolerance of overweight sedentary individuals and that addition of Ala to Cr supplementation brings no further metabolic benefits. A randomised control trial with a bigger sample size should be carried out to confirm these findings.

PRE-EXERCISE ACUTE CREATINE SUPPLEMENTATION EFFECTS ON REPEATED SPRINT PERFORMANCE IN CREATINE LOADED AND UNLOADED YOUNG BASKETBALL PLAYERS

Tok, O., Turnagol, H., Kosar, N.

Health Science Institute

Introduction Creatine has become one of the most popular dietary supplements in the sports nutrition market. The new forms of creatine has been investigated in many research but the efficacy of the liquid form of creatine present in today's marketplace as a dietary supplement is less clear. Therefore, the aim of this study is to determine the pre-exercise acute creatine supplementation effects on repeated sprint performance in creatine loaded and unloaded young basketball players. **Methods** This research involved 13 trained male (17.46 ± 0.66 years, 194.2 ± 4.6 cm, 83.79 ± 9.12 kg ve 6.31 ± 2.29 training age). The study was designed as randomised, double blind, crossover and placebo controlled. Athletes were divided into two groups and attended to 3 performance test (10x15m repeated sprint test with 30sn intervals) on separate days: baseline, after creatine loading (0.3g/kg/d, 5days) and after liquid creatine supplementation (5 ml, sublingual). Pre and post test venous and finger blood samples were collected to determine lactate dehydrogenase, creatine kinase, serum creatinin and serum electrolyte concentrations and lactate levels. Moreover, athletes' heart rate, body composition and urine density were determined. The study's washout duration for crossover design took 3 weeks (21 days). Results Results showed that there were no significant difference in sprint time, lactate, creatine kinase levels and body composition measurements among the groups ($p > 0.05$). It is observed that post-exercise serum lactate dehydrogenase levels decreased and sodium levels increased in creatine unloaded group with acute creatine supplementation ($p < 0.05$). There was a significant increase in serum creatinine levels in creatine loading group ($p < 0.05$). **Discussion** There is no physiological basis for claims that creatine serum enhances exercise performance capacity, improves training adaptations (Kreider, 2003). Present findings also support previous studies reporting that oral ingestion of creatine serum has no effect on blood creatine levels and therefore could not promote creatine retention (Dash et al., 2002; Almada et al., 2001). However, regarding the findings demonstrate that creatine supplementation decreases lactate during incremental cycling exercise and tends to raise lactate threshold (Oliver et al., 2013), we determined in our post-exercise analyses that serum lactate dehydrogenase levels were

decreased. In conclusion, acute creatine supplementation did not enhance sprint performance and creatine loading didn't cause any body composition component change in this study. CREATINE ADMINISTRATION IN ATHLETES: EFFECTS ON RECOVERY OF ACUTE KNEE INJURY

Golshanraz, A., Afravi, N.

Iran Sport Medicine Federation

Do not insert authors here Introduction Acute knee injuries are a growing cause of concern, as these injuries can have serious consequences for the athlete with a greatly increased risk of early osteoarthritis. Using specific exercise training program along with creatine supplementation, it may be possible effective to improve recovery of knee injuries. The main aim of this study was to examine the effects of 4 weeks of creatine administration on the lower limb flexibility, functional ability and the degree of pain intensity in competitive male athletes after acute knee injury. Methods Twenty ex-elite male athletes with sport knee injuries from different fields of sport (football, basketball, martial arts & bodybuilding) were purposefully selected from patients of Behnam Physiotherapy Clinic in Tehran. They divided into two equal groups (n=10) including creatine & control group. Mean age of participants was 29.4, mean height was 177.36cm, and mean weight was 80.85kg. Sport exercise protocol including aerobic exercise, Stretching exercise, strength, coordination training was adopted for both groups. Supplementation with creatine monohydrate for 4 weeks at a dose of 1000 mg per day was administered to control group. lower limb flexibility by using Hamstring flexibility machine, pain and functional ability by using questionnaire of the knee injury and osteoarthritis outcome score (KOOS) were evaluated at the beginning of the study and 28 days after starting treatment (supplementation and sports protocol). Results There are significant differences between males' knee flexibility in creatine & control group at the end of treatment period. Indeed, The creatine group was found to have significantly lower mean values for knee pain, signs, movement dysfunctions in daily activities & better KOOS quality of life scores at week four ($p<0.05$), than control group. Discussion It has been shown that Creatine supplementation, when combined with resistance training, increases lean tissue mass and improves leg strength, endurance, and average power in men of mean age 70 year (Chrusch et al., 2001). Long-term Creatine supplementation increases muscle strength and size, possibly as a result of increased myosin heavy chain synthesis (Willoughby et al., 2001). Our results suggest that midterm creatine Supplementation can provide some degree of pain relief and improved function in persons who experience knee injuries. The trends in the results also suggest that, at a dosage of 1000 mg per day, the majority of improvements are present after eight weeks. References Chrusch, M. J., P. D. Chilibeck, K. E. Chad, K. S. MO-PM02 HF Obesity

DOES PHYSICAL ACTIVITY AND CENTRAL OBESITY INFLUENCE HEALTH-RELATED QUALITY OF LIFE IN AGED POPULATION?

Fernandes, F.1, Rodrigues, L.P.1,2, Silva, B.1, Rodrigues, T.M.1, Costa, N.M.C.1, Leitão, R.1, Bezerra, P.1,2

1- Viana do Castelo Polytechnic Institute; 2- Research Centre in Sports Sciences, Health Sciences and Human Development (CIDESD)

Introduction Central obesity is a major risk factor for chronic diseases with consequences to health-related quality of life (HRQL). It is expected that elderly men and women at risk for central obesity would have lower perception of their physical component of HRQL; that male will have higher HRQL than female; and that individuals with a physical active life would have higher HRQL. The aim of this study was to investigate how HRQL perception differs according to the cardiovascular risk and physical activity status. Methods One thousand and fifty participants (68.3% female and 31.7% male) aged 70 years and over were recruited from Viana do Castelo, northern Portugal. Subjects completed the SF36v2 questionnaire. Physical component, namely general health (GH), role physical (RP), physical functioning (PF) and bodily pain (BP) variables were considered for analysis. Physical activity (PA) and waist circumference (WC) were also assessed. The sample was divided according to sex, PA status and cardiovascular risk as indicated by WC. Student t-test was performed to detect differences on the physical components of SF36v2 between physically active and non-physically active subjects, on each sex group. Significance was set at $p<0.05$. The Human Research Ethics Committee of the IPVC approved testing procedures. Results Within PA male participants, 11.1% and 8.7% were classified in the low and high risk group, respectively. For the non-PA males the results were 6.6% and 5.2% for the same referred groups. Considering PA female participants, 10.6% and 30.0% were included in the low and high risk group, respectively, and for non-PA ones the results were 6.0% and 21.7%. PA female in the low risk group revealed to have significantly higher scores on GH ($p=0.001$), RP ($p=0.009$), PF ($p=0.000$) and BP ($p=0.000$) than PA female in the high risk group. There were no significant differences between low and high risk groups among non-PA female participants. PA male in the low risk group had significantly higher scores than high risk group only in PF variable ($p=0.003$). Concerning the non-PA male, participants classified with low risk showed significantly higher scores than those in the high risk group, only in BP ($p=0.039$). Discussion These findings suggest that PA and central obesity (indicated by WC) might be associated with HRQL. However, contrary to the results found in PA women, PA men at the low risk group did not reveal better scores in all physical component of SF36v2, but only in PF variable. Whether these sex differences are related with methodological aspects or bio psychosocial factors should be investigated. Contact: fabias@esdl.ipvc.pt

EFFECTS OF DIFFERENCES IN WEIGHT-LOSS DEGREE ON IMPROVING PHYSICAL FITNESS

SO, R., Tsujimoto, T., Kim, B., Tanaka, K.

University of Tsukuba

Introduction Obesity is associated with impairments of not only metabolism but also physical fitness such as cardiorespiratory fitness, agility, balance and flexibility. Also, lower physical fitness in obesity may be lead to increasing the risk of physical disability later in life. Thus, it is important that obese individuals maintain their physical fitness when losing weight. However, it is not clear whether the difference in weight-loss degree is affect the changes in physical fitness. The present study aimed to determine the difference of effect by weight-loss degree on physical fitness. **Methods** Ninety-one overweight and obese, middle-aged men were divided into three groups by weight-loss degree: high group (A; $-15.7 < \% \text{body weight}$); middle group (B; $-11.0 \leq \% \text{body weight} \leq -15.7$); and low group (C; $\% \text{body weight} < -11.0$). All obese individual participated to dietary and exercise in a three-month weight-loss program. Body composition, physical fitness elements (hand grip strength, side-to-side steps, single-leg balance with eyes closed, sit-and-reach, and VO_2max) were measured before and after the program. **Results** Body weight, BMI, waist circumference and $\% \text{body fat}$ decreased significantly after the 12-week program in all groups. The program induced a significant increase in physical fitness components: agility, balance, flexibility and cardiorespiratory fitness. Also, we found significant differences between groups in two physical fitness components: flexibility ($B > C$), cardiorespiratory fitness ($A, B > C$). **Discussion** Our data indicate that the improvement of cardiorespiratory fitness can be expected when it exceed the weight-loss certain degree of revealed (in this study, 11% or more). We can supposed that possibility for the greater increase cardiorespiratory fitness in the A group may be a difference in physical activity energy and number of steps between the groups during exercise and daily living. A previous study reported that cardiorespiratory fitness is related to the capacity to perform activities of daily living in obese individuals (1). Furthermore, Miller CT et al., reported that exercise during dietary appears to improve cardiovascular fitness to a greater extent than dietary alone. **Conclusion** Weight-loss with combining dietary and exercise positively influence body composition, cardiorespiratory fitness and flexibility. Also, these improvements were evident as the degree of weight-loss increases. **References** 1. He XZ et al. (2007). *Am J Public Health*. 94: 1567-1573. 2. Miller CT et al. (2013). *PLoS One*. 25; 8 (11):e81692

EFFECT OF ACUTE AEROBIC EXERCISE ON APPETITE AND PLASMA ACYLATED GHRELIN AND NESFATIN-1 OF GRADE 1 OBESE AND LEAN MEN

Reischak Oliveira, A., Lopes, A.L., Friedman, R., Teixeira, B.C., Krüger, R.L., Milanese, T., Gross, J.S., Macedo, R.C.O.

Universidade Federal do Rio Grande do Sul

Introduction Obesity is characterized as a chronic disease which there is an excess of body mass as fat, resulting in a greater risk of comorbidities (Kopelman, 2000). Some stimuli, such as obesity, high fat meal/diet and exercise cause changes in concentrations of peptides involved in energy homeostasis, such as Nesfatin-1 (NES1) and Acylated Ghrelin (GRE), anorexigenic and orexigenic hormones, respectively (Kojima et al, 1999; OH et al, 2006). Thus, the main objective of the study was to compare the acute effect of aerobic exercise on appetite and plasma concentrations of acylated ghrelin and nesfatin-1 in obese and lean men. **Methods** Eleven lean (EUT) and ten obese men (OB), sedentary, signed an informed consent for participation and performed two protocols: control (Con) and exercise (Ex). In Ex, they cycled for 45 minutes at 50% VO_2max . In Con, the participants were at rest throughout the whole period. Two blood samples were taken in each protocol. Plasma GRE and NES1 were determined by specific ELISA kits. Appetite (hunger sensation) was assessed using a visual scale. This study was approved by the University Ethics Committee. **Results** In EUT, exercise induced suppression of GRE ($430,58 \pm 146,81$ vs. $303,42 \pm 96,68$ pg/dl; $p < 0,001$) and appetite levels ($p < 0,001$) but not in OB after the session (both, $p > 0,05$). There were no changes in NES1 over time or protocols ($p > 0,05$) but fasting NES1 had higher concentrations in OB than EUT ($4,22 \pm 0,88$ vs. $2,41 \pm 0,56$ ng/ml; $p < 0,001$). A negative correlation between fasting plasma concentrations of NES1 and GRE (only in EUT) and a positive association with BMI and NES1 (for both groups) were observed. **Discussion** This study showed that acute aerobic exercise induced suppression of appetite and GRE in EUT, which does not occur in OB. Indeed obese may be less responsive than lean subjects to these appetite hormones. The excess of fat might be hampering the hypothalamus signaling from peripheral tissues and/or generating a negative feedback to the hormone-producing cells (Briggs et al, 2010). Chronic exercise may be necessary to induce some appetite-related hormones controlling. **References** Kojima, M; Hosoda, H; Date, Y; Nakasato, M; Matsuo, H; Kangawa, K. *Nature*, 402, 656-660. EFFECTS OF 6 MONTH OF AIT ON FAT METABOLISM IN THE SKELETAL MUSCLE OF METABOLIC SYNDROME PATIENTS

Fernández Elías, V.E., Guadalupe Grau, A., Ortega, J.F., Dela, F., Helge, J.W., Mora Rodriguez, R.

University of Castilla-La Mancha and University of Copenhagen

Introduction Aerobic exercise training (AIT) improves the health of metabolic syndrome patients¹. However, exercise training does not reverse all metabolic syndrome risk factor with dysregulated blood lipids being resilient to improvements. The analysis of muscle cellular metabolism may reveal some of the causes of this resistance. **Purpose** The aim of the present study was to evaluate the effects of 6 months of AIT on key proteins involved in the regulation and utilization of fat in the skeletal muscle of metabolic syndrome patients. **Methods** Eleven metabolic syndrome patients (54.5 ± 0.7 yrs old) underwent 6 month of 3 days a week supervised AIT program in a cycle-ergometer. Cardio-metabolic health was assessed and muscle biopsies were collected from the vastus lateralis prior and at the end of the AIT program. Muscle was analyzed for AMP-activated protein kinase (AMPK), acetyl-CoA carboxylase (ACC), hormone-sensitive lipase (HSL), lipoprotein lipase (LPL), endothelial lipase (EL), citrate synthase (CS) and 3-hydroxyacyl-CoA dehydrogenase (HAD). **Results** After 6 months of AIT, body fat (4 %) and waist circumference (2 %) were reduced while exercise maximal fat oxidation rate was markedly increased (38%; all $p < 0.05$). However, body weight, VO_2peak , and blood cholesterol did not significantly improve with training. Total AMPK (22%), endothelial lipase protein expression (19%) and CS activity (26%) increased (all $p < 0.05$). In contrast, HAD activity, AMPK and ACC phosphorylation, and total expression of ACC, HSL and LPL did not change with training. **Discussion** Six months of AIT in metabolic syndrome patients raised the maximal rate of fat oxidation during exercise without a measurable effect on β oxidation rate-limiting enzyme (HAD), rate-limiting enzymes in triglyceride lipolysis and fatty acid hydrolysis (LPL and HSL) or ACC. The shift towards higher reliance on fat oxidation during exercise could be mediated by improvements in mitochondrial function (CS), endothelial lipase and amount of total AMPK. It is possible that harder training that increases cardiorespiratory fitness is required to observe significant improvements in muscle fat oxidative machinery. **References** 1. syndrome. Mora-Rodriguez R. et al. (2014) *Nutri Metab and Cardiovas Diseases* In press 1. Strength training versus aerobic interval training to modify risk factors of metabolic syndrome. Stensvold, D. et al. (2010) *J Appl Physiol*. 108, 804-810

THE RELATIONSHIP BETWEEN SUBCUTANEOUS FAT AND INTRAMUSCULAR LIPID IN HUMAN LIMB.

Yoshikawa, M.1, Kurihara, T.1, Taguchi, S.1, Yamauchi, J.2,3, Hashimoto, T.1,3

IRitsumeikan University, 2TMU, 3FifSS

[Introduction] White adipocyte tissue (WAT) is located in subcutaneous, visceral and muscle. It has been reported that high intramuscular lipid accumulation is related to obesity and insulin-resistant states such as type 2 diabetes. How frequently we activate muscles is a key for proper metabolic regulation. Because total amount of muscle activity in daily life reflects to the muscle volume, metabolic level of upper and lower limbs should be a different level. In theory, a basal metabolic level is lower when muscle volume is small and muscle activity is low, so that body composition of upper and lower limbs in human could be adapted differently over years after becoming bipedal; however, the chronic metabolic responses or body composition of limbs, especially upper limbs, have seldom been studied. Magnetic resonance imaging (MRI) offers to accurately and non-invasively assess regional muscle and fat size and volume. On the other hand, magnetic resonance spectroscopy (MRS) offers to assess metabolism non-invasively, and using single voxel proton MRS can assess the intramuscular lipid. [Purpose] The aim of this study was to examine the quantitative relationship of subcutaneous fat and intramuscular lipid in human limb. [Materials and Methods] Thirty-three healthy young individuals (male: n=11, female: n=22; age, 20.0±1.2 yrs; height, 162.9±6.8 cm; body mass, 55.9±6.7 kg; mean± S.D.) volunteered. Their body composition was measured by MRI and their intramuscular lipid of triceps brachii was measured by 1H-MRS. For a measurement of MRI, subjects were laid supine on the examination table of a 1.5-T MR system (Signa HDxt, GE Healthcare). The axial image of upper arm was acquired to measure the cross-sectional area of muscle, fat and bone. The images at the midpoint of upper limb was selected due to that the anatomical cross-sectional area (ACSA) of the muscle is the largest at this point. For a measurement of 1H-MRS, image-guided, localized, single-voxel 1H-MRS was performed in the triceps brachii muscle. In every subject, voxels were carefully placed at the same position for repeated measurements. [Result] ACSA of upper arm measured by MRI showed that a subcutaneous fat was 21.7±7.1 cm², which corresponds to 38.3±15.5% in ACSA of upper arm. Intramuscular lipid in the triceps brachii muscle measured by 1H-MRS was 567.9±398.7 au. The subcutaneous fat in ACSA of upper arm and intramuscular lipid in the triceps brachii muscle were significantly correlated each other (r=0.52). In addition, female tended to have higher amount of intramuscular lipid than male, and the subcutaneous fat in ACSA of upper arm was significantly higher for female than for male (p<0.01). [Conclusion] These results suggest that individuals with large amount of subcutaneous fat also store the high levels of intramuscular lipid in upper limb in healthy young people.

EFFECTS OF LIFESTYLE MODIFICATION ON METABOLIC SYNDROME WOMEN

Orbán, K., Pósa, A., László, F., Varga, C.

University of Szeged

Introduction Metabolic syndrome is one of the fastest growing public health problems as a result of the sedentary lifestyle and the increased prevalence of obesity. It is estimated that this 'lifestyle disease' threatens one in six adults in Europe today. The syndrome requires a long-term treatment in which the change of one's lifestyle should have a key role. We investigated the effects of lifestyle modification. Methods The study was performed on women developing metabolic syndrome (n=67; mean age: 43.46 years; age range: 18-60 years). The participants took part in a lifestyle program for 4 months. They were given dietary advice and did regular aerobic physical activity at least three times a week. At the beginning and at the end of the program, the participants' body composition was analysed by Inbody230 and blood samples were collected. We measured in three age groups (young: 18-30; middle-aged: 30-55; older: 55<) the change of relative body fat, triglycerides, total cholesterol, HDL- and LDL-cholesterol and over and above the resting blood pressure and heart rate and also the fitness status (Sloan step test). The intensity of training was followed by Polar Team System (pulse, calorie consumption). Results By the effect of regular physical activity and a healthier diet, the fitness status of the tested women improved significantly and their blood pressure and resting HR decreased in every group. The weight loss of participants was 3.73±0.49 kg and the body fat percentage decreased by 2.07±0.42 % in average. The decrease of abdominal obesity degree was observed in all age groups. The body fat mass decreased most substantially in young group (4.31±0.94 kg) and also the fitness index elevated mostly in this group. Improvement can be detected also by analysing the biochemical laboratory results. The glucose level decreased by 0.69±0.06 mmol/l in average, so it fell below the 6.1 mmol/l limit value in each group. We observed significant decrease of the triglyceride levels in every group. This reduction was 0.31±0.04 mmol/l in average. In the case of total cholesterol, the lifestyle modification significantly reduced the initial high values. It is known that the increase of HDL level has beneficial effects. This trend also appeared in our groups, but we detected a significant increase in HDL level only in group of young adults. The LDL concentration decreased in average by 0.33±0.04 mmol/l. Discussion All the changes in parameters of the study were favourable, so it can be concluded that the effects of regular recreational physical activity are clearly positive in metabolic syndrome women in every age group. METABOLIC SYNDROME, OBESITY INDICES AND CARDIORESPIRATORY FITNESS OF OVERWEIGHT AND OBESE CYPRIOT ADOLESCENTS

Panayiotou, G., Antoniadou, O., Douda, H.T., Christodoulos, A., Papazoglou, D., Tokmakidis, S.P.

European University Cyprus

Introduction Metabolic Syndrome (MetS) is characterized by a clustering of adverse risk factors for cardiovascular disease including central obesity, impaired glucose metabolism, dyslipidaemia and hypertension (Veijalainen et al., 2013). Childhood adiposity is associated with an unfavorable metabolic profile which continues into adulthood (Plourde, 2002; Rizo et al., 2007). Also, low levels of cardiorespiratory fitness and physical activity have been associated with a greater risk of the development of MetS in children (Cantarero, 2012). Therefore, the aim of this study was to examine the relationship among MetS indicators, obesity indices and cardiovascular endurance of overweight and obese children aged 12-14 years. Methods A total of 143 adolescents (boys, n=72 and girls, n=71), aged 13.23±0.79 years, were classified according to IOTF criteria (normal weight, overweight, obese). Measurements were obtained on anthropometric (body mass, BMI, waist circumference, percent body fat), cardiorespiratory fitness (20m multistage shuttle run test) and blood pressure (systolic, diastolic), as well as plasma glucose and lipid profile (triglycerides, HDL-C) were analyzed. The MetS was defined using the IDF

criteria for children and adolescents while MetS risk score was also computed based on the z-values of waist circumference, fasting glucose, triglycerides, HDL-C and systolic blood pressure. Results The incidence of factors MetS \geq 3 criteria for overweight/obese was 10.4%. The 22.7% of overweight/obese children showed increased waist circumference \geq 90th percentile (age and gender), 6.9% fasting glucose \geq 110 mg/dL, 18.8% triglycerides \geq 130 mg/dL, 42.7% HDL-C \leq 40 mg/dL and 52.8% systolic blood pressure \geq 90th percentile (by age, sex and height). A statistically significant positive correlation found between aerobic capacity with HDL-C ($r=0.243$, $p<0.05$) and were negative correlations with body mass ($r=-0.481$, $p<0.001$), the BMI ($r=-0.486$, $p<0.001$), percent body fat ($r=-0.517$, $p<0.001$), waist circumference ($r=-0.327$, $p<0.001$), the systolic blood pressure ($r=-0.273$, $p<0.01$) and the z-score of MetS ($r=-0.319$, $p<0.001$). Discussion The increased obesity indices favor the incidence of MetS indicators and appear to influence the cardiovascular endurance of overweight/obese children aged 12-14 years. The negative correlations of aerobic capacity with obesity indices and MetS z-score suggest that overweight/obese children have lower cardiorespiratory fitness as compared with normal weight children (Christodoulos et al., 2012). Thus, the promotion of lifelong physical activity to improve physical fitness is essential to school age yet to ensure the physical health in adulthood.

HIGH INTENSITY INTERMITTENT EXERCISE TRAINING RESULTS IN MORE SENSITIVE EATING BEHAVIOUR

Sim, A.

University of Western Australia

Objective: We have recently shown that an acute bout of high intensity intermittent exercise suppresses ad-libitum energy intake at the post-exercise meal. The present study examined the effect of 12 weeks of high intensity intermittent exercise training (HI) compared with moderate intensity continuous exercise training (MC) on energy intake and its regulation. **Methods:** Twenty overweight and inactive men (BMI: 27.3 ± 1.2 kg/m²; body mass: 86.7 ± 7.1 kg; body fat: $31.4 \pm 3.7\%$; VO₂peak: 36.2 ± 1.2 mL.kg⁻¹.min⁻¹) were randomly allocated to HI training (n = 6), MC training (n = 8) or a control group (CON; n = 6). HI and MC completed 12 weeks of training (3 sessions per week), while CON continued their inactive lifestyle. Ad-libitum energy intake at a breakfast meal was assessed 70 min after consuming a low-energy (LEP: 1590 kJ) and high-energy preload (HEP: 2413 kJ) (on separate occasions) at baseline and following the 12-week study period. Compensation index (CI), reflecting the adjustment of ad-libitum energy intake in response to the caloric content of the preloads was calculated as the difference in ad-libitum energy intake consumed after LEP and HEP, divided by the difference in preload energy content and expressed as a percentage. Perceived appetite was also assessed throughout each visit. The responses of appetite-related blood variables (PYY, pancreatic polypeptide, active ghrelin, leptin and insulin) will also be measured. **Results:** Ad-libitum energy intake following the two different preloads was similar at baseline in all groups. Following the intervention period, energy intake remained similar following the two pre-loads in the MC and CON group, however, energy intake was lower after the HEP compared with the LEP following HI (HEP 1946 ± 967 kJ vs. LEP 2454 ± 1154 kJ; $P < 0.01$) suggesting more sensitive eating behaviour (i.e. appropriate compensation) in response to previous intake. Furthermore, an improvement in energy compensation following the HI intervention was observed (CI: Pre - $16.4 \pm 28.0\%$ vs. Post $31.9 \pm 15.5\%$; $P < 0.01$), while there was no change for MC or CON. There were no alterations in perceived appetite in any group. HI training resulted in weight loss (Pre 86.8 ± 8.2 kg vs. Post 85.8 ± 8.2 kg; $P < 0.01$), but there was no change in body fat percentage ($P > 0.05$). HI and MC training resulted in comparable improvements in VO₂peak (HI: Pre 37.4 ± 2.9 vs. Post 42.6 ± 2.9 mL.kg⁻¹.min⁻¹, MC: Pre 35.2 ± 6.3 vs. Post 40.2 ± 6.8 mL.kg⁻¹.min⁻¹; $P > 0.01$). **Conclusion:** Our preliminary findings suggest that high intensity intermittent exercise training may improve short-term energy intake regulation by leading to more sensitive eating behaviour in response to previous energy intake.

THREE MINUTES OF ALL-OUT INTERMITTENT EXERCISE PER WEEK INDUCES SKELETAL MUSCLE REMODELING IN OVERWEIGHT ADULTS

Gillen, J.B., Percival, M.E., Tarnopolsky, M.A., Gibala, M.J.

McMaster University

Introduction Short-term high-intensity interval training (HIIT) induces physiological adaptations similar to those elicited by moderate-intensity continuous training despite reduced time commitment (Burgomaster et al., 2008). All-out HIIT protocols involving repeated Wingate tests are effective, but still require a 25 min time commitment per session including warm-up, cool down and rest between intervals. Recent evidence suggests that briefer sessions of all-out HIIT, involving <2 min of intense exercise within a <10 min time commitment per session can improve cardiorespiratory fitness (Metcalfe et al. 2011). Little is known regarding skeletal muscle remodelling to this form of training, but a recent study reported increased protein content — but not maximal activity — of common mitochondrial enzyme markers (Ma et al., 2013). Our purpose was to clarify and advance our understanding of the effect of very low-volume HIT on skeletal muscle oxidative capacity. **Methods** Overweight/obese but otherwise healthy adults (n=7 each; men: 29 ± 9 y; BMI: 31 ± 3 kg/m²; women: 29 ± 10 y; BMI: 29 ± 2 kg/m²) performed 18 sessions of HIIT over 6 wk. Each session consisted of a 2 min warm-up at 50 W, 3 x 20 s all-out cycle sprints against 5.0% body mass interspersed with 2 min rest, and a 3 min cool down at 50 W. Resting skeletal muscle biopsies were obtained from the vastus lateralis at baseline and 72 h following training. **Results** The protein content of cytochrome oxidase 4 increased after training in both groups ($p<0.01$; main effect). The maximal activity of citrate synthase was also robustly elevated by 38% after training in both men (5.4 ± 1.4 vs. 3.9 ± 0.6 mmol/kg protein/hr) and women (5.0 ± 1.1 vs. 3.6 ± 0.4 mmol/kg protein/hr) ($p<0.01$, main effect). However, the maximal activity of β -hydroxy acyl CoA dehydrogenase was increased to a smaller extent, and in men only after training (2.2 ± 0.6 vs. 1.7 ± 0.4 mmol/kg protein/hr; $p<0.05$) whereas there was no change in women (2.2 ± 0.6 vs. 2.3 ± 0.5 mmol/kg protein/hr). **Discussion** A 10 min protocol involving only 1 min of hard exercise, 3x/wk, increased skeletal muscle oxidative capacity in overweight men and women as reflected by the protein content and maximal activity of common mitochondrial enzymes. However, there was a divergent response in one marker of fat oxidation capacity. These data shed new light on the potential for very low volume exercise training to induce skeletal muscle remodelling in a time efficient manner. **References** Burgomaster, K et al. (2008). THE EFFECT OF HIGH-INTENSITY INTERVAL EXERCISE AND RESISTANCE EXERCISE ON QTC INTERVAL IN YOUNG MALES*

Nie, J.1, Shi, X.2, Lin, H.3, Kong, Z.2, Tong, T.4, Zhang, H.5, Shi, Q.1

Macao Polytechnic Institute

1: MPI (Macao, China). 2: UMAC (Macao, China). 3: LNUU (Dalian, China). 4: HKBU (Hong Kong, China). 5: HBNU (Shijiazhuang, China). Introduction A growing body of evidence demonstrates that minimal volume of high-intensity interval training and resistance training can serve as effective alternates to traditional time-consuming training, inducing similar or even superior physiological adaptations (Babraj et al., 2009). However, whether an acute minimal volume high-intensity interval exercise (HIE) and resistance exercise (RES) would affect QTc interval, an index of ventricular depolarization/repolarization, is not known. The purpose of this study was to examine QT interval before and after an acute HIE and RES bout. Methods Fifteen male adults (age: 24.2±2.4 years; BMI: 20.6±1.7) underwent: (1) HIE: all-out cycling exercise 30 sec × 4, interspersed with 4 min of rest; (2) RES: a circuit of nine resistance exercise involved the large muscle groups with ten repetitions, interval with 1 min of rest; and (3) CON: a control session of no exercise. QT interval (corrected by heart rate, QTc) was measured pre-exercise, immediately post-exercise, at 20-min intervals thereafter within 120 min, and 12h, 13h and 14h after exercise. The HIE, RES and CON sessions (total 14 min each) were carried out in random order at the same time of day and separated by at least 7 days. Results QTc increased ($P<0.05$) immediately after exercise in both groups (HIE: 411±6 vs. 462±6 ms; RES: 411±5 vs. 447±4 ms) and peak QTc occurred at this time point followed by a progressive recovery, but 120min recovery QTc data were significantly higher in HIE than RES ($P<0.05$). In the RES QTc had returned to baseline at 60 min after exercise but was still significantly elevated in HIE. For HIE, the QTc length returned to baseline by 12 h post exercise. Discussion Consistent with previous findings from traditional time-consuming exercise (Heffernan et al., 2008), an acute bout of HIE or RES significantly increases QTc length. Thus, during recovery from acute HIE or RES, there is prolongation of depolarization and repolarization of the ventricles. Given drugs that produce mild QT prolongation (i.e., 5–10ms) in healthy individuals have been found to induce much greater and clinically relevant prolongation in susceptible populations (Indik et al. 2006), it is reasonable to speculate that risk of untoward cardiovascular events is increased following such exercise, especially in at-risk populations. In addition, our results also indicate that the magnitude of QTc responses to exercise was significantly higher in HIE than in RES. Thus, arrhythmia susceptibility within 12 h following HIE should be not ignored. *The study was supported by a research grant from Macao Polytechnic Institute (RP/ESEFD-01/2012). THE EFFECT OF HIGH-INTENSITY INTERVAL EXERCISE AND RESISTANCE EXERCISE ON GLUCOSE METABOLISM IN OBESE ADULTS*

Shi, Q.1, Kong, Z.2, Shi, X.2, Tong, T.3, Zhang, H.4, Nie, J.1

Macao Polytechnic Institute

1: MPI (Macao, China). 2: UMAC (Macao, China). 3: HKBU (Hong Kong, China). 4: HBNU (Shijiazhuang, China). Introduction A growing body of evidence demonstrates that minimal volume of high-intensity interval training and resistance training can serve as effective alternates to traditional time-consuming training, inducing similar or even superior physiological adaptations (Babraj et al., 2009). However, limited information is available regarding the impact of minimal volume exercise on glucose metabolism. The study aimed to analyze glucose regulation responses in obese adults following minimal volume high-intensity interval exercise (HIE) and resistance exercise (RES). Methods Fifteen obese adults (age: 21.3±2.4 years; BMI: 34.1±4.8) underwent: (1) HIE: all-out cycling exercise 30 sec × 4, interspersed with 4 min of rest, (total 14 min); (2) RES: a circuit of nine resistance exercise involved the large muscle groups with ten repetitions, interval with 1 min of rest (total 14 min); and (3) CON: a control session of no exercise, (total 14 min). They completed an oral glucose tolerance test (OGTT) ~12 hours after exercises or CON. Blood was collected before and every 30 minutes during the OGTT and was analyzed for glucose and insulin. The HIE, RES and CON sessions were carried out in random order at the same time of day and separated by at least 7 days. Results Blood glucose (mol.l⁻¹) at 30 min during the OGTT in HIE (8.63 ± 1.41) trial was significantly lower ($p<0.05$) than the corresponding values of CON (9.26 ± 0.37), but not in blood insulin (175.4 ± 71.2 vs. 173.6±79.4 nU.l⁻¹, $p>0.05$) at the same time point. Further, there were no differences in glucose or insulin between conditions for other single time points or as area under the curve. Discussion The results of the present study demonstrate that neither exercise produced substantial enhanced glucose removal compared to control, despite the lower level in glucose at a single time point in HIE. It was noteworthy that the marked heterogeneity in glucose and insulin responses during OGTT, even our sample included several non-responders. This study extends the previous literature showing the metabolic beneficial effects of classic time-consuming exercise (Wojtaszewski et al., 2003) by showing that the substantial inter-individual variability in glucose regulation responses to time-efficient exercise intervention strategies in this population might be at risk for the development of metabolic diseases. *The study was supported by a research grant from Macao Polytechnic Institute (RP/ESEFD-02/2012). 6 WEEKS OF HIT DECREASES VISCERAL FAT CONTENT AND INCREASES VO2MAX.

Danielsen, J.H., Larsen, S., Dela, F., Helge, J.W.

Xlab, Center for Healthy Aging

Introduction: Excessive visceral adipose tissue is closely related to the development of insulin resistance. Reduction of visceral adipose content is therefore a possible factor in the prevention of type 2 diabetes (T2D). High intensity training (HIT) is a time-efficient training method that leads to similar improvements in aerobic capacity (VO2max) and insulin sensitivity (IS) as regular endurance training. However, the effect of HIT on the lipid metabolism is not fully elucidated and in the current study we investigated the effects on visceral fat content after 6 weeks of HIT. We hypothesized that HIT would induce beneficial changes in body composition concurrent with improvement in markers of IS. Methods: 33 healthy but overweight men and women (Age: 38 ± 1 years; BMI: 33 ± 1 kg/m²) underwent 6 weeks of supervised HIT. VO2max, body composition (DXA) and a basal blood sample were measured before and 3 days after HIT. Visceral fat content was calculated by an algorithm from the DXA program EnCore. Glycated hemoglobin A1c (HbA1c) and fasting glucose were used

as surrogate indices of IS. Exercise was performed 3 days/week consisting of five 60 seconds cycling bouts at the maximal load sustainable for one minute corresponding to $128 \pm 2\%$ of the maximal load (296 ± 11 W) determined in the VO₂max test. The total training volume per week was 45 min. Diet was not controlled during the intervention. Results: HIT significantly increased ($P < 0.009$) VO₂max ($4.2 \pm 1.4\%$). Lean body mass increased ($P < 0.001$) after HIT ($1.3 \pm 0.4\%$). Android, gynoid and total fat percent were decreased ($P < 0.05$) with HIT (-1.8 ± 0.7 , $-3.7 \pm 0.6\%$ and -1.8 ± 0.6 , respectively) as well as the amount of visceral fat ($-4 \pm 2\%$; $P < 0.032$). In addition, there was a negative correlation between the changes in VO₂max and visceral fat ($r = -0.49$; $P < 0.003$). No differences were seen in HbA_{1c} (5.37 ± 0.05 vs. $5.32 \pm 0.05\%$) or fasting glucose (4.57 ± 0.06 vs. 4.51 ± 0.07 mmol/l). Discussion: HIT improves body fat percentage and aerobic capacity, but surprisingly, without concurrent improvements in HbA_{1c} or fasting glucose suggesting that HIT did not improve insulin sensitivity for this subject group. It is possible that the selected HIT protocol was insufficient to induce changes in the indirect IS markers due to the normoglycaemic status of the subjects. However, the negative correlation between visceral fat content and VO₂max suggest HIT as an effective fat loss strategy and given the decrease in visceral fat content and increase in lean body mass these data support HIT as a beneficial training method for improving metabolic health. ACTIVATION OF FAT METABOLISM DURING HIIT WITH MATCHED MEAN INTENSITY.

Eigendorf, J.1, Maassen, M.2, Pelzer, D.2, Maassen, N.1,2

1Medical High School Hannover; 2Leibniz University Hannover

Introduction During exercise fat metabolism increases over time. The relative amount of fat utilization decreases when relative intensity increases (1) during exercise. To our knowledge no work has examined the activation of fat metabolism during high intensity interval training with supra maximal intervals. **Methods** Four different training protocols, consisting of a continuous training (CT) and interval protocols with a 6/24s (IT06), a 20/40s (IT20) and a 30/30s (IT30) stress to pause ratio were performed. IT and CT were matched for relative workload at 50% of the maximum workload reached in an incremental test (WL_{max}) meaning 250% WL_{max} for the IT06, 150% WL_{max} for the IT20 and 100% WL_{max} for the IT30. All trials consisted of 5min rest, 2min at 10W, a 10min warm up (WU) at 50% WL_{max}, 45min training, 10min cool down (CD) at 50% WL_{max} and 10min recovery (R). Spirometrical breath-by-breath recording was done continuously. For statistical calculations 2min mean values were used. Venous and arterialized capillary blood samples were drawn at rest, at the end of WU and CD and after R. During training phase blood samples were drawn after 5, 15, 35 and 45min. Free fatty acids (FFAven) and free glycerol (fGlyven) were determined from venous plasma and lactate concentration [Lac] was determined from arterialized blood samples. **Statistical calculations:** two way repeated measures anova. **Results** After 5min and 15min and at abortion of training [Lac] was significantly different ($p < 0.01$) between the trials. Post hoc analyses revealed significant differences ($p < 0.01$) for all protocols except IT06 vs. IT30. At 30min of training [Lac] was significantly different for IT30 vs. CT, IT20 vs. CT, IT06 vs. CT and IT20 vs. IT06. RQ was significantly different at the onset of the training phase ($p < 0.05$) but showed no differences at the end of training and during the 10 min rest after the training. No significant differences ($p > 0.05$) were detected for FFAven and fGlyven. RQ significantly ($p < 0.01$) declined over time during all training protocols. **Discussion** The declining RQ showed significant activation of fat metabolism. There were no significant differences between the interval protocols in FFAven and fGlyven. The different RQ at the onset of the training should be caused by the rising ventilation and/or the higher lactate buffering. At the end of all training protocols and during 10min rest RQ showed no significant differences supporting the assumption that the CT and the ITs with different absolute intensities and interval length do not lead to a diverse activation of fat metabolism. Therefore we conclude that activation of fat metabolism is mainly influenced by mean intensity and time of training. **References** 1 Holloszy et al., 1998

THE REPRODUCIBILITY OF SALIVARY CORTISOL AND TESTOSTERONE RESPONSES TO A SHORT DURATION, HIGH-INTENSITY CYCLING BOUT

Hough, J.1, Scott, G.2, Townsend, D.2, Gleeson, M.2

1: University of Bedfordshire 2: Loughborough University

Introduction It has been reported that a short duration (30 min), high-intensity (alternate blocks of 1 min at 55% maximal workload (W_{max}) and 4 min at 80% W_{max}) cycling bout (55/80) can highlight alterations in exercise-induced salivary cortisol and testosterone concentrations following a period of intensified training (11 days) (Hough et al., 2013). This suggests the 55/80 bout may be a useful tool to examining hormonal alterations that occur following a period of intensified training. However, to suggest this as a useful and reliable tool the reproducibility of both hormones to the 55/80 bout must be demonstrated. **Methods** Thirteen endurance trained males took part in this study (means \pm s; age 21 ± 3 years; body mass 78 ± 6 kg; height 178 ± 8 cm; 56 ± 6 ml.kg⁻¹.min⁻¹). Each participant completed 3 main trials that took place at the same time of day (12 noon). During each main trial the participant completed a 55/80 bout followed (40 min post 55/80) by a cycle to fatigue at 70% W_{max} to measure physical performances. Recovery-stress questionnaires (RESTQ) were completed at the beginning of all trials and saliva samples were collected pre, post and 30 min post the 55/80 bout. Testosterone and cortisol concentrations were analysed. **Results** Cycling times to fatigue and RESTQ scores did not differ during this study ($P > 0.05$). Pre to post 55/80 increases in salivary cortisol (101% (Trial 1); 120 % (Trial 2) and 81% (Trial 3)) and testosterone (50% (Trial 1); 57 % (Trial 2) and 63% (Trial 3)) concentrations were found in all trials. Intra-individual CV analysis of the salivary cortisol and testosterone concentrations responses indicated a greater intra-individual variation comparing Trial 1 to 2 (24% cortisol; 14% testosterone) than Trial 2 to 3 (12% cortisol; 7% testosterone). Inter class correlational coefficients (ICC) values of 0.77 (cortisol Trial 1 to Trial 2) and 0.87 (cortisol Trial 2 to 3) and 0.50 (testosterone Trial 1 to 2) and 0.85 (testosterone Trial 2 to 3) were found. In conclusion completing a familiarisation trial reduces the intra-individual CVs in the salivary hormone responses to the 55/80 by 12% (24% to 12% (C)) and 7% (14% to 7% (T)). In addition as indicated by ICC values moderate reliability in the hormone responses to the 55/80 bout were found comparing Trial 2 to 3. These findings suggested that the 55/80 bout is a useful tool once a familiarisation is completed to measure the exercise-induced salivary cortisol and testosterone adaptations that may occur following an intensified training period. **References** Hough, J, Corney, R, Kouris, A, Gleeson M (2013) Salivary cortisol and testosterone responses to high-intensity cycling before and after an 11-day intensified training period. CEREBRAL OXYGENATION DURING REPEATED WINGATE TEST

Perez Valera, M.1, Morales Alamo, D.1, Rodriguez Noda, A.1, Torres Peralta, R.1, Losa Reyna, J.1, Perez Suarez, I.1, De La Calle Herrero, J.1, Garcia Tabar, I.1, Curtelin, D.1, Calbet, J.A.1,2

1Univ of Las Palmas de GC, Spain 2IIBS, Instituto de Investigaciones Biomédicas y Sanitarias, Las Palmas de GC, Spain

Introduction During sprint exercise pulmonary ventilation is dramatically increased, likely due to a string activation of the central command. In fact, blood lactate does not increase in the femoral vein during the first 10 s of a Wingate test (Calbet et al. 2003). At the end of the sprint, pulmonary ventilation (VE) remains elevated leading to low arterial CO₂ pressure (PaCO₂). Since cerebral blood flow is very sensitive to changes in PaCO₂, we hypothesized that cerebral blood and brain oxygenation may be reduced during sprint exercise a more so during repeated sprints with short recovery periods. **Methods** Seven young men volunteered to participate in this study (age: 26±6 yr; weight: 80±10 kg; height: 179±7 cm; % fat: 21±7; VO₂max: 4.2±0.6, mean±SD). After familiarization, the VO₂max was assessed using an incremental exercise on a cycle ergometer. On a different day, NIRS optodes (Niro 200Nx, Hamamatsu) were fixed on the skull to measure frontal lobe oxygenation, and Doppler probes (DWL, Singen, Germany) were positioned bilaterally to insonate both middle cerebral arteries (MCA) and the MCA velocity (MCAv) calculated. Then, the subjects were connected to the metabolic cart (Vmax N29; Sensormedics) and after a standardized warm-up, they performed 3 isokinetic Wingate test (80 RPM) with 4.5 min recovery periods in between. **Results** Compared with the first sprint, the MCAv was 13% lower during the 2nd and 3rd sprint (P<0.005). This coincided with 14 and 28 % lower PETCO₂ values (33±1, 28±1, and 24±1 mmHg, 1st, 2nd and 3rd sprint, respectively) and 39 and 43% higher VE values, during the 2nd and 3rd sprints, respectively (P<0.001). Despite this reduction in MCAv, frontal lobe oxygenation was reduced only by 3.6 % during the second Wingate test (P<0.05), and the reduction was not statistically significant during the 3rd sprint, compared to the 1st sprint, despite a much lower PETCO₂ in the latter. **Discussion** This study shows that the MCAv is barely diminished during sprint exercise, despite a considerable reduction of PETCO₂, a valid estimate of PaCO₂. The observed mild reduction of MCAv had no functional effects on brain oxygenation. These findings imply that vasodilator mechanisms counteract the vasoconstrictor effects caused by the reduction of PaCO₂ during repeated sprint exercise in man. **References** Calbet et al. (2003). PSYCHOLOGICAL RESPONSES TO AN ACUTE BOUT OF HIGH-INTENSITY INTERVAL AND MODERATE-INTENSITY CONTINUOUS TRAINING IN SEDENTARY OVERWEIGHT AND OBESE WOMEN

Hsiang Chi, Y., I Hua, C.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction The high-intensity interval training (HIIT) has been shown to have health-related benefits for healthy children, adults, and individuals with metabolic syndrome and congestive heart failure (Burgomaster et al., 2008). A single bout of aerobic exercise can improve mood and increase positive feelings in apparently healthy individuals (Gauvin, Rejeski, & Reboussin, 2000). Yet, differences in psychological responses between HIIT and moderate intensity continuous training (MICT) are still unknown. Different training programs may result in different emotional responses. Thus, the purpose of this study was to investigate the effects of an acute bout of HIIT and MICT on psychological responses in sedentary overweight and obese women. **Methods** Twelve sedentary women (mean age 21.67±1.15 yr; mean BMI 28.3±35.7kg/m²; mean body fat 35.72±3.73 %) participated in the study. All participants completed a graded exercise test on a cycle ergometer to determine their peak oxygen uptake (VO₂) and maximal heart rate. Next, participants performed two exercise sessions (HIIT and MICT) in random order. The HIIT consisted of 3 minutes of warm-up and 18 minutes of main exercise, in which participants cycled 60 seconds at maximum intensity followed by 75 seconds of recovery at 50 watts repeated for 8 intervals. The MICT consisted of 3 minutes of warm-up and 16-22 minutes of main exercise at 50% VO₂ reserve. The two sessions were scheduled at least 48 hours apart. Psychological responses were assessed at baseline, midpoint, the end of exercise session, and 5, 15, and 30 minutes post exercise, using the rating of perceived exertion (RPE) and Self-Assessment-Manikin (SAM). SAM is a non-verbal pictorial assessment technique that measures three dimension of person's affective reaction: pleasure, arousal, and dominance (Bradley & Lang, 1994). **Results** The pleasure scores of SAM were significantly lower in HIIT as compared to that in MICT at midpoint (p=.004) and end (p=.004) of the exercise. Arousal scores of SAM were significantly higher in HIIT at midpoint (p=.001) of the exercise. Dominance scores of SAM were significantly higher in HIIT at midpoint (p<.001) and end (p=.014) of the exercise. The RPE scores were also significantly higher in HIIT at midpoint (p=.007), end (p=.047) of the exercise, and 5 min (p=.001) and 15min (p=.008) post exercise as compared to that in MICT. **Discussion** The results of this study showed that psychological responses in MICT were better than in HIIT. It is suggested that MICT may be a more suitable and acceptable exercise program for sedentary overweight and obese women. **References** Bradley, M. M., & Lang, P. J. (1994). Mini-Orals**MO-BN01 BM Running****THE SPATIO-TEMPORAL DIFFERENCES BETWEEN GAIT PARAMETERS FROM 8 WEEKS MINIMALIST FOOTWEAR HABITUATION: A COMPARISON OF THREE FOOTWEAR CONDITIONS.**

Gravestock, H., Corbett, M., Griffiths, L., Mizen, R., Thomas, G., Eastough, D.

University of Worcester

Introduction Preventing injury in the athletic population is of interest; one suggested technique to achieve this is to modify the gait pattern, which can potentially be attained by barefoot running (Murphy et al. 2013). Manufacturers have now developed minimalist shoes to alleviate the obvious surface hazards that are present while barefoot (Willy & Davies 2013). To date, this intermediate option, that is now

readily available, has received limited scientific investigation regarding the effects the footwear may have on spatio-temporal gait parameters, particularly after prolonged habitual wear. **Methods** Participants (healthy adult males $n=15$) were randomly allocated to a control or intervention group. The intervention group were provided with a pair of minimalist shoes (Feelmax) to be worn at least 6 hrs a d, 5 d a wk, over an 8 wk habituation period. Spatio-temporal data were obtained both before and after the 8 wk period for all participants. A 16 camera 3D motion capture system (Vicon) and analysed (Vicon BodyBuilder) were utilised. The Statistical Package for the Social Science (SPSS) was used for the statistical data analysis. All spatio-temporal parameters of gait were compared for each trial. **Results** Complete statistical analysis is pending. The gait parameters to be reported include, but are not limited to; stride length, stride frequency, cadence, step time, stride time, swing time, and stance time. **Discussion** After the 8 week intervention period, a tendency for alterations in spatio-temporal gait parameters was observed. Bonacci et al. (2013) did not find any kinematic differences between the minimalist shoe and other shod conditions tested. Additionally Willy & Davies (2013) also reported no changes in spatio-temporal gait parameters when compared with the standard running shoe. The dissimilarity in results of previous work, and the present study may be caused by different habituation periods utilised between each investigation. Only a 10 min (Willy & Davies 2013), and a 10 d (Bonacci et al. 2013) habituation period were utilised in comparison to the 8 week period prescribed here. This may suggest a 10 d habituation period is not long enough to modify gait pattern, and therefore prevent injury. Squadron & Gallozi (2009) observed a reduced sagittal plane ankle and knee angle just before foot strike while adopting a minimalist shoe. However, the participants of this study were habitual barefoot runners. Therefore, the modification in spatio-temporal gait parameters may be due to the long term barefoot running adaption, and not to the immediate effect of wearing minimalist footwear. **References** Bonacci, J., Saunders, U., Hicks, A., Rantalain, T., Vicenzino, T. & Spraford, W. THE BIOMECHANICAL CHANGES ASSOCIATED WITH AN 8-WEEK PROGRESSIVE BAREFOOT RUNNING PROGRAMME

Tam, N., Astephen Wilson, J.L., Tucker, R.

University of Cape Town

Introduction: Barefoot running has been proposed as the most natural, efficient and safest way to run. Biomechanical differences have been explored between barefoot and shod running. Studies have yet to track both kinetic and kinematic changes over a 'purely' barefoot training programme. The aim of this study is to provide insight into the changes in lower limb biomechanics over an 8-week barefoot running programme. **Methods:** Twenty-five habitually shod recreational runners with a 10km race time <60 minutes participated. Data was collected whilst participants ran down a 40m runway and over a floor embedded force plate at 4.3min/km, 3D motion analysis was also collected in both shod and barefoot conditions. Overground running economy was also obtained. These were conducted prior to and post a prescribed 8-week progressive barefoot running programme. Initial loading rates were calculated from the force plate. Joint angles of the ankle, knee and hip were calculated from the 3D motion analysis. **Results:** No differences in running economy were observed between the pre- and post-testing sessions. Runners landed in greater plantarflexion when shod after the training programme. Also, increased knee flexion at ground contact was found after the programme in the barefoot condition. Interestingly, initial loading rates were increased after the programme in the barefoot and minimalist but decreased in the shod condition. Barefoot and minimalist loading rates remained higher than in the shod condition. **Discussion:** Changes in kinematics and kinetics are possible over an 8-week programme. It appears that training in the barefoot condition maybe beneficial for running in general. The risk factors of injury still remain, but appear to be attenuated or shifted to other locales. Barefoot running appears to be a beneficial mode of exercise, but whether or not a full transition with the maintenance of performance is possible remains elusive.

DECISIVE ANTHROPOMETRIC, PHYSIOLOGICAL AND BIOMECHANICAL VARIABLES FOR HALF-MARATHON PERFORMANCE

Ogueta, A., Rodríguez Marroyo, J.A., García-López, J.

University of León

Introduction The relationship between long-distance running performance and some anthropometric and almost all physiological variables is well-known (Basset and Howley, 2000; Zillman et al., 2013). However, the possible influence of biomechanical variables is quite unclear. While forefoot/midfoot strike patterns are associated with better performance (Hasegawa et al., 2007), contradictory results have been found between contact time, step rate and length (Storen et al., 2011). Therefore, the aim of the study was to analyse simultaneously the influence of anthropometric, physiological and biomechanical factors on half-marathon performance. **Methods** Forty-eight runners participated and were classified into 4 groups according to their performance level in half-marathon (hh:mm:ss): Group 1 ($n=11$, <1:10:00), Group 2 ($n=13$, <1:20:00), Group 3 ($n=13$, <1:30:00), Group 4 ($n=11$, <1:45:00). An anthropometric (height, body mass, BMI, skinfolds, circumferences and lengths) evaluation was carried out, and physiological (VO_{2max} , anaerobic threshold and running economy) and biomechanical variables (foot strike pattern, contact time, step rate and step length) were registered during an incremental and a sub-maximal test on a treadmill (Ogueta-Alday et al., 2013). **Results** Significant differences between groups and correlations ($p<0.05$) with running performance were observed in training-related variables (experience and km per week), anthropometrics (mass, BMI and skinfolds), physiological (VO_{2max} , anaerobic threshold and running economy) and biomechanical (foot strike pattern, contact times in sub-maximal test, contact times and step length in incremental test) variables. No differences between groups were observed in step rate and length at the same submaximal running speed. **Discussion** Differences in contact times could be explained by runners' foot strike pattern and speed where physiological variables were obtained (thresholds and VO_{2max}) (Ogueta-Alday et al., in press). Thus, except from step length, which is also dependent of speed, the rest of biomechanical variables have shown not to be very sensitive to half-marathon performance. From the analyses, an equation to predict (96.3%) half-marathon performance was obtained: Performance (s) = $10142.5 - 150.8$ peak running speed - 133.9 RCT speed - 20.3 years of experience. **References** Basset DR, Howley ET. 1. *Toin University of Yokohama, Kanagawa, JAPAN*, 2. *Tokyo Metropolitan University, JAPAN*, 3. *Future Institute for Sport Sciences, JAPAN*

[Introduction] The popularity of running is increasing for maintaining and improving health. Meantime, running injuries, such as plantar fasciitis and tibial stress fractures, are also being increased (Diebal et al., 2011). It has been shown that running shoes has a shock absorption function and thus, wearing shoes is an important way to prevent such injuries. On the other hand, wearing shoes habitually causes to decrease in the forefoot contact and to increase in the impact force of heel foot contact (Daniel et al., 2010). This study suggests that during a fast running, impact force at landing depends on the foot angle at initial contact. However, it has been unclear the effect of wearing running shoes on the pattern of ground reaction force during slow running or jogging. [Purpose] This study investigated the effect of wearing running shoes on the ground reaction force during jogging. [Methods] Seven healthy men (age, 21.0 ± 0 years; height, 1.75 ± 0.05 m; body mass, 70.5 ± 11.5 kg; mean \pm SD) performed jogging in barefoot (BARE) and shod (SHOD) conditions. They jogged along a 10m-long runway at self-selected speed (jogging) and were instructed to naturally contact with right foot within the area of the force plate (Kistler, Switzerland) at 1 kHz. Jogging was performed three trials of each condition with sufficient time for recovery between trials. Vertical ground reaction force (GRF) during foot contact was calculated for time-series vertical ground reaction force (GRFs), maximum GRF (MGRF), rate of loading (RL), and contact time (CT). GRFs were defined as the relative range between initial contact (0% GRFs) and take-off (100% GRFs). RL was determined by calculating the slope of the line associated with the initial peak in GRF, and it was calculated as the changes in force divided by time across the interval of 0-100% of the peak impact force. All data were presented as the mean of the 3 measurements. [Results] GRFs in BARE was significantly higher than SHOD at 5, 20, 25% of the total time of the contact phase (BARE: 8.4 ± 2.8 , 16.1 ± 1.4 , 19.6 ± 2.3 N/kg vs. SHOD: 3.4 ± 1.4 , 14.2 ± 1.5 , 18.4 ± 2.5 N/kg), while it was significantly lower at 40, 45, 50% of the total time of the contact phase (BARE: 21.9 ± 5.3 , 20.7 ± 5.7 , 19.2 ± 6.0 N/kg vs. SHOD: 24.0 ± 3.6 , 23.2 ± 3.9 , 21.4 ± 3.9 N/kg). MGRF in BARE was significantly lower than SHOD (BARE: 22.6 ± 4.9 N/kg vs. SHOD: 24.3 ± 3.7 N/kg), while RL in BARE was significantly higher than SHOD (BARE: 873.3 ± 274.3 N/kg/s vs. SHOD: 308.1 ± 47.6 N/kg/s). CT was not significantly different between the two conditions. [Conclusion] These results suggest that wearing running shoes reduce the rapid loading at initial contact of the foot during jogging.

MODIFYING FACTORS OF OSCILLATIONS AT THE ACHILLES TENDON

Meinert, I., Alt, W., Ruch, K.

University of Stuttgart

Introduction: Achilles tendon injuries are known to commonly occur in runners and their prevalence in ultra-marathon is higher than that of any other musculoskeletal injury (Lopes, Hespanhol Júnior, Yeung, & Costa, 2012). Even though several injury inducing factors have been discussed in the literature, no conclusion could fully explain or predict these injuries. During running repeated impacts are transferred in axial direction along the lower leg, therefore possibly affecting the vibration behavior of the Achilles tendon. Large oscillations may impair the musculoskeletal system and are minimized by muscle tuning in order to prevent damage (Wakeling & Nigg, 2001). The goal of the present study was to explore differences in the vibration behavior of the Achilles tendon while running in different running shoes and at different running speeds. Methods: Vibrations at the Achilles tendon were measured in 20 male runners using a skin mounted tri-axial accelerometer. Participants performed 9 running trials on a treadmill: running in three different shoes (Con1, Con2, NS) at 3 different speeds (10.4 km/h, 12.6 km/h, 15.1 km/h). Mean vibration frequencies were measured at the Achilles tendon during stance phase. A statistical comparison was performed between trials different running speeds, between different shoe conditions and between accelerations measured at the three axes of the sensor. Results: Oscillation frequencies in anterior-posterior direction (31.02 ± 3.4) were significantly higher than these measured in cranio-caudal direction (23.47 ± 3.3) and in medio-lateral direction (24.45 ± 3.5 ; $p < 0.01$, $p = 0.01$ respectively). A significant increase in oscillation frequency was found in NS (26.96 ± 5.12) compared to Con1 (25.82 ± 4.43 ; $p = 0.02$). No frequency difference was present between running speeds ($p = 0.11$). Discussion: Running speed has been discussed as an injury inducing factor in the past (McCrory et al., 1999) but does not have an effect on oscillation frequencies at the Achilles tendon. Therefore running speed alone is not a factor which leads to changed oscillation frequencies. However, vibrations may be altered when speed variations are combined with other factors that were not considered in the present study. Since different shoes influenced oscillation frequencies, the prevention or the treatment of Achilles tendon injuries may in the future be assisted by appropriate footwear. Lopes, A. ALTERATIONS IN LOWER LIMB RECRUITMENT AND KINEMATICS DURING ACUTE EXPOSURE TO BAREFOOT RUNNING.

Fleming, N., Walters, J., Fife, L., Grounds, J.

Indiana State University

Introduction: A significant body of research has previously described the effects of barefoot (BF) running on kinetics, joint kinematics and lower limb recruitment patterns. However, much of this published research used habitually BF runners. Other studies using habitually shod participants performed familiarisation protocols in order to provide time for runners to adjust their recruitment patterns and kinematics. Less is known about how rapidly these adjustments take place. Therefore the aim of the current study was to assess the acute effects of BF running on lower limb recruitment and kinematics in habitually shod participants. Methods: Recreational male runners ($n=10$; age 24 ± 3 yr, height 1.79 ± 0.07 m, body mass 75.1 ± 9.5 kg) with no experience of BF running volunteered for this study. Participants ran in a randomised trial order at 3 fixed velocities ($V1=3.13$, $V2=3.80$ and $V3=4.47$ m.s⁻¹, respectively) on a treadmill in two conditions (BF and shod). Surface EMG data were recorded from the Tibialis Anterior (TA), Medial Gastrocnemius (GM), Lateral Gastrocnemius (GL), Biceps Femoris (BF), Vastus Lateralis (VL) and Rectus Femoris (RF) during the final 30s of each trial. Synchronous sagittal plane kinematic data were recorded at 60Hz facilitating quantification of ankle, knee and hip kinematics via reflective markers placed at discrete anatomical locations on the lower limb. Results: BF running resulted in significantly greater plantarflexion at initial contact ($P<0.05$; -4 ± 5 vs. -1 ± 6 , -6 ± 4 vs. -3 ± 5 and -5 ± 6 vs. -2 ± 5 degrees at $V1$, $V2$ and $V3$, respectively) and ankle ROM ($P<0.05$) during the stance phase. In addition, knee and hip ROM during the absorptive phase of the stance were both significantly lower during BF running ($P<0.05$). Overall GM and GL pre-activation was significantly higher ($P<0.05$) and TA pre-activation significantly lower ($P<0.05$) in BF compared to shod. In addition, RF and VL activity were greater ($P<0.05$) during the propulsive phase of the stance in BF. Discussion: The main finding of the current study is that as little as 30s of BF running is sufficient to alter lower limb kinematics and recruitment patterns in habitually shod runners. In the case of ankle kinematics, it appears that increased pre-activation of GM and GL, coupled with decreased activation of TA

produced greater plantarflexion at initial contact. Leg stiffness was greater in BF running, as observed by lower knee and hip ROM during the stance phase, brought about by increased RF and VL activity. These results suggest that even runners with no previous BF running experience can rapidly alter their recruitment patterns and kinematics in response to changes underfoot.

SPRINT RUNNING WITH A BODY-WEIGHT SUPPORTING KITE - ARE THERE NEGATIVE EFFECTS ON 'FRONT SIDE MECHANICS' IN WELL TRAINED SPRINTERS?

Kratky, S., Buchecker, M., Pfusterschmied, J., Szekely, C., Müller, E.

University of Salzburg

Introduction Data of elite sprinters indicate that faster athletes realize shorter ground contact times (GCT) compared to slower individuals (Mann, 2010). Further, Mann underlines the importance of the so called 'front side mechanics' during sprinting, which is characterized by not extending the hip joint to an excessive amount at take-off and therefore to be able to attain a greater hip joint flexion in the late swing. This trend was also reported in a biomechanical analysis of the 100m sprints at the world championships 2007 (Ito, Fukuda, & Kijima, 2008). Recently it was demonstrated that using a body-weight supporting kite during full effort sprints in highly trained sprinters leads to a reduction in GCT (Kratky & Müller, 2013). The aim of this study was to investigate possible negative effects of this body-weight supporting device on sprint mechanics during full-effort sprints. **Methods** A kite with a lifting effect combined with a towing system to erase drag was utilized. Eleven well trained Austrian sprinters performed flying 20m-sprints under two conditions: (1) free sprint (FS); and (2) body-weight supported sprint (BWS). Sprint cycle characteristics were recorded during the high-speed phase by a 16 camera 3D-system. Paired sample t-tests and Cohen's d effect-size were used to determine differences between sprinting conditions. **Results** Running velocity was equal during FS and BWS (ICC=0.95). Compared to FS, BWS caused a decrease in the horizontal distance between the foot and the centre of gravity at touchdown by 52mm ($p<0.001$, $d=2.96$), whereas it remained unchanged at take-off. BWS provoked a small decrease in the hip extension angle at take-off ($p<0.001$, $d=1.46$) and the maximal hip joint extension ($p<0.001$, $d=1.42$), while maximal hip joint flexion was increased ($p=0.01$, $d=0.95$). **Discussion** The current study demonstrated that sprinting with a body-weight supporting kite appeared to be a highly specific method to reduce GCT in well trained sprinters without negative effects on 'front side mechanics' of sprinting (no increased hip extension at take-off or reduced hip flexion in the late swing). Therefore, we recommend body-weight supported sprinting as an additional tool in sprint training. **References** Ito, A., Fukuda, K., & Kijima, K. (2008). A NEW PRESSURE PLATE-BASED METHOD FOR FOOT STRIKE PATTERNS EVALUATION

Santuz, A., Ekizos, A., Arampatzis, A.

Humboldt-Universität zu Berlin

Introduction Foot strike patterns (FSP) during running are associated to injury risk (Daoud et al., 2012) and performance (Hasegawa et al., 2007). Heel strike (HS), midfoot strike (MS) and forefoot strike (FS) are the common classifications of FSP depending on the location of the first contact area with the ground. The most cited evaluation methods are based on visual observation (VO), location of centre of pressure at first contact and kinematic analysis, but a substantial standardisation is currently missing. This study aims to validate an original FSP assessment technique based on a numerical analysis of pressure distribution, in order to avoid any observer dependence. **Methods** A total of 65 men (age 30 ± 9 yr) and 35 women (age 29 ± 11 yr) were recruited. On a treadmill, participants conducted a self-selected warm-up. Then they ran, shod, for 120 s at three different velocities: preferred (2.9 ± 0.5 m/s), faster (3.6 ± 0.6 m/s), slower (2.3 ± 0.4 m/s). Afterwards they ran, barefoot, for 120 s at the preferred velocity. For each condition, the ground pressure distribution was recorded with a pressure plate (Zebris, 120 Hz), together with a high-speed (550 Hz) video of the sagittal plane. FSP data were obtained in two ways: by VO analysis and through a numerical approach, with a custom algorithm taking into account the stance time, the distribution and timing of the forces, the collision forces values (Lieberman et al., 2010) and the static footprint length. **Results** The VO analysis was conducted by eight trained observers, among which the ICC values for the identification of the FSP were 0.991 (HS), 0.992 (FS) and 0.136 (MS). The numerical analysis gave the FSP distribution among the studied population. Pref. vel.: 85% of subjects showed a HS pattern, 11% MS, 4% FS. Faster vel.: 83% HS, 9% MS, 7% FS. Slower vel.: 80% HS, 12% MS, 8% FS. Pref. vel. barefoot: 28% HS, 7% MS, 64% FS. **Discussion** FSP assessment through the VO method showed low conformity among observers, mainly in determining MS cases. The developed algorithm allows for an observer-independent FSP evaluation. The numerical analysis gave results that are consistent with previous findings (Hasegawa et al., 2007, Lieberman et al., 2010), showing a dominance of HS patterns in the shod condition and FS patterns in the barefoot condition. The influence of speed in the shod condition showed that, in comparison to the preferred, both the faster and the slower velocities decreased the HS and increased the FS cases. **References** Daoud AI, Geissler GJ, Wang F, Saretsky J, Daoud YA, Lieberman DE (2012). *Med. MECHANICAL PROPERTIES OF TRICEPS SURAE MUSCLE-TENDON UNIT IN KENYAN DISTANCE RUNNERS

Oda, T.1,2, Toyoda, Y.1, Hisano, T.1,3, Kusumoto, K.1, Kunimasa, Y.3, Sano, K.3, Nicol, C.4, Komi, P.V.5, Ishikawa, M.3

1: HUTE (Hyogo, Japan), 2: RIKEN (Saitama, Japan), 3: OUHS (Osaka, Japan), 4: CNRS (Marseilles, France) 5: NMRC-JYA (Jyväskylä, Finland)

Introduction It has been suggested that superior running economy is one of key factors for the great success of Kenyan distance runners (Saltin et al. 1995). The running economy and performance would be significantly influenced by mechanical properties of muscle and tendon tissues, but detailed information has been limited. In this study, we determined passive joint torque, and indices of stiffness and Young modulus on the both tissues in triceps surae muscle of Kenyan distance runners. **Methods** Eight Kenyan (KDR) and Japanese distance runners (JDR, as a control group) were volunteered for this study, respectively. Morphological as well as mechanical parameters of triceps surae muscle-tendon unit were measured by the B-mode musculoskeletal ultrasonography. For the measurements of mechanical properties, ankle joint torques and length changes of both muscle and tendon tissues were measured during passive dorsiflexion (from the 20-degree plantar-flexion position to 10-degree dorsiflexion position) and during maximum voluntary plantar flexion at 0-degree. The stiffness index and young modulus index were calculated by the ankle joint torque and length changes of tissues. **Results and Discussion** Length of shank and Achilles tendon were 10% and 25% longer in KDR than in JDR, respectively. Gastrocnemius muscle

belly were 35% shorter in KDR than in JDR. In the mechanical properties, the passive joint torque at the 10-deg dorsiflexion was 52% greater in KDR than in JDR ($p < 0.05$), but not at the 0-deg position. The muscle stiffness index at 0-deg was 181% greater ($p < 0.01$), and the corresponding young modulus index was 138% greater in KDR than in JDR ($p < 0.05$). In contrast, the stiffness and young modulus indices on tendon tissues did not show any significant differences. Therefore, the higher passive joint torque and stiffer muscle tissues in KDR would positively contribute to joint torque generation and power output required in stance phase of running. Also, their differences of not only stiffness index but also young modulus index in muscle tissues might indicate the intrinsic high stiffness of muscles and/or less muscle slackness in KDR. RESISTANCE TRAINING SUPPRESSES THE HSPB1 GENE EXPRESSION IN SKELETAL MUSCLE OF RATS

Fayazmilani, R., Khaledi, N.

shahid beheshti university

Introduction Hspb1 gene expresses one of the small heat shock proteins (HSP25) which protects muscle cells against damage and probably involves in both remodeling and hypertrophy process of skeletal muscles (Huey et al., 2006). The protein content of HSP25 has been shown to increase in response to resistance training previously (Murlasits et al., 2006; Paulsen et al., 2012). However, adaptive response of Hspb1 gene expression to resistance training is not well understood yet. The aim of this study was to investigate the changes in mRNA level of Hspb1 gene and its protein (Hsp25) level in response to resistance training in flexor hallucis longus (FHL) muscle of rats. **Methods** Forty Sprague-Dawley rats were assigned to a control (C; n=18) and resistance training (T; n=22) group. Resistance training consisted of ladder climbing with carrying a load suspended from the tail of rats (five days per week for eight weeks). Protein content of HSP25 was measured using WB and Hspb1 mRNA level using real-time PCR in FHL muscle, 48 hours post last training session. Differences between groups were measured by independent t-test ($P < 0.05$). **Results** Muscle wet weight of FHL increased by 26% after eight weeks of resistance training. HSP25 level was significantly higher in trained rats ($p = 0.011$). Although, Hspb1 gene was DOWN-regulated in training group compared to control, as the mRNA level of this gene decreased significantly ($p = 0.006$). **Discussion** According to increment in FHL muscle mass, this study indicates muscular hypertrophy after resistance training. Increasing the protein level of HSP25 is in line with other studies which indicated that resistance training or functional overload on skeletal muscle increases myocellular content of HSP25 (Huey et al., 2006; Murlasits et al., 2006; Paulsen et al., 2012). As other studies suggest that this adaptation occurs in cytosolic fraction (Paulsen et al., 2012), the existence of HSP25 in cytosol may suppress more Hspb1 gene expression. Although the regulatory mechanism of HSP gene expression is still unclear, the content of available HSP25 might be a key regulatory factor for Hspb1 gene expression. It seems that this pool of HSP25, as a cellular storage, will assist skeletal muscle to more properly encounter with upcoming stressors to protect itself by immediate translocation of HSP25 from cytosol to myofibril compartment. **References** Gjovaag TF, Dahl HA (2006). THE INFLUENCE OF RESISTANCE EXERCISE ON SUBSARCOLEMMA CYTOSKELETON STIFFNESS AND ANABOLIC SIGNALING EVENTS IN HUMAN SKELETAL MUSCLE: A PILOT STUDY

Lysenko, E.A., Popov, D.V., Ogneva, I.V., Miller, T.F., Bachinin, A.V., Vinogradova, O.L.

Institute for Biomedical Problems of Russian Academy of Sciences

Introduction Resistance exercise activates muscle fiber protein synthesis. The main signaling consequence of this influence is mTORC1 activation and following translation acceleration. Among the most important stimuli for activation of mTORC1 are mechanic stimuli, but mechanosensor in skeletal muscle is not identified yet. Anabolic response after acute resistance exercise in skeletal muscle of untrained subjects is more pronounced compared with strength trained athletes. This could be partially explained by mechanical properties of muscle fibers cytoskeleton. In this pilot study we tried to find a link between subsarcolemmal cytoskeleton stiffness and anabolic signaling events in skeletal muscle. For this purpose, we compared subsarcolemmal cytoskeleton stiffness and anabolic signaling events in trained and untrained subjects after acute resistance exercise session. **Methods** Four healthy young volunteers (two strength trained and two untrained) performed strength exercise session composed of 5 sets of 85% 1RM legs press to exhaustion with 5 minute rest between sets. Before, 1, 5 and 10 hours after the exercise biopsies from vastus lateralis muscle were taken. Part of fresh muscle tissue was taken to measure transversal stiffness by atomic force microscopy (AFM). Remaining part was frozen for later evaluation of genes expression (β -actin, α -actinin 1 and 4, myostatine, MGF), proteins (β -actin, phospholipase D2) localization in membrane and cytosol fraction, as well as p70S6 kinase activity. **Results and discussion** The basal muscle fiber transversal stiffness was higher in trained subjects, whereas dynamics of this parameter after exercise was similar in all subjects: the significant decline after 1 hour of recovery and the increase after 10 hours were observed. The potential relationship between the changes of subsarcolemmal cytoskeleton stiffness and anabolic signaling events in trained and untrained subjects after acute resistance exercise session will be discussed.

DEVELOPMENT OF A NEW TRAINING PROTOCOL TO INDUCE SKELETAL MUSCLE HYPERTROPHY IN MALE RATS – ANALYSIS OF COMBINATORY EFFECTS OF TRAINING AND ANABOLIC STEROIDS

Hengevoß, J., Tenfelde, O., Reitzner, S., Diel, P.

German Sport University Cologne

To understand molecular mechanisms of skeletal muscle hypertrophy suitable animal models are sufficient. These models open new prospects for investigations of the complex interaction of training and anabolic steroids as well as the identification of physiological and endocrine side effects due to their abuse. Therefore in this study we developed a treadmill based hypertrophy training protocol for rats with the aim to simulate the situation of human athletes abusing steroids as close as possible. The rats were trained on a treadmill for six weeks. Training started with a velocity of 12 m/min and was increased progressively up to 29 m/min during the following five weeks. The rats performed two training sessions per day for 10 minutes and maintained a training rhythm of 3 days training and one day rest. The whole training protocol was performed at a steep angle of 25°. Between the end of the training and the section two additional days of rest were included to exclude short time effects on the endocrine system. The 32 trained intact male rats (strain=Wistar) were allocated into four groups. Group 1 = sedentary control group (C), group 2 = trained Group (EX), Group 3 = sedentary control group treated with metandienone (Meta) and Group 4 = metandienone + training (Meta/EX). Meta animals were treated with a dose of 5mg/kg/bw/d Meta diluted in 20% ethanol and 80% peanut oil via s.c. injection. After six weeks animals were sacrificed and the weight of the heart, liver, kidney, seminal vesicle, visceral fat, testis, tibia, prostate, m. levator ani, m. soleus and m. gastrocnemius was determined. In addition blood and tissue samples were collected and prepared for histological and molecular analysis. In EX and Meta/EX animals the weight of the heart, m. soleus and m. gastrocnemius was significantly increased. Interestingly in EX and Meta/EX animals also the weight of the m. levator ani which is not involved in locomotion and the tibia weight was increased. Here additive effects of training/ Meta treatment could be observed. The visceral fat mass was significantly decreased due to training and/or steroid stimulus. Treatment with the anabolic steroids affected the weight of reproductive organs like prostate, seminal vesicle and testis, and has toxic effects on liver and kidneys. In summary the results demonstrate that our training protocol simulates the human situation of resistance training and anabolic steroid abuse very closely. Studies on molecular mechanisms involved in skeletal muscle hypertrophy as well as toxic and endocrine side effects of anabolic agents are under investigation.

THE EFFECT OF MYOADENYLATE DEAMINASE'S GENETIC VARIANT ON THE POWER PERFORMANCE OF ELITE LITHUANIAN ATHLETES

Gineviciene, V.1, Jakaitiene, A.1, Tubelis, L.2, Utkus, A.1

Vilnius University

Introduction Adenosine monophosphate deaminase (AMPD also known as myoadenylate deaminase) is very important regulator of muscle energy metabolism during exercise. Inherited deficiency of skeletal muscle myoadenylate deaminase (AMPD1) is a genetic disorder characterized primarily by a 34C>T transition in exon 2 of the AMPD1 gene. AMPD1 deficient individuals (TT genotype) exhibit alterations in ATP catabolic flow, resulting in greater adenosine accumulation during high intensity exercise. The aim of this study was: 1) to determine the AMPD1 allele/genotype frequency distributions among Lithuanian elite athletes and healthy non-athletes controls; 2) to compare common anthropometric measurements and physical performance phenotypes between the groups of athletes depending on their AMPD1 genotype. Methods A total of 204 Lithuanian elite athletes (endurance-oriented (n=84), power-oriented (n=47), mixed endurance/power athletes (n=73)) and 260 controls, were genotyped (PCR-RFLP). Anthropometric measurements, anaerobic muscle strength (grip strength, vertical jump and stair climbing test) and aerobic capacity function (VO2max) were evaluated. Results The results showed that the AMPD1 genotypes frequencies were significantly different between the total athlete group and the control group (AMPD1 CC/CT/TT 74.2/24.9/0% vs 72.2/25.5/2.4%). There were more power-orientated athletes with the CC genotype (86.3%) compared with the endurance-orientated athletes (72.9%), mixed athletes (67.1%) and controls (74.2%) (P<0.05). The short-term explosive muscle power value (based on vertical jump test) of CC genotyped athletes from the power group was higher than that of the endurance group athletes (P<0.05). A statistically significant difference was also obtained for the vertical jump test value in the subgroup of CC-genotyped male athletes. Mixed athletes carrying the CC genotype had higher handgrip strength compared with the CT genotyped athletes (P<0.05). Indexes of endurance performance (VO2max) did not differ (P>0.05). Discussion This data indicates that AMPD1 deficiency could have a detrimental effect on sprint/power performance and AMPD1 variant does not play a significant role in the athletes' aerobic muscle performance phenotype. Results support the positive association of the AMPD1 CC genotype with sprint/power performance. In conclusion, the AMPD1 C allele may help athletes to attain elite status in sprint/power-oriented sports, and the T allele is a factor unfavourable for athletics in sprint/power-oriented sports categories. Hence, the AMPD1 C allele can be regarded as a marker associated with the physical performance of sprint and power. Contact valentina.gineviciene@gmail.com

RESPONSE OF ACTN2 GENE EXPRESSION AFTER DAMAGING EXERCISE IN SLOW-TWITCH MUSCLES

Khaledi, N., Fayazmilani, R., Javeri, A.

Kharazmi university, Shahid beheshti university, National institute of genetic engineering & biotechnology

Introduction: Myofibrillar Z-disc streaming and loss of cytoskeleton's proteins are considered the morphological hallmarks of eccentric contraction-induced injuries (Yu et al., 2003) Alpha (α)-actinins are one of the major structural proteins in the skeletal muscle Z-line and forms the bridges crosslinking the thin actin filaments from neighboring sarcomeres (North and Beggs, 1996). Also previous studies indicated the important role of ACTN2 against muscle damage in absence of ACTN3 of type II muscle fibers (Vincent et al., 2010). However, the protective role of α-actinin 2 after damaging exercise in slow twitch fibers is not indicated yet. Methods: Male Wistar rats (n=24; W= 300±10gr) were divided into two groups of exercise (EX) and control (C). Exercise group divided into two subgroups for two time-courses (3 and 48 h after exercise). Unaccustomed exercise consists of 90 min interval downhill running (18×5 min, 2 min rest between intervals, 20m/min, and 17° decline). This study examined the effects of one bout of eccentric exercise on α-actinin-2 gene expression levels in different post exercise time course. ACTN2mRNA level was measured in soleus muscle using Real-Time PCR. Results: Results showed that the mRNA level of α-actinin-2 in exercised muscles was decreased significantly in both time courses (p<0.05). Although, the amount of expression 48hr post exercise was significantly lower than 3hr group (p=0.01). Conclusion: It seems that exercise induced muscle damage has suppressed α-actinin-2 gene expression up to 48 h post exercise. Previous study indicated that protein levels of α-actinins decreased following damaging exercise (Martinez-Amat et al., 2005). It must be considered that we investigated early time courses (degeneration phase) post damaging exercise. This study suggests measuring α-actinin-2 gene expression levels in later time courses

(regeneration phase). Other role of α -actinin-2 is protective effect after damaging exercise. also, Vincent et al. (2010) study was in contrast with our findings (Vincent et al., 2010). This study demonstrates that probably the role of α -actinin 2 in slow twitch muscles is slightly different to other type of skeletal muscle. ACTN3 R ALLELE IS SPEED-ORIENTED GENE RATHER THAN STRENGTH-ORIENTED

Kim, C.I, Kim, H.2

Soonchunhyang University

Introduction Previous researches on the ACTN3 variant have been focused mainly on speed performance without differentiating its influence on power components, i.e., speed and strength. It remains still unclear which components of human power is most strongly associated with the ACTN3 variant. Therefore, the aim of this study is to examine the distribution of the ACTN3 R577X genotypes and alleles in power-oriented, speed and strength athletes and to search for differential associations of power components with the ACTN3 R577X polymorphism. **Methods** ACTN3 genotyping was carried out for a total of 975 Korean participants: top-level sprinters (n=58), top-level strength athletes (n=63), and healthy controls (n=854). The SNP of the ACTN3 R577X (rs1815739) was analyzed with custom designed primers and probes (Assay ID: C_590093_1_) for the MGB TaqMan® SNP genotyping assay. PAWE software program was used to test sample size validity and sample size validity was confirmed by having type I error set at 0.05 and type II error as 80% power level. Genetic associations were evaluated by chi-square test or Fisher's exact test. **Results** In the power-oriented group composed of sprinters and strength athletes, the frequency of the XX genotype was significantly underrepresented (11.6% versus 19.1%) in comparison to its representation in the control group (P<0.05). When the power-oriented group was divided into the strength-oriented group and the speed-oriented group, no significant difference in the ACTN3 XX genotype was found between the strength-oriented athletes and the controls (15.9% versus 19.1%, P<0.262). Only the speed-oriented athletes showed significant differences in the frequency distributions of the ACTN3 XX genotype (6.9% versus 19.1%, P<0.05) from that of the controls. **Discussion** These results could support the contention that the lack of α -actinin-3 in fast-twitch muscle fibers by the XX genotype only slightly affects the muscular strength of a single maximum contraction. On the other hand, the null type of the α -actinin-3, ACTN3 XX genotype, showed a significantly low distribution in speed performance as consistently reported in previous studies and also in this study. Therefore, it is thought that the α -actinin-3 deficient genotype, the ACTN3 XX genotype, may affect speed performance that needs rapidly repeated muscular contraction. In conclusion, the ACTN3 genotype seems to mainly affect sports performance and especially on speed. **References** Yang, N., Garton, F., & North, K. (2009). GENETIC RISK ASSESSMENT MODELS FOR ACHILLES TENDINOPATHY

Saunders, C.J., Collins, M.

University of Cape Town

INTRODUCTION: Several polymorphisms within various genes encoding proteins functioning within the extracellular matrix of tendons have been implicated in Achilles tendinopathy (AT). The aims of this study were to investigate the contribution of (i) the interactions between these polymorphisms in modulating AT risk and (ii) the identification of key biological components of these interactions in risk susceptibility. **METHODS:** Genotype data from 519 South African (SA-TEN =94; SA CON= 131) and Australian (AUS-TEN=85; AUS CON=209) cases (TEN) and control (CON) participants for several polymorphisms were included: rs4143245 (COL27A1), rs1249744 (COL27A1), rs753085 (COL27A1), rs946053 (COL27A1), rs13321 (TNC), rs2104772 (TNC), rs1330363 (TNC), rs2161468 (COL5A3), rs1559186 (COL5A3), rs2303099 (COL5A3), rs2056156 (COL3A1), rs3106796 (COL3A1), rs1800255 (COL3A1), rs4667264 (COL5A2), rs13031549 (COL5A2), rs1800795 (IL-6), rs1143627 (IL-1 β), rs16944 (IL-1 β), rs1045485 (CASP8), rs3834129 (CASP8), rs12722 (COL5A1), rs17146744 (COL5A1), rs16399 (COL5A1), rs1134170 (COL5A1), rs4919510 (MIR608), rs143383 (GDF5) and rs4789932 (TIMP2). Stepwise logistic regression was used to compare allele-combination frequencies between the TEN and CON groups and to derive risk models for AT. Receiver operating characteristic (ROC) curves were used to analyse the strength of the risk models. **RESULTS:** Significant allele-allele combinations were noted between polymorphisms within COL27A1 and polymorphisms within the IL-6, IL-1 β and CASP8 genes (p<0.05). Similarly, significant combinations were noted between TNC and IL-6, IL-1 β and CASP8; and between COL5A3 and IL6. The best fit risk model included variables age (years), sex (male), COL27A1 rs946053, COL5A1 rs12722, COL5A3 rs1559186, IL-6 rs1800795, CASP8 rs1045485 and CASP8 rs3834129 with a specificity of 86.5% and a sensitivity of 58.1%. The AUC for the optimal risk model was 0.801. **CONCLUSION:** These findings suggest that there are significant genetic interactions between the structural components of the ECM and cell signalling molecules in modulating AT risk. The biological mechanisms which may underlie these interactions are diverse and point to an intricate homeostatic relationship between cell-signalling pathways and the structural integrity of the ECM collagen network. THE EFFECT OF PHYSICAL ACTIVITY ON BLOOD FLOW OF THE ACHILLES TENDON

Wezenbeek, E., Blancke, B., Borrey, N., De Wilde, S., Mahieu, N.

Ghent University

Which exercise modality increases tendon blood flow the most? Wezenbeek, E., Blancke, B., Borrey, N., De Wilde, S., Mahieu, N. Department of Rehabilitation Sciences and Physical Therapy, Ghent, Belgium **Introduction** An inadequate blood supply plays an important role in the development of injuries. It is known that physical activity has an influence on the blood flow of a tendon. However, it remains unclear which type of activity leads to the highest increase in blood flow. Therefore, the aim was to compare the immediate effect of 5 different physical activities (running, stretching, plyometrics, eccentric heel drops, T-test) on the blood flow of the Achilles tendon. **Methods** 30 healthy subjects performed each of the 5 activities spread over a period of 3 weeks. The blood flow was measured in each tendon before

and after each activity at 12 well-defined tendon points, which were summarized into 4 regions: insertion, distal midportion, proximal midportion and musculotendinous junction. Changes in blood flow were statistically analyzed using a mixed model analysis. Results At the insertion, running is the only activity which has an immediate effect on the Achilles blood flow ($P < .001$). This significant increase in blood flow due to running is also found in the distal midportion ($P < .001$), the proximal midportion ($P = .001$) and the musculotendinous junction ($P = .019$). When compared to the other 4 physical activities, running differs significantly, especially at the insertional region and at the distal midportion. The P-values range from 0.000 to 0.016. In the proximal midportion, running also shows the highest increase and differs significantly from heel drops, stretching and T-test. At the musculotendon unit, only 2 significant P-values are seen; between running and stretching and between running and heel drops. Discussion The results demonstrate that running implicates the highest increase in blood flow of the Achilles tendon and this throughout the four regions of the Achilles tendon. The present results are in agreement with the observation of a decrease in blood flow after eccentric training and stretching (Knobloch et al., 2007). It is reasonable to assume that due to a tendon stretch the blood vessels within the tendon stretch and become thinner, which results in a slower flow. The higher increase due to running might be explained by the exercising time. The duration of tuck jumps and T-test may not have been sufficient to induce a vasodilation to increase tendon blood flow (Malliaras et al., 2012). In conclusion, if one wants to increase the blood flow of a tendon, it can be recommended to perform physical activities, which are cyclically loading the tendon. References Boesen, M. I., et al. AWARDING RED CARD IN SOCCER: DOES POSSIBLE CONSEQUENCES INFLUENCE REFEREES' DECISION-MAKING?

Erikstad, M.K., Johansen, B.T.

University in Agder

Introduction According to the rules of soccer made by FIFA, a player might get sent off by collecting a red card as a result of violations of the rules. By examining 140 matches in German soccer in where a player were given a red card, Ridder, Cramer, & Hopstaken (2004) found out that teams who receives a red card are more likely to lose the match. Error Management Theory predicts that if judgments are made under uncertainty, selection should have favored a bias toward making the least costly error (Hasselton & Nettle, 2006). The aim of this study was to examine whether Norwegian Premier League (NPL) referees in soccer tend to avoid giving red cards, as an error will be experienced as especially costly. Methods Potential red card situations ($n=66$) from 174 matches of the NPL 2012 season were identified by objective match reports. Available video clips from the situations were gathered and edited. Each situation was thereby shown from different angles, zoomed in, and in slow motion. An expert panel of three referees of the NPL 2012 evaluated the situations individually as if they were the actual match referee. Results The expert panel judged mean 13 (range 11-14) of the 66 situations to qualify for a red card, while the actual match referees awarded only 2 red cards in these situations. Discussion The results revealed that the expert panel of referees' evaluation of red card situations is in such larger extent than the actual match referees' evaluation that a single explanation is insufficient. The possibility that this is due to that the EP judged each situation from different, angle, zoomed in, and in slow motion is plausible. However, the agreement rate between the individuals in the expert panel indicates that the situations are in at least some extent ambiguous. When judging ambiguous situations, EMT predicts that referees decisions should have favored a bias toward making the least costly error. In potential red card situations, the results thereby indicates that not to award a red card will be experienced as the decision where an error is least costly. PHYSICAL TRAINING AND MENTAL PREPARATION AMONG NORWEGIAN TOP-CLASS FOOTBALL REFEREES

Johansen, B.T., Giske, R., Haugen, T.

University of Agder

Introduction Johansen & Haugen (2013) have claimed that the role of the football referee requires a high degree of physical fitness as well as complex decision-making. Scientific knowledge related to elite football referees training and mental preparation was sporadic before the millennium, but it has increased slowly the last decade (Cattewu et al 2009). The aim of this study was to examine the amount of physical training and mental preparation among top-class referees in Norway. Methods This cross-sectional study was conducted as a part of the "Norwegian Elite Referees in football"-study. A total of 83 from 98 (84.7%) top-ranked referees (73 males and 10 females) from age 20 to 46 (mean age 33.3 years) completed a questionnaire using, SurveyXact, a web based program for electronic questionnaires. The referees were asked to estimate how much (in hours per week) of the physical training was endurance training (running, cycling, skiing) and how much of this training was sprint related (interval training, strength fitness, football playing). Mental training was assessed from one item with 4 response categories (twice a week or more; once a week; less than once a week; never). Results Results revealed that 85.5% (71/83) of the top-class referees conducted physical training five times or more per week. 14.6% (12/83) conducted physical training three times per week. A median (Q1, Q3) of 5 (3, 6) hours per week for endurance training and 2 (1, 3) hours per week for sprint related training were also reported. Regarding mental training the referees reported the following: 6.2% twice a week or more; 30.9% once a week; 30.9% less than once a week; 32.1% never. Discussion Due to the participation rate of nearly 85% of the Norwegian top-class referees, one may claim that they are conducting physical training according to the physical demands of a football match at top flight level (Krustrup et al 2009). The frequency of mental training reported is rather partial. However, it is in line with findings from Cattewu et al (2009). References Johansen, B.T., & Haugen, T. (2013). *J Sport Exer Psych*, 11 (2): 215-216. Cattewu, P., Helsen, W., Gills, B., & Wagemans, J. (2009). *J Sports Sci*, 27 (11): 1125-1136. ASSISTANT REFEREES USE THE SOUND OF THE MOMENT OF THE FINAL PASS IN JUDGING OFFSIDE IN FOOTBALL

Koedijker, J., Kredel, R., Schnyder, U., Hossner, E.J.

University of Bern

Introduction The task of the assistant referee (AR) is to judge whether an attacker is in offside position at the exact moment that the ball is played on another part of the field. Dominant perceptual-cognitive explanations argue that errors occur due to optical illusions that distort the ARs' percept of the positions of the involved players (e.g. Oudejans et al., 2000). These theories, however, neglect how ARs actually judge the moment of the pass. According to the modality appropriateness hypothesis (Welch, Dutton-Hurt, & Warren, 1986) sound is dominant over vision in the temporal modality, suggesting that ARs could use the sound of foot-ball contact of the final pass to estimate to moment of passing. In the first experiment it was predicted that removing all sound information would lead to more errors in general. In the second experiment the timing of the sound of foot-ball contact was manipulated. It was predicted that attackers in an onside position would be perceived leading their real position if the sound effect was manipulated to be later, leading to more false alarms (flag errors). In contrast, attackers in an offside position would be perceived to be trailing their real position if the sound effect was manipulated to be earlier, leading to more signal misses (non-flag errors). **Experiment 1 Methods** Four Swiss national level ARs judged 3-on-3 offside situations on a real football field under normal conditions (Control condition) and under conditions without auditory information (No Sound condition). Auditory information was removed by using earplugs and sound-proof ear protectors. **Results** Results showed that the ARs made more errors in the No Sound condition (30%) compared to the Control condition (13%), $\chi^2(1, N=161)=7.09$, $p<.05$. **Experiment 2 Methods** Twenty-eight highly experienced football players judged virtual offside scenes created with Autodesk 3ds that were projected on a large screen (2.4 x 2.0m). Sound effects recorded at a national league game were incorporated in the scenes and the sound of foot-ball contact of the final pass was manipulated to create experimental conditions: Control (at the moment of the pass), Early (100ms earlier), and Late (100ms later). **Results** A Type of Error x Condition ANOVA revealed that the sound manipulation significantly changed the errors in the expected direction, $F(2,54)=7.44$, $p<.01$. **Discussion** Both studies confirm that sound of the moment of passing plays an important role in judging offside. **References** Oudejans, RRD, Verheijen, R, Bakker, FC, Gerrits, JC, Steinbrückner, M, Beek, PJ (2000). THE GOALKEEPER POSITIONING EFFECT AND PENALTY KICK STRATEGY

Noël, B.1, van der Kamp, J.2,3, Memmert, D.1

1: DSHS (Cologne, Germany), 2: MOVE (Amsterdam, The Netherlands), 3: IHP (Hong Kong, China)

Introduction The position of the goalkeeper relative to the centre of the goal plays an important role in a penalty kicker's decision where to kick the ball. Strikingly, that is also the case if penalty takers perceive the goalkeeper to be in the centre of the goal, pointing to an influence of non-conscious perception on decision-making (Masters et al., 2007). Furthermore, penalty takers can employ either a keeper dependent (KD) or a keeper independent (KI) strategy (van der Kamp, 2006). It is currently not known if the goalkeeper's position affects decision-making of penalty takers independent of the penalty kick strategy employed. Considering that non-conscious effects on decision-making are thought to be only possible if a certain stimulus is attended and that penalty kick strategy was shown to affect a penalty taker's allocation of attention during a penalty kick (Noël & van der Kamp, 2012) it seems worthwhile to analyse if the goalkeeper positioning effect exists regardless of penalty kick strategy employed. **Methods** In Experiment 1 we advised soccer players to carry out penalty kicks under the terms of certain penalty kick strategies and keepers to start their movement before or after foot-ball contact. In addition, keepers were positioned either 10 cm to the left or right of the goal's centre. Experiment 2 was alike the first experiment besides the fact that keepers were positioned in the perceived centre of the goal. **Results** Results of Experiment 1 and 2 showed that the goalkeeper's position relative to the (perceived) centre of the goal does not affect penalty takers' decision-making if penalty takers employ a KD strategy and the goalkeeper moves before foot-ball contact. If the goalkeeper initiates his movement after foot-ball contact and if a penalty taker employs a KI strategy (regardless of the keeper's behavior) the effect of the goalkeeper's position exists. **Discussion** The results of both experiments expand current research on penalty kicks in soccer (Memmert et al., 2013) by showing that the effect of position of the goalkeeper is dependent on the goalkeeper's and penalty taker's behavior. **References** Masters, R.S.W., van der Kamp, J., & Jackson, R.C. INJURY EXPERIENCES IN ADOLESCENT FEMALE SOCCER

Gledhill, A., Forsdyke, D.

Leeds Metropolitan University; York St John University

Introduction Sports injury rehabilitation is an arduous task for injured athletes. Not only do athletes have to cope with the demands of physical rehabilitation, the psychosocial rehabilitation is another difficult barrier to overcome. Despite the importance of psychosocial factors in injury rehabilitation, there is a disparity between this and the knowledge and application of psychosocial considerations in sports injury rehabilitation. Moreover, there is a lack of understanding of adolescent injury experiences (Podlog et al. 2013); with developmental experiences of female soccer players being particularly underserved (Gledhill & Harwood, 2014). Consequently, the aim of this longitudinal study was to examine the lived injury experiences of a talented female soccer player, from the point of suffering a serious traumatic injury through to her return to competitive soccer. **Methods** Data were collected via seven Photo-Elicitation "autodriven" Interviews (PEIs – Clark, 1999) with a talented 17 year-old female soccer player. Interviewee photographs formed the 'semi-structured' basis of the PEIs, ensuring interviewee familiarity with the interview topics thus eliciting a greater understanding of the subjective meaning of the injury experience (Clark-Ibáñez, 2004). PEIs were analysed according to procedures of Interpretive Phenomenological Analysis. Further Composite Sequence Analysis was used to demonstrate the temporal changes in the injury experience throughout rehabilitation and return to soccer. **Results and Discussion** Three superordinate themes that characterised the injury experience emerged from the soccer player's rich PEIs: Perceived isolation, personal growth and development, and availability and use of coping resources. Her accounts provide a critical insight into impact of long-term traumatic injury on the life of a talented female soccer player, as well as highlighting

salient applied recommendations for those supporting athletes during long-term injury. Given the greater susceptibility of female soccer players to long-term injury (e.g. anterior cruciate ligament ruptures), future research should seek to extend current understanding of injury, rehabilitation, and return to sport experiences of adolescent female soccer players with a view to helping them navigate lived injury experiences. SPORT PSYCHOLOGY: A KEY COMPONENT OF A FOOTBALL ACADEMY

Fink, C., Galvin, E.

High Performance Sports

Introduction Sport psychology programs often include skills such as attentional focus, energy management, recovery from mistakes, and developing a consistent pre-performance routine. Literature has demonstrated the effectiveness of these programs in improving performance (Morris & Thomas, 2004; Vealey, 1994). Still, programs are likely to be most effective when they are integrated with sport sciences. For example, the physical demands of training should be considered when implementing mental skills. So, a team undergoing a period of intense physical training could benefit from practicing mental skills like goal setting, resilience, and composure, and learning skills like progressive relaxation or visualization during recovery periods. Tailoring the presentation of mental skills to fit what the players are experiencing on the field and in the weight room can help players recognize and understand the relationship between mental and physical skills and maximize the benefit of a sport psychology program. This presentation will discuss how to develop and integrate a sport psychology program with a physical skills training program by explaining how a program was developed for approximately 60 elite youth football players in a development academy. The program objectives are to teach players to develop their mental game to facilitate peak performance on the field. Players complete online sport psychology activities and participate in group and individual consultation sessions. The activities and group consultation topics are customized to match the technical training and strength and conditioning schedule to best meet the needs of the players. Discussion Attendees will learn about creating and implementing a sport psychology program and integrating it fittingly with training phases. Attention will be paid to working with coaching and physiology staff in order to stay present with training phases. Also, the presenters' experiences with various successes and pitfalls will be discussed and advice will be provided for how to best handle barriers to program implementation. DIFFERENCES OF ANTHROPOMETRIC CHARACTERISTICS, CARDIOVASCULAR DISEASE RISK FACTORS, PHYSICAL ACTIVITY OF JAPANESE CHILDREN ACCORDING TO VO2MAX

Sasayama, K.1, Ochi, E.2,3, Adachi, M.1,3

1: Hyogo University of Teacher Education (Hyogo, Japan), 2: Meiji Gakuin University (Kanagawa, Japan), 3: Okayama University (Okayama, Japan)

Introduction There are many reports of aerobic fitness related to cardiovascular disease (CVD) risk factors in adults and European children. However, there is limited evidence of the same Japanese children. Therefore, this study aims to compare anthropometric characteristics, CVD risk factors, and physical activity (PA) according to maximum oxygen uptake (VO2max) in children. Methods The subjects were 299 elementary school children (140 boys and 159 girls; 9.1±0.3 years). We measured the height, body weight, body mass index (BMI), waist circumference, waist-height ratio, percentage of body fat, fat mass, and fat-free mass as anthropometric characteristics. CVD risk factors were defined as blood pressure, total cholesterol (TC), high density lipoprotein cholesterol (HDL-c), and low density lipoprotein cholesterol (LDL-c). Regarding PA, we performed a day-specific (weekday and weekend) evaluation of step count and activity time according to intensity (light-to-moderate PA; vigorous PA) measured by using a uniaxial accelerometer (Lifecorder, Suzuken, Japan). VO2max was calculated by the date of a 20-m shuttle run. One-way analysis of variance was used to compare the parameters, CVD risk factors, and PA between the low VO2max, middle and high VO2max groups. Analysis of covariance, which was adjusted for BMI, was used to compare the HDL-c values among the three groups. Results The results showed that BMI, waist circumference, waist-height ratio, body fat percentage, percentage body fat, and fat mass were higher in the low VO2max group than in the middle and high VO2max groups. There was no difference in blood pressure, TC, or LDL-c among the three groups in either boys or girls. On the other hand, HDL-c was significantly lower in the low VO2max group than in the other groups in both boys and girls. Furthermore, HDL-c adjusted for BMI in the three groups was significantly lower in the low VO2max group than in the high VO2max group in boys and girls. Both step count and vigorous PA were significantly lower in the low VO2max group than in the high VO2max group in boys and girls. Discussion We confirmed that low VO2max group showed higher BMI and fat mass and lower HDL-c and PA. These findings are similar to the previous studies. (Ekelund et al; 2007, Mesa et al., 2006) The low VO2max group showed significantly lower HDL-c than the high VO2max group, even after adjustment for BMI. In conclusion, the present study suggests that improvements of aerobic fitness and PA are important for the decrease in CVD risk factors. TEACHERS OF PHYSICAL EDUCATION AND THE ACTIONS OF PREVENTION AND FIGHTING OBESITY

MIRANDA, M.

PONTIFÍCIA UNIVERSIDADE CATÓLICA DE GOIÁS / UNIVERSIDADE ESTADUAL DE GOIÁS - ESE

Introduction Overweight and obesity are defined as abnormal or excessive accumulation of body fat that can be harmful to health. Obesity has reached global epidemic proportion and there are about 250 million obese people and 500 million overweight (WHO, 2011). Therefore, the purpose of this research was to collect data of view and possible interventions that physical education teachers (EFI) made or may make with their students who are overweight and /or obese. **Methods** We interviewed in 2013, via Survey Monkey questionnaire, 234 professionals EFI in Goiânia-GO/BR, with teachers, students and recently graduated from two public universities and one private. The preparation of the questions was based on the translation of the questionnaire enveloped by the Belgian researchers Isaline Feron & Marc Cloes, from the University of Liège Department of Sport Sciences. It was applied in the 2012 among the Belgic EFI teachers. It was an exploratory study. For the data analysis, the frequency and percentage presented by the survey and the interpretation of comments made in the open questions we reused. **Results** Among other important results, we observed that most of the respondents strongly agreed or agreed that: a) EFI teachers have a lack of general knowledge on the topic of overweight (71.7 %) and obesity (74.3 %), b) overweight students (84.6 %) and obese (94.7 %) have difficulty in accepting their body image, c) overweight students (69.1 %) and obese (89.7 %) refused to participate in certain activities and sometimes they exclude themselves. The three options preferred by respondents for possible interventions were: a) special training of mid-career EFI teachers with other professionals specialized in overweight and / or obesity (doctors, psychologists...) (83.8 %), b) web site that provides theoretical and practical information (70.3 %), c) an article published in a professional journal (67.6 %). **Discussion** This research showed that there is an imbroglio that involves the practical actions related to controlling and fighting overweight and obesity by EFI professionals (CLOES, 2011) which corroborates the public health surveys, that show an increase of this worsening of global and local health (IOTF, 2010; WHO, 2012; IBGE, 2013). Therefore, even with a good portion of the society that is involved in the problem being conscious and aware of the basic mechanisms to control the situation, in practice there is no effective control of the disease. **References** Cloes M. THE REALTION BETWEEN THE LEVEL OF PHYSICAL FITNESS AND SPORTS PRACTICE SPORTS MANIFESTED BY YOUNG WITH 12 TO 16 YEARS OLD, IN BOTH GENDERS.

Martins, J.1,2, Louro, G.1, Cardoso, J.1, Batista, M.3, Honório, S.3

University of Beira Interior

Introduction The purpose of this study was investigating the relationship between the level of physical fitness (PF) with the sport expressed by young people from 12 to 16 years of age, of both sexes. **Methods** The sample consisted of 157 youths (79 girls and 78 boys) aged between 12 and 16 years, divided by the following types of practitioners: 103 students realize that only PE classes, called NP; 19 students practicing school sports (SS); 16 students practicing sports federated (SF), 11 students practicing SS/SF; 7 students practicing sports leisure (SL) and even one student practitioner SS/SL. The information was obtained from the application of an anamnesis questionnaire (adapted from André, 2010) and the Fitnessgram test battery. The statistical procedures used were the mean and standard deviation, t-test for independent samples and analysis of variance (one-factor ANOVA). **Results** Results showed that boys showed higher rates of PF tests "Shuttle", "Abdominals" and "Extensions Arms", while girls proved best in tests associated with flexibility, including "Trunk Extension", "Sit and Reach Left" and "Sit and Reach Right". In both sexes, the test "Extensions Arms" was one that met the highest rate of failure. Rather, the tests were "Extension Trunk" and "Abdominals" that emerged the highest success rates. SF practitioners are those that best meet success rates in 4 of the 8 tests, including %FM (88,9%), "Shuttle" (88,9%), "Abdominals" (100%) and "Extensions Arms" (81,5%). Instead, the group of NP, except for tests BMI, %FM and "Abdominals", in the remaining 5 tests revealed the highest failure rates. In Body Composition, in both sexes and testing (BMI and %FM), all types of practitioners presented their mean values of "Within the Healthy Fitness Zone", except for SL practitioners in BMI. In PF, in the girls, the practitioners of SF showed the highest values in all tests, except for tests "Extension Trunk" and "Sit and Reach Left". In boys, the NP were the ones who showed the worst values in all tests. **Discussion** Students who practice sport(s) in addition to the PE classes (SF, SS and SL) showed better results in the Fitnessgram test battery, in both sexes, except for tests BMI and %FM in girls. **References** -American College of Sports Medicine (2009). UNDERSTANDING ADOLESCENT SEDENTARY BEHAVIOUR USING ACCELEROMETRY AND SELF-REPORT

Powell, D., Issartel, J., McGrane, B., O'Brien, W., Belton, S.

Dublin City University

Introduction Physical inactivity is associated with a higher risk of obesity, type II diabetes, hypertension, stroke, psychological problems, and some cancers (1). Currently there are no recommendations in Ireland for sedentary behaviour (SB), however, Australian guidelines recommend <2hours a day in sedentary screen time (ST) behaviour (2). The purpose of this study was to identify the current levels of SB in a cohort of 11-13 year old adolescents. **Methods** 266 participant's wore Actigraph accelerometers for a period of 9 days, and completed a self-report questionnaire to determine ST. Accelerometer data were included in analysis if they met the following inclusion criteria; >10hours wear time per day for a minimum of 3week days and 1weekend day. Data were then processed using the Evenson et al. (3) cut points. Data were subsequently filtered to give standardised average daily, weekday, weekend day, Before School (7:00-9:00), During School (9:00-16:00), After School (16:00-18:00), and Evening minutes (18:00-22:00) of SB. **Results** Accelerometer data showed participants spent on average 657.2minutes (10.95hours) per day in SB, with males accumulating significantly less time sedentary than females ($p<0.001$). Participants were significantly more sedentary on weekdays than on weekend days ($p<0.001$). Participants were significantly more sedentary in the During School period than the After School and Evening periods. Based on self-report data participants spent on

average 1hour 54minutes per day on ST pursuits. A strong, positive correlation ($r=.81$, $n=266$, $p<0.001$) between levels of ST (self-report) and overall levels of SB (accelerometer) was found. Discussion This study illustrates youths are spending 10.95hours in SB per day, with 1hour 54minutes of this being spent on ST pursuits. As expected a positive relationship was identified between ST and time spent in SB. Although participants are not exceeding the sedentary guidelines (<2hours/day) the relationship between ST and time spent in SB would suggest that it may be fruitful to reduce ST in an attempt to reduce overall SB. The During School period provides opportunity for specific interventions and strategies aimed at encouraging physical activity participation. SB is difficult to classify adequately. In order to fully analyse and understand SB it is essential that a definition be developed, as well as global guidelines which consider total sedentary time in addition to ST guidelines. THE RELATIONSHIP BETWEEN SCHOOL TIME PHYSICAL ACTIVITY AND BODY COMPOSITION OF PRIMARY SCHOOL CHILDREN.

Rodrigues, L., Caldas, A., Silva, T., Macieira, R., Novo, D.

Instituto Politécnico de Viana do Castelo & CIDESD

The association between weight status and physical activity in children is still to be fully understood. Children tend to be more active than adults, but unlike adults their activity level it is not always related to their weight status or body composition. Since school takes much of the children's day time it is crucial to understand how it contributes or affects their daily levels of physical activity (PA), and how the school PA characteristics relate to their weight status. Methods This study assessed PA (number of steps, minutes, and intensity) and body composition of 245 children (124 boys, 121 girls) from the 2nd and 4th grade within the school time (6,5 hours) of two primary schools located in the northern Portugal. A pedometer (Silva Connect Ex3) was used to assess the daily school time PA (steps and time) during three consecutive days. Weight and height were measured on a fourth day, and BMI was used to categorize children's weight status according to age related cut-off points (Cole et al, 2001). BMI related recommendations the minimum number of daily 15 000steps for boys and 12 000 for girls (Tudor-Locke & Bassett, 2004) were used to evaluate the percentage of PA completed during a school day. Student t-tests were used to compare PA between groups of interest. Pearson correlation coefficient was used to test for the relationship between PA indicators and BMI. The Human Research Ethics Committee of the IPVC approved testing procedures and the written informed consent was obtained from the subjects. Results Overall in a school day, boys walked more steps than girls (5438 vs 3950; $p<.001$), were more minutes in movement (58 min vs 44 min; $p<.001$), maintained a higher intensity on the activity (92 steps / min vs. 90 steps / min; $p<.001$), and reached a higher percentage of the recommended number of steps per day (36% vs 33%; $p<.001$). Both sexes reached, on average, about one third of the recommended minimum daily steps during the school day. As to weight status (BMI) 19,6% of children were overweight and 8,6% obese. The relationship between PA (steps, time, intensity) and BMI it was nonexistent in girls, but a negative correlation between IMC and PA intensity ($r = -.21$; $p<.05$) was found in boys. Conclusion Although children spend about half of their daily awaked time at school, they only fulfill about one third of the recommended minimum daily steps. BMI and weight status do not relate to time in PA or to total number of steps, but it shows a significant relationship with the intensity of the movement. ACTIVE AND OUTDOOR LEARNING; A STUDY OF PEDAGOGICAL APPROACHES FOR TEACHING CORE CURRICULUM SUBJECTS AND PROMOTING PHYSICAL ACTIVITY IN PRIMARY SCHOOLS

Dorling, H., Mwaanga, O.

Southampton Solent University

Introduction A more active and outdoor learning focus within primary schools serves to address several notable areas of worldwide concern around obesity and inactivity (Zieff 2011; Mandic et al 2012) with a significant body of knowledge developing that shows pupils gain much more academically, socially and personally from being outside the classroom environment and learning experientially and interactively, adding value to curriculum based work. (Sproule et al 2013). This paper aims primarily to assess the effectiveness of the mechanisms and processes of an innovative active learning pedagogical approach and additionally the introduction of an outdoor learning framework in a specific primary school curriculum. Methods Semi structured interviews were conducted with school teachers ($n = 5$) and with university student practitioners ($n = 6$). A Priorities Assessment Tool (PAT) (Waite and Gilchrist 2013) was administered ($n=100$) in the individual school to assess areas of concern around the implementation of active and outdoor teaching and learning methods. Results Data collected tended to demonstrate a positive attitude in those pupils involved in a more active curriculum and an increase in their motivation and interest in the particular core curriculum subject. Teachers overall saw a benefit from the school pupils being involved in such an environment but were unsure as to the more holistic reasons for the intervention. The PAT data indicated some reticence in the achievability of a more outdoor based curriculum, mostly based on a lack of knowledge in delivery strategies. Resource availability and time constraints were also of concern with parental influence and opinion also seen as an inhibiting factor in some cases. Discussion The habitus or cultural density of a school can be shown to have an overriding effect on the efficacy of the processes and thus outcomes. Each primary school has a different notion of how and when to deliver curricula, and what priorities the school sets in those defined areas. The physical habitus of a school is also a mitigating factor in attempting to embed active and outdoor learning principles into the curriculum. Habitus within a school setting relates most appropriately to the idea of perceived power and identity dependent on the locality of the school which significantly links to parental influence. It remains a challenge for practitioners to advocate the use of these methods within a restrictive context of school attainment, cultural density, parental expectation and lack of teacher experience. AWARENESS LEVEL OF EXERCISE RECOMMENDATIONS AMONG PHYSICAL EDUCATION TEACHERS

Rosenhagen, A., Boden, M., Vogt, L., Banzer, W.

Goethe University

Introduction Health promoting sports and physical activity in childhood and adolescence are of increasing public interest. Targeted initiatives and campaigns to raise awareness and increase the acceptance of guidelines (e.g. WHO Global recommendations on Physical Activity and Health / EU Health Strategy) already show a positive effect and seem to increase physical activity behaviour. Physical education (PE) teachers in schools hold an important position for distributing this information. However it has not been investigated if (and to what extent) the current evidence and the corresponding national and international recommendations for implementation of day-to-day physical activity are known by PE teachers. **Methods** A standardised questionnaire sent to the PE teachers of all primary-, junior-, intermediate-, special- and high schools (n=1876) in the state of Hesse (Germany) asked for the personal dose recommendations of physical activity to promote age-appropriate performance and healthy development (4, 7, 10, 13 or 16 h / wk). It assessed the personal opinion regarding pupils weekly movement time (≤ 4 , $>4-7$, $>7-10$, $>10-13$ or >13 h / wk) and asked the teachers about their awareness of official recommendations and / or guidelines for physical activity in childhood. **Results** Age distribution of the teachers was 26.3%: 25-34yrs, 29.1%: 35-44yrs, 22.4%: 45-55yrs, 21%: >55 yrs. A total of 17% of all respondents answered to be aware to the current recommendations of health-enhancing physical activity in childhood and adolescence. The mode of childrens estimated time of activity was 7-10 h / wk. No PE teacher estimated the overall movement time to be more than 13 h / wk. 17% recommend the minimum activity dose of 7 h / wk corresponding to the WHO guidelines. 10 h and 13 h / wk are recommended by about 29% of the teachers respectively. **Discussion** According to the survey, irrespective of the individual working age, less than 1/5 of the PE teachers of all investigated school forms report to be informed about current physical activity recommendations. The majority of the teachers overestimate the minimum amount of activity necessary to gain health effects. More specific measures to communicate information for PE teachers in their moderator function of sport, exercise and health appear to be necessary.

TEACHER EDUCATION STUDENTS' AND SUPERVISORS' KNOWLEDGE OF PHYSICAL ACTIVITY RECOMMENDATION FOR CHILDREN

Guimaraes, M., Carreiro da Costa, F.

Lusofona University - Lisbon

Introduction The fundamental role that schools and Physical Education (PE) can assume in the promotion of active and healthy lifestyles has been largely accepted both by researchers and by numerous organizations. However, literature shows that PE teachers demonstrate a narrow knowledge about how to achieve the objectives of health-related PE. Without adequate teacher preparation, it is very difficult, if not impossible, to create physically educated youngsters. The aim of this study was to examine physical education teacher education students' knowledge of physical activity (PA) recommendation for children and that of their school supervisors. **Methods** Participants were 46 PE students and 34 supervisors on a two-year Physical Education Teacher Education (PETE) master programme at one University in Portugal. Participants were asked to answer the following question; "How active should children and young people be?" Responses were analysed by means of the generation of themes using constructivist grounded theory methods, following the same procedures of Harris (2013). **Results** None of the PETE students accurately recorded the PA recommendations. Only three (8, 8%) supervisors have answered correctly, and four (11, 8%) have given incomplete responses (23% students). Most of the responses of both students and supervisors revealed inaccurate (32% students; 35% supervisors) or some confusion with other PA recommendations and targets (39% students; 35, 3% supervisors). Two students and three supervisors have not responding. **Discussion** These findings are in line with Harris (2013) results about PETE students' knowledge of how active young people should be. Students and supervisors show lack of knowledge of PA recommendation for young people, limited attention to physical activity to develop strength and flexibility, and some confusion with PA recommendation for adults. Question arises about PETE programmes if they are preparing properly their student-teachers and teachers, i.e., developing in them the required knowledge and competences to promote active life styles at schools. This study reports the need to examine in the future the impact of PETE Master programmes on student teachers' knowledge, their behaviours when teaching PE classes during the Practicum, and teacher educators. **References** Harris, J. (2013). Physical education teacher education students' knowledge, perceptions and experiences of promoting healthy, active lifestyles in secondary schools, *Physical. DEVELOPMENT OF PREDICTIVE MODELS ON THE BASIS OF GENETIC, ANAMNESIS'S AND BIOCHEMICAL ANALYSES IN A GROUP OF STUDENTS

Glotov, O.S., Tarkovskaya, I.V., Danilova, M.M., Vashukova, E.S., Glotov, A.S., Pakin, V.S., Namozova, S.S., Shadrin, L.V., Aseev, M.V., Sarana, A.M., Ivashchenko, T.E.

St-Petersburg State University

Background: Now taking into account genetic data programs of preventive inspection of the population for the purpose of identification of groups of the increased risk various monogenic and multifactor diseases and predisposition to physical performance are created (Puthucherry et al., 2011). Due to such projects it is possible not only to reduce incidence, but also to avoid risk of the complications connected with expressed hereditary predisposition. Students of high school are deprived now of opportunity to pass genetic test. Today they are surveyed in the traditional ways which include collecting the anamnesis, by medical examinations (otolaryngologist, dermatovenerologist, neurologist, therapist, gynecologist (for girls), register pulse and measure arterial pressure, and if necessary, direct on consultations of experts (surgeon, oculist, rheumatologist, etc.). Meanwhile, the problem of health of students is aggravated with acceleration of their development which not seldom becomes complicated such violations as arterial hypertension, obesity and a metabolic syndrome. In combination with low physical activity these factors can lead to considerable decrease in level of health of students and to reduction of their intellectual potential. **Materials and methods:** Using the PCR-RFLP method we have studied polymorphism of 26 genes renin-angiotensin system, factors of a fibrillation, detoxication, metabolism and others in 189 students of St.Petersburg State University aged from 18 till 19 years of the North-West Region of Russia (St. Petersburg). **Results:** We found the association of some studied genes in aggregate with anamnesis and biochemical indicators with body mass index, weight, growth, vital capacity of lungs, pulse, arterial pressure. We proposed a model for the prediction of examined parameters based on logistic regression method. **Conclusion:** Our findings confirm the possibility of primary assessment of body mass index, weight, growth, vital capacity of lungs, pulse, arterial pressure in

students based on genetic, anamnesis and biochemical markers. References: Puthucherry Z., Skipworth J.R., Montgomery H.E. (2011) Sports Med. June 1. T. 41. V.6. P. 433-448. Contact: olgotov@mail.ru

CHARACTERISTICS OF PHYSICAL ACTIVITY OF OBESE CHILDREN IN HUNAN, CHINA

Pengyu, D., Liangfu, Z., Naito, H.

Juntendo University

Introduction Many children do not meet current policy of 1 – h Physical Activity (PA) every day in China¹). Also increasing sedentary behaviors and reduced PA in children have been considered as the essential risk factor in the increased rate of obesity. An important strategy in order to achieve healthier body composition is to encourage a lifetime PA participation in overweight and obese children (WHO, 2004). Therefore, assessing PA is especially important because increasing PA in childhood might be essential to develop a lifetime physically active lifestyle. This study aimed to objectively measure the PA characteristics of urban city primary school children and to examine the influence of weight status, gender and grade levels on PA. **Methods** Participants in this study were children in level 2 and 5 who attended a private primary school (aged 8.8 ± 1.3 years, 106 boys and 86 girls), in Loudi urban area. The samples consisted of normal children (boy (n = 61), girl (n = 52)), overweight children (boy (n = 28), girl (n = 22)) and obese children (boy (n = 17), girl (n = 12)) who determined by BMI according to Working Group for Obesity in China cut offs. The PA was quantified by one axis - accelerometer (Lifecorder EX) measuring daily step counts, and Moderate-to Vigorous Physical Activity (≥ 3 METs, MVPA), for 7 days. **Results** The total sample averaged 17208 ± 3678 steps for weekday and 13532 ± 3978 steps for weekends. Obese children were significant lower daily steps than normal children for boys and girls during weekdays (19551 ± 3454 versus. 16047 ± 2915 steps for boys, 15463 ± 3328 versus. 15047 ± 1810 steps for girls, $p < 0.05$) and weekends (15174 ± 5102 versus. 12142 ± 3034 for boys, 12709 ± 2686 versus. 10927 ± 2900 for girls, $p < 0.05$). During weekdays more children achieved physical activity recommendations versus weekends. The majority of the obese children (58.9 % obese boys and 66.7 % obese girls) did not reach the recommended of 60 minutes in MVPA. **Discussion** The present study found obese children was substantially lower levels of PA than normal children for boys, this difference did not hold true for girls. Although weekends are likely to offer more free time to be active than weekdays, only a few children met the current policy of 1 – h PA every day regardless of weight status. Similar to findings from European countries²), more children not achieved the PA guideline during the weekends. In the light of this study, more effort needs to be devoted to promoting appropriate opportunities for Chinese obese children and girls across the day and promoting PA during weekends for all children. **References** 1. THE RELIABILITY OF SELF-PACED PERFORMANCE DURING A TEAM-SPORT SIMULATION ON A NON-MOTORISED TREADMILL

Tofari, P.1, McLean, B.D.1,2, Kemp, J.1, Cormack, S.1

1: ACU (Melbourne, Australia), 2: CFC (Melbourne, Australia)

Purpose Treadmill-based match-simulation protocols are used to assess running performance in team-sport athletes. (Aldous et al., 2013; Sirotic & Coutts, 2007) Typically, these are externally paced, even with non-motorised treadmill (NMT) protocols. (Nedelec et al., 2013; Nicholas et al., 2000; Sirotic & Coutts, 2008) The purpose of this study was to assess the reliability of a self-paced, team-sport simulation on a new generation NMT. **Methods** Ten male team-sport athletes (20.3 ± 1.2 y, 74.4 ± 9.7 kg, VO_{2peak} 57.1 ± 4.5 ml.kg⁻¹.min⁻¹) attended five testing sessions (VO_{2peak} testing + familiarisation of simulation; four reliability trials). The 30-min simulation consisted of three identical 10-min activity blocks, with visual and audible commands to direct locomotive activity (e.g., Walk, Run, Jog, Sprint, and Stand Still) but actual locomotive speeds were self-selected (no feedback on speed/distance). Data were separated into speed zones for analysis of reliability; including total, maximum, and average distance/speed per zone, between 10-min blocks, and inter-trial (e.g., Trial 1 v Trial 2). Reliability of variables was estimated using typical error \pm 90% confidence limits expressed as a percentage [coefficient of variation (CV)]. The smallest worthwhile change (SWC), defined as the smallest change of practical importance, was calculated as $0.2 \times$ between participant standard deviation. **Results** All variables across the entire 30-min protocol (CV < 5%), and across each 10-min activity block (CV < 6%) were deemed reliable. The most reliable variables were maximum and average sprint speed for the entire trial (CV 1.8% and 1.9%, respectively). The range of CV% for all variables between trials 2-1 was 1.8 to 6.8%, similar to trials 4-3 (CV 2.1 to 5.7%). All variables analysed produced a CV% greater than the SWC. **Conclusions** The current self-paced team-sport protocol, completed on a new generation NMT, produces highly reliable results across a range of variables. Moreover, this protocol required just one familiarisation session to reproduce self-selected speeds across a range of locomotive tasks. Given the self-paced design, this protocol provides an ecologically valid alternative to externally-paced match simulations. Contact Paul Tofari (ptofari@gmail.com) **References** Aldous, J. EXPERTISE DIFFERENCES IN PATTERN RECALL SKILLS AT REST AND DURING PHYSICAL EXERCISE

Schapschroer, M., Schorer, J.

University of Oldenburg

Introduction General perceptual-cognitive abilities improve under submaximal physical exercise (Pesce, Tessitore, Casella, Pirritano, & Capranica, 2007). Sport-specific skills like pattern recall are in contrast so far only investigated in rested conditions (cf. Williams & Aber-

nethy, 2012). Aim of this study was to examine sport specific pattern recall expertise both at rest and under moderate physical exercise. Methods Participants (n = 33) were differentiated in three groups (handball experts, advanced handball players, and novices). They were tested in a handball specific pattern recall task both at rest and under a moderate physical exercise on a ergometer with 60 % heart rate reserve (Pesce et al., 2007). We measured pattern recall performance in both conditions as the accuracy of the recalled players' positions as RMSE. Results An analysis of variance revealed significant main effects for group differences, $F(2,30) = 8.49$, $p < .01$, $f = .75$, with experts performing superior to novices, $D = 20.42$, $p < .01$. Differences were revealed neither for within subject differences between two conditions, $F(1, 30) = .48$, $p = .50$, nor for the interaction between both factors, $F(2, 30) = .07$, $p = .94$. Discussion Results replicate prior research of expertise differences in pattern recall tasks (Williams & Abernethy, 2012). Missing positive effects of physical exercise might be explained by the physical exercise not being handball specific enough. Belka and Hulka (2013) demonstrate higher intensities of physical loads for female handball players during game situations than used in the current study. Another explanation might be the specificity of the pattern recall task. Potentially submaximal exercise only has a facilitating effect on general perceptual-cognitive abilities. SEASONAL ADAPTATIONS IN THE PHYSICAL PERFORMANCE OF FUTSAL PLAYERS AND ITS EFFECTS ON OFFENSIVE SKILLS.

Domingues, D.1, Sampaio, J.2, Fonseca, T.1, Barbosa, T.3, Costa, M.1

1: IPG-CIDESD (Guarda, Portugal), 2: UTAD-CIDESD (Vila Real, Portugal), 3: NTU (Singapore)

Introduction Knowing the mechanism adaptations to training is an important aspect to reach success in a futsal season. The information on the topic is limited and simply reports to heart rate measurements and changes in physical performance throughout seasonal periods (Oliveira et al., 2013). The knowledge of possible effects on match-performance statistics remains scarce. The aim of this study was to identify the seasonal adaptations on futsalers physical performances and its effects on offensive skills. Methods Eight competitive futsal players (age=24.5±5.17 years; height=175±6.12 cm; weight=69.7±8.4Kg) were monitored during training periods (M1= beginning of the pre-season; M2= mid in season). A progressive and intermittent shuttle-running test (Castagna and Barbero-Alvarez, 2010) was applied to obtain physical variables: (i) maximal velocity reached (vmax) and (ii) distance covered in the test. Match-performance statistics were assessed using a computerised video-analysis system of three sets of an 8 min game. The offensive skills analysed were: (i) goals scored; (ii) shots on goal; (iii) wrong passes, and; (iv) ball losses. Results The v (vmaxM1=15.20±0.69, vmaxM2=15.45±0.55 m/s, $p=0.20$) and d (dM1=1095±140, dM2=1157±126 m, $p=0.14$) were similar. Non-significant differences were also identified for the game determinants, with the exception for wrong passes, which decreased from M1 to M2 (wrong passesM1=3.50±1.41, wrong passesM2=1.75±0.97, $p=0.05$). Discussion As previously reported, futsal played at high level is an intensity exercise heavily taxing the aerobic and anaerobic pathways (Castagna et al., 2009). The physical indicators were much similar through the season, which sustains the hypothesis of small changes across the considered periods of the season (Sampaio et al., 2010). Although, these decreases in wrong passes can be suggesting an adaptation to game energetic, muscular and perceptive demands. Coaches or sport scientists monitoring or modifying fitness of futsal players should recognize there is generally little overall change in mean fitness within the season. ENERGETICS OF SHORT SHUTTLE RUNS IN BASKETBALL PLAYERS

Zamparo, P., Bolomini, F., Beato, M.

University of Verona

Introduction Basketball is a sport characterized by an intermittent game model of which short shuttle runs (SR) are typical components. Buglione and di Prampero (2013) measured the energy cost (EC) of SR over the distances of 10 and 20 m and showed that EC increases with the shuttle speed and decreases with the shuttle distance; no data are reported in the literature over shorter distances. Thus, the aim of this study was to assess the EC of short SR (5 m) at different shuttle speeds. Methods A descriptive design was used in this study. Ten male basketball players (age 24 ± 1.5 years, body mass 80 ± 8.6 kg, height 1.84 ± 5.8 m) performed a preliminary test on a treadmill in order to estimate the EC of "linear running" (at a speed of 10 km/h). They were then asked to perform 10 SR (with 30 seconds of passive recovery in-between) over a distance of 5+5 m with 180° change of direction; these experiments were repeated at different speeds (2, 2.5, 3, 3.5 m/s). During both protocols oxygen consumption ($\dot{V}O_2$) was determined on a breath-by-breath basis by means of a portable metabolimeter (K4b2, Cosmed, Italy) and blood lactate concentration was determined at the end of each test (Biosen C-Line, Germany). Based on these data EC (the energy expended to cover one unit distance, normalized per body mass: J/kg.m) was then calculated as proposed by Zadro et al. (2011). Results The EC of linear running amounted to 3.96 ± 0.47 J/kg.m whereas the EC of shuttle runs was 4 to 7 times larger: 15.67 ± 2.85 J/kg.m (2 m/s), 19.20 ± 2.87 J/kg.m (2.5 m/s), 23.81 ± 4.69 J/kg.m (3 m/s), 29.42 ± 6.21 J/kg.m (3.5 m/s). Significant differences were observed in EC at the different speeds, $p < 0.001$, $\eta^2 = 0.788$. The relationship between EC and speed is well described by the following equation: $EC = 10.12.v - 5.20$, $N = 39$, $R = 0.66$, $p < 0.001$. Discussion These findings confirm data reported in the literature since they show that EC increases with the shuttle speed; moreover, these data show that the EC of short SR (5 m) is larger than for the 10 and 20 m distances thus confirming that EC decreases with the shuttle distance. These findings have a practical application since they allow calculating EC of short SR (at different shuttle speeds) and thus can be utilized to develop train protocols in basketball as well as in other team sports (characterized by repeated sprints over short distances and with changes of direction). IMPACT OF MATURATION ON JUNIOR ELITE AFL ATHLETES MOVEMENT PROFICIENCY AND FIELD BASED PERFORMANCE.

Ball, N.1, Riddington, S.2, Ibbott, P.3, Hunt, D.3

1: University of Canberra (Canberra Australia) 2: GWS Giants (Western Sydney, Australia), 3: ACT Academy of Sport (Canberra, Australia)

Introduction Assessing junior athlete's movement capabilities is important to enhance long term development, and is considered to discriminate between levels of pubescence and identify injury problems (Paszkevicz et al, 2013; Kiesel, et al, 2007). Little work has been done to assess the movement abilities of elite junior athletes and its relation to field based fitness tests, whilst also considering the impact of maturation on movement screen variables. **Methods** 42 junior elite athletes (U16 n=22, U18 n=20) underwent anthropometric, movement screen and fitness testing (20m and 40 m sprint, running jump, CMJ, MSFT, Yo-Yo, 3km). The movement screen comprised of 6 actions (Lunge & return, jump & single leg hold, single-leg bridge, vertical CMJ, push-up, squat) and were judged on an ordinal scale (0=poor; 3=competent) by qualified strength coaches. Correlations were used to assess the relationships of movement screen and anthropometrics to fitness scores. Independent t-tests were used to compare fitness variables between groups (U16 vs U18) (P=0.05). **Results** Age at Peak height velocity did not correlate with any fitness or movement screen variable. Height and leg length had moderate correlations with repeated shuttle and MST test ($R=0.30-0.35$), whereas leg length negatively correlated with the lunge & return and jump and single leg hold ($R=-0.38>-0.44$). The U18 group had superior results ($p<0.05$) to the U16 group in jump & single leg hold, all sprint tests, CMJ and Yo-Yo. **Discussion** This study supports previous literature showing little relationship between movement screens and physical performance in mature age athletes (Parchmann and McBride, 2011). Maturation did not relate to movement screen performance, indicating that between 1-4 years post PHV no differences in movement proficiency exist. Thus observed differences in physical performance are likely due to increased training age and muscle strength that accompanies being further from the age at peak height velocity (Carvalho et al, 2012). The benefit of movement screens in terms of performance enhancement may lay in improving the ability to train opposed to manifest themselves in direct relation to fitness test performance. Movement proficiency alone does not influence physical performance in junior elite athletes. **References** Carvalho H, Coelho-e-Silva M, Valente-dos-Santos J, Gonçalves R, Philippaerts R, Malina R. PERFORMANCE PREDICTION IN PROFESSIONAL BASKETBALL: INFERENCES FROM PRE-SEASONAL FITNESS SCORES OF JUNIOR AND SENIOR ELITE PLAYERS

Hoos, O.1, Latzel, R.1, Fehske, K.2, Beneke, R.3

1: JMU-SS (Wuerzburg, Germany), 2: UKW (Wuerzburg, Germany), 3: PUM-IOSS (Marburg, Germany)

Introduction Professional basketball is a fast, demanding and highly complex game. Although high physiological and physical fitness seem essential for being successful in elite basketball (Drinkwater et al., 2008, Ziv & Lidor, 2009), a direct link between game performance scores and fitness measures is rarely shown (McGill et al., 2012). Therefore the aim of this study was to relate the outcome of basketball specific pre-seasonal fitness tests with game performances in the following season in a cohort of junior and senior professional basketball players. **Methods** 73 male elite players from teams of the highest German basketball junior (JBBL: n= 28, age: 14,8±0.7 years, height: 183±8 cm, weight: 67,8±14.6kg; NBBL: n= 20, age: 17,0±0.8 years, height: 194±9 cm, weight: 78,6±9.5 kg) and senior (BBL: n= 25, age: 26,3±3.6 years, height: 196±9 cm, weight: 101,3±9.8kg) leagues participated. All athletes performed a battery of pre-seasonal fitness tests linked to speed (21m-Sprint (21S, s), 10x15m Repeated Sprint Test (RST, s)), jumping ability (No step vert (NSV, cm), maxVert (MV, cm)), aerobic endurance (YoYoIR1-Test (m)) and agility (lane-agility-test (LAT, s)). During the following season, games and minutes played, points scored, assists, rebounds, steals, and blocks were assessed as dependent variables of game performance. **Results** In young junior players (JBBL) all fitness measures were significantly related to one or more game performance scores ($p<0.05$; 0.18

THE USE OF 2D AND 3D VIDEO CLIPS IN A PERCEPTUAL-COGNITIVE JUDGEMENT TASK

Put, K., Wagemans, J., Spitz, J., Armenteros Gallardo, M., Williams, A.M., Helsen, W.F.

K.U.Leuven

Introduction To better understand the perceptual-cognitive constructs underlying expert perception and performance, it is necessary to develop experimental tasks in which the specificity and complexity of real-life situations are closely reproduced.^{1,2} Therefore, we examined whether the use of 3D video simulations in an offside decision-making task is beneficial compared to the more widely available 2D simulations. **Methods** Thirty-three assistant referees (ARs), who were all involved in professional football, participated in the experiment. They assessed 40 offside situations in both 2D and 3D format using a counterbalanced design. A distinction was made between offside situations near (i.e., 15 m) and far (i.e., 30 m) from the touchline. Subsequently, a recognition task was performed in which ARs were asked to indicate which of the 5 pictures represented the position of the attacker at the precise moment of the pass. **Results** A higher response accuracy score was observed under 3D (80.0%) compared to 2D (75.0%) conditions, in particular for the situations near the touchline (3D: 81.8%; 2D: 72.7%). No differences were reported between 2D and 3D in the recognition task. **Discussion** The results clearly suggest that in highly dynamic and complex situations, the visual system can benefit from the availability of 3D information, especially for relatively fine, metric positional judgments. In the memory task, in which a mental abstraction had to be made from a dynamic situation to a static snapshot, 3D stereo disparities appear to not add anything to 2D simulations. The specific task demands should be taken into account when considering the most appropriate format for testing and training. **References** 1. Ericsson, K. A., & Williams, A. M. (2007). DOES BODY LOAD INDICATE ECCENTRIC LOADING?

Yeo, V., Newton, M., Nosaka, K.

Edith Cowan University

Introduction Global Positioning System (GPS) with a triaxial accelerometer is widely used to monitor movements of athletes in games and training, and "Body Load" (BL) representing the accumulation of rate of change in three planes of movement is often obtained (1). Deceleration, changes of directions and stopping require eccentric contractions of leg muscles, potentially causing muscle damage and affecting performance (2). Thus, it is important to monitor eccentric loading in games and training. The present study tested the hypothesis that BL would represent eccentric loading by setting a drill consisting of several movements requiring eccentric contractions of leg muscles and modulating the eccentric loading by running velocity. **Methods** Eight university students performed a drill consisting of 3 segments separated by 2 vertical jumps; 1st segment (70 m): run – 90° turn to the right – run – 180° turn – run – 45° turn to the left – run – jump, 2nd segment (50 m): run – 45° turn to the left – run – 45° turn to the left – run – jump, and 3rd segment (60 m): run – 90° turn to the left – run – complete stop – run. All subjects performed the drill at 30%, 60%, and 100% of their perceived maximal velocity with 2 trials performed for each velocity and a 5 min rest between trials. BL of each segment was calculated using specific software (GPSports SPI PRO X, Australia), time to complete the drill was measured by timing gates, and time to complete each segment was calculated from GPS data. Paired t-tests compared the three velocities and three segments for BL and time. **Results** Time to complete the drill was 110.0 ± 13.0 s for 30%, 59.0 ± 6.5 s for 60%, and 43.0 ± 4.4 s for 100%, with each significantly different from the other ($P < 0.01$). BL of the 1st, 2nd and 3rd segment was 1.59 ± 0.39 , 1.01 ± 0.16 and 1.40 ± 0.14 , respectively for 30%, 0.96 ± 0.41 , 0.51 ± 0.12 and 0.79 ± 0.13 for 60%, and 0.88 ± 0.37 , 0.38 ± 0.06 and 0.75 ± 0.37 for 100%. When comparing the three velocities for each segment, BL was smaller for 100% and 60% than 30% for all segments, and for 100% and 60% no significant difference in BL was found for segments 1 and 3 ($P < 0.01$). When comparing the three segments for each velocity, no significant differences in BL between segments 1 and 3 were found for all velocities. **Discussion** BL decreased with increased running velocity. Due to the movements included in each segment, it was assumed that eccentric loading would be greater for the 3rd followed by 1st, then 2nd segment, but BL was similar between the 1st and 3rd segments. These results suggest that BL does not reflect eccentric loading, and another parameter to monitor eccentric loading is necessary. **References** 1) Casamichana et al. (2013). *J Strength & Cond Res*, 27, 369-74. 2) Varley et al. (2012). *J Sports Sci*, 30, 121-7. Contact c.yeo@ecu.edu.au

13:00 - 14:00**Mini-Orals****MO-BN02 BM Kinematics****KINEMATICS OF SHOTS AND SHOULDER MUSCLES ACTIVATION IN NOVUS PLAYERS**

Talts, V., Ereline, J., Gapeyeva, H., Kums, T., Pääsuke, M.

University of Tartu

Introduction The aim of this study was to investigate the kinematics of shots and shoulder muscles activation in competitive novus players. **Methods** Nineteen novus players – 9 more skilled (MS) and 10 less skilled (LS) volunteered in the study. The subjects performed 3 series of novus shots – penalties, cut, and rebound shots with 10 shots in each series. Motion time and movement trajectory of the player's cue were measured using reflective markers and 3-D movement analysis system (BTS S.p.A., Italy). Velocity of the cue and shot power were calculated. Surface electromyogram (sEMG) amplitude of posterior and lateral deltoid and trapezius muscles was measured during the shot. The data of successful and unsuccessful shots were compared. **Results** Performance of shots in MS players was remarkably higher as compared to LS players ($p < 0.05$). In both groups successful penalties, cut shots and rebound strokes compared to the unsuccessful ones were committed with significantly lower velocity of the cue ($p < 0.001$). No significant differences were noted in the velocity of the cue between MS versus LS novus players. The shot power did not differ significantly between MS and LS players, nor between successful and unsuccessful shots of MS players. LS players' unsuccessful shots were committed with higher shot power than successful ones ($p < 0.01$). Besides, a tendency of higher shot power during MS players' unsuccessful shots compared to the successful ones emerged. Shoulder muscle bioelectrical activity (sEMG amplitude) differed between MS players versus LS players and also between successful versus unsuccessful shots in all studied muscles, however, in trapezius muscle the differences were especially distinctive. In both groups higher activity of trapezius muscle was noted during unsuccessful penalties ($p < 0.01$) and rebound shots ($p < 0.01$) as compared to the successful shots. Successful penalties, cut shots and rebound strokes in MS players were characterised by lower activity in trapezius muscle ($p < 0.05$) as compared to LS players' successful shots. **Discussion** The lack of differences in cue velocity and shot power between MS and LS groups could be caused by the fact that both groups had practised novus for a long period (mean 28.3 ± 3.6 ; 7.1 ± 2.4 years, respectively) and used a similar movement pattern. Applying higher velocity during the shot may cause its failure. sEMG amplitude data show that MS players had acquired a different, and, apparently a more efficient muscle recruitment pattern than the less skilled players. REPRODUCIBILITY OF SPATIO-TEMPORAL AND DYNAMIC PARAMETERS IN VARIOUS, DAILY OCCURRING, CURVE WALKING CONDITIONS

Krafft, F.C.1, Eckel, M.1, Köllner, A.1, Wehrstein, A.1, Stein, T.1, Potthast, W.1

1: Karlsruhe Institute of Technology (KIT), 2: German Sport University Cologne

Objective This study aims to assess the test-retest reproducibility of specific spatio-temporal (foot placement, foot contact time) and dynamic (horizontal and vertical ground reaction force) gait parameters of three different, everyday occurring, curve walking conditions. The subjects were tested at two subsequent days. The purpose of the study was operationalized with the research objective, if curve walking locomotion is stable when performed at different test occurrences. **Methods** Eight subjects completed three different walking conditions along curves with a given walking velocity of 5 km/h ($\pm 10\%$). Subjects had to complete the curve conditions three times clockwise and counter clockwise. The measurements were recorded with a 3 D motion analysis system (Vicon®) and two force sensitive platforms

(AMTI®), connected to the motion analysis system. Results The analysis yields for most of the parameters and curve conditions ICCs from good ($r = 0.72$) to high ($r = 0.96$) magnitude for the measured spatio-temporal and dynamic parameters. Conclusions Based on our findings it can be assumed that locomotion strategies, related to the measured gait parameters of common daily curve walking tasks, are stable and reproducible.

COMPARISON OF KINETIC VARIABLES AND THEIR TIMING BETWEEN WALKING BAREFOOT AND WALKING IN TONING SHOES

Klous, M., Groseclose, E.G., Engel, J., Barfield, W.R.

College of Charleston

Introduction Previous studies have compared the kinetics of walking in toning shoes (TS) with walking in conventional shoes (CS) (Nigg et al., 2006; Stöggel et al., 2012; Taniguchi et al., 2012). However, the rationale for the development of the MBT shoe (a type of TS) was to mimic barefoot walking (<http://www.mbt.com>). Additionally, a limited number of studies focused on the timing of kinetic variables (Stöggel et al., 2010/2012; Taniguchi et al., 2012), whereas the timing of these variables is essential to accurately describe loading on the body during gait. Therefore, the goal of the current study was to compare the kinetics of TS with BF walking including the timing of the variables. **Methods** Three-dimensional ground reaction force (Bertec) and kinematic data (Flock of Birds) of the dominant leg were recorded for 13 college age females during gait at self-selected speed. Subjects performed three trials for the BF condition and three trials walking in TS (Sketchers Shape-Ups). Interpolation and filtering of kinematic and kinetic data as well as synchronization and time normalization of kinematic data with kinetic data were performed using Motion Monitor interface. Exported data were processed off-line using Matlab 7.6 software. Selected kinetic variables and their timing were studied to describe differences between the two conditions. Results Walking in TS showed greater impact peak and braking force in ground reaction force (GRF) than BF walking. This was accompanied by a more posterior center of pressure at heel strike and an earlier transition from deceleration to acceleration phase in TS condition. Shorter times were observed between the peak in ankle plantar flexion moment and the push-off-peak of vertical GRF, and acceleration force in anterior-posterior direction, respectively. **Discussion** Results suggest different strategies between the two conditions (BF vs. TS) to prepare for the swing phase. Furthermore, several of the observed characteristics of TS walking were similar to characteristics reported when walking in CS compared to BF walking. Further research will specifically focus on variability when comparing TS and BF. References Nigg BM, Emery C, Hiemstra LA (2006). *Med & Sci in Sports & Exer*, 38,1701–1708. INDIVIDUAL GAIT PATTERNS ARE CHANGING MUCH MORE BY ITSELF

Horst, F., Eekhoff, A., Schöllhorn, W.I.

Johannes Gutenberg University of Mainz

Introduction Biomechanical diagnoses as well as therapeutic interventions typically assume quasi-constancy or nearly reproducibility in their subjects. Despite the knowledge of continuous changes in living systems, only a small amount of variation is tolerated without intervention. The aim of this study is to look for the reliability of force time curves of gait patterns over several hours. **Methods** Nine healthy and physically active subjects (three female, six male; 27.4 ± 3.0 years) performed six sessions of 15 gait trials at a self-selected speed. The time intervals after the first, second and fifth session to the beginning of the subsequent session were ten minutes. The interval between session two and three and between session four and five were 30 and 90 minutes, respectively. For each trial the ground reaction force of one gait cycle was recorded by two force plates (Kistler, Switzerland) at a frequency of 1000 Hz. The estimation of changes over time based upon the classification rates of support vector machines, which were conducted for each subject individually by means of a multi-session- and session-on-session-classification. The Liblinear Toolbox 1.4 (Fan et al., 2008) was used with a leave-one-out cross-validation to distinguish the classification rates. Descriptive results were presented and statistically tested by a repeated measures ANOVA in four time intervals (T1: 10 min, T2: 30-50 min, T3: 90-110 min and T4: 130-150 min). **Results** The mean classification rate for the multi-session-classification is $59.5 \pm 9.0\%$. The mean classification rates for the session-on-session-classification result T1 ($71.6 \pm 14.3\%$), T2 ($85.8 \pm 14.7\%$), T3 ($83.3 \pm 12.3\%$) and T4 ($92.2 \pm 9.3\%$). The statistical test shows significant results over the four time intervals ($p = .000$). The pairwise comparisons of T1 and T2 ($p = .006$) as well as T1 and T4 ($p = .001$) are significant, T1 and T3 ($p = .085$) show a statistical trend, whereas T2, T3 and T4 show no statistical trend. **Discussion** The multi-session-classification rate of 59.5% clearly differs from a random classification of 16.7% and points out differences between the sessions. The session-on-session-classification trends that increasing classification rates go along with increasing time durations between the sessions. This shows differences of the gait patterns and thus indicates changes of the movement. Several reasons like structural system changes, adaptation to the experimental setup and the effects of pauses could cause these changes and should find consideration in further research. The results lead to rethink the classical relationship between diagnosis and therapy or training fundamentally. ANALYSIS OF IMMEDIATE EFFECTS OF UNEVEN GROUND ON GAIT PATTERNS BY MEANS OF SUPPORT VECTOR MACHINES

Eekhoff, A., Horst, F., Schöllhorn, W.I.

Johannes Gutenberg University of Mainz

Introduction The direction and amount of immediate and delayed effects of interventions are of most interest for training and therapy. The purpose of this study is the immediate (proprioceptive) effect of a mechanical stimulus by an uneven ground surface on the human gait. Effects of ground incline on the muscle activity in a gait study were shown by Klint et al. (2008). For the diagnosis of individual characteristics a complex pattern recognition approach has been suggested (Janssen et al., 2008). With a similar approach Tschanner et al. (2013) could show influences of shoe midsoles on gait patterns. In this context the holistic and immediate effects of an uneven ground surface on time continuous data of the normal human gait were analyzed by means of Support Vector Machines (SVM) and Root Mean Square Error (RMSE). **Methods** In this study 22 young adults completed ten gait trials before and ten gait trials immediately after an intervention of ten minutes. Kinematic data was captured with a marker based infrared camera system (Qualisys, Sweden) at 250 Hz. The joint angles of the lower body were calculated for the hip, knee and ankle. Kinetic data was measured as ground reaction force (GRF) with two force plates (Kistler, Switzerland) at 1000 Hz for one gait cycle. After post-processing both datasets were used separately for further analysis.

The intervention consisted of ten minutes barefoot walking on a path of 6 m length and 0.5 m width. The path was mounted with ter-rasensa® foam panels with an uneven ground surface. Support Vector Machines were applied to classify conditions before and after the intervention intra-individually using the leave-one-trial-out method. RMSE was calculated over the continuous data of all trials of one condition for every participant and statistically tested for significance with the paired t-test. Results The mean classification rates were 68.4% ($\pm 15.1\%$) for the kinetic and 83.4% ($\pm 15.2\%$) for the kinematic dataset. No significant differences between the conditions could be found in the RMSE ($p > 0.2$). Discussion The mean classification rates for the GRF data are relatively low and do not indicate a clear influence of the uneven ground surface. On the other hand the kinematic data results remarkable mean classification rates. Influence of the intervention on the individual gait variability could not be shown. In summary, although the results are ambiguous, they give an advice for an immediate effect of the uneven ground surface on human gait patterns. 3D KINEMATIC ANALYSIS OF TWO DIFFERENT ROUNDHOUSE KICK IN ELITE KARATE PLAYERS

Paydar, A., Golmoghani Zadeh, N., Zorba, E., Korkusuz, F.

Ph.D of biomechanics branch

Introduction The main objective of this study was to determine differences, if any, in three-dimensional (3D) kinematic characteristics of the two kind of roundhouse kick (Giako and kizami mawashi geri), elite level karate players. Specifically, the kinematic variables related to the displacement, linear velocity and acceleration of the lower body segments, translational leg acceleration and vertical ground reaction force generated by karate players were analyzed. **Methods** The subject of this study composed of 21 elite level amateur male karate players. Ages of the subjects ranged from 20 to 26 years old. All subjects executed two kick. The motions were captured with Phases pace real time optical tracking system with 8 high speed cameras at 240 fps. Then, the motions captured were analyzed to quantify the kinematic factors associated with each kick. **Results** The results showed that the kizami mawashi geri generated larger linear velocity compared to the giako mawashi geri. Similarly, the kizami mawashi geri generated larger linear acceleration compared to the giako mawashi geri. Moreover, the giako mawashi geri generated larger transitional leg acceleration compared to the kizami mawashi geri. **Discussion** As a conclusion, the results for all kinematic variables demonstrated that the type of kick was the major determinant of the magnitude of each factor studied. Moreover, the technique employed can significantly affect the resulting displacement, linear velocity and acceleration, and transitional leg acceleration of the kick. **References** Mori S, Ohtani Y, Imanaka K. A KINEMATIC ANALYSIS OF THE DOUBLE-SIDE KICK IN POINT-FIGHTING

Hölbling, D., Preuschl, E., Baca, A.

ISW at the University of Vienna

INTRODUCTION Point-fighting is a kickboxing discipline, which is characterized by a scoring-system, in which only the first regular strike scores. After a short break, the fight is then continued from the starting positions. This affects the tactics and techniques generally used. The basic movements comprise offensive and defensive foot- and hand techniques to attack head and body of the opponent. The aim of the study was to analyse the offensive combat kicking technique 'double-sidekick' which seems to be the basic movement for all offensive kicking techniques in pointfighting. This technique comprises two kicks with distance reduction to the target whereby the second kick reaches. In high level fights, realizations of this technique have been observed, which differ from those predominately taught. Top class fighters seem to raise up their kicking knees very high and accomplish to straighten up their upper body simultaneously. **METHODS** 44 fighters from 7 countries participated in the study. 8 won at least one world championship, 8 at least one European championship, 25 at least one national championship and 20 at least one high ranked international tournament; 15 participants were at advanced level without any noteworthy success at competitions. The athletes performed double-sidekicks to chest level with the aim to score, like in competitions. A Vicon 3D-motion capturing system comprising 8 cameras was used for kinematic data acquisition. The fastest one (of at least 3 kicks) was taken for further analysis. Knee height of the kicking leg (KHK) and distance between knee and shoulder (DKS) at two measuring points (MP1 and MP2) defined by the highest elevation of the knee before the first and the second kick were determined and normalized by anthropometric measurements. 10 experts with long-term experience in coaching of international top athletes scored the competition techniques (1-10) by assessing their chances of success based on videos of the individual executions (ICC: 0.952). By this, the fighters got categorized in 5 groups. The Spearman test was used to analyse the correlation between normalized DKS, KHK at MP1 and MP2 and the experts' categories. **RESULTS AND DISCUSSION** Normalized KHK is larger and DHS smaller for better categorized athletes at MP1 and MP2 (KHK: $r=0.677/0.402$, DKS: $r=-0.664/-0.487$; $p<0.01$ for all tests). The kicking technique of successful point-fighters is characterized by a high elevation of the kicking knee and a concurrent erected body position before and between the two kicks (at MP1 and MP2). Practical implications for physical training are to improve the strength of the hip flexor, the abductor and the lateral abdominal muscles and to stretch the adductor and ischiocrural muscles.

EFFECTIVENESS OF MUSCULAR STRENGTH DRILLS IN ACHIEVING BALANCE OF ARM AND SHOULDER MUSCLES AND THEIR EFFECT ON KINEMATIC VARIABLES OF STRAIGHT PUNCHES

Habib, H., Mostafa, N.

Faculty of Sport Education

During any boxing match, muscular Strength is one of the most important physical components needed by the boxer to perform various offensive and defensive skills and improve the speed and effectiveness of his or her punches. The aim of this study was to study the effectiveness of muscular strength drills on achieving balance of arm and shoulder muscles and their effect on the kinematic variables of straight punches for Boxers. To do so, an experimental study with a one-group pretest-post test design was conducted. The study participants were ten boxers aged 17-18 years from Mansoura Sports Stadium. The participants completed 6 alternating units of weightlifting and special power training sessions per week for 12 weeks. Pretests and posttests measured the balance in muscle strength via 1 RM, the muscular ability of arm and shoulder muscles, and the strength endurance of the boxers. In addition, two 250-fps SportsCams were used for 3-D Motion Analysis and Simi Motion software was used for kinematographic analysis. Comparison of the pre- and posttest results suggest that the participants did benefit from the experimental program. Average muscle strength increased by 25.82% for flexors

and by 11.32% for extensor muscles, which resulted in increased muscular balance between the power of flexors and extensor muscles for the elbow joint (1:1) and strength of the muscles drape extension of the shoulder joint (2:3). Results of the biomechanical analysis indicated a gradual decrease in the average punching, back, and total time between the pre- and post- measurements for straight punches with the back time experiencing the highest improvement followed by punching time. Pre- and posttest comparison of average speed of punches revealed that while the average speed of the first and second punches was higher in the pretest (209.314 cm/sec and 223.022 cm/sec respectively), the average speed of the last punch was higher in the posttest (234.341 cm/sec). Results also clearly indicate a gradual increase in the averages of angular displacement and angular velocity between pre and post measurement of the shoulder and elbow joints. Since successful performance depends on the integration between the work of the joints and the muscular forces exerted during the punch execution process, and since the shorter the extent of displacement and angular velocity, the greater the degree of control in the joint, it was not surprising to see that the ability to control the shoulder joint was larger than its counterpart in the elbow joint.

INFLUENCE OF PLAYERS' LEVEL ON RACKET SPEED AND BALL ACCURACY IN THE TENNIS SERVE

Tubez, F., Croisier, J.L., Cordonnier, C., Denoel, V., Bruls, O., Degehet, M., Forthomme, B., Schwartz, C.

University of Liège

INTRODUCTION Serve in modern tennis game is an important offensive weapon for players (1-2). In kinematic analysis, serve is the most studied stroke of this game. The aim of our study was to compare the performance of two specific populations: international players versus national players. In particular, racket speed at impact and accuracy of ball were assessed. **METHODS** A tennis court was reconstructed in a motion analysis laboratory. The position of the racket was evaluated in 3D at a frequency rate of 200 Hz. Tests were performed on 6 professional players (international level) and 9 non-professional players (national level). Each of them served 25 trials in direction of the "T" area of deuce diagonal. Two squares of 1m² and 2 m² respectively were delimited on the corner of the serve square. The instruction for both groups was to serve in the "T" area with the highest ball speed and minimal ball rotation (flat serve). **RESULTS** Although the forward speed of the racket at impact was identical between the two groups of players (International 36.35 ± 2.37 m/s and national 36.37 ± 2.90 m/s, p-value 0.991), the accuracy and consistency of serves on the target area is better for international players group (1m² area: International 33% ± 7% and national 14% ± 12%, p-value 0.0053; 2m² area (including 1m² area): International 71% ± 8% and national 54% ± 12%, p-value 0.0096; Out of zone: International 29% ± 8% and national 46% ± 12%, p-value 0.014). **DISCUSSION** High-velocity ball seems to be a key factor for serve performance (3). It is known that there is a relationship between racket speed and ball velocity (4). Both groups have high racket speed. However, international players serve with better accuracy and consistency than national players. We hypothesize that these differences are due to capacity of international players to adapt to a particular environment. Moreover, international players could give priority to consistency over velocity. We conclude that high-velocity serve is not a sufficient criterion to perform at international level; consistency and accuracy are two important factors to reach this level. **REFERENCES** 1. HEART RATE PREDICTS ANEROBIC LACTATE THRESHOLDS IN PROFESSIONAL TEAM SPORTS

Garcia Tabar, I., Llodio, I., Setuain, I., Sánchez-Medina, L., Ruesta, M., Ibañez, J., Gorostiaga, E.M.

Instituto Navarro de Deporte y Juventud

Introduction Anaerobic lactic thresholds (ATs) often occur at a mean intensity close to 90% of maximal heart rate (HRmax) (Hurley et al., 1984; Garcia-Tabar et al., 2013). Notwithstanding, whether the speed at a given percentage of HRmax (%HRmax) could be used as an endurance performance variable has never been investigated. The aim of this study was to investigate whether the speed associated with 90% of HRmax (S90%HRmax) could predict the speeds at fixed blood lactate concentrations of 3 (S3) and 4 mmol•l⁻¹ (S4). **Methods** Professional team sports' players of futsal (n=10), handball (n=16) and basketball (n=10) performed a four-stage discontinuous progressive running test followed, if exhaustion was not previously achieved, by an additional maximal continuous incremental running test in order to attain HRmax. Blood lactate concentration was measured after each exercise stage, and HR was monitored throughout the exercise tests. The individual S3, S4 and S90%HRmax were determined by linear interpolation. **Results** S90%HRmax (12.0±1.2 km•h⁻¹) neither differed (p>0.05) from S3 (11.6±1.5 km•h⁻¹) nor S4 (12.5±1.4 km•h⁻¹). Significant (p<0.001) linear relationships were found between S90%HRmax and S3 (r=0.82), as well as between S90%HRmax and S4 (r=0.82). S3 and S4 also correlated with %HRmax at which these ATs occurred (r=0.67-0.68; p<0.05) and %HRmax at 10 and 12 km•h⁻¹ (r=0.78-0.81; p<0.001). **Discussion** The magnitudes of the correlations between S90%HRmax and ATs found are similar to those observed between S4 and MLSS (Vobejda et al., 2006) and higher than those observed between ATs and heart rate deflection points (Bodner and Rhodes, 2000). On the other hand, the large correlations between S3 or S4 and %HRmax at which S3 or S4 occurred suggest that team sports' players with higher ATs achieve the thresholds at higher %HRmax compared to those with lower ATs. **Conclusion** S3 and S4 can be accurately predicted by S90%HRmax in professional team sports' players. The use of S90%HRmax as a simple, low-cost and non-invasive endurance performance variable would facilitate the assessment and monitoring of aerobic capacity. **References** Bodner M.E., Rhodes E.C. THE USE OF HEART RATE FOR MONITORING THE ACCLIMATIZATION STATUS TO HIGH ALTITUDE TRAINING IN CROSS-COUNTRY SKIERS

Takeda, M.1, Kato, H.1, Mimura, T.2, Shimamoto, H.3, Endoh, H.4, Radak, Z.5

1: Doshisha University (Kyoto, Japan), 2: Osaka Sangyo University (Osaka, Japan), 3: Osaka University (Osaka, Japan), 4: Ryukyu University (Okinawa, Japan), 5: Semmelweis University (Budapest, Hungary)

Introduction Because of the fact that there are benefits and risks in high altitude training (Wilber, 2003), it is reasonable to have an index for monitoring physical condition and acclimatization status in high altitude training. In this study, we have evaluated physiological meanings of resting heart rate for monitoring the physical condition and acclimatization status during 2 weeks of high altitude training in cross-country skiers. **Methods** Collegiate cross-country skiers (8 males, 6 females, 20 ± 1.0 yrs.) lived 1 day at sea level and lived and trained for 14 days at 2,200 m. Just soon after getting up, the following items were measured in every 2 days, i.e., heart rate (HR) during orthostatic test, hemoglobin concentration (Hb), and HR, blood lactate concentration (La), and ratings of perceived exertion (RPE) during 3 minutes of submaximal cycling test at the intensity of 75% of maximal HR of each subject and 3 minutes of recovery. Erythropoietin (EPO), ferritin, red blood cell (RBC), hematocrit (Hct) were measured at sea level and day 2 and 15 stayed at high altitude. One way repeated measure of variance and correlation analyses were used for the statistical evaluations. **Results** Supine and standing HR significantly increased at day 2 (vs sea level) and, after that, gradually decreased during acclimatization process of 2 weeks of high altitude training. Supine HR was significantly decreased at day 12 (vs. day 2). Likewise, salivary cortisol was significantly increased at day 2 (vs sea level) and, after that, significantly decreased at day 14 (vs day 2 and 8). EPO was significantly increased after 48 h at 2,200 m (vs. before altitude training) and significantly returned to the same level with sea level at day 14. Hb was significantly increased day 14 (vs. con, day 2). No significant changes were found in other hematological parameters. Average HR during submaximal exercise significantly increased from sea level to day 2, however, no significant difference was found after day 12. La and RPE after submaximal exercise remained unchanged. Interestingly, the amount of changes (Δ) in supine HR from day 2 to 14 significantly correlated with Δ cortisol (from pre to day 8 & 14), Δ average HR during cycling test and La after cycling test (from day 2 to 14). The amount of change in standing HR from day 2 to 14 significantly correlated with Δ EPO (from pre to 48 hours), Δ Hb (from day 2 to day 8 & 14), and Δ average HR during submaximal cycling test (from day 2 to 14), and Δ cortisol (from day 2 to 14). **Conclusion** This study suggested that heart rate at supine and standing positions reflected physical condition and adaptation status to high altitude training in endurance athletes. **Reference** Wilber R. COMPARISON OF ATHLETE-COACH PERCEPTIONS OF INTERNAL AND EXTERNAL LOAD MARKERS FOR ELITE JUNIOR TENNIS TRAINING.

Murphy, A., Duffield, R., Kellett, A., Reid, M.

Charles Sturt University; Tennis Australia

Introduction: To investigate the discrepancy between coach and athlete perceptions of internal load and notational analysis of external load in elite junior tennis. **Methods:** Fourteen elite junior tennis players and 6 international coaches were recruited. Ratings of perceived exertion (RPE) were recorded for individual drills and whole sessions, along with a rating of mental exertion, coach rating of intended session exertion, and athlete heart rate (HR). Further, total stroke count and unforced error count were notated using video coding following each session, alongside coach and athlete estimations of shots and errors made. Finally, regression analyses explained the variance in the criterion variables of athlete and coach RPE. **Results:** Repeated measures analyses of variance and interclass correlation coefficients revealed that coaches significantly ($p < 0.01$) underestimated athlete session-RPE, with only moderate correlation ($r = 0.59$) demonstrated between coach and athlete. However, athlete drill-RPE ($p = 0.14$; $r = 0.71$) and mental exertion ($p = 0.44$; $r = 0.68$) were comparable and substantially correlated. No significant differences in estimated stroke count were evident between athlete-coach ($p = 0.21$), athlete-notational analysis ($p = 0.06$), or coach-notational analysis comparison ($p = 0.49$). Coaches estimated significantly greater unforced errors than either athletes or notational analysis ($p < 0.01$). Regression analyses found that 54.5% of variance in coach RPE was explained by intended session exertion and coach drill-RPE, while drill-RPE and peak HR explained 45.3% of the variance in athlete session-RPE. **Discussion:** Coaches misinterpreted session-RPE but not drill-RPE, whilst inaccurately monitoring error counts. Improved understanding of external and internal load monitoring may assist coach-athlete relationships in individual sports like tennis to avoid maladaptive training. **Contact:** amurphy@tennis.com.au

STUDY OF HEART RATE VARIABILITY, METABOLIC MARKERS AND FUNCTIONAL BIOMECHANICS PARAMETERS IN BASKETBALL PLAYERS SUBMITTED TO IVE LOADS PERIODIZATION SYSTEM

Mazon, J.H., Souza, H.C.D.

University of São Paulo

Introduction The aim of this study was to investigate if the application of selective loads periodization system (SLPS) promoted alterations in autonomic modulation of heart rate variability (HRV), functional biomechanics parameters, as well same metabolic markers in basketball players. **Methods** Sixteen male basketball players were submitted to SLPS and evaluated before and after a preparatory period. The HRV was evaluated by a spectral analysis of R-R intervals in the supine position. The evaluation of metabolic markers consisted of measuring plasma catecholamines, cortisol, free testosterone, urea and creatine kinase. Functional biomechanical parameters were assessed through tests of strength (peak torque, maximal work) and power (countermovement jump - CMJ) of the lower limbs using isokinetic dynamometer and a force platform, respectively. **Results** The results demonstrated that the training load used did not promote changes in the autonomic modulation of HRV. This affirmation is supported by the absence of change in oscillations of low frequency (LF), and high frequency (HF) of HRV. Regarding metabolic markers, we observed reductions in plasma dopamine and adrenaline, and increased plasma cortisol. Additionally, no significant differences in the parameters of strength and power were observed. **Discussion** It is possible that the absence of change in LF and HF oscillations of HRV are associated with the fact that basketball is a predominantly anaerobic sport. The reduction in the levels of dopamine and adrenaline seem to reflect positive adjustments to the workloads during preparatory period since previous study reported an increase in the secretion of these hormones as a result of physiological stress in athletes during a competition period (Garatachea et al., 2012). In turn, the increased cortisol is still controversial, since the literature reports no consistent patterns for the training-induced adaptations in the basal concentrations of this hormone. However, we did not observe changes in testosterone/cortisol ratio, which is considered a potent endocrine biomarker of the anabolic-catabolic balance in athletes. Finally, the absence of changes in the strength and power parameters seem to be related to the applicability of tests in the verification the effective-

ness of training, since the maximum expression of these capacities hardly occurs during play. References Garatachea N, Hernández-García R, Villaverde C, González-Gallego J, Torres-Luque G. (2012). *J Sports Med Phys Fitness*, 52, 1-10. Grants: FAPESP – 2011/07878-6; 2012/04299-8

FUNCTIONAL OVERREACHING IN ENDURANCE ATHLETES: EFFECTS ON PERFORMANCE, PHYSIOLOGICAL RESPONSE AND HEALTH

Le Meur, Y., Aubry, A., Louis, J., Coutts, A., Hausswirth, C.

National Institute for Sport, Expertise and Performance

Purpose: To examine whether performance supercompensation during taper is maximized in endurance athletes after experiencing overreaching during an overload training period. **Methods:** Thirty three trained male triathletes were assigned to either overload training ($n=23$) or normal training groups ($n=10$, CTL) during 8 weeks. Cycling performance and maximal oxygen uptake (VO_{2max}) were measured after one-week of moderate training, a 3-week period of overload training and then each week during four-week taper. Physiological responses were assessed during an incremental cycling to volitional exhaustion, including catecholamines release, VO_2 , cardiac output (Q), systolic and diastolic blood pressures. **Results:** Eleven of the 23 subjects from the overload training group were diagnosed as functionally overreached after the overload period (decreased performance with concomitant high perceived fatigue, F-OR), while the 12 other subjects were only acutely fatigued (no decrease in performance, AF). The AF group demonstrated a small to large greater peak performance supercompensation than the F-OR group ($2.6 \pm 1.1\%$) and the CTL group ($2.6 \pm 1.6\%$). VO_{2max} increased significantly from baseline at peak performance only in the CTL and AF groups. 60%, 83% and 73% of peak performances occurred within the two first weeks of taper in CTL, AF and OR, respectively. VO_{2max} was reduced only in OR subjects at Post. Lower Q and systolic blood pressure values with greater arteriovenous O₂ difference were reported in OR subjects at all exercising intensities, while no significant change was observed in the control and AF groups. Concomitant decrease in catecholamines excretion was reported only the F-OR group. All values returned to baseline, when performance was restored. Ten cases of infection were reported during the study with higher prevalence in F-OR (70%) than in AF (20%) and CTL (10%). **Conclusion:** This study showed that 1) greater gains in performance and VO_{2max} can be achieved when higher training load is prescribed before the taper but not in the presence of F-OR; 2) peak performance is not delayed during taper when heavy training loads are completed immediately prior; and 3) F-OR provides higher risk for training maladaptation, including increased infection risks and altered cardiac response at exercise.

RELATIONSHIP BETWEEN AEROBIC FITNESS AND HEART RATE RECOVERY IN DIFFERENT SPORTS

Riani Costa, L.1,2,5, Peçanha, T.1, Pereira da Silva, N.3,4, Schor, B.5, Parmigiano, T.6, Helfstein Fonseca, F.6, Murad Neto, A.2

1: USP (São Paulo, Brazil), 2: DASA (São Paulo, Brazil), 3: UFRJ (Rio de Janeiro, Brazil), 4: CBJ (Rio de Janeiro, Brazil), 5: Instituto Vita (São Paulo, Brazil), 6: UNIFESP (São Paulo, Brazil)

Introduction Heart rate recovery (HRR) is considered as a marker of aerobic fitness and cardiovascular health. Furthermore, HRR is a critical determinant of success in several sports, including martial arts. However, aerobic aspects of physical training are frequently underestimated in detriment of technical, strength and power training. This study was designed to test the hypothesis that higher aerobic fitness level is related to faster HRR and, consequently, with better competitive performance, rising the importance of include aerobic training in specific judo training program design. **Methods** 32 male athletes (13 judo Brazilian Olympic team, and 19 competitive long distance runners) performed a maximal cardiopulmonary exercise test in treadmill with individualized ramping protocols until exhaustion and active recovery phase at 3 mph during the first minute after the exercise. We analyzed heart rate (HR bpm), oxygen consumption (VO_2 ml/kg.min) and velocity (Km/h) at resting (R), anaerobic threshold (AT), respiratory compensation point (RCP), peak of exercise (P) and 1 minute after the end of exercise (R1). Data were compared between 2 groups by Student's T test and the correlations inside each group were performed by Pearson's test ($p < 0.05$). **Results** When comparing the 2 groups, runners presented higher HR decrease in R1 ($54 \pm 9 \times 34 \pm 8$), higher VO_2 in RCP ($52.9 \pm 4.5 \times 45.9 \pm 5.1$) and P ($58.7 \pm 4.4 \times 49.2 \pm 6.3$) and lower HR in AT ($139 \pm 14 \times 160 \pm 13$) and RCP ($169 \pm 10 \times 180 \pm 11$), with higher velocities in AT ($13 \pm 1 \times 12 \pm 1$), RCP ($18 \pm 1 \times 15 \pm 1$) and P ($21 \pm 2 \times 17 \pm 1$). Correlations analyses showed positive association between HRR and velocity in AT ($r = 0.6164$, $p = 0.025$), RCP ($r = 0.5609$, $p = 0.046$) and P ($r = 0.5532$, $p = 0.05$) and inverse correlation with resting HR ($r = -0.7609$, $p = 0.03$) only in judo group. Any significant correlation between specific markers of aerobic performance and HRR was identified in runners. **Discussion** Long distance runners have better aerobic performance and higher decrease in HR after maximal effort than elite judo fighters. In judo athletes a better aerobic fitness correlates positively with higher HRR while runners showed high and homogenous aerobic fitness level with any significant correlation with HRR inside the group. These results suggest that aerobic training could improve HRR and fight sports performance. Contact: luriani@usp.br

NONLINEAR HRV INDICES IN RESPONSE TO AN INCREMENTAL TEST IN YOUNG CYCLISTS

Camarena, B., Blasco Lafarga, C., Mateo, M., Montoya, A.

University of Valencia

Introduction Volume is a key factor in cycling sports, what may trigger negative effects, increasing the importance of individualizing workloads, mainly in younger cyclist. Ventilatory thresholds become, thus, of paramount importance. Recent studies suggest that some non-linear indices of Heart Rate Variability (HRV) are sensible to the specific changes in the neural cardiac modulation at different intensities (1), providing objective and non-invasive information on the Anaerobic Threshold (AT) (2-4). This study aims to analyze HR dynamics in a graded test in trained cadets, looking for relationships between HRV indices and ventilatory cut-points, since little is known about HRV changes in younger cyclist and its application in determining AT. **Methods** 14 male national-level road cyclists (15 ± 0.5 y) underwent a cycle-ergometer graded-test (increments of 30 W every 4:30 sec; from 60% to 100% in a previous test), ending at voluntary exhaustion, or when cyclists were unable to maintain the required cadence. RR intervals were recorded along the test, retaining the last 3 min of every stage for further analysis (Kubios HRV 2.0). A one way repeated measures ANOVA, controlling for the weight, was employed to elucidate the effect of fatigue on RRI, and the nonlinear SD1, DFA1 and SampEn. Bonferroni post-hoc was applied when necessary. Correlation analysis between conventional performance parameters RQ, [La] and RPE, and nonlinear indices were also considered at 100%. **Results** DFA1 decreased largely along the test (DFA100%: 0.29 ± 0.13). Regarding Fatigue, Bonferroni showed changes at 80% for DFA1 ($p = 0.003$; 0.45 ± 0.14) and RQ ($p = 0.049$; 0.96 ± 0.03). Significant negative correlations were found between DFA1 and RPE ($p < 0.05$; $r = -0.7$) and $VO_2/Kg/min-1$ ($p < 0.05$; $r = -0.8$), while RPE and SampEn correlated positively ($p < 0.05$; $r = 0.7$). **Discussion** Compare to adults (3), SD1 has no

reflected the AT, whilst DFA1 and SampEn have changed significantly at 80%, with lactate around 4 mmol. Further studies should analyze differences in the nonlinear HRV indices regarding the age at the AT. References 1.Simoes RP, Mendes RG, Castello V, Machado HG, Almeida LB, Baldissera V, et al. ANAEROBIC THRESHOLD ASSESSMENT FROM HEART RATE VARIABILITY IN RUNNING: USING THE ACTUAL RESPIRATORY SPECTRAL COMPONENT

Di Michele, R., Merni, F.

University of Bologna

Introduction The assessment of the anaerobic threshold (AT) from heart rate variability (HRV) collected during graded exercise testing has gained increasing interest in the last years (Cottin et al., 2007). Recent studies, focusing on swimming (Di Michele et al., 2012) and roller skiing (Mourout et al., in press), refined this method by analysing the respiratory spectral component isolated from the high-frequency component that originates from cardiocomotor interactions. In line with such approach, this study aimed to estimate the AT from the analysis of the actual respiratory component of the HRV spectrum in a running test. **Methods** Ten male soccer players (22 ± 2 years) completed an incremental running test. The speed was initially set at 8.5 km/h, and was increased by 0.5 km/h every minute until exhaustion. Respiratory parameters were collected using a portable gas analyser (Cosmed K4b2) to calculate the reference AT, while R-R intervals were collected using a heart rate monitor (Polar RS800cx). A short-time Fourier transform was used to estimate the power spectral density of the HRV signal. The AT was associated to an abrupt increase of the HRV spectral power of a 0.15 Hz wide frequency range centered at the estimated breathing frequency. **Results** The AT HR values determined from HRV (185.2 ± 8.1 bpm) and from the ventilatory-based method (186.0 ± 8.9 bpm) were highly correlated ($r=0.95$, $p<0.05$), and not significantly different ($p>0.05$). The 95% limits of agreement for AT HR were -5.6 to 4.0 bpm. **Discussion** The results showed that AT estimation from HRV in a running test is very accurate when considering the actual respiratory component rather than the whole high-frequency region of the HRV spectrum. The present findings provide further support to the use of the HRV-based approach as a practical and non-invasive method to measure the AT. **References** Cottin F, Medigue C, Lopes P, Lepretre PM, Heubert L, Billat V. BALANCING THE IMBALANCE OF STROKE SURVIVORS WITH BACKWARD SLOPE WALKING ON DIFFERENTIAL TREADMILL GRADIENTS

Agbonlahor, E.

university of benin, benin city, nigeria

Do not insert authors here ABSTRACT The purpose of this study was to balance the imbalance of stroke survivors by using backward slope walking on differential treadmill gradients to challenge the cardiovascular and neuro-muscular systems and by synthesizing an analysis of lower limb biomechanics during this task. Thus, a total of thirty (30) stroke survivors randomly drawn participated in this study. Balance and co-ordination were tested in relation to backward slope walking on differential treadmill gradients (00, 50 and 100). Analysis of covariance was used to test the hypotheses at 0.01 level of significance. The F-values of 68.80* and 33.32* for balance and coordination were respectively found to be statistically significant at 0.01. Turkey HSD was used to determine the source of the significant difference among the groups. It was discovered that there was a significant difference at 100 gradient compared to 50 and 00 (100>50>00) in the balance and co-ordination of the participants. It was therefore recommended that backward slope walking should be used as an additional component in intervention/rehabilitation programme to provide cardiovascular fitness, balance control/proprioception by increasing the amount of blood pump at each stroke and the efficiency of the heart of stroke survivors. **Keywords:** Backward slope walking, Stroke survivors, and Differential treadmill gradients

IMPACT OF DIFFERENT TRAINING MODALITIES ON GLYCEMIC CONTROL AND BLOOD LIPIDS IN SUBJECTS WITH TYPE 2 DIABETES: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Schwingshackl, L., Missbach, B., Hoffmann, G.

University of Vienna

Introduction: A recent network meta-analysis ranked combined aerobic and resistance training (CT) as the most likely exercise model in the treatment of overweight and obesity (1). The aim of this systematic review of randomized controlled trials was to compare the effects of aerobic training (AET), resistance training (RT), and CT on glycemic control and blood lipids in subjects with type 2 diabetes mellitus, to establish the most efficient training modality (2). **Methods:** Electronic searches for randomized controlled trials were performed in MEDLINE, EMBASE and the Cochrane Trial Register until January 2014. Inclusion criteria were: type 2 diabetes mellitus, 19+ years of age, supervised exercise training, and a minimum intervention period of 8 weeks. Pooled effects were calculated by inverse-variance random effect pairwise meta-analyses and Bayesian random effects network meta-analyses (3). **Results:** 12 trials enrolling 808 participants were included in the meta-analysis. AET was more effective than RT in improving glycosylated hemoglobin [mean differences (MD): -0.17 %, $p =$

0.01]. Compared to AET, CT resulted in a significantly more pronounced reduction of glycosylated hemoglobin [MD: -0.24 %, $p = 0.0003$]. When comparing CT with RT, MD in change of glycosylated hemoglobin [MD: -0.51 %, $p = 0.003$], body weight [MD: -1.08 kg, $p = 0.02$], total cholesterol [MD: -14.88 mg/dl, $p = 0.03$], and low-density lipoprotein cholesterol [MD: -12.63 mg/dl, $p = 0.04$] were all in favor of CT. Results from the network meta-analyses confirmed these findings. Discussion: Evidence from both pairwise and network meta-analyses suggests that CT is the most efficacious exercise modality to improve glycemic control and blood lipids and should be recommended in the treatment of type 2 diabetes mellitus. HEART RATE RECOVERY AND AEROBIC ENDURANCE CAPACITY IN CANCER SURVIVORS: ASSOCIATIONS AND EXERCISE-INDUCED IMPROVEMENTS

Gonzalez-Rivera, J., Vogt, L., Niederer, D., Schmidt, K., Banzer, W.

Goethe university frankfurt

Introduction Established non-invasive measures to determine autonomic cardiac regulation capacity often include assessments of heart rate variability (HRV) and heart rate recovery (HRR) following maximal exhaustion. Whilst evidence supports the positive effects of exercise on physical capacity, quality of life and HRV (Niederer et al., 2013), its impact on HRR and possible associations of exercise capacity and HRR have not been investigated yet. **Methods** Cancer patients ($n=309$, 125 males) undergoing either adjuvant (curative), palliative or post-adjuvant therapy performed bicycle spirometry testing at baseline, and at a four-month interval follow-up. During spirometry VO_2 and heart rate (HR) were recorded continuously with HRR-assessments at 60 and 120 seconds after test termination. Following baseline testing, participants received individualized exercise counseling for home-based training and the opportunity to participate in a guided Nordic-Walking training. Based on a median-split of the VO_{2peak} baseline values, patients who completed the follow-up period were dichotomized into two groups: below median ($n=81$; 31 male; 62 ± 17 yrs) and above median ($n=77$; 32 male, 45 female; 57 ± 10 yrs). Associations of HRR and VO_2 (baseline) were examined using Pearson correlation analyses. (Adjusted) t-tests were used to reveal between-group differences in absolute changes from baseline to follow up for HRR and VO_{2peak} . Results Correlation analyses in the total baseline sample ($n=309$) revealed significant correlations between VO_{2peak} and both HRR60 ($r=.327$, $p<.01$) and HRR120 ($r=.524$, $p<.01$). Group comparisons demonstrated differences between the below median vs. above median group in absolute changes of HRR60 (3.2 ± 10.5 (95% CI: +0.6; +5.4) vs. -1.8 ± 8.7 (95% CI: -3.7; +0.5)) and VO_{2peak} (2.9 ± 3.5 ml/kg/min (95% CI: +2.1; +3.7) vs. 0.66 ± 4 ml/kg/min (95% CI: -0.6; +1.5)) ($p<.01$), but not in HRR120 (3.9 ± 11.8 (95% CI: +1.2; +6.6) vs. 0.8 ± 10.8 (95% CI: -1.7; +3.5); $p>.05$). Discussion These findings point toward a positive linear relationship between actual aerobic capacity and vagal reactivation in cancer patients. According to the p-values and CIs, patients with initial VO_{2peak} values below median showed improved VO_{2peak} , HRR60 and HRR120 following the moderate aerobic exercise intervention and differences in all outcomes compared to patients above median. Results suggest that HRR enhancements might occur coincidentally to VO_{2peak} improvements. Thus, future research is warranted to evaluate the potential of HRR to monitor training progress. SUBJECTIVE AND OBJECTIVE AEROBIC PERFORMANCE MONITORING IN BREAST CANCER PATIENTS

Hacıbayramoglu, M., Bernardi, A., Schmidt, K., Vogt, L., Lungwitz, A., Banzer, W.

Goethe University Frankfurt am Main

Introduction The use of effort perception via ratings of perceived exertion (RPE) has been proven to elicit training loads within recommended ranges in healthy persons and patients with coronary artery disease. Although, RPE values have shown to be associated with metabolic and respiratory thresholds, the relationship has not been established in cancer patients. Therefore, the present study systematically explored ratings of perceived exertion and objectively measured physiological exercise parameters in cancer patients. **Methods** 31 cancer patients (4 male, 49.7 ± 10.2 yrs., VO_{2max} 22.8 ± 5.3 ml/min/kg) participated in one cardiopulmonary exercise test until exhaustion (cycle ergometer: 0 +25W, 3min). Subjects rated their RPE at the end of each stage and after test termination. Ventilatory threshold (VT) and respiratory compensation point (RCP), as well as lactate threshold (LT) and individual anaerobic threshold (IAT) were determined according to established methods. RPE values were calculated by a cubic polynomial function versus power relationship. Results Mean work rate values at LT, VT, IAT and RCP were all within the ACSM recommendations for exercise intensities of 46–90% VO_{2max} (Garber et al., 2011) (50.1 ± 5.0 , 53.8 ± 9.5 , 73.1 ± 7.5 and 83.6 ± 5.3). RPE values at LT, VT, IAT and RCP were 10.3 ± 2.1 , 10.5 ± 2.0 , 13.3 ± 1.8 and 14.4 ± 1.9 , respectively. Sports history, training status or cardiorespiratory fitness (CRF) had no significant influence on RPE at submaximal thresholds. Discussion The RPE values of cancer patients at physiological thresholds are comparable to those described for healthy elderly, athletes and patients with coronary artery disease (Scherr et al. 2013). Thus, the use of self-rating via RPE seem to be applicable for monitoring exercise intensity in cancer patients. As oxygen uptake values at physiological thresholds were within current guideline-ranges, the application of RPE might be useful for endurance training regulation (Scherr et al., 2013). In contrast to the guidelines our findings suggest, that even values below the recommended RPE threshold of twelve (Garber et al., 2011) seem to be sufficient to induce appropriate moderate exercise intensities. Further research should explore the potential of RPE values for exercise prescription in cancer patients, which may help implementing a physiologically based training routine even when no laboratory-based testing is available. THE EFFECT OF A 12 WEEKS RANDOMIZED CONTROLLED TRIAL OF VIGOROUS EXERCISE ON MOTOR SKILLS IN A GROUP OF OVER65 PEOPLE

Melis, S., Migliaccio, G.M., Fois, F., Siccu, M., Collu, G., Melis, F., Todde, F.

CONI-Italian Olympic Committee

Purpose: The purpose of this study was to assess the effects of exercise on motor abilities by means of the Senior Fitness Test (SFT) in a group of elderly adults. **Methods:** Forty healthy and inactive people were recruited and assigned in two randomized groups of different training activities: a Vigorous Activity Group (VAG: 12 men and 8 women, aged $69,60 \pm 3,99$ years; weight $70,75 \pm 12,09$ kg; height $161,33 \pm 6,95$ cm), and a Control Activity Group (CAG: 13 men and 7 women, aged $70,29 \pm 5,71$ years; weight $80,28 \pm 16,44$ kg; height $163,02 \pm 12,00$ cm). At the beginning of the study (T0) and after 3 months (T1) each subject underwent thorough a medical examination and a series of testing procedures to assess the functional abilities of muscular strength, power and agility. The testing protocol included: Chair Stand, Arm Curl, 2-Minutes Step, Chair Sit-and-Reach, Back Scratch and 8-Foot Up-and-Go Tests according with Rikli et al. The VAG was designed with both aerobic and anaerobic workout, along with functional exercises with the use of a platform (step) in accordance to ACSM guidelines in an inclusive range between 40% and 84% of the Heart Rate Reserve (HRR), monitored continuously with a heart rate monitor (Polar®) and a telemetry system (Hosand®). The CAG was designed with low intensity activities (<40% of HRR), including patterns of real life movements, postural and balance exercises with the use of tools (fit-balls and softballs). Both training protocols were conducted by fitness professional trainers over a period of 12 weeks (36 sessions of 60 minutes/3 times a week). **Results:** Statistical analysis (2 way ANOVA for repeated measures) have shown no significant differences neither inter VAG and CAG groups nor intra groups at T0 and T1. Nevertheless a tendency has emerged to an improvement in the VAG in comparison to the CAG, with the upgrading of some tested motor abilities, such as the Chair Stand Test. **Conclusions:** These results suggest that further studies on a more numerous sample and with a longer protocol may be needed to elicit an improvement of the motor abilities in such a population, and with the particular purpose to establish which protocol of physical activity could be more specific and suitable to increase the motor skills described in the SFT. **References:** 1. POSTEXERCISE HYPOTENSION IN CHRONIC HEART FAILURE PATIENTS AFTER CONTINUOUS AND INTERVAL EXERCISE TRAINING

Bieniek, S.

Klinikum rechts der Isar

Introduction: Regular physical exercise is an important component in the prevention and treatment chronic heart failure (CHF). Alongside pharmaceutical treatment, e.g. diuretics, ACE-inhibitors, continuous moderate-intensity exercise training (CT) has also been shown to have a rehabilitative effect on chronic hypertension in patients with CHF. Similar effects on blood pressure (BP) have also been observed through interval training (IT). However, exercise training can also lead to clinically significant postexercise hypotension (PEH), and very little data is available comparing the acute effects of CT and IT on BP in CHF. This study investigates the effects of isocaloric CT and IT on PEH in patients with CHF. **Methods:** Twenty-four stable CHF patients (81% male, 63 ± 7 y, LVEF: $31 \pm 3\%$) were assigned to CT (n=9) or IT (n=15), and performed cardiopulmonary exercise testing to determine peak oxygen uptake (VO_{2peak}). Both groups performed 36 supervised exercise training sessions on cycle ergometers within 12 weeks (CT: 254 patient-hours, IT: 342 patient-hours). The CT duration was 47 minutes (50-70% VO_{2peak}). IT consisted of four, 4-minute intervals at (80-90% VO_{2peak}) separated by 3-minute recovery phases (50-70% VO_{2peak}), for a total of 38 minutes. Blood pressure was measured sitting quietly at rest before exercise and five minutes after exercise termination by trained personnel using manual sphygmomanometry. Statistical analyses were performed on BP data to determine within and between group differences. **Results:** There were no adverse events during exercise training. In CT, pre- and postexercise systolic blood pressure (SBP) was 116.9 ± 15.8 mmHg and 109.6 ± 15.9 mmHg (BPdiff = - 7.3 mmHg, p = 0.001). Diastolic blood pressure (DBP) was 70.7 ± 10.2 mmHg and 71.1 ± 11.6 mmHg (BPdiff = 0.4, p = 0.75), respectively. In IT, pre- and postexercise SBP was 111.3 ± 15.2 mmHg and 106.9 ± 13.4 mmHg (BPdiff = -4.4 mmHg, p = 0.004). DBP was 67.2 ± 8.8 mmHg and 66.8 ± 9.6 mmHg (BPdiff = 0.5, p = 0.61), respectively. There were no statistically significant between-group differences in BP at either pre- or postexercise investigations (SBPdiff: p = 0.15, DBPdiff: p = 0.57). **Discussion:** The results of the current study illustrate a considerable and significant decrease in systolic blood pressure after both continuous and interval endurance exercise in patients with chronic heart failure. Although the BP-lowering effect of exercise training is desirable, clinically significant PEH in CHF patients could lead to adverse events (e.g. syncope) and therefore should be carefully monitored.

EXERCISE INTERVENTIONS FOR PATIENTS WITH PERIPHERAL NEUROPATHY

Streckmann, F.1, Zopf, E.M.1, Lehmann, H.C.2, May, K.1, Rizza, J.1, Gollhofer, A.3, Bloch, W.1, Baumann, F.T.1

1. German Sport University Cologne, 2. University hospital Cologne, 3. IFSS Freiburg

INTRODUCTION Peripheral neuropathies (PNP) encompass a large group of disorders of heterogeneous origin which can manifest with sensory and / or motor deficits depending on the predominantly affected nerve fiber modality. It represents a highly prevalent and disease group that frequently goes along with severe disability and poor prognosis. Especially for oncological patients, it is a clinically relevant side-effect of chemotherapy, representing a decisive limiting factor for medical therapy and consequently affecting patients' clinical outcome. Exercise has the potential to improve side-effects of PNP. Our objective was to analyze exercise interventions for neuropathic patients and evaluate possible benefits of exercise for neuropathic patients. **METHODS** Three independent reviewers used PubMed, MEDPILOT® (Medline), Cochrane and relevant reference lists to obtain the data. Relevant studies were graded according to the Oxford Levels of Evidence. **RESULTS AND CONCLUSIONS** We screened 9653 search results. After careful reviewing, the total number of studies meeting inclusion criteria for this review is 16 studies: Eight randomized controlled trials (RCT) and eight controlled clinical trials (CCT) evaluated the effects of an exercise intervention on the side-effects of PNP, assessing a total of 699 patients. Critical grading of the 16 studies revealed ten high quality (Level 1 and 2) studies (5 diabetic PNP, 1 CIPN, 4other) and six of poor quality (Level 4) (4 diabetic PNP, 2others). Current data suggests that exercise is feasible, safe and currently the best evaluated and most beneficial supportive measure for neuropathic patients, besides pain medication. Overall, balance training seems to be most effective. Further conclusions and recommendations will be ready to be presented at the conference.

CRITICAL TIME FOR CYCLE ERGOMETER EXERCISE IS DEPENDENT ON EXERCISE INTENSITY IN TYPE I DIABETES – A SINGLE CASE STUDY

Moser, O.1,2, Mueller, A.3, Köhler, G.2, Gröschl, W.3, Tschakert, G.3, Hofmann, P.3

1: University of Potsdam (Germany), 2: Medical University of Graz (Austria), 3: University of Graz (Austria)

Introduction To perform sports in patients with type I diabetes (T1DM) they need to reduce insulin dose and/or increase carbohydrate intake to avoid hypoglycaemia (Kym et al., 2005; Rabasa-Lhoret et al. 2001). There is a lack in the guidelines how to adapt therapy related to different exercise intensities (Direcnet Study Group, 2006). The purpose of this study was to investigate the relationship between the blood glucose concentration (GLUC) and the intensity of the work load applying a standardized pre exercise glucose and insulin regimen. As a hypothesis we expected an energy expenditure and intensity dependent decrease of GLUC which offers the opportunity to calculate a critical time (tcrit). **Methods** One male T1DM subject (VO2max: 55.4 ml.kg⁻¹.min⁻¹; C-Peptide positiv, HbA1c 48 mmol.mol⁻¹) performed 4 hours after the last insulin/carbohydrate supplement, with a reduction of short time insulin to 40%, a maximal incremental cycle ergometer exercise test to determine the first (LTP1) and the second lactate turn point (LTP2) by means of computer based linear regression break point analysis (Hofmann & Tschakert, 2011). Four constant load ergometer exercise tests (30 min) were performed at 5% of Pmax below and above LTP1 and LTP2 with reductions of short time insulin doses of 25% at 5% Pmax below and above LTP1 and 50% at 5% Pmax below LTP2 and 75% at 5% Pmax above LTP2. Heart rate and gas exchange variables were determined continuously; blood lactate concentration and GLUC were determined at rest, at the end of every workload step and every 5 min in constant load ergometer tests. **Results** Linear declines of GLUC were found in all tests. At 5% < LTP1 GLUC decreased from 191 mg/dl to 149 mg/dl, 5% > LTP1 from 131 mg/dl to 96 mg/dl, 5% < LTP2 from 169 mg/dl to 91 mg/dl and 5% > LTP2 from 187 mg/dl to 144 mg/dl. The decline of the GLUC were calculated by a linear extrapolation to tcrit (50% rest of the baseline value) without any other supply of carbohydrates. tcrit: 5% < LTP1 – 77 min; 5% > LTP1 – 31 min; 5% < LTP2 – 31 min; 5% > LTP2 – 29 min. **Discussion** The results show a linear reduction of GLUC in relation to the intensity of the work load. We suggest that it is possible to calculate a tcrit for a certain GLUC threshold in T1DM patients to avoid hypoglycaemia during exercise. **References** Hofmann P, Tschakert G. MO-PM09 TT Agility

THE EFFECTS OF MULTIPLE CHANGES OF DIRECTION TRAINING ON NEUROMUSCULAR PERFORMANCES

Padulo, J.1,2, Attene, G.2, Pizzolato, F.3, Zagatto, A.4, Laffaye, G.5, Migliaccio, G.M.2, Chamari, K.6, Salernitano, G.7, Chaouachi, A.1

National Center of Medicine and Science in Sports (CNMSS)

Introduction The aim of this study was to assess the influence of intensive repeated sprint ability (RSA-2) training (Padulo et al., 2013) with double changes of direction (COD) and repeated sprint ability (RSA-1, with only one COD) training on jump performances (Bosco et al., 1982) after 4 training weeks. **Methods** Eighteen young male basketball players (16.4±0.5 yrs) were randomly assigned to RSA-1 group (n=9) and RSA-2 group (n=9). **Study design:** one week of tests pre- and post- to four weeks of training (twice per week) followed by one week of tapering and test-retest. The randomized tests were: RSA-1 (Castagna et al., 2007) with 1-COD (15m+15m), RSA-2 with 2-COD (10m+10m+10m) and jumping tests (squat jump (SJ) and counter movement jump (CMJ)). The RSA-1 and RSA-2 training consisted of: 3 sets (4-min recovery) with 6 maximal sprints in the first two weeks and 8 maximal sprints in the second two weeks (20-sec recovery in-between sprints). ANOVA was conducted to compare the effect of the two training modes for each variable and Intra-class correlation coefficient (ICC) for the reliability of the measures. **Results** ICC was 0.95/0.98 for each test. Training have led to improved Sprint Performance (Best 2%-3% and Worst time 5% p<0.05) in both RSA-1 and RSA-2, respectively. CMJ (F=9.691 with p=0.007) increased of 4.5% (p<0.0001) and 3.4% (p=0.016) in the RSA-2 and RSA-1 groups, respectively. While SJ showed (F=0.682 with p=0.421) improvements of 3.5% (p=0.003) and 3.2% (p=0.095) in RSA-2 and RSA-1 groups, respectively. **Discussion** These results showed that the RSA1 and RSA2 produce high activity for lower limb muscles due to COD (Morio et al., 2011). This training is able to influence the jump performance that is also a good predictor of the muscle power (Mataulij et al., 2001). The advantage of these methods (RSA-2 and RSA-1) is to play a crucial role in both aerobic fitness (COD) and neuromuscular performance (CMJ/SJ) with RSA-2 resulting in higher improvements than RSA-1. **References** Bosco C, Ito A, Komi PV, Luhtanen P, Rahlila P, Rusko H, Viitasalo JT. AGE RELATED DIFFERENCES IN AGILITY DURING A TRAINING SEASON IN YOUTH ELITE SOCCER PLAYERS

Bidaurrezaga Letona, I., Carvalho, H.M., Lekue, J.A., Gil, S.M.

Faculty of Physical Activity and Sport Sciences

Acknowledgements This study was supported by a grant from the Basque Government (IT700-13) IBL is supported by a predoctoral grant from the Basque Government (BFI2010-35) **INTRODUCTION** Agility performance is of relevance in soccer given its multidirectional nature and may be an indicator of performance (1). Therefore, the aim of this study was to examine the age group variation in agility responses within a training season in youth soccer players. **METHODS** Thirty-three youth soccer players of the professional soccer club Athletic Club of Bilbao participated in this study. The sample included players of the under-11 (n=18) and under-13 teams (n=15), aged at

baseline 10.4 ± 0.3 and 11.98 ± 0.77 years, respectively. Age at peak height velocity (APHV) and maturity offset were estimated at the start of the season. Player's agility, body mass and stature were evaluated on two occasions during the training-season: at the beginning of the season in October 2009 and in June 2010, the end of the season. The agility protocol used was a modification of the Barrow zig-zag run test (2). Multilevel linear regression analysis was used to estimate individual changes across the season, and the differences in changes between competitive age groups. Logarithmic transformations of dependent and independent variables were used to analyze changes in percentage. RESULTS All maturity offset values were negative indicating that the sample was behind the age at PHV. Increases in body size over the training period were significant ($p < 0.05$), reflecting pubertal growth. The multilevel models showed that the agility performance presented a significant improvement ($p < 0.01$) suggesting a possible beneficial effect of soccer specific training in agility. Older players had significantly better performances ($p < 0.01$), but the rate of improvements appeared to be similar in both age groups. The changes in agility performance were independent from the maturity offset, as the inclusion of the variable in a separate model was not significant. DISCUSSION There was an improvement in agility performance, on average. Also, a substantial group age effect on the agility performance pre- and end-season was observed. Older adolescent players appear to perform better compared to younger players but the rate of improvements was similar in both age groups. Since selection in soccer tends to favor early mature boys (3), the differences between groups may be partially attributed to linear growth and gains in muscle mass with age. REFERENCES 1. AGILITY TESTING IN TOP-LEVEL PROFESSIONAL BASKETBALL PLAYERS

Moreno, D.1, Peña, X.2, Buscà, B.3

1: Club Joventut de Badalona (Badalona, Spain), 2: University of Vic (Vic, Spain), 3: FPCEE Blanquerna. Ramon Llull University (Barcelona, Spain)

Introduction In the last years, agility has become an important topic in team sports testing being included within the training contents and assessment procedures of the main professional leagues, such as the NBA and the NFL. Regarding to basketball, many studies have currently approached the relationship between agility and physical performance using several tests (Jackovljevic et al. 2012), while trying, at the same time, to explore the different characteristics of playing positions (Scanlan et al., 2013). Our purpose was to investigate those position-related differences in top-level professional players. Methods Thirty-nine male adult subjects participated in the study during the last four years and were tested at least twice a year. After performing a specific warm-up, players completed two tests, a 2x10m test and a 4x5m test, using two Velleman PME10D® photocell gates connected to a Chronojump® software that provided speed outcomes. Comparisons were made considering three specific game positions ('G': guards, 'F': forwards and 'C': centers). Results Both tests showed a moderate, but significant, correlation ($r = 0.589$; $p < 0.001$). Forwards showed best performances in the 2x10 test when compared to the rest of the groups ($p = 0.001$), and in the 4x5 test when compared to guards ($p = 0.001$). Discussion Agility measurements are commonly based in closed-skill tests, such as the 4x5m or the 2x10m (Scanlan et al. 2013). The findings of the current study are consistent with those of Jackovljevic et al. (2012), suggesting that results from both tests seem to be closely related. At the same time, the observed correlations lead us to believe that there is a close relationship between speed and agility explaining the 2x10 m test results (Sekulic et al., 2013). Comparisons among roles revealed that forwards have better ability to accelerate, decelerate and to change directions than any other position in the game. IS JUMP ABILITY RELATED TO SPECIFIC SHORT SPRINTS IN YOUNG FEMALE VOLLEYBALL PLAYERS?

Buscà, B.1, Peña, J.2, Moreno, D.3, Morales, J.1

1: FPCEE Blanquerna. Ramon Llull University (Barcelona, Catalunya, Spain), 2: FCE University of Vic (Vic, Catalunya, Spain), 3: Club Joventut de Badalona (Badalona, Catalunya, Spain)

Introduction Volleyball players sprint in two game-situations: block and court-defence. To react as quick as possible and complete the balanced displacement required for a satisfactory ball contact is necessary to perform specific techniques. It is widely known that jumping ability and muscular leg power are related to sprint ability (Sheppard et al, 2008; Rigs & Sheppard, 2009). The objective of the study is to examine the relationship between jump ability and specific short-sprint velocity using specific movement patterns. Methods A group of 14 female young volleyball players (age = 18.2 ± 0.8 , height: 178.3 ± 3.1 cm, weight: 63.2 ± 7.2 kg), members of a training group based at the National Training Center of Barcelona, participated in this study. Time of short-sprint were assessed using two photocell gates Velleman PME10D® connected to a Chronopic of Chronojump®. Jumps were measured with the same system but using a jump mat. The measurement protocol was performed in the following order: SJ, CMJ, ABK, VJ (volleyball jump), DEF (defensive short sprint) and BLOCK (block short displacement). A correlation analysis was performed to evaluate the association between the variables. Results We observed a significant correlation between all jump protocols ($r > 0.89$; $p < 0.01$). We found significant relationship between BLOCK and SJ ($r = -0.79$; $p < 0.01$), CMJ ($r = -0.78$; $p < 0.01$), ABK ($r = -0.79$; $p < 0.01$) and VJ ($r = -0.80$; $p < 0.01$). But only a significant relationship between DEF and ABK ($r = -0.51$; $p < 0.05$). Both short sprint protocols were also related ($r = 0.68$; $p < 0.01$). Discussion These findings suggested the importance of the vertical jump skills for the acceleration phase, brake phase and the abrupt change of direction actions in sprint ability. So, this ability requires a high validity of the assessment method. From our point of view and knowledge, the only specific test in volleyball, the 5-meter agility test used by Barnes et al (2007), was conducted without this specificity because no instructions about how the subjects had to move were done. Moreover, the distances proposed were too long and redundant. The higher relationship observed in our study could be explained by the higher specificity of our test. ENDURANCE AND AGILITY PROFILE BETWEEN MALE SOCCER PLAYERS OF DIFFERENT AGE CATEGORIES

Shalaj, I., Tishukaj, F.1, Gjaka, M.1, Ademi, B.1, Pllana, A.1, Wessner, B.2, Csapo, R.3, Tschan, H.2

1. University of Prishtina 2. University of Vienna 3. University of California (San Diego, USA)

Introduction Elite performance in soccer depends upon a vast number of factors most important technical and tactical skills. However, evidence exists demonstrating that improved oxygen uptake enhances soccer performance and that modern soccer is characterized by

an increasing number of brief, intensive actions such as agility tasks. Aim The study aimed to assess differences in endurance- and agility performance between elite male soccer players of different age groups (U13, U15, U17) and compare them with senior elite players in Kosovo. Methods 192 subjects (U13, n=59; U15, n=48; U17, n=32), and 53 senior players were tested for body composition, endurance capacity and agility performance (IAT), respectively. A Multistage Fitness Test (20m shuttle test to exhaustion) was performed to assess aerobic capacity of the players, whereas Illinois Agility Test was used to determine agility performance. Analyses of variance (ANOVA) has been used to compare means in the different age groups. Results As expected adult elite players had significantly better endurance and agility performance ($p < 0.001$) compared to all other age groups. Surprisingly estimated $\dot{V}O_{2\max}$ of U13 players have been found to be significantly higher compared to players of U15 and U17 team, respectively (U13: 52.9 ± 2.8 ; U15: 47.9 ± 3.1 ; U17: 48.0 ± 2.5 and adult elite players: 55.0 ± 3.0). Conversely, using One-Way ANOVA showed that as chronological age increased, performance in agility increased significantly ($p < 0.001$) among all categories. Weight and Illinois Agility Test were strongly and negatively correlated with aerobic endurance only among senior players ($R^2 = 0.50$; $cc = -.475^{**}$). Discussion Current study demonstrates that there is an age and development-related development of agility and endurance performance with highest performance in adult elite athletes. Another finding is that excess weight has a negative impact on aerobic performance and IAT only in senior soccer players. E-mail: ishalaj1@hotmail.com

SPEED TESTING IN FOIL AND EPEE FENCERS DURING SPECIFIC ATTACKS

Weichenberger, M.1, Steegmueller, W.2, Steinacker, J.M.1

1: Universitätsklinikum Ulm, 2: German Fencing Federation (DFB), Bonn, Germany

Introduction The speed during fencing attacks is considered to be very important for success in competition. It is assumed that foil fencers move faster than epee fencers, but the speed during specific attacks has not been analyzed before. The aim of our study was to compare movement speed and reaction time during specific fencing attacks in foil and epee fencers. **Methods** 9 male epee fencers (EPEE, 15.6 ± 0.5 yrs, 72.2 ± 9.8 kg, 181.0 ± 7.0 cm) and 8 foil fencers (FOIL, 16.3 ± 1.6 yrs, 76.2 ± 8.8 kg, 179.9 ± 5.1 cm) of the German national junior team took part in the study. The measurements were focused on speed of the weapon hand during the fencing attacks touch (TOU), lunge (LUN), step forward lunge (SFL) and flèche (FLE). An optical motion capture system (2000 Hz, Lukotronic, Austria) with 16 active infrared markers was used to analyze speed and technique during the attacks. A fencing dummy with target areas was integrated into the system for detecting reaction time (RTIME). The study participants performed 5 trials for every fencing attack. During attacks, mean speed (MEANSPD), maximum speed (MAXSPD), time to reach maximum speed (TMAXSPD) and speed in the moment of hit (HITSPD) were measured. Results FOIL had greater MEANSPD and MAXSPD during TOU (1.23 ± 0.33 m/s, 2.25 ± 0.44 m/s), LUN (1.86 ± 0.28 m/s, 3.26 ± 0.39 m/s) and SFL (2.03 ± 0.15 m/s, 3.83 ± 0.56 m/s) than EPEE (TOU: 1.05 ± 0.33 m/s, 1.85 ± 0.65 m/s; LUN: 1.76 ± 0.19 m/s, 3.18 ± 0.31 m/s; SFL: 1.92 ± 0.21 m/s, 3.56 ± 0.63 m/s, $p < .05$). MAXSPD for FLE was higher in EPEE (3.65 ± 0.60 m/s) than in FOIL (3.39 ± 0.31 m/s, $p < .05$). TMAXSPD in FOIL during LUN and SFL was greater than in EPEE (0.40 ± 0.06 s vs. 0.46 ± 0.08 s; 0.78 ± 0.08 s vs. 0.95 ± 0.08 s). HITSPD during TOU (1.56 ± 0.40 m/s vs. 1.25 ± 0.65 m/s), LUN (2.52 ± 0.58 m/s vs. 2.21 ± 0.44 m/s) and SFL (3.06 ± 0.82 m/s vs. 2.57 ± 0.53 m/s) was greater in FOIL. RTIME for LUN and SFL was better in EPEE than in FOIL (0.21 ± 0.05 s vs. 0.24 ± 0.05 s and 0.22 ± 0.05 s vs. 0.26 ± 0.04 s, $p < .05$) but there were no differences for TOU and FLE. **Discussion** The newly developed fencing-specific method and the described speed parameters are suitable to analyze movement speed and reaction time during fencing attacks. Data confirm the assumption that foil fencers generally move faster than epee fencers. The slower reaction times of foil fencers during LUN and SFL can be explained by the fact that foil fencers start these attacks, in contrast to epee, with the lower limbs. These differences are most likely due to different competition rules and should be considered during reaction tests in fencing. Contact mario.weichenberger@uni-ulm.de

A STUDY ON THE METHOD OF MEASURING SIMPLE REACTION, CHOICE REACTION AND DISCRIMINATIVE REACTION TIMES OF THE TURKISH AIR FORCE ACADEMY CADETS

Kamuk, Y.

Turkish Armed Forces

This study is conducted to set a new reaction time measuring system and measure the simple, choice and discriminative reaction times of the Turkish Air Force Academy Cadets. The equipment (Academy Reaction Timer) and all of the related components including the computer program are designed and produced by the author. The study is carried out with 555 cadets who were willing to participate. The data was collected in a specially designed test room. Before the test, the testing procedure was explained to the cadets and they were asked to react as fast as possible. This is a descriptive study in which a recently developed reaction timer was used. The data collected was analyzed through SPSS 14.0 which is obtained via internet download from the official internet site of the SPSS. The arithmetic means, standard deviations, minimum and maximum values were calculated and Independent Samples t-Test was used to find any possible differences ($p < 0.05$). One-Way ANOVA was used to find if there was a difference between groups at the class level ($p < 0.05$). Half-split test was used to determine the reliability of the testing equipment. In addition, the upper and the lower quarters are examined through the t test to determine whether the application is discriminative or not. At the end of the study, it was found that the developed reaction time system reliably measures what it was intended to. A significant difference was found between the freshmen and seniors for the simple, discriminative and sound reaction time tests ($p < 0.05$). The discrimination level of the measurement system is pretty high ($p < 0.01$).

A COMPARISON BETWEEN THE REACTION TIMES OF ADVANCED MARTIAL ARTS ATHLETES AND ADVANCED COMPUTER GAME PLAYERS AND THEIR ACHIEVEMENT SCORES OF COMPLEX ACTION FORMAT

Sagdilek, E., Sahin, S.K.

Uludağ University, Faculty of Medicine

Introduction Martial arts are sports based on hand and feet striking or drop-kicking techniques that are done without arms. Strikes and dropkicks require fairly complex muscle coordination and also reaction time is short. In addition to being the most popular entertainment tool for the youth, computer games are regarded as a sports branch and its players are referred as e-athletes in the literature. The present study aims to compare the reaction times of advanced martial arts athletes and advanced computer game players (e-athletes) and their rate of achievement scores in the complex action format. **Methods** The experimental group consisted of two sub groups; 10 male e-athletes whose average age was 19.6 years and 14 male martial arts athletes whose average age was 22.6 years. E-athletes spent their last five years playing on the computer for 10 hours a week whereas martial arts athletes spent 10 hours a week practicing martial arts for the last five years. The control group consisted of 9 male Physical Education students who had not been interested in any professional

sports and whose average age was 23.8 years. The participants' dominant hand/feet reaction times to voice and light stimuli were recorded. The complex action format was set up by a table tennis robot. It was set up to throw 90 balls per minute of which balls are thrown to different places of the table selecting any of the 3 colors (white-yellow-pink) randomly (total: 120 balls). The participants were asked not to react to white balls, but to touch yellow balls and catch the pink ones after they hit the table by using their dominant hand only. Actions were converted into scores according to a scale. Results and Discussion The dominant hand-voice reaction time was estimated approximately as 170.5 ms in martial arts athletes whereas it was estimated approximately as 176.1 ms in e-athletes and as 196.3 ms in the control group. There was no statically significant difference between the martial arts athletes and e-athletes in terms of reaction times. Nevertheless, both groups have statically significant shorter reaction times than the control group. Although the average of total scores in the complex action format was estimated at 166 for the athletes, 156 for the e-athletes and 138 for the control group. The precision level of the performed action was the highest for martial arts athletes and the lowest for the control group for each color of balls. The shorter reaction time of the martial arts athletes was an expected result. That the reaction times of e-athletes were nearly the same as the ones of martial arts athletes and were expressively shorter than the control groups. That the precision levels of the e-athletes in the complex action format were better than the control group can be regarded as the increase in visual perception and decrease in reaction times. As far as the literature review, the methodology for the complex action format has been designed for the first time and is still in the process of development. Contact: esagdilek@hotmail.com

MO-PM10 Thermoregulation 1

THERMOGRAPHIC SKIN TEMPERATURE RESPONSE TO DIFFERENT MOVEMENT VELOCITY OF SQUAT EXERCISE UNTIL EXHAUSTION: A PRELIMINARY REPORT

Formenti, D.1, Trecroci, A.1, Ludwig, N.2, Gargano, M.2, Caumo, A.1, Alberti, G.1

Università degli studi di Milano

INTRODUCTION Blood flow restriction resistance training is an effective training method for improving muscular function using low and moderate load intensity (Alberti et al., 2013). It has implications in the regulation of skin blood flow, with important consequence for the blood involved in heat dissipation through the skin. The aim of this study was to investigate the skin temperature (ST) response by using infrared thermography during slow speed low intensity exercise as compared to normal speed low intensity exercise in squat trial (Tanimoto et al., 2006). We hypothesized that low intensity resistance exercise with slow movement would result in a ST response slower than the one of the normal speed exercise with the same intensity. **METHODS** 9 active males (23.6 ± 1.1 yrs, 69.7 ± 6.8 kg, 176 ± 6.2 cm) performed 2 sessions of deep squat exercise until exhaustion, with 50% of 1 RM. The pace of movement was set in 1s eccentric / 1s concentric and 5s eccentric / 5s concentric phase in the 1st and in the 2nd session respectively. Thermal images were recorded every 20s before exercise (2min), during exercise (until exhaustion), and after exercise (10min). ΔT (Tpeak-Tbasal) and Time50% (time to reach 50% of ΔT) were identified and compared in 1s vs 5s trials by using paired t-test. **RESULTS** Surprisingly, a different behaviour of ST during and after exercise was observed among subjects: a decrease in ST in 5 subjects (down group) and an increase in the other 4 (up group). Thus, statistics was performed in each group separately. The ΔT of the up group in 1s ($1.1 \pm 0.42^\circ\text{C}$) and 5s ($1.0 \pm 0.50^\circ\text{C}$) were approximately twice that of the down group in both 1s ($-0.50 \pm 0.15^\circ\text{C}$) and 5s ($-0.42 \pm 0.28^\circ\text{C}$). The ΔT in 1s was similar to ΔT in 5s in both groups. The ST changes (Time50%) in the down group occurred slowly ($p < 0.01$) in 1s (30.1 ± 17.2 s) vs 5s (107.3 ± 25.3 s) as well as in the up group (139.1 ± 17.2 s in 1s vs 184.9 ± 58 s in 5s; $p > 0.05$). The ST changes during 1s and 5s trials occurred more rapidly in the down group than in the up group. **DISCUSSION** It was shown that the response of cutaneous circulation to dynamic exercise is characterized by a initial vasoconstriction to dissipate heat from the core through the skin followed by vasodilation driving the blood flow from inactive tissue (including the skin) to active muscles involved in exercise (Kellogg D.L., 2006). We speculate that the unexpected different behaviour of the ST response in the 2 groups was probably due to a time-dependent predominance of vasoconstriction over vasodilation or viceversa. **REFERENCES** Alberti G. et al. VASTUS LATERALIS REPRESENTS THE ASSOCIATION BETWEEN NEUROMUSCULAR ACTIVATION AND THERMOREGULATION IN CYCLING

Priego, J.I.1,2, Carpes, F.P.3, Bini, R.R.4, Salvador, R.2, Pérez Soriano, P.1, Cibrián, R.M.2

1:GIBD (University of Valencia, Spain), 2:Dep. of Physiology (University of Valencia, Spain), 3:GNAP-UNIPAMPA (Uruguiana, Brazil), 4:LAPEX-UFRGS (Porto Alegre, Brazil)

Introduction Fitness level improves the efficiency of the thermoregulatory system. However, it is still unknown how neuromuscular activation affects skin temperature. Therefore, this study assessed the relationship between neuromuscular activation and skin temperature during cycling exercise. **Methods** Ten male physically active participants underwent an incremental cycling test to exhaustion while muscle activation was recorded from rectus femoris (RF), vastus lateralis (VL), biceps femoris (BF) and gastrocnemius medialis (GM). Muscle recruitment was assessed via frequency band analyses of muscle activation signals. Thermography images were recorded before and immediately after exercise at four body regions of interest corresponding to the muscles where EMG activity was recorded. **Results** Significant inverse relationship between variation in skin temperature and variation in overall neuromuscular activation ($p < 0.04$, $r > 0.5$) and significant positive relationship between skin temperature and low frequency components of neuromuscular activation ($p < 0.01$, $r > 0.7$) were observed for vastus lateralis. **Discussion** A recent study (Abate et al. 2013) showed differences in thermoregulation due to level of physical fitness. Higher maximum overall activation is associated with better fitness level (Häkkinen et al. 1998) and our participants used large motor units rather than small (less low frequency component) to sustain the increases in workload (Gregory and Bickel 2005). For this reason, larger increases in skin temperature for participants presenting increased low frequencies and limited overall activation of vastus lateralis during maximal aerobic exercise could be associated to their reduced fitness level. In conclusion, participants with higher overall muscular activation and lower frequency content in activation for vastus lateralis presented a better adaptive response of their

thermoregulatory system by showing limited increases in skin temperature. Vastus lateralis seems to be the muscle that better illustrate relationships between skin temperature and muscle activation. EFFECT OF COOLING STRATEGIES ON CYCLING PERFORMANCE IN THE HEAT: THERMAL STATE VS. THERMAL COMFORT

Schulze, E.1, Daanen, H.1, Levels, K.1, Kilding, A.2, Skleryk, J.3, Plews, D.3, Siegel, R.3, Laursen, P.3

1: MOVE (Amsterdam, Netherlands), 2: SPRINZ (Auckland, New Zealand), 3: HPSNZ (Auckland, New Zealand).

Introduction Strategies for enhancing endurance performance in the heat include pre-cooling and consuming cold fluids or ice slurries during exercise (Ross et al., 2013); strategies which may elicit different thermal states and sensations (Burdon et al., 2013). Our aim was to examine the effects of pre-cooling and ice slurry ingestion on prolonged cycling performance, using ecologically-valid conditions. Methods Seven well-trained male triathletes (33 ± 8 yr) completed 3 trials, consisting of 60-min cycling at a fixed rating of perceived exertion (RPE; 14) followed by a 20-km time trial in hot (30°C), humid (80% RH) conditions. In a randomised order, cyclists either 1) drank 30°C fluid ad libitum during exercise (CON), 2) drank ice slurry (-1°C) ad libitum during exercise (ICE), or 3) pre-cooled with iced towels and ice slurry ingestion (15 g/kg) before drinking ice slurry ad libitum during exercise (PC+ICE). Power output, rectal temperature, and ratings of thermal comfort were measured. Results Overall mean power output was possibly and likely higher in ICE ($+1.4 \pm 1.8\%$; 90% CL) and PC+ICE ($+2.5 \pm 1.9\%$) compared with CON, however no substantial differences were shown between PC+ICE and ICE (unclear). Time trial performance was likely enhanced in ICE compared with CON ($+2.4 \pm 2.7\%$) and PC+ICE ($+2.9 \pm 3.2\%$), whereas no clear differences were observed between PC+ICE and CON. Rectal temperature was very likely lower after pre-cooling in PC+ICE, however no differences resulted from ICE (unclear). Ratings of thermal comfort were likely and very likely lower during exercise in ICE and PC+ICE, respectively, compared with CON. Discussion The PC+ICE trial led to a larger overall performance enhancement compared with CON, than did ICE; however time trial performance was fastest for ICE. Ice slurry ingestion had little effect on thermoregulatory measures, but did elicit an improved thermal comfort. Therefore, cooling the gut region, along with associated adjustments in thermal comfort may play a role in allowing a higher motor output during exercise in the heat. While pre-cooling appeared to be beneficial during the early stages of the exercise, caution for pacing strategy is warranted if an end-spurt is key to overall performance. These findings suggest that thermal comfort may be at least of equal importance as thermal state during exercise performance in the heat. EFFECTS OF ACTIVE OR PASSIVE RECOVERY MODALITIES BETWEEN TWO 1000-M KAYAK ERGOMETER TIME TRIALS IN THE HEAT ON THERMOREGULATORY STRAIN AND PERFORMANCE IN ELITE KAYAKERS

Borne, R.1, Hausswirth, C.1, Bieuzen, F.1

1: INSEP

Introduction In hot environmental conditions, humans decrease their capacity to perform time trial exercise. In order to limit the body temperature increase induced by the heat, pre- and/or post-cooling techniques such as cooling vest wearing are commonly used by athletes and present positive results [1]. Furthermore, active recovery is a regular modality used by kayakers between races. However, in the heat, active recovery could induce a sustained thermoregulatory strain, which could have an adverse effect on homeostasis restoration. The purpose of this study is to compare the effects of cooling vest wearing combined with either passive with low frequency electromyostimulation (PASLFES) or active recoveries (AR) between two 1000-m kayak time trials. We hypothesized that negative effects of AR compared to PASLFES could be delayed with cooling vest wearing in hot condition. Methods Eight elite kayakers completed two sessions of two 1000-m time trials on a kayak ergometer separated by a 75-min recovery period with either AR or PASLFES combined with cooling vest wearing. All the protocol was conducted in the heat but subjects were non-acclimated. Performance time was recorded during each 1000-m. Body temperature was calculated from core and skin temperature measured by thermic pill and thermal camera, respectively. Subjects were asked to rate their perception of thermal sensation on a -3 to +3 scale. They also had to evaluate the recovery intervention (efficacy, sensation) by using a 0 to 10 scale. Results The AR modality presents the most important decline in time-trial performance (pre-AR: $+6.7$ -s; pre-PASLFES: $+2.1$ -s). The greatest increase in blood lactate clearance occurring during AR (AR-30min: 1.92 -mmol/L; PASLFES-30min: 3.9 -mmol/L). There is no significant difference between the AR and PASLFES interventions for body temperature at the end of the recovery (pre-AR: $+0.1^\circ\text{C}$; pre-PASLFES: $+0.3^\circ\text{C}$). The PASLFES recovery induces a lower heat sensation than AR. The means perceptions of recovery indicate a better positive effect induced by passive recovery. Conclusion Results of this study suggest that an efficient post-cooling recovery can limit the additional thermal strain induced by AR, in hot environment. However, the benefits on performance restoration induced by AR are not as important as with PASLFES recovery, despite a better effect on lactate clearance. This could be partly explained by positive passive recovery effects obtained on subjective parameters such as the feeling of recovery, which might help to maintain maximal performance in hot conditions. EXERCISE-INDUCED RESPONSE IN SWEATING AND BODY TEMPERATURE DURING CYCLING EXERCISE WITH MODERATE INTENSITY

Koike, H.1, Kobayashi, K.1, Yamauchi, J.1,2,3

1. Tokyo Metropolitan University, JAPAN, 2. Future Institute for Sport Sciences, JAPAN, 3. Khon Kaen University, THAILAND

[Introduction] Human radiates heat generated by exercise by non-evaporative expansion of the skin blood vessel and evaporative sweat action to maintain body temperature. Meantime, this thermoregulatory sweating causes to loss in water and solute. Thus, many studies have examined how the fluid intake before and during exercise affects to sweating and exercise performance. Also, several studies have reported that there are changes in the sweating rates (SR) during exercises with different intensities. It has been shown that SR increase with increase in exercise intensity (Takano et al. 1996). However, little is known how changes in regional SR relate to body temperature changes in a relatively long period of exercise with moderate intensity. [Purpose] This study examined how regional sweating was relat-

ed to core and skin temperature during a relatively long period of aerobic exercise with moderate intensity. [Method] Eleven healthy young men (age, 22.1 ± 2.9 years; mean \pm SD) exercised on a cycle ergometer at 55% $\dot{V}O_{2\max}$ for 40 minutes and sat a recovery for 40 minutes. Room temperature was set at 25 degrees. Before and after experiment, body mass (BM) was measured. SR was measured using a capsule with a small temperature-humidity sensor that measured the relative changes of humidity on the basis of the dry air by silica gel. SR and skin temperature was measured on the same 3 different regions; forehead, back and forearm. Tympanic membrane temperatures was measured as core temperature. [Result] After the experiment, body mass was significantly lost about 0.45 ± 0.15 kg. SR significantly increased in all 3 regions 10 min after the start of exercise and reached a peak value in the forehead at 15 min after the start of exercise, in the back at 20 min after the start of exercise, in the forearm at 30 min after the start of exercise. Skin temperature significantly increased in the forehead 10 min after the start of exercise and in the forearm 30 min after the start of exercise, whereas it significantly decreased in the back 20 min after exercise as compared to resting values. Core temperature significantly increased 15 minutes after the start of exercise until 15 minutes after exercise. During exercise and recovery, SR is correlated with changes in core and skin temperatures. [Conclusion] This study suggests that changes in SR during and after exercise with moderate intensity are related to the core and skin temperature changes with some regional differences.

CARDIOVASCULAR AND THERMOREGULATORY RESPONSES TO VARIOUS WORK INTENSITIES WHILE WEARING PERSONAL PROTECTIVE CLOTHING IN THE HEAT

Costello, J.T., Stewart, I.B.

Queensland University of Technology

Introduction Numerous occupations require that employees perform arduous physical activity, while wearing personal protective equipment (PPE), in extremely challenging environments. The accumulative effects of the metabolic and environmental heat during these tasks may predispose an individual to exertional heat illness (Stewart et al, 2013). Therefore, our aim was to examine if performances were limited by the cardiovascular or the thermoregulatory response to activity in the heat. **Methods** Wearing an explosive ordinance disposal bomb suit, respirator and air-permeable, charcoal impregnated chemical protective undergarment (total weight ~35kg) twelve healthy males undertook three trials. The trials involved walking on a treadmill at 2.5, 4 or 5.5 km.h⁻¹ at 1% grade in 37°C wet bulb globe temperature in a randomized controlled crossover design. The trials were ceased if the participants' core temperature reached 39°C, if heart rate exceeded 90% of maximum, if walking time reached 60 minutes or due to fatigue/nausea. Tolerance times, heart rate, core and mean skin temperature at the end of each trial were analyzed using a one-way repeated measures analysis of variance. **Results** A total of twenty-seven (75%) trials were ceased due to excessive heart rate. Five (14%) trials were terminated due to volitional fatigue and an additional four (11%) trials based on core temperature. As expected tolerance time was reduced (mean \pm sd; 37.8 ± 7.2 , 28.4 ± 7.9 , 15.9 ± 5.2 min for the 2.5, 4 or 5.5 km.h⁻¹ trials respectively; $2.5 > 4 > 5.5$ km.h⁻¹; $p < 0.001$) with increasing intensity. The increase in workload intensity also had a significant effect on maximum core temperature (38.6 ± 0.4 , 38.5 ± 0.5 , 37.9 ± 0.3 °C; $p < 0.001$), mean skin temperature (38.4 ± 0.4 , 38.4 ± 0.5 , 37.9 ± 0.7 °C; $p = 0.014$) and heart rate (167 ± 17 , 173 ± 11 , 174 ± 10 beats.min⁻¹; $p < 0.003$) at the end of the trial. Post-hoc analysis demonstrated that core and mean skin temperature at the end of the 5.5 km.h⁻¹ trials was lower ($p < 0.05$) than the 4 km.h⁻¹ trials. Final values recorded for core temperature and heart rate were also lower ($p < 0.05$) in the 5.5 km.h⁻¹ trials compared to the 2.5 km.h⁻¹ trials. No other significant differences ($p > 0.05$) were observed. **Discussion** The study has provided a systematic evaluation of the physiological tolerance times while wearing cumbersome and encapsulating PPE in the heat. Regardless of the external workload, trials were predominantly ceased due to the attainment of a heart rate equivalent to 90% of maximum. In conclusion, cardiovascular rather than thermoregulatory strain appears to be most important factor influencing the physiological tolerance times in this PPE during exercise in the heat. **References** Stewart IB, Townshend A, Rojek AM, Costello JT. COMBINED EFFECTS OF PASSIVE HYPERTHERMIA AND MENTAL FATIGUE ON ENDURANCE CAPACITY DURING HEAVY EXERCISE IN THE HEAT

Otani, H.1, Kaya, M.2, Tamaki, A.2, Goto, H.3, Tsujita, J.4

1; Himeji Dokkyo University, 2; Hyogo University of Health Sciences, 3; Kyushu Kyoritsu University, 4; Hyogo College of Medicine

Introduction Passive hyperthermia has been demonstrated to attenuate endurance capacity in the heat (Gonzalez-Alonso et al., JAP 1999) and mental fatigue has been reported to link with a reduction in an ability to perform high intensity exercise in a temperate environment (Marcora et al., JAP 2009). However, a combined effect of passive hyperthermia and mental fatigue on endurance capacity has not been systematically evaluated during heavy exercise in the heat. Hence, the present study examined the effects of passive hyperthermia and mental fatigue on endurance capacity during heavy exercise in the heat. **Methods** Eight male volunteers completed four cycling trials at 80% $\dot{V}O_{2\max}$ until exhaustion in a climatic chamber (30 degrees C, 50%RH). Participants cycled after: a 90 min seated rest (CON), a 90 min demanding cognitive task to induce mental fatigue (MF), a 30 min water immersion (40 degrees C) to induce hyperthermia following a 60 min seated rest (HT), or a 90 min demanding cognitive task with a 30 min water immersion (40 degrees C) during the last 30 min of task to induce both mental fatigue and hyperthermia (MF+HT). A demanding cognitive task involved the completion of several computer-based tests which included the Stroop colour-word test, Sternburg's short-term memory scanning task and the rapid visual information processing test. Rectal temperature, skin temperature, heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. **Results** Rectal temperature at the start of exercise was significantly higher in HT and MF+HT than in CON and MF (CON 36.7 ± 0.5 degrees C; MF 36.8 ± 0.2 degrees C; HT 38.1 ± 0.4 degrees C; MF+HT 38.0 ± 0.1 degrees C; $P < 0.0001$). Self-reported mental fatigue at the start of exercise was significantly higher in MF and MF+HT than in CON and HT ($P < 0.05$). Exercise time to exhaustion was 18 ± 7 , 17 ± 7 , 10 ± 6 and 9 ± 3 min in CON, MF, HT and MF+HT, respectively, and was significantly less in MF+HT than in CON and MF ($P < 0.05$). At the point of exhaustion, rectal temperature, mean skin temperature, heart rate and cutaneous vascular conductance were not different between trials, but body heat content was significantly higher in MF+HT than in CON ($P < 0.05$). **Conclusion** This study demonstrates that a combination of passive hyperthermia and mental fatigue elicits significant reductions in endurance capacity during heavy exercise in the heat. This early fatigue is accompanied by higher body heat content. However, mental fatigue alone does not influence endurance capacity to perform high intensity exercise in the heat.

RELIABILITY OF SERUM BIOMARKERS ASSOCIATED WITH HEAT STRESS, INFLAMMATION AND IMMUNOSUPPRESSION IN HEALTHY, TROPICALLY ACCLIMATISED, ACTIVE INDIVIDUALS.

Guy, J.H.1, Edwards, A.M.1, Miller, C.M.1, Deakin, G.B.1, Pyne, D.B.1,2

1: James Cook University, Cairns, Australia, 2: Australian Institute of Sport, (Canberra, Australia)

Introduction Cytokines, lipopolysaccharides, and shock proteins play an important role in regulating the levels of stress, inflammation and heat acclimation during exercise in hot environments. The aim of this study was to quantify the within-subject variability of serum biomarkers that have been commonly used to examine immune function and inflammation following heat exposure in healthy active males. **Methods** Twelve recreationally active healthy males (age; 24 ± 4.0 years, $\text{VO}_{2\text{max}}$; 50.8 ± 6.4 ml.kg.min⁻¹, height; 1.78 ± 0.05 m, weight; 74.1 ± 8.9 kg, mean \pm SD) participated in this study. Over a 14 day period subjects abstained from high intensity exercise and reported to the laboratory on three occasions at a similar time of day on day 0, day 7, and day 14. On each visit, subjects provided an 8ml serum blood sample. Commercially available ELISA bench top kits were used to analyse the samples for the serum concentrations of C-reactive protein (CRP), Interleukin-6 (IL-6), Heat Shock Protein 72 (HSP72), and Lipopolysaccharides (LPS). Data are presented as mean within-subject coefficients of variation \pm SD (CV) with units of measurements for each variable expressed as a minimum-maximum range. **Results** The biomarkers with the least variation across the 14 day study period were LPS ($7.66 \pm 6.41\%$; 0.16 - 0.27 EU/ml) and IL-6 (CV of $13.7 \pm 18.6\%$; 0.47 - 4.21 pg/ml). HSP72 levels were consistently beneath the detectable range, demonstrating very low concentrations of this protein at rest in the human body. The most variable marker was CRP with a CV of $37.7 \pm 26.9\%$ (0.70 - 29.0 mg/ml). **Discussion** These data indicate LPS, HSP72, and IL-6 are relatively stable biomarkers of inflammatory status in the absence of a heat stress or exercise interventions across a 14-day period. Although CRP produced a substantially larger within-subject CV ($\sim 38\%$), CRP values can increase up to 10,000-fold following an acute stress response (Pepys & Hirschfield, 2003). Consequently, evaluation of CRP should not necessarily be discounted as a biomarker of acute stress if the magnitude of change following an intervention is similar to, or larger than, the day to day biological variability. Further research examining the efficacy of these biomarkers following heat and/or exercise stress is required to clarify their use in clinical and research settings. **References** Pepys MB, & Hirschfield GM., (2003). HYDRATION PRACTICES, THERMOREGULATORY RESPONSES, AND ACTIVITY PATTERNS OF ADOLESCENT MALE FIELD HOCKEY PLAYERS TRAINING IN A HOT AND HUMID ENVIRONMENT – AN OBSERVATIONAL STUDY

Chia, M., Huang, D., Mukherjee, S.

National Institute of Education

Introduction Singaporean team sports athletes are at a higher risk of heat-associated ailments due to physiological demands of training and exposure to hot and humid weather all year round. No study on adolescent team sport has describes the hydration practices, thermoregulatory responses and activity patterns of heat-acclimatised youth athletes during training in a hot and humid climate. **Methods** 18 hockey boys (14.8 ± 7 years, 1.68 ± 0.07 m, 55.1 ± 8.2 kg, body fat $13.1 \pm 2.9\%$) were observed during an outdoor hockey field training session (WGBT, DryBulb, RH: $28.4 \pm 9^\circ\text{C}$, $31.3 \pm 7^\circ\text{C}$, $60.3 \pm 6.4\%$). Participants completed 2.7 hrs of training with aerobic training (AT), skills training (ST) and a modified match-play (MP). Urine samples (USG) were collected in the morning ($n=18$) and immediately prior to training ($n=17$). Weigh-in was conducted immediately prior to and after training. Different drinks (mineral water, isotonic drink & Milo) were available for players' ad-libitum consumption and ingested volumes were recorded. Core temperature (T_c , $n=14$) and physical activities ($n=14$) were measured using a telemetric sensor and a global positioning system. **Results** were analysed with statistical significance accepted as $p < .05$. **Results** Participants arrived in school moderately dehydrated and remained so prior to training ($\text{USG}_{\text{am}} = 1.0245 \pm .0073$, $\text{USG}_{\text{pt}} = 1.0250 \pm .00652$, $t(16) = -.248$, $p > .05$). Immediately after training, players lost $0.77 \pm .86\%$ of their body mass (Lost $> 2\%$ BM=2, lost $< 2\%$ BM=13, gained BM=3). The boys replaced $80.2 \pm 21.6\%$ (range= 43.3 – 134%) of their sweat loss through ad-libitum drinking of water (407 ± 256 ml), isotonic drinks (371 ± 242 ml) and milo (600 ± 211 ml) during training. 7 boys had peak $T_c \geq 39^\circ\text{C}$ (range= 39.00 – 39.87°C), but did not exceed 40°C . During training, participants covered a distance of 6151.5 ± 507.1 m (AT= 2433.0 ± 193.1 m, ST= 752.4 ± 216.6 m, MP= 2966.1 ± 436.7 m) with 56.5% , 33.3% , 6.1% and 4.1% at low, moderate, high and sprint intensities respectively. On average, the boys performed at $80.9 \pm 4.2\%$ of their calculated max heart rate (Machado & Denadai. 2011) during MP. A strong correlation was found between number of sprint efforts at MP and USG_{pt} ($r = -.76$, $n=13$, $p=.002$). **Discussion** Youth athletes were moderately dehydrated at the start of training and were further dehydrated post-training. They were unaware of the appropriate beverage to consume for effective rehydration during exercise. Despite being dehydrated and exercising in a hot and humid environment at 80% HRmax during MP, the athletes were capable of regulating their T_c below 40°C , suggesting that they were not at immediate risk of exercise heat stroke (Binkley et al. 2002). Improvement in pre-exercise hydration may help to increase the number of sprint efforts during match-play. **References** Binkley HM, et al. (2002). J Athl Train. 37(3), 329–343. Machado FA & Denadai BS. (2011). Arq Bras Cardiol. 97(2), 136-140. Contact Shihui.huang@nie.edu.sg

PERIPHERAL BLOOD FLOW CHANGES IN RESPONSE TO POST-EXERCISE COLD WATER IMMERSION

Choo, H.C.1, Nosaka, K.1, Peiffer, J.2, Ihsan, M.1, Yeo, C.C.1, Abbiss, C.R.1

1: ECU (Joondalup, Australia), 2: Murdoch University (Perth, Australia)

Introduction Cold water immersion (CWI) improves short-term (< 24 h) recovery and exercise capacity in the heat through a rapid reduction in body temperature. Water temperature can influence the magnitude of core, muscle and skin cooling, but, the effects of post-exercise CWI on compartmental distribution of limb blood flow are unclear. This study compared changes in limb, muscle, and skin blood flow after 5 min of passive rest (CON) or water immersion at 8°C (WI8), 14°C (WI14), and 35°C (WI35) following exercise. **Methods** In a counterbalanced order, nine men performed 25 min cycling at a power output equivalent to first ventilatory threshold, followed by repeated 30s effort (90% peak power) in the heat ($32.8 \pm 0.4^\circ\text{C}$ and $31.5 \pm 4.8\%$ rh) until volitional exhaustion. Participants then completed one of four recovery conditions (WI8, WI14, WI35, and CON). Measurements of thigh cutaneous vascular conductance (CVC), total haemoglobin (tHb) in vastus lateralis (VL), common femoral artery blood flow (CFA), mean arterial pressure (MAP), muscle (T_{mu}), rectal (T_{re}), skin (thigh, calf, biceps, and chest), and mean body (T_{body}) temperatures were obtained prior to exercise and over 60 min post-immersion. **Results** Calf and thigh skin temperatures, T_{body}, and T_{mu} were lower in WI14 and WI8 than both WI35 and CON ($p < .05$). Calf skin temperature and T_{body} were lower in WI8 than WI14 ($p < .05$). Decreases in T_{re} from post-exercise to 60 min post-immersion were less in WI35 ($-0.65 \pm 0.30^\circ\text{C}$) and CON ($-0.56 \pm 0.33^\circ\text{C}$) compared with WI14 ($-0.95 \pm 0.33^\circ\text{C}$; $p < .05$), but not different from WI8 ($-0.96 \pm 0.34^\circ\text{C}$). tHb, CVC, and CFA were similar between WI8 and WI14. Compared with CON and WI35, CVC and CFA in WI14 and WI8 decreased by $\sim 28\%$

and ~18%, respectively ($p < 0.05$). tHb in CON was greater than WI14 and WI8, while tHb in WI35 was greater than WI14, but not different from WI8. Relative to pre-immersion, differences were noted for tHb, CVC, and CFA between measurement sites. MAP was greater during all water immersion conditions than CON. Discussion Although WI8 was more effective than WI14 in reducing Tbody, there was minimal difference in the peripheral vasoconstriction. It appears shivering thermogenesis and hydrostatic effects confounded the extent of decline in tHb in WI8 compared with WI35, despite significant muscle cooling. The results indicate vascular beds other than tHb in VL and thigh CVC contribute to overall decline in CFA. Decreases in CVC and tHb during CWI may have resulted from an interaction between suppressed vasodilators (Hodges et al., 2006) and altered baroreflex mediated sympathetic nerve activity (Charkoudian et al., 2004). References Charkoudian et al. (2004) Am J Physiol Heart Circ Physiol, 287, H1658-62. Hodges et al. (2006) J Physiol, 574, 849-57. Contact h.choo@ecu.edu.au

MO-PM11 Physical Activity in Children 1

FITNESS PROFILE AMONG 15 YEAR OLD ADOLESCENTS IN PRISHTINA, KOSOVO

Tishukaj, F.1, Shalaj, I.1, Gjaka, M.1, Ademi, B.1, Pllana, A.1, Wessner, B.1, Tschann, H.2

1. University of Prishtina 2. University of Vienna

Introduction Scientific evidence now indicates that the declining levels of physical activity and fitness in children and youth are associated with adverse impacts on their health, including rising levels of obesity, diabetes mellitus, heart disease, metabolic syndrome and specifically influence young people's health towards adulthood. **Aim** The aim of the current study was to examine gender differences in body composition and physical fitness in 15 year-old adolescents in Prishtina, Kosovo. **Methods** 73 adolescents (n=38 boys; n=35 girls) aged 14.0 ± 0.7 from Prishtina / Kosovo were included in the current research. Anthropometric measurements included weight, height, skinfolds (biceps, triceps, suprailiac and subscapular), waist circumference, and BMI was calculated. Handgrip strength was used to measure arm strength, countermovement jump (CMJ), standing broad long jump (SBJ) and medicine ball throw (MB) were used to assess power of lower and upper extremities, whereas 10 and 20m sprint (10mS; 20mS) were used to measure running speed. Finally sit and reach (SR) and shuttle run test were used to assess flexibility and aerobic endurance (AE) respectively. **Results** Analyses of anthropometric data show no gender differences in weight, BMI, subscapular skinfold, as well as waist circumference ($p > 0.05$). Subcutaneous fat (SUMSF) however was significantly higher in girls compared to boys ($p < 0.001$). Boys performed better in all fitness parameters compared to girls ($p < 0.001$). Weight and height were positively correlated with grip strength, but no correlation was found when analyzed for subcutaneous fat. No correlation in power development was detected among both groups between lower and upper extremities. Horizontal and vertical jump have been significantly correlated ($r = .483^{**}$ for boys; and $r = .593^{**}$ for girls respectively). Aerobic endurance was positively related only to SBJ in boys ($r = .343^{*}$); and SBJ and CMJ in girls ($r = .443^{**}$, respectively $r = .342^{*}$), but not with other fitness parameters. Except MB, SUMSF in boys was shown to be an impeding factor being negatively related to all the other fitness parameters ($r = -.363^{*}$; $-.467^{**}$; $-.491^{**}$; $-.420^{**}$; $-.429^{**}$ for SBJ, CMJ, MSFT, 10mS and 20mS respectively), whereas in girls was correlated to SBJ $r = -.336^{*}$; CMJ $r = -.343^{*}$; MSFT $r = -.389^{*}$; no correlation was noticed in MB, 10 and 20mS. Finally sit and reach test was slightly positively correlated to SUMSF only among boys ($r = .340^{*}$). **Discussion** Current study presents pilot data of an ongoing representative study performed in Kosovo. Subcutaneous fat in this sample was negatively associated to most of the fitness parameters yielding for possible health hazards. faton.tishukaj@uni-pr.edu

A COMPARISON OF CHILD OBESITY PREVALENCE CHANGES USING INTERNATIONAL AND UNITED KINGDOM NATIONAL GROWTH REFERENCES FOLLOWING A 10-WEEK INTERVENTION

Brown, E.1, Cavana, J.2, Wyatt, F.3, Buchan, D.1, Baker, J.1, Kilgore, L.1

University of the West of Scotland

Introduction BMI standard deviation scores (BMI-SDS) are commonly used in children, but a number of issues regarding statistical and epidemiological methods toward this approach of defining child obesity exist. The aim of this study was to compare prevalence changes from a 10-week child healthy weight intervention, Fit for School (FFS), based on International Obesity Task Force, UK1990 clinical, and UK1990 population surveillance child weight scales. **Methods** In order to compare the magnitude of the relationships between weight categories and across scales, the overall available differentiation and logarithmic magnitudes for prevalence changes were determined. To further examine the relationship of scales, Pearson correlations between scoring scales rates of change (ROC) were also calculated. **Results** Using the UK1990 population surveillance scale, a 7% decrease in the severely obese group, 1% decrease in the obese group, 0% change in the overweight group, and increases of 7% and 29% occurred in the underweight and severely underweight categories, respectively. When using the clinical UK1990's definitions, a 1% decrease in severely obese, 10% decrease in obese, 3% decrease in overweight occurred, but underweight increased by 32 percent. The IOTF scale suggested a 2% and 1% decrease in the obese and overweight categories, respectively, and a 1% increase in the thinness grade 1 category with no change in the lower two thinness categories. Significant correlations of ROC were found between each of the scoring scales. There was a correlation of 0.490 between the UK1990 clinical and UK1990 population surveillance ($p < 0.01$), 0.277 between IOTF and UK1990 clinical ($p < 0.01$), and 0.295 between IOTF and UK1990 population surveillance. The use of 3 appropriately deemed BMI scales of child obesity for British children is problematic using the same data set yielding very different results in prevalence changes following an intervention. The results highlight the practical implications of using BMI as an indicator of child obesity. Using an accurate, easy to implement, and comparable measure of child obesity is paramount for decision making regarding government policy and funding. The aim of classifying child obesity should be to determine what degree of overfatness is associated with adverse health outcomes, not how a child's height and weight compares with peers. This may be accomplished through use of a criterion referenced evaluation such as waist-to-height ratio rather than BMI-SDS, a norm referenced evaluation. Contact Elise.brown@uws.ac.uk

EXPLORATORY DEVELOPMENT OF A RISK SCORE FOR CHILDREN'S PHYSICAL ACTIVITY CORRELATES BASED ON THE YOUTH PHYSICAL ACTIVITY PROMOTION MODEL

Fairclough, S.J., Noonan, R., Knowles, Z.R., Boddy, L.M.

Liverpool John Moores University

Background. Identification of the least active children is needed for targeted interventions but this is hampered by the cost and technical complexities of using objective measurement methods, and degree of error in self-report methods. Youth physical activity (PA) is also influenced by multidimensional correlates which are not accounted for by PA measurement tools. Study purposes were to [1] identify predictors of youth PA based on correlates representing 'enabling', 'predisposing', 'reinforcing', and 'demographic' factors described in the Youth PA Promotion Model (YPAPM)1; [2] develop a composite score for PA correlates risk; [3] explore the construct validity of this score. **Methods.** One hundred and twenty children aged 9-10 y (60 girls) provided measures related to PA (PAQ-C), and factors described in the YPAPM (Enabling: 20m SRT, waist circumference, sex; Predisposing: PA enjoyment, PA self-efficacy, perceived sport competence; Reinforcing: parental support for PA, parental PA, peer support for PA; Demographic: Area level deprivation). Multiple regression was performed with YPAPM predictors entered based on their known associations with PA. Significant PA predictors were converted to z-scores, weighted, then summed to form a composite score of PA correlates risk. Scores categorised children into 'normal' and 'high' risk groups2. In the absence of objectively assessed PA as a source of criterion validity, logistic regression was used to explore the construct validity of the risk scores by assessing the odds of children belonging to the high risk group according to self-reported PA3 and fitness status4. **Results.** Significant predictors of PA were perceived sport competence ($p=.016$), parent PA support ($p<.001$), peer PA support ($p=.004$), and sex ($p=.018$). The normal PA correlates risk group included 102 children, the high risk group 18 children. Normal PA correlates risk was associated with children not being at risk of low PA ($OR=7.50$, 95% $CI=2.49$, 22.60, $p<.001$), and being fit ($OR= 5.85$, 95% $CI=1.99$, 17.15, $p=.001$). **Conclusions.** A composite score for PA correlates risk based on a conceptual model of youth PA can be generated from 3 short surveys with a total of 11 Likert scale items. Further work is needed to test the concept of the risk score against objectively measured PA in larger sex-specific samples of varying ages. **References** 1. Welk GJ. *Quest*. 1999; 51:5-23. 2. PARKOUR AS A MEAN TO INCREASE PHYSICAL ACTIVITY IN ADOLESCENTS

Zangerl, R., Ekblom, O.

GIH The Swedish School of Health and Sport Sciences

Introduction Interventions for increasing physical activity levels in children and adolescents show varying results. One commonly reported problem is to attract the least active children. The effect of using the play-like, non-competitive but challenging activity "parkour" as a mean to increase activity has not yet been investigated. Parkour is a holistic training discipline using movement developed from military obstacle course training (1). This paper investigates the participation rate in parkour training and its correlates in a sample of Swedish 10-15 year-olds following a school-based intervention. **Methods** A total of 335 subjects from four different schools were recruited to the study. Their schools were included in a parkour intervention, with extra parkour PE-lessons given and access given to a specially designed training park. One year after the intervention, subjects were interviewed about their sports club membership, habitual physical activity level, number of intervention PE-lessons attended to and participation in parkour activities (frequency and intensity). **Results** Before the intervention, participation in parkour was non-existing. Results showed that following intervention, frequent (>1-2 sessions/week) participants in parkour were more likely to be boys and sports club members ($p<0.05$). However, parkour participants were only slightly more physically active, compared to non-participants. In a logistic regression, gender, sports club membership and physical activity level were all non-significant predictors of frequency of parkour participation. Higher participation in the added specially designed PE-lessons was related to parkour training frequency. Frequent participants trained at a higher intensity compared to less frequent participants. **Discussion** In this study, intervention led to frequent parkour participation in both habitually physically active and inactive children, as well as in children with and without sports club membership. This is encouraging, since earlier interventions have reported problems in attracting less active children. **References** 1. Angel, Julie (2011). *Cinê Parkour*. pp. 17-20. ISBN 978-0-9569717-1-5. RELATIONSHIP BETWEEN OBJECTIVELY MEASURED PHYSICAL ACTIVITY AND FMS IN CHILDREN

Uvacsek, M.1, Makó, L.1, Tóth, M.1, Johnson, A.W.2, Vehrs, P.2, Mitchel, U.2

1: SU (Budapest, Hungary), 2: BYU, (Provo, USA)

Introduction Little objective data have examined the effectiveness of physical education (PE) in schools to augment students' physical activity (PA) level. We believe that PE is one of the most important methods to increase PA among school aged children. Most studies have shown that students spend less than 50% of PE class time in moderate to vigorous PA (MVPA) (Fairclough és Stratton 2006, WHO 2008). The Hungarian government decided to facilitate an increase in the amount of PA in children with the introduction of everyday PE in schools. This study aimed to examine the PA levels of children during school days, after the change to everyday PE lessons and to examine the relationship between functional movement (which includes flexibility, stability, and strength requirements) and measured PA, and the differences between boys and girls in these variables. **Methods** Thirty-seven 9-13 yr old children participated in the study, and after statistical data filtering, 32 children' data were analyzed (19 boys and 13 girls). The body dimensions were taken following the ACSM' recommendations, the activity were measured using GT3X ActiGraph equipments. The PA was detected on 5 weekdays using 5sec. epoch length. Functional movement was measured via the Functional Movement Screen (FMS). Descriptive statistics were calculated using the STATISTICA software version 11.0, the gender differences were analyzed with t-tests. **Results** Boys were heavier and participated in significantly more MVPA/day than girls. Boys spent significantly more time (23.46%) of their school time in MVPA compared to girls (17.87%). Girls achieved higher scores in FMS than boys, and we found a weak opposite relationship ($r=-0.34$) between the measured PA and FMS. **Conclusion** Everyday PE is significantly contributed to the daily MVPA, and thus most of the children reached the 60 min. daily recommendation during school time. The boys' activity was higher; however, the girls' functional movement ability was better. From our results, we note that a higher PA does not necessarily relate to better functional movement. **References** Fairclough, S.J., Stratton, G. HOW ACTIVE ARE GERMAN CHILDREN AND ADOLESCENTS AND WHERE SHOULD ACTIVITY PROMOTION FOCUS ON IN FUTURE?

Manz, K., Schlack, R., Poethko Müller, C., Mensink, G., Finger, J., Lampert, T.

Robert Koch-Institut

Introduction Physical activity during childhood and adolescence has numerous health benefits, while sedentary behavior, especially electronic media use, is associated with the development of overweight (Janssen & LeBlanc 2010, Rey-Lopez et al., 2008). Therefore, the promotion of physical activity during childhood and adolescence is an integral part of national public health efforts. The aim of this study is to describe the daily physical activity behavior, sport and sport club participation of German children and adolescents based on the nationwide data of the German Health Interview and Examination Survey for Children and Adolescents (KiGGS Welle 1). Furthermore, the association between physical activity and sports participation and use of screen-based media in youth aged 11 to 17 years should be analyzed. **Methods** The analyses included data from 10.426 children and adolescents aged 3-17 years collected by telephone interviews. Children older than eleven years answered the questions by themselves, whereas a parent was interviewed for younger children. The descriptive analyses were performed under consideration of social and demographic factors. Results 77.7% (95% CI 76.3-79.1) of the children and adolescents participated in sports activities, and 59.5% (57.9-61.1) were members of a sports club. Children and adolescents with a low socioeconomic status (SES) participated more seldom in sports activities than children of higher SES groups (low: 68.1% (63.7-72.2), middle: 79.0% (77.4-80.5), high: 85.7% (83.9-87.4)). The recommendation of the WHO to be physically active at least 60 minutes per day was achieved by 27.6% (26.2-29.1). Especially adolescent girls had a low compliance [8.4% (6.4-10.9)]. Further analysis of the data like logistic regressions and the association between physical activity and media use are under progress. **Conclusion** First results indicate that preventive measures should promote the daily physical activity of children and adolescents with focus on adolescent girls and additionally encourage children and adolescents with low SES to participate in sports activities. **References** Janssen I, Leblanc AG (2010) Systematic review of the health benefits of physical activity and fitness in school-aged children and youth. *Int J Behav Nutr Phys Act* 7:40 Rey-Lopez JP, Vicente-Rodriguez G, Biosca M, Moreno LA (2008) Sedentary behaviour and obesity development in children and adolescents. *Nutr Metab Cardiovasc Dis* 18:242-251 manz.kristin@gmail.com

WHERE DOES THE TIME GO? PATTERNS OF DAILY PHYSICAL ACTIVITY IN ADOLESCENT YOUTH AS MEASURED BY ACCELEROMETER

Belton, S.I, Issartel, J.I, McGrane, B.I, Powell, D.I, O'Brien, W.2

Dublin City University

Where does the time go? Patterns of daily physical activity in adolescent youth as measured by accelerometer 1. School of Health and Human Performance, Dublin City University, Ireland. 2. College of Arts, Celtic Studies and Social Sciences, University College Cork, Ireland **Introduction** Despite known benefits of regular physical activity for health and well-being, many studies suggest that levels of physical activity in young people are low, with the majority of youth not meeting the minimum 60-minute daily moderate to vigorous PA (MVPA) guideline for health. The purpose of this study was to explore daily patterns of physical activity in early adolescent youth, and identify whether those meeting the 60-minute daily guideline exhibited a different daily PA pattern to those not meeting the guideline. **Methods** 716 adolescents (11 – 13 years) were asked to wear an Actigraph accelerometer for a 9-day period, and had their height and weight measured. BMI was calculated and classified using the Cole et al. (2000) cut points. Accelerometer data sets were included in analysis if participants had > 10 hours wear time for a minimum of 3 weekdays and 1 weekend day. Data was processed applying the Evenson et al. (2008) cut points to give average daily, weekday, weekend day, before school, lunch time, after school, and evening minutes of MVPA. Results 415 participants met the inclusion criteria and had data included in analysis. Based on BMI 76.2% of participants were classed as normal weight, 21% overweight, and 3% obese. Participants accumulated an average of 52 minutes of MVPA per day, and were significantly more active on weekdays than weekend days ($p = 0.000$). 66% of participants met the minimum 60-minute daily MVPA guideline. Both males and females were significantly less active in the evening compared to the other three time periods ($p < 0.001$). Participants that met the 60 minute PA guideline were significantly more active than those that didn't in the lunchtime, after school and evening periods (all $p < 0.001$), but no significant differences were observed in the before school period. **Conclusion** Understanding patterns of PA participation in youth should be a central concern in the development of targeted PA interventions. Findings suggest that those meeting the guidelines are accumulating their 60 minutes across the day- being more active than those not meeting the guidelines in the school lunchtime, afterschool and evening periods. This would point to these three-time periods as potential times when less active youth have scope to increase their activity levels. Future research should examine the reasons when some youth choose to be active during these periods while others don't, with a view to developing strategies for intervention. **References** Evenson KR, Cattellier D, Gill K, Ondrak K, McMurray RG. *J Sports Sci.* (2008)26:1557-65. CHANGE IN SALIVARY BIOMARKERS OF THE CHILDREN AND ADOLESCENTS IN A TSUNAMI DISASTER AREA.

Sakamoto, Y.1, Suzuki, K.2, Okazaki, K.2, Sasaki, K.2, Ueki, S.3

1: Tohoku Institute of Technology (Japan), 2: Tohoku Gakuin University (Japan), 3: Tohoku Bunka Gakuen University (Japan)

Introduction It has been reported that change of life style and physical activity related environment under the influence of the Great East Japan Earthquake 2011 brings about the decrease of physical activity levels of the children and adolescents of disaster areas. The decrease of the physical activity in children and adolescents of growth period also may have an influence to psychosomatic health. The purpose of this study is to clarify the actual condition of salivary biomarkers (saliva flow (SF), cortisol concentration (COR), secretory IgA (SIgA) concentration and SIgA secretion rate) in children and adolescents living in a town affected by the earthquake and tsunami 2011. **Methods** The participants were 403 elementary and junior high school students aged 9-13 in the town of Onagawa (where housing damage affected 60% of participants). The survey was performed in September 2011 (the disaster after 6 months), March 2012 (after 1 year) and March 2013 (after 2 years). Whole saliva samples were collected using Sali-kids salivette tube, and SF (ml/min), COR ($\mu\text{g/dL}$), SIgA concentration (SIgA-C: $\mu\text{g/ml}$) and SIgA secretion rate (SIgA-SR: $\mu\text{g/min}$) were determined. Results The SF and COR was significantly decreased after 2 years comparison with disaster after six month and/or one year, but SIgA-C was significantly increased after 2 years. In addition, these results were the same even when it classified and analyzed for every elementary and junior high school students. On the other hands, SIgA-SR did not have the significant change. **Conclusion** Although the factor, which has on the salivary biomarker, can-

not be specified, these results suggest the possibility that the decrease of the physical activity caused by the disaster has an influence on the mental and physical health of the children and adolescents. Contact: u_sakamoto@tohtech.ac.jp

FUNDAMENTAL MOVEMENT SKILLS OF PRESCHOOL CHILDREN IN NORTHWEST ENGLAND

Foulkes, J.D.1, Stratton, G.2, O' Dwyer, M.3, Knowles, Z.1, Ridgers, N.D.4, Fowweather, L.1

1: Liverpool John Moores University, 2: Swansea University, 3: Early Childhood Ireland, 4: Deakin University

Introduction Despite being considered the initial building blocks for more complex movements, research into the development and competency of fundamental movement skills (FMS) among typically developing young children is sparse. The aim of this study was to gather data on FMS among preschool children in England, with the additional aim of exploring gender differences in FMS. **Methods** A total of 240 children were recruited (mean age 4.5, SD \pm 0.6, 51.7% boys), from which 210 children completed FMS analysis. For this study 12 FMS skills were assessed by video analysis, six locomotor and six object control, following procedures outlined by Ulrich (2000). FMS competency was assessed in accordance with Williams et al (2009), performance criteria were scored as absent (marked as 0) or present (1). A FMS total skill score (TSS) was calculated for each child by summing the number of performance criteria present for both trials across the twelve skills, locomotor and object control TSS were obtained by summing the number of criteria present across both trials for the skills in each subscale. Component scores (CS) for individual skills were attained by totalling the number of criteria successfully demonstrated across both trials. Gender differences were examined using t-tests and the Mann-Whitney U test. **Results** There was no significant gender difference found for FMS. Although boys had a significantly higher object control TSS ($P = .01$), with significantly higher CS for the kick ($z = -4.73$, $P = .000$) and overarm throw ($z = -2.88$, $P = .004$). Although not significant, girls performed better than boys at locomotor skills, achieving significantly higher CS for the run ($z = -2.86$, $P = .004$), hop ($z = -2.88$, $P = .004$) and gallop ($z = -2.86$, $P = .004$). **Discussion** This is the first study to report FMS competency among English preschool children using a process based measure. The greater proficiency of boys at object control skills corresponds with the findings of previous studies (Goodway et al., 2010). This study's findings could help to inform practitioners, influencing their teaching and coaching of object control skills, helping to ensure girls receive the relevant practice, instruction and encouragement, in order to help reduce the gender difference in FMS proficiencies in the preschool years and beyond. **References** Goodway J. VALUE THEORY: A NEW PARADIGM FOR SPORT PSYCHOLOGY?

Whitehead, J., Lambert, J.

University of Brighton

Introduction Values are enduring beliefs about what is desirable. They determine individual priorities and transcend situations, thus providing standards to guide decision-making and behaviour. Although the value theory of Schwartz (1992) has been widely studied in social psychology, it has been relatively neglected in sport. This paper outlines how value systems and value structure interact, how values influence achievement goals, attitudes, and behaviour, and how an understanding of value structure underpins effective intervention for value change in conflict situations, e.g. between winning and playing fairly. **Method** The paper summarises the development of the Youth Sport Values Questionnaire (YSVQ: Lee et al., 2000) and the Youth Sport Values Questionnaire-2 (YSVQ-2: Lee et al., 2008) by a range of qualitative and quantitative methods. It compares youth sport value systems across 9 nations spanning 5 continents, and with a global hierarchy of human values. Path models are used to confirm hypotheses about the effect of values on other variables, and a field study illustrates the teaching of values through soccer in a divided society (Whitehead et al., 2013). **Results** The UK youth sport value system shows values of enjoyment and personal achievement rank first and second followed by group of socio-moral values including sportsmanship, fair play and keeping a contract, with winning in last place. Values ranked at the extremes of the hierarchy are consistent across nations and these rankings correspond with the global human value system when age differences are considered. Values directly predict attitudes and motivational variables representing achievement goal theory and self determination theory. **Discussion** An interactionist model for development of the research field is presented. Current findings are summarised, value theory is compared to achievement goal theory, and further research is proposed. Applications are discussed in relation to mechanisms for intervention and value change. **References** Lee, M.J., Whitehead, J. & Balchin, N. (2000). CORPORAÇÃO PROJECT: PRACTICE OF SPORTS IN THE COMPANY FOR PSYCHOLOGICAL ABILITIES' DEVELOPMENT

Analha, G.O., Kishimoto, S.T., Yoshida, H.M., Ferndandes, P.T.

State University of Campinas - UNICAMP

CORPORAÇÃO PROJECT: PRACTICE OF SPORTS IN THE COMPANY FOR PSYCHOLOGICAL ABILITIES' DEVELOPMENT Faculty of Physical Education State University of Campinas/UNICAMP - São Paulo, Brazil **Introduction** Sports in corporate environment, besides stimulating bio motor capabilities are also a means of development for psychological skills. In this concept, the "Corporação" (Body and Action) project has been created and carried out at Estre Institute, through sports practice (team sports such as soccer, basketball, volleyball and hand-

ball; martial arts as Kung Fu and Brazilian Capoeira; Gymnastics – artistic gymnastics, rhythmic, general and aerobics gymnastics; Dances – contemporary dance and Brazilian rhythms) to develop psychological skills as assertiveness, social skills and resilience. In this research, the goal was to analyze how sports from “Corporação” influenced the development of the team’s ability for resilience. Methods Sports practices were applied to 12 employees over a period of 4 months, on 3 weekly meetings, totaling 32 meetings and 16 hours. The analysis was based on behavioral data from individuals and research on project documents, which was the resilience questionnaire adapted from Wagnild & Young (PESCE et al., 2005), reviewed by Angelo e Rubio (2007) applied before and after this period. Results The results showed that after sports practices were carried out, company’s staff developed resilience ability, increasing average from 124.5 to 137.6 ($p = 0.024$), according to the resilience questionnaire. Discussion Given the results, we can say that the practice of sports was important for the development of the group’s resilience. Thus, sports practiced in companies, may influence the development of psychological abilities and can also promote more sustainable interpersonal relationships. FACTORS INFLUENCING POPULARIZATION OF RECREATIONAL RUNNING. A PILOT STUDY ON POLISH RUNNERS

Czajka, K.1, Stannard, A.B.2, Pluta, B.1

1: AWF (Poznan, Poland), 2: MSU (Lansing, MI, USA)

Introduction Running is becoming a popular recreational activity especially in society of new members of EU, also in Poland according to report of PSB (Paskal, 2013). It is important to learn more about various factors that encourage people to run and participate in recreational road races. The purpose of this pilot study was to determine the reasons why Polish runners decide to run recreationally, to compete in races and how they rate the impact of various factors in promotion of recreational running. Methods Recreational runners living in the city of Poznan, Poland were recruited to participate in the study via word of mouth ($n=40$). Participants completed a questionnaire on the impact of various factors that encouraged them to participate in running. Likerts scale was used to rate the factors that influenced the runners to become involved in running and in competing in recreational races. Descriptive statistics were used to present demographic data and to analyze survey responses. Results Age of runners, educational level and gender was reported in this study. All runners were employed and one was retired. The most significant factor influencing involvement in recreational running was family and friends (55%). Organized local races influenced runners in a large (35%) and small (33%) degree respectively. Media and school setting had no or small influence. Organization of races was the only significant factor that impacted runners’ decision to begin competing in races (50%). Runners rated the efforts of organizing local races as good and very good (43% and 20%, respectively). Efforts of schools in promotion of running activities were rated low (75%). Infrastructure and media efforts were relatively evenly distributed. Discussion Family and friends had the greatest impact on initial participation in recreational running. Organization of local races encouraged Poles to become active runners as well as to compete in local races. However, runners reported that schools did not impact their participation in running activities and they rated the efforts of schools in promotion of recreational running as low. The impact of media and infrastructure on recreational running activities was inconclusive. Research on motivation to being physically active was observed from different point of view in paper (Romanowska-Tolloczko et al., 2012). Future studies need to examine factors influencing engagement in recreational running and racing on larger, more heterogeneous population. Socioeconomic factors also should be examined in greater extent. References H. Paskal, Statistics of road races in Poland 2011–2013, Annual Conf. of Polish Road Races Assoc., November 21–23, 2013, Trzebnica (Poland). A. Romanowska-Tolloczko, J. Marciniuk, (2012), Rozprawy Naukowe AWF we Wrocławiu (in polish), 38, 22-25.

A STUDY ON THE ASSERTIVENESS LEVEL OF PHYSICAL EDUCATION AND SPORTS COLLEGE STUDENTS

Erbasi, F.M.1,2, Erdogan, B.S.2, Eraslan, M.2, Aldemir, G.Y.3, Sahan, H.1, Kaya, E.4

1:AU(Antalya,Turkey), 2:MAKU(Burdur,Turkey), 3:MU(Istanbul,Turkey), 4:AIKU(Ağrı,Turkey)

Introduction The purpose of this study is to examine some of the variables in the level of students’ boldness who study at Physical education and sports colleges and to compare the findings with the other studies in the literature. Method The Research Group contains 92 male and 64 female ($\text{age} = 21,612 \pm 1,921$), in total 156 students from Selcuk University physical education and sports college. In order to reach the purpose of the study “Rathus Assertiveness Schedule” has been used as the methodology which is developed by Rathus (1973 and 1977), and adopted to Turkish by Voltan (1980). For the interpretation of the data, the Kolmogorov-Smirnov test, one way anova test have been applied and to determine the difference between the groups Turkey test has been applied too. The significance was $P < 0.05$. Results According to the level of sports; the difference between the average levels of scores of the assertiveness is meaningful (t value = 4,327 $P = 0,000 < 0,05$). Looking at average values; average levels of the assertiveness of students doing some sports is ($=86,5614$), average levels of the assertiveness of students doing some sports is ($=80,7857$) As a result of this study; According to the level of sports observations, the difference between the average levels of scores of the assertiveness is meaningful (t value = 4,327 $P = 0,000 < 0,05$). Discussion Looking at average values we see that students, who engaged in sports, has been obtained more level of average score of assertiveness than students engaged in no sports. From the point of assertiveness, participation in sport from the perspective of individuals there is a difference in favor of those engaged in sports References Rathus, S. A., & Nevid, J. S. (1977). ANALYZING THE CONNECTION LEVEL OF THE STUDENTS IN SCHOOL OF PHYSICAL EDUCATION AND SPORTS BETWEEN THEIR MOODS AND THE ACHIEVEMENT GOAL CORRELATION

Baykose, N., Sahin, A.2, Acar, G.3, Eravsar, H.4, Yildiz, M.5, Sakar, M.6

1:SU(Konya,Turkey), 2:MAEU(Burdur,Turkey), 3:KU(Kastamonu,Turkey), 4:AU(Antalya,Turkey), 5:MU(Mugla,Turkey), 6:AU(Adiyaman,Turkey)

Introduction The purpose of this study was to analyze the connection level of the young students in School of Physical Education and Sports between their moods and the achievement goal correlation. Methods Research groups included 224 students who are in the faculty of BESYO in Antalya, 125 of whom were men and 99 of whom were women ($\text{age}=22,08 \pm 2,593$). Achievement Goal Orientation Questionnaire developed by Midgley, 1998 and translated into Turkish by Akın (2006) and Positive and Negative Affectivity Schedule developed by Watson Clark and Tellegen (1988) and translated into Turkish by Gençöz (2000) were used to reach the purpose of this study. Significance level $P < 0,05$ and $P < 0,01$ were obtained by using Pearson Correlation during the process of data’s analysis and inter-

pretation . SPSS (Statistical package for social sciences) was used to find and examine the data. Result As a result negative connection ($r=-.157$) between sub dimensions of achievement goal orientation and avoidance of performance and positive and nonlinear correlation were obtained ($P<0.05$). Positive and linear correlation was concluded at the level of meaningfulness ($P<0.01$) in the other sub dimensions achievement goal orientation. Discussion As a result of this study while the students having positive mood adopted performance- approach achievement orientation more in comparison with the students having negative mood, the students having negative mood adopted performance- avoidance achievement orientation more in comparison with the students having positive mood. EFFECTS OF LIGHT PHYSICAL ACTIVITIES ON INACTIVE STUDENTS' MOOD IN DAILY LIFE: AN AMBULATORY ASSESSMENT STUDY

von Haaren, B., Stumpp, J., Shammass, L., Hey, S., Ebner Priemer, U.

Karlsruhe Institute of Technology

Introduction Acute and regular exercise and physical activity are related to wellbeing and positive affect. Even short bouts of unstructured physical activity can improve positive affect in daily life (1). Despite the "feel better effect" of physical activity, too many people are inactive. Light physical activities (1.6 – 2.9 MET) frequently occur in daily life and are less aversive than high intensities. Thus, they may offer a potential for inactive people to adopt an active lifestyle. This study examined if an association between light activities and mood can be observed in inactive young adults in daily life. Methods 60 inactive students (max. 1x active/week) were monitored on two subsequent days during their daily routine. Physical activity was assessed continuously via accelerometry. Mood was operationalized by three basic dimensions, valence, energetic arousal and calmness. A six-item short scale (2) of the Multidimensional Mood Questionnaire (MDBF) was used and applied to electronic diaries. Participants had to rate their current mood state every two hours (10am-10pm) based on the statement "At the moment I feel..." on a scale from 0 (not at all) to 6 (very), with two bipolar items for each dimension. The sum of minutes spent in light physical activity was calculated over the 15 minute interval prior to every diary prompt. Results Across all 984 diary prompts, participants had a mean value of 4.4 (± 1.1) for valence, 3.8 (± 1.3) for energetic arousal and 4.5 (± 1.1) for calmness. Across the two days of monitoring, participants spent on average 2.7 (± 1) minutes per hour in light activities. To test if light activities predicted subsequent mood state, multilevel analyses will be conducted after the final dataset is completed (middle of February). The results will be presented at the conference. A pilot study showed significant results ($\beta=0.67$; $t=2.4$; $p=.019$) for the association between activity intensity and subsequent mood state ($N=30$). Discussion In inactive young students, even activity episodes of light intensity seem to be sparse. To intensify the examination of the mood enhancing effects of light activity, interventions inducing light activity in daily life should be conducted and combined with frequent mood assessments. STUNKARD IMAGES, BMI AND PERCEPTION OF STRENGTH AND SELF-ESTEEM IN A SAMPLE SIZE OF SPANISH SCHOLARS

Pulido, J.J., Sánchez Miguel, P.A., Chamorro, J.L., Sánchez Oliva, D., Amado, D., González Ponce, I., Leo, F.M.

UNIVERSITY OF EXTREMADURA

Introduction Body fat is often measured by an objective assessment of body mass index (BMI), which is determined by height and weight, and reported in units of kilogram/meter squared (kg/m^2). Furthermore, body fat can be subjectively tested by the Stunkard figure Rating Scale, which uses gender-specific body figures. Both types of measurements are very common in order to know the relationship between body weight and different consequences (Lo, Ho, Mak, & Lam, 2012). On the other hand, adolescent is a period with great changes at psychological levels. Thus, the aim of this study was to examine the relationships between BMI, Stunkard figure Rating Scale and perception of strength and self-esteem in youth scholars from Extremadura (Spain). Methods The sample was formed by 1042 youth scholars from Extremadura (Spain), both male ($N = 510$) and female ($N = 532$), ranging in age from 15 to 17 years old ($M = 15.42$; $SD = 0.86$), belonged to different High Schools from Extremadura (Spain). Participants were measured through height and weight, and were asked to select the figure that best resembled their current body size on the Stunkard's figure rating scale. Finally, the adaptation into Spanish by Moreno & Cervelló (2005) of the Physical Self-Perception Profile (Fox & Corbin, 1989) was used to measure perception of strength and self-esteem. Results The outcomes revealed normal values in BMI in participants ($BMI = 21.74$), and Stunkard figure rating Scale. Moreover, results showed a significant relationship between BMI, Stunkard's current body size and perception of strength and self-esteem. Furthermore, self-esteem emerged as a strong predictor of estimated physical dissatisfaction. Discussion The results showed the importance of the body size and body status in order to have a good perception of strength and self-esteem. Besides, these outcomes revealed the importance to have an adequate body status in order to improve psychological factors. Hence, the outcomes are discussed with other studies to compare findings. Finally, the study concluded that current body size is a potentially useful indicator to measure weight status of adolescents when assessed and self-reported are not available. Further investigations are needed to enhance the knowledge about body status. References Fox KR, Corbin CB. (1989). *J Sports Exe Psy*, 11, 408-430. Lo WS, Ho SY, Mak KK, La TH. THE ANALYSIS OF TEACHER SELF-EFFICACY OF PHYSICAL EDUCATION INSTRUCTORS ACCORDING THEIR ACTING AREA

VENDITTI JR, R., VENDITTI, A.C., ZAGATTO, A.M., SANTOS, J.W.

UNESP (UNIVERSIDADE ESTADUAL PAULISTA), SERVIÇO SOCIAL DO COMÉRCIO (SESC)

Introduction: Self-efficacy concept is characterized as the beliefs on individual capacities of organizing courses of action, which are necessary to the achievement of certain tasks directed to a goal setted (BANDURA, 1997). In this study, the self-efficacy is applied on the comprehension of the internal control of belief perception which involves the teaching in Physical Education (PE), specifically for the Adapted Physical Education (APE) area (VENDITTI JR, 2005). The fact of the PE configures itself full of contends and practical body activities reinforces the need of understanding the phenomenon of the self-efficacy in a singular applied ways: the discipline criteria and evaluate methods, space of the classes and its practical contends, show the need of special attention to differential details of PE teaching in different areas inside PE practices. **Methods:** Through 3 psychometrical instruments applied on 44 acting professionals of the field, we can highlight some factors and aspects related to teacher self efficacy, dividing the research group in 5 areas of acting: adapted physical education; school; fitness; sportive training and leisure. We applied the self-efficacy scales (VENDITTI JR, 2005) using cluster analysis and non-parametrical tests. The question is the analysis of the possible contributions of the self-efficacy and its association with professional motivation, satisfaction, professional acting preferences and availability for the PE teaching continuity. Moreover, associations to the perception of competence arise, as well the security, engagement and contend mastery for the PE teaching in the inclusive PE environment. **Results:** The results show the associations of self-efficacy with the teaching motivational questions through their personal satisfaction and availability to continue with the teacher PE career, as well the levels of efforts and persistence. There are also relations related to the professional career influence and the self-efficacy configuration to the PE professional, which really worships the outcome expectations, the performance and the direct evaluation of the body activities of its students as parameters related to their teaching skills. **Discussion:** Among the interviewed professionals the highest levels of teacher self-efficacy were the teachers with preferences of acting on the sportive training area, followed by those who chose the APE. The social cognitive perspective and the proposals of the reflexive teaching showed themselves as excellent referentials, and complement the discussion about the teaching beliefs, professional career and PE educational acting. We also point the needing of specifics trainee stages in APE to reinforce the self-efficacy levels of the teachers in the research. **References:** BANDURA, A. TRACTION FORCE AND HEART RATE DURING TETHERED SWIMMING USING 2 DIFFERENT PROTOCOLS

Lampadari, V.1, Thanopoulos, V.1, Rozi, G.1, Dopsaj, M.2, Okicic, T.3, Geru, E.4

National & Kapodistrian University of Athens

Introduction Tethered swimming is one of the most popular forms of training in swimming in order to improve strength (Maglischo, 2003). Specific strength training in water is more efficient for improvement of swimming performance (Tanaka & Swensen, 1998). The purpose of the present study was to compare traction force and heart rate produced in freestyle tethered swimming with maximum intensity using the protocol of a) three strokes followed by one breath, and b) six strokes followed by one breath. The duration of both tests was equal to the individual maximum performance time of 100m freestyle. **Methods** The sample consisted of 10 competitive female swimmers, aged 16.0 ± 2.0 years, BH 166.8 ± 4.5 cm and BW 56.3 ± 2.0 kg. Their basic swimming style was freestyle and all of them were swimmers of small and middle distances. In order to determine the maximum performance time of 100m freestyle swimming, a 100m freestyle test of maximum intensity was measured in a 50m outdoor pool. All tests were completed in 3 different sessions. Heart rate and traction force was measured after each session. **Results** The results were first submitted to a descriptive statistical analysis (averages and standard deviations). In order to identify differences between swimming with one breath followed by 3 strokes and 6 strokes, ANOVA analysis was used. The level of significance was set at $p < .005$. The mean maximum strength in the protocol of one breath followed by 3 strokes was 149.4 Newton and in 6 strokes was 136.3 Newton. The results showed that no significant statistical differences were found in maximum strength, mean strength and heart rate between the two different swimming protocols (Sig. .234, .217, .547, respectively). **Discussion** Results showed that strength and heart rate of swimmers is not influenced by changes in breathing frequency in maximum swimming efforts. The results of this study provide useful information for swimming coaches, for the strength produced during swimming. **References** Maglischo E. (2003). JOINT-SPECIFIC POWER CONTRIBUTION AT INCREASING DOUBLE POLING INTENSITIES

Danielsen, J., Sandbakk, Ø., Ettema, G.

Norwegian University of Science and Technology

Introduction The double poling (DP) technique in cross-country (XC) skiing is a complex and dynamic whole-body movement. One DP cycle can be divided into a poling phase, where the propulsive forces are generated, followed by a retrieval phase, where the body is repositioned and mechanical (potential+kinetic) energy (ME) increases. Although it is known that dynamic upper body and leg work both are of high importance in DP, the specific role and relative contributions from the various upper and lower body joints and interaction with ME requires further examination. Therefore, the present study performed an inverse dynamics analysis to investigate the joint-specific power and ME contributions at low, moderate and high DP intensities in a double poling ergometer. **Methods** Six male XC skiers (age 22 ± 5 yrs, body mass 80.3 ± 5.5 kg, VO_{2max} 5.9 ± 0.6 L min⁻¹) completed three 4-min submaximal stages at low, moderate and high intensities on a modified Concept2 SkiErg. All exercises were performed on a Kistler force platform and the SkiErg was equipped with a

Kistler force cell, while reflective markers (Qualisys motion capture) were positioned on anatomical landmarks. All data were collected and synchronized in the Qualisys system. By applying inverse dynamics, individual joint powers (ankle, knee, hip, shoulder and elbow) and ME were calculated for the poling and retrieval phase, and for the complete cycle. DeLeva (1996) was used for estimates of body segments mass and inertia. Results Net DP power increased from low to high intensity (109 ± 11 , 170 ± 20 , and 215 ± 31 W, $p < 0.001$). Relative to net DP power the upper body contribution were 27, 29, and 31%, while the lower body contribution were 39, 39, and 44% at low, moderate and high intensities. More specifically, the relative ankle, knee, hip, shoulder and elbow powers were within 4-6%, 3-4%, 32-35%, 21-27%, 4-6% respectively, and hardly affected by intensity. Movements in the pelvis and trunk were not differentiated in this study but may account for 25-30%. During poling most power was produced by the upper body (~37%) and by utilization of ME (50-60%) while some absorption took place in the lower body. The retrieval phase was characterized by positive power produced by the lower body (almost 100% of total joint power) and thus an increase in ME. Discussion This study demonstrates that most power is produced in the body's core (hip, shoulder and pelvis-trunk) during DP. Although the various segments have different roles in the poling and retrieval phase, the relative power produced during a whole cycle remains evenly distributed over upper and lower body and is unaffected by intensity. The exchange of joint power and ME is essential for the lower body's contribution. References DeLeva P (1996) J Biomech, 29, 1223-1230. Contact jorgend@stud.ntnu.no

THE EFFECT OF CARBON INSOLES ON LEFT AND RIGHT BALANCE IN CYCLING

Koch, M.1, Fröhlich, M.1, Weiler, B.2, Emrich, E.1, Urhausen, A.2,3

1:Saarland University (Germany), 2: Clinique du Sport (Luxembourg), 3: Sports Medicine Research Laboratory (Luxembourg)

Introduction: In cycling, athletes with a more or less asymmetric body structure intend to move the crank-set on a symmetric bike with a set and fixed positioning of saddle, handlebar and pedals. To compensate the body's asymmetry, cyclists actively adapt their movement to the static bike, which could lead to overuse injuries and reduced power output. Special insole devices made of carbon are expected to influence the biomechanical structures of the foot and the linked body parts such as leg, hip, and spine in such a way that asymmetries are reduced (Jeukendrup & Martin, 2001). Hence, by using the insole devices, the power output should be higher in total and the power of the left and right leg should be more balanced (Schmidt et al., 2011). Methods: The effects of cycling-specific carbon insoles were evaluated with respect to their impact on the lateral difference of the left and right leg during a steady-state test with sub-maximal load and in an isokinetic maximum test. 8 male cyclists and 2 male triathletes (age: 26.2 ± 5.6 years, height: 181.0 ± 5.1 cm, mass: 76.6 ± 4.4 kg, foot length 28.3 ± 1.0 cm, mean power in test: 804.1 ± 114.6 Watt) at least at national level were tested twice for lateral difference in a randomized blind application regarding (a) mean power, (b) tangential force, and (c) efficiency during 30 s at 280W steady-state resistance with randomized application of a standard insole or the cycling-specific carbon insole. The same parameters were measured twice during a 20 s isokinetic maximum test. Results: There was no general significant difference in all tests between the carbon insole and the standard insole. The lateral power difference was reduced from $19.3 \pm 15.4\%$ with standard insoles to $18.2 \pm 10.7\%$ in the sub-maximal test and from $11.5 \pm 6.4\%$ to $10.4 \pm 4.2\%$ in the isokinetic max test. Additionally, the tangential force difference between the left and right leg was reduced in both subtests with 1% (sub-maximal) and 0.2% (isokinetic max test), respectively. Meanwhile, the lateral difference of the efficiency increased from $11.5 \pm 10.3\%$ to $11.7 \pm 11.3\%$ in the sub-maximal test and from $4.2 \pm 4.1\%$ to $4.6 \pm 3.7\%$ in isokinetic max test. Discussion: At an individual level, the cycling-specific carbon insoles show partly positive effects in terms of three parameters, however, the overall result is not conclusive. THE EFFECT OF CADENCE ON HIP, KNEE AND ANKLE CONTRIBUTION DURING CYCLING EXERCISE.

Skovereng, K., van Beekvelt, M., Ettema, G.

Norwegian University of Science and Technology

Introduction During cycling, power is produced mainly by muscles spanning the hip knee and ankle joint and is transferred to the pedals. Both work rate and cadence have been shown to affect efficiency during cycling (Ettema and Lorås 2009) and is also thought to influence technical variables. Increasing hip joint contribution has been shown with increasing work rate (Elmer et al 2011), but the effect of cadence has been investigated to a far lesser extent. Accordingly, the purpose of the present study was to investigate the effect of cadence on the hip, knee and ankle joint contribution during cycling exercise. Methods 27 male recreational cyclists ($\text{VO}_{2\text{peak}}$ 53.0 ± 5.6 ml/kg/min) participated in the study. The participants cycled at approximately 75% the workload corresponding to the onset of blood lactate accumulation. All subjects cycled six four-minute stages at 60, 70, 80, 90, 100 and 110 rpm. The joint power contribution was calculated using inverse dynamics for measured pedal forces and kinematics. Results Hip joint percentage contribution decreased significantly as cadence increased from $42.8 \pm 6.8\%$ at 60 rpm to $18.1 \pm 7.8\%$ at 110 rpm. Correspondingly knee joint contribution increased from $44.9 \pm 7.2\%$ at 60 rpm to $72.1 \pm 7.4\%$ at 110 rpm. Ankle joint contribution decreased from $12.4 \pm 3.9\%$ at 60 rpm to $9.8 \pm 3.0\%$ at 110 rpm but the change was not significant. Discussion The main finding of the present study was a decreasing contribution of the hip joint and increasing contribution from the knee joint in power production as cadence increased. The very clear differences in percentage joint contribution between hip and knee joint at different cadences indicate that there are distinct technical differences in cycling technique at different cadences. Elmer (2011) reported hip extension to be the most powerful action during high intensity cycling. Also Mornieux et al (2007) reported a larger hip contribution at high work rates. In accordance with these previous studies, our results indicate that low cadence at a medium intensity, have a larger hip contribution and thus resemble more the action at high intensity. THE EFFECT OF SEAT TYPE ON KINEMATICS DURING MAXIMAL KAYAK ERGOMETER PADDLING

Willmott, A.P., López Plaza, D.

University of Lincoln

Introduction Kayakers have traditionally used a fixed seat but in 2005 a "swivel seat", able to rotate in the horizontal plane, was approved for use in races. To date only limited data are available with regard to how the swivel seat influences technique and performance. The aim of this study was to investigate the effect of the swivel seat on kinematics during maximal intensity paddling on an ergometer. **Methods** Nine experienced kayakers (five male and four female) completed two maximal trials of 30 s duration at a free pace on a Lawler ergometer, one with a Nelo swivel seat and the other with a fixed seat. Flywheel, trunk, arm, leg, seat and paddle kinematics during the middle 10 s of each trial were recorded at 200Hz using eight Qualisys ProReflex MCU500 cameras. After Shapiro-Wilk tests of the normality of the data, differences between the two seat conditions were analysed using paired t-tests or Wilcoxon signed-rank tests, as appropriate. **Results** The use of the swivel seat resulted in a higher peak and mean flywheel angular velocity ($p = 0.033$ and $p = 0.052$, respectively). There was an increased rotation of the shoulders ($p = 0.076$) and pelvis ($p < 0.001$) with the swivel seat, but a decreased rotation of the shoulders relative to the pelvis ($p = 0.019$) and the pelvis relative to the seat ($p < 0.001$). The knee range of motion between simulated paddle catch and exit was greater when using the swivel seat ($p < 0.010$) but there was no difference between the two seat conditions in elbow range of motion over the same period ($p > 0.200$). **Discussion** This study has extended our understanding of the impact of the swivel seat on performance and technique, building on previous research that has analysed the effects at lower stroke rates (Fohanno et al., 2011) or from a physiological perspective (Michael et al., 2010). Greater knee range of motion with the swivel seat results in increased pelvis and shoulder rotation during maximal paddling, aiding performance, while an accompanying decrease in torso rotation could potentially benefit the spine through mechanisms such as reductions in pulposus pressure and endplate damage (van Deursen et al., 2001; Aultman et al., 2004). As expected, upper limb kinematics are less affected by the choice of seat than lower limb kinematics. **References** Aultman, CD, Drake, JD, Callaghan, JP, McGill, SM (2004). Spine, 29(15), E304-09. A NOVEL APPROACH OF MEASURING FORCE TRANSMISSION AND EFFICIENCY OVER KNEE JOINT IN CYCLING-CASE STUDY

Dordevic, S.I, Milic, R.2, Cucek, G.M.1, Berdajs, M.1, Zumer, J.1, Modic, Z.1

1: TMG-BMC (Ljubljana, Slovenia), 2:University of Ljubljana, Faculty of Sport, Institute of Sport, (Ljubljana, Slovenia)

Introduction Efficiency is a measure of effective work expressed as the percentage of total energy expended that produces mechanical work. To our knowledge there are no studies that have quantified the reliability of a measure of mechanical efficiency. Pedal force effectiveness in cycling is usually measured by the ratio of force perpendicular to the crank and total force applied to the pedal (1). **Methods** Measurements were made on professional and amateur cyclists. Pedal force was measured with a pedal system developed at TMG. All cyclists wore MC sensors (2) on vastus lateralis (VL) and medialis (VM) and the patellar tendon (PT) on both legs. The data was collected with the TMG data logger at 1Ks/s. Stroke cycles were collected on the crank with the TMG 3D motion sensor containing a gyroscope and accelerometer. Measurements were done at standardized terms, every cyclist pedalled at 200 W, 300 W and 350 W at a constant cadence of 80 rpm. **Results** Monitoring muscle/tendon activation, sustain time and force on the pedal gives us an estimation of muscle/tendon efficiency during pedalling stroke. Quadriceps force is transmitted to the pedal over 2 joints. This leads to delays between peak force on the quadriceps and peak torques on the crank. Basic repeatability of movement force production/transmission was very high for each set and repetition. Also, significant nonlinear correlation was found between VL, VM and pedal force. **Discussion** With our approach we can track how generated energy/force in the quadriceps group muscles is transmitted over the knee joint to patellar ligament and further on to the pedal. Thus the effectiveness of each muscle can be evaluated. The first sets of measurements confirmed the hypothesis that MC can be utilized for measuring force on muscles and patellar ligament while cycling. Further measurement are necessary for testing specific relations between muscles, joint mechanics, tendon and pedalling force/torque. **References** (1) De Marchis, M. Schmid, D. Bibbo, I. REAL-TIME VISUAL FEEDBACK ABOUT OAR FORCE AND POSITION HELPS TO ADAPT ROWING TECHNIQUE

Scholtens, E.J., Lintmeijer, L.L., van-Soest, A.J., Hofmijster, M.J.

*NOC*NSF, VU University*

Introduction Although previous research indicates the importance of precise and accurate feedback (e.g. Ford et al, 2007), feedback in rowing commonly only consists of verbal input by the coach. In this field study we investigated whether feedback of stroke-related parameters may help a rower improve his technique. According to the coach of the participating crew, its members applied insufficient force on the oar during the final part of the stroke. We investigated whether real-time augmented visual feedback about handle force could help these rowers to postpone the decline of force during the final part of the stroke. **Methods** Force on the oar and oar angle were measured using commercial sensor technology (Peach Innovations, UK). Using a custom-made interface, data was streamed in real time to a smartphone, acting both as a data processing unit and a feedback device. The coxless four crew was instructed to row six 3-minute trials while maintaining a high force during the final part of the stroke. In trials 2, 4 and 6 they received feedback about the oar angle at which force dropped below 70% of maximum (provided after each stroke cycle). Dependent variables were the oar angle at which force dropped below 70% of maximum force (angle@70%) and the force on the oar when the oar was at 10 degrees past the orthogonal position (force@10deg). For each trial, 30 consecutive strokes were selected, resulting in a comparison within each rower between 90 strokes in the feedback condition and 90 strokes in the control condition. **Results** Due to technical problems, accurate data were obtained for three of the four participants only. These rowers each showed higher values for angle@70% (control: $M=17.2$, $SD=0.656$; $M=5.87$, $SD=3.43$; $M=5.89$, $SD=1.67$, feedback: $M=17.3$, $SD=0.576$; $M=7.49$, $SD=2.70$; $M=6.02$, $SD=1.91$) and force@10deg (control: $M=911$, $SD=47.4$; $M=642$, $SD=33.8$; $M=597$, $SD=32.7$, feedback: $M=923$, $SD=51.2$; $M=672$, $SD=31.3$; $M=601$, $SD=53.8$) during the feedback conditions. On average, force@10deg was 15.3 ± 13.3 N higher and angle@70% was 0.617 ± 0.869 degrees higher in the feedback conditions. **Discussion** This study suggests that a single training session with augmented real-time feedback may lead to behavioral changes in

well-trained rowers. Thus, these results show the potential of real-time augmented feedback in rowing. The combination of a smartphone platform combined with precise sensor technology allows tailoring the type of feedback to the wishes of coach and rower, likely increasing the potential for performance enhancement. In future work, we will investigate to what extent real-time augmented feedback improves rowing performance and whether feedback-induced changes in movement execution are also maintained when feedback is withdrawn. THE DIFFERENCE OF THE KICK START MOVEMENT IN COMPETITIVE SWIMMING BY SKILL LEVEL

Keita, A., Kurokawa, T., Deguchi, T., Nishiyama, K., Moriki, G., Adachi, T.

Hiroshima University

Introduction Kick start (KS) is the starting technique which swimmers set up their rear leg on a back plate of the starting platform, which has been recently introduced in international swimming competitions. It is reported that KS can achieve higher performance than the traditional start in the start phase (Petryaev 2010), but the detailed characteristics of the KS movement has not been clarified. Thus, the aim of this study was to reveal the differences in the KS movement by skill level. **Method** After enough warm-up, 6 male university swimmers (upper skilled group), 7 male university swimmers (lower skilled group) and 12 male students majoring physical education (unskilled group) were asked to perform the KS. They were divided into three groups by the 5m time. The KS movement before entering the water was analyzed by 3D-DLT method, and after entering the water was analyzed by 2D-DLT method. **Result** In the 5m time and the 5m velocity, there were significant differences between many groups, and there was a tendency that the higher the group's skill was, the higher these were. In the block time, there was a tendency that the higher the group's skill was, the shorter the block time was, and a significant difference was especially seen between the upper skilled group and the unskilled group ($p < 0.05$). In the velocity maintenance rate (the entering water velocity/the 5m velocity), the higher the group's skill was, the higher the velocity maintenance rate was, and there was a significant difference between all the groups ($p < 0.05$). In the time in when the knee angle of the rear leg starts extending, there was a tendency that the higher the group's skill was, the earlier the time was, and significant difference was especially seen between the upper skilled group and the unskilled group ($p < 0.05$). The unskilled group significantly had a larger entering water angle than other groups ($p < 0.01$), and the lower skilled group significantly showed shorter flight distance than other groups ($p < 0.05$). **Discussion** The higher the subject's skill was, the higher performance of both the 5m time and the 5m velocity were shown by the subjects. Such result was caused because the higher the group's skill was, the shorter the block time was and the less the speed deceleration was after entering the water. The time in which the knee angle of the rear leg starts extending caused the block time of the upper skill group to be shorter. The entering water angle and the flight distance caused the velocity maintenance rate of the upper skill group to be larger. Reference Petryaev, A.V. (2010) Proceedings of the XIth International Symposium on Biomechanics and medicine in Swimming. Oslo:100.

COMPARISON OF TWO METHODS OF ESTIMATING THE ACTIVE DRAG OF ELITE FREESTYLE PARA-SWIMMERS

Oh, Y.T., Miller Briggs, L., Osborough, C., Payton, C.J.

Manchester Metropolitan University, Cheshire

Introduction The hydrodynamic resistance experienced during swimming is called active drag. A number of methods for measuring active drag have been proposed but there is no gold standard, with the most current methods still producing conflicting data (Toussaint et al., 2004). To date, all active drag studies have been on able-bodied swimmers; no study has yet examined the active drag of Para-swimmers. The two aims of this study are to: 1) determine the active drag of elite Para-swimmers, and 2) compare two current methods of measuring active drag – the Assisted Towing Method (ATM) and the Naval Architecture Based Approach (NABA). **Methods** Maximum swimming speed (v_{100}) of five female and three male elite Para-swimmers (IPC classes S5-S14) was determined. Participants were then towed, using a motorised drum, while holding a fixed 'passive' position with their arms at their sides. Passive drag was recorded at v_{100} (F_{p100}) and 10% faster speed, v_{110} (F_{p110}), using a load cell incorporated into the towing cable. Finally, the cable force (F_t) was recorded as participants swam maximal effort freestyle while being towed at v_{110} . All trials were repeated three times to assess the repeatability of the methods. Active drag (F) at each participant's v_{100} was calculated as follows: Assisted Towing Method (ATM): $F = (F_t \cdot v_{110} \cdot v_{100}^2) / (v_{110}^3 - v_{100}^3)$ Naval Architecture Based Approach (NABA): $F = F_{p100} + F_t - (F_{p110} - F_{p100})$ **Results** Swimmer's v_{100} ranged from 1.27-1.74 m/s. F range was 54.7-252.2 N (ATM) and 72.2- 129.5 N (NABA). When normalised for speed (F/v_{100}^2), the active drag range was 20.4-58.3 kg/m (ATM) and 28.7-45.0 kg/m (NABA). No association was found between IPC Class and speed normalised active drag. NABA produced more repeatable ($(|F_{max} - F_{min}|/F_{mean}) \times 100$) active drag values over the 3 trials (NABA: 0.1-11.9%; ATM: 11.9-50.4%). **Discussion** Previous research has shown a significant correlation between passive drag and IPC Class (Oh et al., 2013). The current study found no relationship between active drag and IPC class. Active drag will be greatly influenced by the technique used by the swimmer. This does not apply to passive drag. NABA and ATM both require measurement of v_{100} . Measurement errors in v_{100} will be propagated to a much greater extent in the ATM method, than in the NABA, as the former method incorporates the square and the cube of v_{100} in the active drag calculation. RELATIONSHIPS OF FREESTYLE SWIMMING PERFORMANCE WITH STRENGTH AND ANAEROBIC POWER-CAPACITY

Akdogan, E., Erkan, M., Kale, M.

Anadolu University

Introduction Squat jump shows explosive strength of an athlete. Countermovement jump describes speed strength. Anaerobic power-capacity test is the criteria for explaining of anaerobic performance. It is thought that squat and countermovement jump and anaerobic power-capacity parameters are related with freestyle swimming performance. The purpose of this study was to investigate relationships of freestyle swimming performance with squat and countermovement jump, and anaerobic power-capacity parameters. **Methods** Nine male swimmers of Anadolu University Swimming Team (height: 177.5 ± 5.2 cm, body weight: 74.1 ± 7.0 kg, body fat percent (%): 12.4 ± 4.9) voluntarily participated to the study. Freestyle swimming performances (25m and 50m) were tested by a touchpad chronometer system for a semi-Olympic swimming pool (25m). Squat jump and countermovement jump tests were used as explosive strength and speed strength. The difference between countermovement jump height and squat jump was evaluated as elastic power of each subject. Relationships of freestyle swimming performance with jumping heights and anaerobic power-capacity parameters were analyzed with Pearson Correlation Coefficient. Probability level was ≤ 0.05 . **Results** The results of this study showed that there were no statistically corre-

lations of freestyle swimming performance with jumping heights and anaerobic power-capacity. Discussion In conclusion, 25m and 50m freestyle swimming are not suitable swimming distance for explaining the relationships with explosive strength, speed strength, elastic power, and also anaerobic power-capacity. MO-SH03 Athletes & Achievements

THE SWEDISH SPORTS FEDERATIONS' DEPICTIONS OF THE ECONOMIC CONDITIONS OF ATHLETES

Hellborg, A.

Malmö University

Introduction Sports are becoming more professionalized (Westerbeek & Smith, 2003) that together with the fact that the demands on elite athletes to devote more time to their sport raise questions of financial support. The purpose of the study is to gain knowledge of Swedish sport federations depictions of athletes' economic compensation. Is the focus different in different sports, and how are men and women's conditions described? Method In this presentation depictions of two Swedish sport federations are studied. Contents from two sport federations' magazines (football and curling) on athlete's economic conditions and compensation are analysed. Gender theory is used to analyse the material. Of specific importance are Ridgeway's (2011) ideas about why gender inequality still persists in the modern society. Results The study shows that there are differences in attitudes to economic conditions and compensations related to gender, place and the actual sport. In the magazine of the football federation the conditions for the female players are often pointed out as different from the male players. In addition it is mentioned that the female players have jobs alongside their football career. When the economic conditions for the male players are discussed these are discussed in relation to the possibility of making money in the European leagues. In the magazine of the Swedish curling federation not much is written about athletes' financial conditions and whether they have to work alongside their sporting career. Instead there is some critique against attempts to create a professional tournament in Canada, which may reflect a negative attitude towards making money on one's sport. Discussion In the magazine of the federations there are clear differences in the depictions of athletes getting financial compensation for their elite sport. In the football magazine there is a debate on whether male and female players should be fulltime professionals. In the curling magazine this is not an issue. The idea of economic compensation even seems to be viewed as offensive. The magazines also differ in their view of who "the other" is. In the football magazine women are compared to men, and men to other men. In curling the gender order isn't as clear as in football. One might question why it seems to be so important to emphasize the gender order in football and not in curling? Maybe because Sweden (and Europe) have a history of seeing football as a men's game and therefore have been more excluding towards women (Andersson, 2002). Maybe it can be explained by the sports' class connotations. References Andersson, T. (2002) *Kung fotboll*. Symposium Fotbollmagasinet/ Magasinet fotboll (1987-2013) Ridgeway, C. STRUCTURE OF SPORT SCIENCE IN EUROPE: PRELIMINARY RESULTS OF A "SCIENCE STUDIES" RESEARCH PROJECT

Camy, J.

University of Claude Bernard Lyon

Introduction Science studies are an interdisciplinary research area that seeks to situate scientific expertise in a broad social, historical, and philosophical context. It is concerned with the history of scientific disciplines, the interrelationships between science and society, and the alleged covert purposes that underlie scientific claims. Our purpose is to present the first results of a "science studies" research project on "Sport Science in Europe: structure and design of an academic discipline". That project is run with the support of ECSS by a team of sport scientists (by alphabetic order of their institutions): Bengt Saltin (Copenhagen); Thomas Delaveaux (ECSS); Thierry Zintz (Louvain); Jean Camy, Raphaël Massarelli, Matthieu Quidu, Yannick Van Pouille (Lyon); Joakim Akesson, Susanna Hedenborg, Aage Radmann (Malmö); Sigmund Loland (Oslo); Mike Mc Namee (Swansea). Methods In our pre-inquiry, interviews have been conducted with 30 European sport scientists and 15 "sport science stakeholders" (mostly heads of European sport organisations and of sport public authorities). For the first ones the objective has been to analyze their representations of Sport science, their research practices and publication strategies, their relations with 'sport science stakeholders'. For the second ones, we have put under question their expectations and effective relations with sport scientists... Results Results are presented in a space structured by two axes corresponding to 4 poles: 'academic' versus 'socially embedded' and 'disciplinary' versus 'transdisciplinary'. The "academic" perspective considers that sport is only providing objects for research with the idea that producing knowledge is enough. The 'socially embedded' dimension promotes the idea that the key purpose of Sport Science is to contribute to the better understanding and development of sport in its different forms. The "disciplinary" pole designs a sport science mostly based on already existing sciences (biology, biomechanics, psychology, sociology, etc...) using sport as a field of experiment for those sciences. The forth pole we have called "transdisciplinary" experiments the capacity to provide answers to systemic/complex problems often arising from the field. That quite basic framework will be confronted to a more quantitative analysis based on an e-questionnaire sent to the whole European sport science community. UNDERSTANDING STUDENT-ATHLETE'S FLUNKED EXPERIENCE.

SoRa, K., Jeong Min, K., Jung Rae, L.

Kyungpook National University

Introduction Korean student athlete has flunked for many reasons. To avoid premeditated flunking, regulation was consolidated but flunking of student-athlete occurs continuously. The purpose of this study is to investigate when and why student-athlete flunked when they were middle school or high school and how flunking affected the student-athlete's life. Furthermore, the study explored what is flunking of student athletes according to kind of sports which are team sports and individuals sports. Methods In this study, the participants, five are individuals of team sports and five are individuals of individuals sports, were student-athletes who have experienced flunking. Data were collected by using in-depth interview, related data and text analysis. Results The results were as follows: First, causes of flunking were different according to time. The causes were due to being injured, became to student-athlete late and external pressure. Second, flunking experience affected to student-athlete that gaining chance of successful student-athlete, losses of athletic performance and changes life style that was discontinuing performance. Third, experiencing of flunking depended on sports type that are team sports and individual sports References 1) Lee, Hyuck-Gi, Lee Won-Hee: 4th Grade in the High School, The story of Flunked student-athlete: the reason, experience and plan. 2013.

TALENT IDENTIFICATION AMONG FEMALE SOCCER PLAYERS TO NATIONAL YOUTH TEAMS AND PLAYER ION TO A-NATIONAL TEAM

Rafoss, K., Welde, B.

UIT - The Artic University of Norway, HINT (Levanger) Norway

TALENT IDENTIFICATION AMONG FEMALE SOCCER PLAYERS TO NATIONAL YOUTH TEAMS AND PLAYER SELECTION TO A-NATIONAL TEAM Rafoss, K.1, Welde, B.2 1: UIT – The Artic University of Norway (Alta, Norway), 2: HINT (Levanger, Norway) Introduction The Norwegian Soccer Association has since 1986 identified female players to national youth teams. Youth sports commonly divide participants according to chronological age, based on specific cut-off dates, to establish eligibility for inclusion. The majority of research has examined males and, therefore, the aim of this study was first to study whether an effect of birth-date exists among Norwegian female talented soccer players and, second, to analyse the selection process to sift out players for A-national engagements. Methods 261 female soccer players selected to the youngest national team in the years 1988 - 2005 constituted our sample. The samples of youth selections were U-16 for the period 1988 -1997 and U-17 for the period 1998 – 2005. A Chi-square test was carried out to check for the existence of relative age effect in the youth teams. Cox regression analysis was applied to evaluate time to event. The event was defined as being selected to the women's A-national team. Time to event was defined as years elapsed from the first U-16 or U-17 appearance to the first appearance on the women's A-national team. Date of birth, provincial belonging, if the player had been selected for more than one of the national youth teams, as well as if the player had been selected for the U-21 national team, was chosen as covariates in the Cox regression. Results 24.9% of the subjects experienced the event. The results showed an over-representation of players born in the first quarter of the selection year in the U-16 and U-17 categories ($\chi^2_{23} = 12.60$, $P = 0.006$). The results from the Cox regression analysis (Wald $\chi^2_{28} = 45.00$, $P < 0.004$) showed that being selected for the U-21 national team ($\beta = 1.39$, $P < 0.004$), as well as provincial belonging, significantly predicted time to event. Players born in the Western ($\beta = 1.78$, $P = 0.02$) and Eastern ($\beta = 1.50$, $P = 0.04$) part of Norway had significantly diminished time to event as compared to Oslo. Date of birth ($\beta = 0.10$, $P = 0.68$) and being selected for more than one of the youths national team ($\beta = 0.12$, $P = 0.68$) did not significantly impact time to event. Discussion This study demonstrates an effect of early birth-date upon selection to the youth teams. However, there was no effect of birth-date upon selection to the women's A-national team. This finding, together with no effect of being selected for more than one of the youths national team, may indicate that selections early in the teens is of minor importance in predicting performance at adulthood. The diminished time to event for players being selected for the U-21 national team, may indicate that identification of future A-national team players are more valid as players approach adult age. DEVELOPMENT PLAN OF ATHLETES, SWIMMERS, AND GYMNASTS IN KOREA

Nam, Y.

Duksung Women's University

The level of elite sports in Korea has reached the world level. Overall ranking of Korea since the 2004 Athens Olympics is steadily in world's top 10 holding (Korean Olympic Committee, www.sports.or.kr). Although the basic events have many medals, Korean government gives no special support to these events since it is very difficult to have medals and the player base is not in a good condition. The purpose of this study is to suggest how to expand the player base of the basic events in Korea. For this purpose, literature survey and field research, including in-depth interviews, were conducted. We analyzed the importance of the basic events, logical development of policy support, the development status of the player base by sports associations and expansion status of underlying basic events in advanced countries. The first survey was performed on 31 responses consisted of athletic directors of school sports on the basis of population of 48 elementary, middle, and high school. The second survey was performed on 7 representative populations of school physical education. The third survey was conducted by Korea Association of Athletics Federations, Korea Swimming Federation, Korea Gymnastic Association. All surveys were conducted via e-mail. The site survey was conducted on development and operating status by sports organizations. Study area was in Seoul, Gyeonggi, and Daejeon. Every two school was selected for the site survey. In-depth interviews were conducted on school sports club leaders and instructors, school athletic leaders of athletics, swimming, and gymnastics. As the result, although school sports club enrollment was significantly increased, the enrollment ratio of the school sports clubs was found to be quite inflated numerically due to the lack of physical education space, poor physical facilities, and the lack of leadership. Unclear future of players and lack of competition in physical education-centered schools caused unactivation of the basic events. To expand the player base of the basic events, first of all, business promotion should be performed through pre-school life sports / school physical education. As the business of Korea Council of Sport for All related to the basic events, classroom, group and competition projects should be included for the extension of the player base. In particular, the government needs to promote the expansion business for the player base of the basic events separately or to promote youth physical activity business. The business on Sports Council for Gifted, which is being carried out by Korean Olympic Committee and Korea Foundation for the Need Generation Sports Toward, should be promoted mainly by Korean Olympic Committee, and performed by dividing it into two parts: pre-school from the age of seven to fourth grade of elementary school,

and from fifth grade of elementary school to first grade of middle school. While the basic events are considered to be difficult and uncertain, these events must be a very valuable asset to the player and an extremely useful for pragmatic sociability.

THE ACADEMIZATION OF SPORT IN SWEDEN

Wirén Aakesson, J.

Institution of Sport Sciences

Introduction In recent years, sport has undergone a remarkable academisation process in Sweden. Since the 1970s a broad field of sport research has been established within which scientific knowledge is being produced. A series of higher educations in the area has formed since the new millennia - through which scientific knowledge is mediated to students. In addition, the demand for labor in the sports labor market has increased in recent decades - and the demand for academic background is not unusual. This study deals with the sport academisation process. The purpose is to extend knowledge and understanding of higher sport science education and its relationship to sport research, and the sport labor market. The research questions are: What knowledge is produced within sport research, what knowledge is mediated through higher sport education, and what knowledge is demanded in the sport labor market? How does the production, mediation and demand for scientific knowledge relate to each other? Do they differ and if so in what ways and why? The study has two main theoretical perspectives. The first is Academisation (Dellgran & Hojer 2000) - which concerns how a field of general knowledge develops into a field of scientific knowledge. The second is Institutionalization - which is used to study how sport as an academic area has become structured in Sweden (Powell & DiMaggio 1991). **Methods** The empirical material mainly consists of various documents, such as: dissertations, journal articles, educational curriculums, job listings, and various statistical materials. The documents have been analyzed quantitatively as well as qualitatively, through content analysis. **Results** The study shows that there are discrepancies between produced, mediated and demanded knowledge. The largest proportion of research has been produced within fields that are closely connected to PE-teacher educations. At the same time, almost half of the educations are within Sport Management - an area where there is very little research being conducted in Sweden. Although there is a large demand for labor in the sport labor market, the employment opportunities mainly consist of temporary part-time employments. The demand for scientific knowledge also varies between different professional roles. For some professions, an academic background is essential, for others it has less importance. **Discussion** Sport research, higher sport education and the sport labor market has its own distinct histories and institutions, and therefor reproduces different ideas, ideals and logics. The three arenas are partly separate and have their own distinct characteristics, but are also interwoven in specific ways. **References** Dellgran, Peter & Hojer, Staffan (2000). SECOND CAREER DEVELOPMENT OF RETIRED ELITE ATHLETES IN HONG KONG

Sum, K., Ha, A.C.

The Chinese University of Hong Kong

This study set out to explore the process of career termination and second career development of retired elite athletes (REAs) of Hong Kong. The aim of this study was to generate a substantive theory, based on semi-structured interviews of 7 retired elite athletes (REA), 5 men and 2 women, aged 24-35 years who represented Hong Kong to participate in international and regional sport competitions and retired from their elite athletes' career within three years. Grounded theory was used to analyze the transcribed interview data. A core category namely "Self-selected Social Support System" emerged in describing how Hong Kong REAs develop their second career. The findings from this study generate a series of four core discoveries that represent core propositions. These include: (1) the support of significant others; (2) an important sense of occupational autonomy; (3) a timely determination to the second career development; and (4) an integration of social skills that learnt in athletic career were labelled to explore the process of career termination and second career development of REAs of Hong Kong. The theory provides an insightful examination on influences of REAs' career lives after retirement which in turn eventually leads to changes in their second career development. The study concludes with a review of the study's limitations and recommendations for future research.

MO-PM12 PH Resistance Exercise

LOWER SATELLITE CELL CONTENT PARTLY EXPLAINS BLUNTED HYPERTROPHIC RESPONSE IN OLD MICE, BUT IS NOT ALLEVIATED BY RESVERATROL

Ballak, S., Jaspers, R.T., Peters, E.L., de Haan, A., Degens, H.

MMU Manchester

Resistance exercise is an effective way to reverse age-related loss in muscle force and mass. However, the hypertrophic response to resistance training may be blunted in old age(1). This may be related to an attenuated proliferation of satellite cells (SC) and consequent accretion of myonuclei compared to young subjects(2). Systemic inflammation may impair SC function. Resveratrol, an anti-inflammatory anti-oxidant may be able to rescue, to some extent, muscle function and the capacity to hypertrophy with increasing age. Here we addressed the question whether the hypertrophic response in old mice was blunted compared to adult mice, and whether this was associated with differences in muscle SC content. Furthermore, we investigated the efficacy of resveratrol to restore the hypertrophic response in old mice. To address this question the left plantaris muscle of male 8- (n=11) and 24-month-old (n=10) C57Bl/6j mice was overloaded for six weeks by denervation of its synergists. An additional group of old mice received 0.4% resveratrol in the chow for 7 weeks. After overload, irrespective of fibre type, fibre CSA increased more in adult than in old mice (P<0.01). With overload, there was a fibre type shift from type IIB to type IIA and IIX fibres (P<0.01) which was more pronounced in adult (50-27% IIB) than old muscle (42-38% IIB; age*overload

interaction; $P < 0.01$). SC per fibre (SC/f) was about 35% lower in muscles from old than adult mice ($P < 0.05$) and increased similarly (~50%) with overload ($P < 0.01$) in both young and old muscles. Resveratrol supplementation did not result in an increased SC/f in old mice ($P > 0.05$). Additionally, both in adult and old muscle SC/f increased after overload. In conclusion, the hypertrophic response (increase in fibre CSA) and shift in fibre type proportions were blunted in 25-month-old mice. The lower number of SC in old muscle rather than their ability to respond to mechanical stimuli, may partially explain the blunted hypertrophic response in old muscle. Resveratrol did not induce an increase in SC number. This research was funded by the European Commission through MOVE-AGE, an Erasmus Mundus Joint Doctorate program (2011-2015). References: 1. PREVALENCE OF SARCOPENIA AND IMPACT OF RESISTIVE EXERCISE IN A FULLY INDEPENDENT ELDERLY POPULATION

Longo, S.1, Cereda, F.2, Vago, P.2, Pettarin, A.2, Narici, M.V.3

1Università degli Studi di Milano; 2Università Cattolica del Sacro Cuore di Milano; 3University of Nottingham

INTRODUCTION Sarcopenia, the age-associated loss of muscle mass (Narici&Maffulli, 2010) is a main determinant of functional impairment and physical disability in old age. However, the prevalence of sarcopenia amongst fully independent individuals and its reversibility in response to resistive training (RT) are scarcely known. Hence, this study aimed at establishing (i) the prevalence of sarcopenia in fully independent older individuals and (ii) the efficacy of a 12-week RT programme in reversing sarcopenia and its associated muscle weakness. **METHODS** 26 participants (14 men and 12 women), aged 65-83 yrs, were recruited for this study and underwent 12-week of RT, (3 times/week, 3 sets, 14-16 reps), on a leg press machine. Pre- and post-training measurements included: Skeletal Muscle Index (SMI, by bioelectrical impedance); Gait speed (GS) over 4 m; Stair climbing power (SCP); Muscle Architecture of vastus lateralis muscle (pennation angle (θ) and muscle thickness (MT) measured by ultrasonography); 1RM on the leg press. Data were analyzed with descriptive statistics and paired Student's t-test. **RESULTS** Before training the prevalence of type I sarcopenia was 61.5% and of type II was 38.5% (classified according to Janssen, 2002). Considering the changes in functional performance, 77% participants (20/26) were responders, while 23% of the participants were non-responders (6 out of 26). For the responders, SMI increased by 2.5% (29.5 ± 4.7 vs 30.3 ± 4.5 %, $p < 0.001$), GS by 5.2% (1.32 ± 0.2 vs 1.39 ± 0.2 ms⁻¹, n.s.), SCP by 7.7% (300.3 ± 111.2 vs 321.8 ± 144.5 W, $p = 0.04$), θ by 8.5% (13.8 ± 3.7 vs 14.9 ± 3.3 deg, $p = 0.03$), MT by 3.5% (1.72 ± 0.4 vs 1.78 ± 0.4 cm, n.s.). 1RM increased by 69% (89.2 ± 59.2 vs 150.8 ± 69.0 kg, $p < 0.001$). 2 participants moved from class II to I sarcopenia and 5 participants from I to a normal SMI. **CONCLUSIONS** The present findings show that sarcopenia affects >50% of a population of fully independent older individuals (65+ yrs), and that significant improvements in muscle mass, strength are afforded by resistive training. It is noteworthy that these structural and functional gains are associated with a net improvement in key activities of daily living such as stair climbing. **REFERENCES** 1. Narici MV, Maffulli N. Sarcopenia: characteristics, mechanisms and functional significance. Br Med Bull. 2010;95:139-59. 2. Janssen I, Heymsfield SB, Ross R. et al. O2 PULSE DURING SINGLE SET VS. MULTIPLE-SET RESISTANCE EXERCISE

Mookerjee, S.

Bloomsburg University

Introduction During upper body resistance exercise, the varied sympathetic drive, as well as accompanying Valsalva effect can influence venous return and stroke volume. Therefore, the pattern of change as well as the absolute values of O₂ pulse (VO₂/HR) can provide useful information about these responses and how they may also be influenced by the exercise dose (e.g. 1 set versus 3 sets). The purpose of this study was to investigate the effects of a single set versus a multiple set resistance exercise regimen on changes in O₂ pulse. **Methods** Twelve male, recreationally trained subjects aged (mean \pm SD) 21.8 ± 1.6 years performed a 5- exercise routine, (bench press, military press, biceps curl, lat pull down and triceps pushdown). The exercise order was from large muscle to smaller muscle groups, and multiple joint to single joint exercises. The intensity was set at 70% of one-repetition maximum and 10 repetitions for all of the exercises. A lifting cadence of 15 repetitions•min⁻¹ was set via a metronome. O₂ pulse was determined from breath-by-breath measurements via a portable, telemetry system. Repeated measures ANOVA was used to determine differences in O₂ pulse between the 10 repetitions in the 1 set routine versus the O₂ Pulse in the 3rd set of 10 repetitions in the 3-set routine. Results Weight loads used were as follows: bench press (8.26 ± 21.34), military press (54.92 ± 15.65), lat pulldown (60.98 ± 15.68), tricep press (28.41 ± 8.48), bicep curl (40.34 ± 8.94). Significant differences ($p < 0.05$) were found between the single and third sets for heart rate, relative VO₂ (ml.kg.min⁻¹), and O₂ pulse. Bench Press Lat Pulldown Military Press Tricep Press Bicep Curl 1 set mean (s) 6.41 8.8 7.0* 7.0* 6.9* SD 3.54 4.9 4.2 3.3 3.9 N 12 12 12 12 3 set mean (s) 6.86 7.9 5.7 6.0 6.0 SD 3.7 3.9 3.5 2.6 3.1 N 12 12 12 12 12 * $p < 0.02$ **Discussion** Variations in O₂ pulse during exercise, reflect the magnitude of changes in stroke volume and the arterial – mixed venous O₂ difference (Cl(a-v)O₂). These findings indicate that exercises involving smaller muscle masses and fewer joint segments elicited a significantly higher O₂ Pulse. This could be due to increasing sympathetic drive, smaller muscle mass involvement, the greater isometric component involved in gripping. Finally, in the bench press exercise, the supine body positioning could have resulted in greater venous return, affecting the stroke volume and thereby, the O₂ pulse. Further investigations are needed to investigate these changes during resistance exercise routines involving the lower body as well as varied set regimens.

EFFECT OF A SHORT DURATION HIGH INTENSITY/LOW VOLUME RESISTANCE TRAINING ON SKELETAL MRNA IN YOUNG HEALTHY SUBJECTS.

Introduction Resistance training may be carried out via different methods that have been shown to have differing effects on muscle metabolism and signalling pathways. As a matter of fact a resistance training program is a composite of several important variables including that may affect physiological outcomes. On the other way also an high intensity interval exercise performed on cycloergometer has been demonstrated to influence some metabolic pathway as PGC-1 α . Thus, the aim of our study was to analyse mRNA response to a single bout of high-intensity resistance training (HIRT), traditional resistance training (TRT) and high-intensity interval training (HIT). **Methods** 12 healthy subjects performed in two different moments and with different legs HIRT and TRT protocol. HIRT consisted in 2 sets of 6/2/2

reps with incomplete rest between (20") sets while TRT consisted of 4 sets x15 reps with 1'15" of rest between sets. HIT was performed on a cycloergometer as follow: 30' of all out with 4' of rest, repeated for 4 times. Biopsies from the vastus lateralis were taken one week before training sessions (pre), immediately after (T0), 6 hours after (T6) and 24 hours after (T24) training. The following genes, related to hypertrophy, metabolism, autophagy and inflammation, was analysed by RT-qPCR: IGF-1, IGF-14a, MGF, myostatin, STARS, PGC-1 α , PGC-1 α -4, Atrogin, Beclin, IL6, myogenin Results Our data showed that HIRT seems to influence in a greater extent the gene linked to mechanical deformation (MGF) and STARS, whilst TRT seems influence STARS and IGF-1. HIT influenced IGF-14a, Beclin, IL6, myogenin, PGC-1 α and myostatin. Discussion Our results suggest that different kind of exercise may influence different early genes after exercise. An high resistance training (HIRT) affects mechanical-related factors whilst a more traditional, long duration resistance training (TRT) seems to influence the IGF-1 pathway. The HIT exercise increases in a significant manner PGC-1 α but also muscle atrophy related genes as atrogin, beclin and myostatin. References Paoli A. CHANGES IN MUSCLE ACTIVATION DURING 72 HOURS FOLLOWING AN ACUTE PLYOMETRIC BOUT

Mavropalias, G., Bremander, A.

Halmstad University

CHANGES IN MUSCLE ACTIVATION DURING 72 HOURS FOLLOWING AN ACUTE PLYOMETRIC BOUT Mavropalias G. 1, Bremander A. 1, 1: HH (Halmstad, Sweden) Introduction Plyometric training (PT) has been used widely in sport training to improve characteristics such as power, strength and to induce beneficial neuromuscular improvements. Previous evidence has demonstrated a significant impact of this training method on muscle activation patterns during training, however there is a lack in research literature of studies examining its follow up effects in the recovery period. The purpose of this study was to examine any possible changes in the muscle activation of the lower extremities up to 72 hours after high intensity PT. Methods An experimental study design with repeated measures was used. Twelve (n=12) male subjects (mean age 24.33 \pm 2.6) executed a high intensity PT protocol for the lower extremities. Countermovement jump test (CMJ) was performed pre, immediately post, 24, 48 and 72 hours after the PT. Surface electromyography (sEMG) evaluation examined the activation of Gluteus Maximus (GM), Vastus Lateralis (VL), Biceps Femoris (BF) and Gastrocnemius (GAS) during the CMJ in all the time points of the recovery. A one way ANOVA with repeated measures was used to analyze differences between the five time points ($p \leq 0.05$). Results The results indicated a statistical significant decrease in CMJ performance at 24 and 48 hours, compared with the baseline, that peaked at 24 hours (-7.16%), and recovered at 72 hours. Muscle activation levels for GM, VL and BF followed the same pattern, decreasing significantly post training compared to the baseline, recovering at 72 hours post. Muscle activation decrease peaked immediately post training for GM (-21.8%), VL (-14.04%) and BF (-19.82%). Muscle activation for GAS decreased significantly post training (-6.77%), recovering faster than the other muscle groups, at 48 hours. Discussion CMJ jump performance impairment was in accordance with previous research, peaking at 24-48 hours and recovering at 72 hours after the bout (Chatzinikolaou et al., 2010). The impairment pattern observed in the sEMG values peaked immediately post training, recovering at 72 hours; however the magnitude of the decrease was not as extended as observed after eccentric training (Hortobágyi et al, 1998). GAS activation recovered 24 hours faster than the rest of the tested muscle groups probably due to the higher percentage of slow twitch fibers which are less susceptible to muscle damage than fast twitch. In conclusion PT significantly decreases muscle activation and jump performance up to 72 hours after the bout in GM, VL and BF, while GAS recovered in 48 hours. FUNCTIONAL AND ARCHITECTURAL ADAPTATIONS OF SKELETAL MUSCLE TO A 6 WEEKS PLYOMETRIC TRAINING INTERVENTION IN YOUNG AND OLDER MEN

Carter, A.W., Reeves, N.D., Franchi, M.V., Narici, M.V.

King's College London, University of Nottingham

Functional and architectural adaptations of skeletal muscle to a 6 weeks plyometric training intervention in young and older men. Introduction: We investigated the architectural, functional, and morphological responses of human skeletal muscle to a plyometric training protocol, in young and older male subjects. Methods: 9 volunteers (5 young, 4 elderly) performed a plyometric training protocol (3xwk for 6-wk, 3-5x30 repetitions per session). Training was performed on a "Trampoline-Trainer" exercise device. Ultrasound was used to determine muscle architecture (fascicle length, Lf; pennation angle, PA; muscle thickness) of the vastus lateralis muscle. Muscle function was assessed by testing leg extension power (Nottingham power rig) and isometric MVC (isokinetic dynamometer). Results: Lf increased significantly in both groups (elderly +11.45 vs. young +8.95%), as did muscle thickness (elderly +9.44 vs. young +6.09%). PA increased significantly in the elderly group but not in the young group (+12.19 vs. +2.12%). Leg extension power increased significantly in both groups (elderly +33.51 vs. young +23.01%). No significant increases were observed in isometric MVC testing in either group. Discussion: The novelty of the study is the application of a plyometric training protocol in a population of older adults. The increase in muscle thickness observed in both groups is indicative of an increase in muscle mass. The increase in leg extension power seen in both groups is consequential to the increase in muscle mass. The increase in Lf, also observed in both groups, suggests that the eccentric phase of the stretch-shortening cycle may be a greater stimulus for the addition of sarcomere in series than the concentric component, i.e. the adaptations reflect the predominant fascicle behaviour seen during the training (stretching). The greater architectural response in the elderly group is likely explained by the fact that the elderly had lower muscle mass, PA, Lf, and muscle thickness values before training, associated with sarcopenia. Furthermore, the significant increase in quadriceps muscle power output (crucial in older populations) supports the benefit of this training program. Thus, plyometric training seems particularly beneficial for the elderly population. References: Blazevich et al. (2003). Med Sci Spor Ex Kyrolainen et al. (1991). Scand J Med Sci Spor Narici et al. LACTATE AND RPE IN RESISTANCE TRAINING

Brown, N., Hauber, C., Bubeck, D., Brack, R., Alt, W.

University Stuttgart

Introduction RPE (rating of perceived exertion) is widely used in current research to either determine current training intensity, or the regulation of training load in resistance training. Although it is unclear, what is represented by the RPE in physiological terms. Blood lactate (BLa) as an indicator of anaerobic metabolism could mediate the perception of exertion in resistance training. The aim of this study is to

validate different types of RPE-scales with BLA, thus give advice on which scale to use and when to ask the athlete for RPE. Methods 16 male Athletes (24.9±2.0 years, 186.9±8.3cm, 83.0±9.5kg, 4.7±2.2 years of strength experience) performed 3 sets with 8-12 RM (repetition maximum) of lat-pull, bench press and leg press with 3 minute break between sets and 5 minutes of rest between exercises. Diet was controlled and all subjects where pre-tested on 8-RM and resting BLA and RPE. RPE-forms questioned where RPE-AM (active muscle) and RPE-O (overall exertion) with 0-10 scale. RPE and BLA where measured before each set and 2 minutes after the end of each set (RPE-AM_2, RPE-O_2). Also directly at the end of each set, RPE was questioned (RPE-AM_0, RPE-O_0). 30 minutes after the session, the session-RPE was measured. Blood (20µl) was extracted from the earlobe and then preserved in 1ml glucose/lactatehaemolysis solution. BLA-values where then analysed with Biosen S-Line (EKF Diagnostics). Correlations between RPE-values and BLA where observed with spearman correlation. Individual correlations where fisher-z-transformed for mean correlations. Results Highest BLA-values where observed after the last set of leg-press (mean=8.8±2.7 mmol/l, Range= 4.6-15.2 mmol/l). RPE-AM values where higher than RPE-O values. BLA and RPE increased with the number of sets and also with the number of exercises performed. Mean correlation for RPE-O_0 and BLA was the highest (r=0.71). RPE-O_2 had the lowest correlation (r=0.54). RPE-AM_0 showed a correlation of r=0.67, RPE-AM_2 correlated with BLA with r=0.65. Session-RPE was 6.7±1.5 for the training session. This value had the highest correlation with the mean RPE-AM_0 values (r=0.52). The correlation of mean BLA and Session-RPE was low (r=0.31) Discussion RPE-O questioned directly after the exercise showed the highest correlations with the BLA-value. Thus this form of RPE-questioning is recommended for use in further studies. All correlation coefficients where low to medium, showing, that the RPE seems to partly represent anaerobic metabolism. Although greater populations should be tested. Also the high individuality of RPE-results show, that RPE-values can only be interpreted individually.

ESTABLISHING EQUIVALENT TRAINING INTENSITIES FOR ISOMETRIC BILATERAL-LEG AND HANDGRIP EXERCISE USING THE CATEGORY RATIO SCALE

Baross, A.W.1, Silvey, W.1, McGowan, C.L.2, Milne, K.J.2, Swaine, I.L.3

1: Sport and Exercise Science, UON (UK) 2: Kinesiology, UW (CAN) 3: Sport and Exercise Science, CCCU (UK)

Introduction Isometric handgrip (IHG) training is commonly undertaken at an exercise intensity of 30% of a subject's maximum voluntary contraction (MVC) (McGowan et al., 2007). Matching this intensity with isometric bilateral-leg (IBL) exercise is difficult due to the different muscle mass involved. Comparative studies (Howden et al., 2002) have tended to use different exercise intensities without providing a strong rationale. Therefore, the purpose of this study was to use the Category Ratio Scale (CR-10) to establish equivalent exercise intensities for IHG and IBL, based on participant effort perception and to test the extent to which intensity can be matched, when using this method during training sessions. Methods A total of 26 healthy participants (male, n = 18; female, n = 8) undertook two minutes of unilateral IHG to establish the mean CR-10 values. Then, performed IBL exercise at 15, 20 and 25%MVC. The IBL intensity at which CR-10 most closely matched the values for IHG, was identified as 20%MVC. Subsequently, an IHG and IBL training session was used, to test the extent to which the intensities were matched, according to effort perception. Ten participants (male, n = 6; female, n = 4) undertook 4 x 2 minutes unilateral IHG (30%MVC) and IBL (20%MVC) training, with 2 minutes recovery between contractions with CR-10 measured at the end of each exercise bout. A one-way independent ANOVA was used to identify the IHG and IBL intensities that were most-closely matched. To determine whether CR-10 values were significantly different during the IHG and IBL training sessions, a two-way mixed-model ANOVA was used. Results The intensity at which CR-10 was most-closely matched between IHG and IBL was 20%MVC. There were significant differences in the CR-10 values between IHG contractions at 30%MVC and IBL at 25%MVC (P > 0.05) but not at 20%MVC (P < 0.01). Further analysis of the training data indicated that there were no significant differences in the CR-10 values between IHG (30%MVC) and IBL (20%MVC) following the first 3 bouts of exercise (P < 0.05). However, there was a significant increase following the final bout of exercise (P > 0.05). Discussion These results suggest when performing IBL exercise, the intensity most closely matching the IHG intensity (30%MVC) is 20%MVC. Furthermore, it can be seen from the simulated training sessions that CR-10 does not significantly differ between the two intensities until the final 2-minute bout. Therefore, it may be advantageous when undertaking one-off IBL exercise or IBL training protocols with the purpose of comparing data to that from IHG, to use 20%MVC. However, when a 4 x 2 minute training protocol is used, it may be necessary to attenuate the intensity of the 4th bout of IBL. McGowan CL, Levy AS, McCartney N, MacDonald MJ. (2007). Clin. BIOLOGICAL FEATURES RELATED TO FORCE-VELOCITY MECHANICAL PROFILE.

Rodríguez Juan, J.J.1, Samozino, P.2, Ríos Díaz, J.1, Marfínez Payá, J.J.1, Jiménez Reyes, P.3, Morin, J.B.2

It is well known that muscle geometry strongly influences force production characteristics (Blazevich, 2006). Recently, Earp et al showed that gastrocnemius lateralis (GL) pennation angle was a predictor of relative power or height during vertical jumps. The force-velocity (FV) mechanical profile encompasses other muscle biological features (Samozino, Morin, Hintzy, & Belli, 2010). The aim of this study was to experimentally test the influence of muscle architecture on mechanical features related to FV individual profile. Squat jump (SJ) FV profiles were computed in healthy subjects and related to GL pennation angles. 26 subjects (26.5; SD: 4.30 yr) with different physical condition performed maximal SJ against additional loads. From vertical ground reaction force and displacement data individual linear F-v relationships and were determined using the best trial for each condition. Individual mechanical F-v imbalance (FVimb) was determined as the difference between actual and optimal FV profiles (Samozino et al., 2013) Ultrasonography (LogiqE ultrasound machine with a 12L-RS linear array transducer with a 5-13 MHz acquisition frequency) examinations were performed by the same researcher with 12 years of experience in musculoskeletal imaging. The ultrasonograms were analyzed using ImageJ 1.46a software. The positive influence of theoretical maximal isometric force (F0) is in line with studies relating jumping ability to pennation angle, it is believed that a greater number of fibers can be aligned within a given cross-sectional area, which increases the physiological cross-sectional area of the muscle, and in turn allows for greater force development (Blazevich, Cannavan, Coleman, & Horne, 2007). We found that GL pennation angle was significantly related to F0 during SJ (r2=0.472, p=0.029), which is in line with Earp et al who determined that GL pennation angle was strongly related to relative power and height for SJ, countermovement jump, and drop jump (Earp et al., 2010). 14:00 - 15:00**Mini-Orals****MO-PM13 TT Clinical 1****OPTIMIZING PATIENT SELECTION FOR CARDIAC RESYNCHRONIZATION THERAPY THROUGH CARDIOPULMONARY EXERCISE TESTING**

Pinto, R.1, Santa Clara, H.1, Abreu, A.2, Melo, X.1, Santos, V.1, Cunha, P.2, Oliveira, M.2, Silva, S.2, Soares, R.2, Ferreira, R.2
 1: CIPER, FMH-UL (Lisbon, Portugal), 2: Cardiology Service, Santa Marta Hospital (Lisbon, Portugal)

Introduction Cardiac resynchronization therapy (CRT) is an established treatment modality for moderate to severe heart failure (HF). However 30% of patients treated with CRT do not experience clinical improvement. Echocardiographic (ECO) and clinical parameters predict response to CRT, although there may be more parameters to be unveiled. The aim of this study was to identify predictors of response to CRT by using the cardiopulmonary exercise testing (CPET) before CRT implantation on two distinct definitions of responders: (A) those with $\geq 10\%$ improvement in left ventricular ejection fraction (LVEF); (B) those with improvement of peak $\text{VO}_2 > 10\%$. **Methods** Participants were 37 HF patients (68 ± 11 years) NYHA class III or IV undergoing CRT, with a $\text{LVEF} \leq 35\%$. Clinical CPET and ECO assessment using standard methods were performed at baseline and at follow-up (5 months). Differences between groups were tested with paired sample t-test and logistical regression analyses were performed to identify predictors. **Results** At 5 months the number of patients classified as responders was 70.3% and 51.4% in (A) and (B), respectively. According to (A), LVEF post CRT (41.4 ± 9.5 vs 30.3 ± 8.8 $p < 0.05$) and the difference between LVEF pre and post CRT (16.9 ± 6.0 vs 2.6 ± 7.2 $p < 0.01$) was higher in responders. According to (B), responders had a lower VO_2peak pre-CRT (10.5 ± 2.4 vs 19.1 ± 4.5 $p < 0.01$) and a higher difference between VO_2peak pre and post-CRT (5.1 ± 4.7 vs -2.3 ± 2.7 $p < 0.001$) compared to non-responders. In (B), the predictors of CRT response were: VO_2peak (odds ratio: 2.3, $p < 0.05$) and CPET duration (odds ratio: 1, $p < 0.05$) independent of age and sex. **Conclusion** Patients with pre-CRT lower VO_2peak and CPET duration are more likely to be responders to CRT. Baseline measurements of CPET might be utilized in order to identify patients who will benefit from CRT. Funded by PTDC/DES/120249/2010 Contact: mritapinto89@gmail.com

A NEW FIELD TEST PROTOCOL FOR PHYSICAL PERFORMANCE OF WHEELCHAIR BASKETBALL

de Laat, B., Hollander, L.

NOC*NSF ISLP

INTRODUCTION Along with team tactics and ball handling skills, physical performance is an important component of wheelchair basketball. Good physical performance may lead to good wheelchair basketball specific qualities, such as high speed, good agility and the ability to maintain high performance of these qualities until the game ends. As these qualities are important, it is therefore important to be able to perform at a high physical level. However, the coach is missing the insight into the physical performances of the players throughout the season. Previous wheelchair basketball specific field tests studies (Brasile, (1986); De Groot, (2012); Vanlandewijck, (1999)) were lacking specificity. Therefore, the purpose of this study is to develop a new wheelchair specific test, which should measure the game qualities and is easy to execute and analyze, accessible and not dependent on environment or equipment. **METHOD** Each part of the test was developed using a combination of literature, experience of the coach and pilots. Tests were adjusted when the required speed was too high, when no extra pushes were needed to maintain speed or when no extra acceleration was possible with a prolonged test. **RESULTS** Four tests were found to meet our criteria and thus comprised the final field test. 1) A 15-meter sprint, where times of each 5-meters were recorded, 2) An agility test, performed to the left and the right (4 corners, 90 degrees to the left and right, 180 degrees to the left and the right, total distance 30-meter), 3) A repeated sprint test of 8 times 15 meter with 7 seconds of rest, 4) A modified submaximal Yo-Yo test, duration of 6 minutes, with heart rate recovery after 1 and 2 minutes (originally Bangsbo et al, 4). **DISCUSSION** The purpose of this study was to develop a new field test, appropriate for wheelchair basketball. The results identified 4 different tests, which can specify physical performance. The results are presented in seconds and heart rate, both easy to measure. The test is executed in the normal training environment with simple test equipment, making the test easy to execute and analyze, accessible and not dependent on environment. A comparison with competition is lacking, which could prove the validity of the test. Furthermore, future test moments can be used to study the reliability of the field test. **REFERENCES** - Bangsbo, J. VARIABILITY OF 3 D GROUND REACTION FORCES DURING SELF-PACED WALKING ON THE DUAL-BELT TREADMILL

Funato, K.1, Kashiwagi, Y.1, Hirano, T.1, Hakamada, N.2, van Loon, E.3, Bakker, P.3

1: Nippon Sport Science University (Tokyo, Japan), 2: Japan Institute of Sports Sciences (Tokyo, Japan), 3: Motek Medical (Amsterdam, Netherlands)

Introduction In spite of long history of human gait research, not so much evidence on kinetic analysis during walking has accumulated. One of the main reasons is that gait analysis was strictly limited to analysis based on artificially targeted single step on the force plate as well as time consuming, complex and thus expensive procedures. Development of new technology as instrumented dual-belt treadmill enables to analyze continuous recordings of each step during gait. This study was designed to describe the variability of 3D ground reaction forces (GRF) during self-paced normal walking at different constant speeds. **Methods** Subjects walked on dual-belt treadmill instrumented with respective force platform (GRAIL; Gait Real-time Analysis Interactive Lab, Motek Medical, The Netherlands). Self-paced target walking speeds (60-140 m/min) were set by synchronizing with motion capture system. 3D GRFs (Fa-p: anterior-posterior, Fm-l: medio-lateral and Fvert: vertical) during each step were continuously recorded and stable 15-20 steps in each walking speed were used for analysis. Each GRF was synchronized and superimposed at onset of foot contact, and average GRF curve as well as coefficient of variance was calculated. **Results** As walking speed increased, foot contact time became to decrease, which was accompanied by the increases in first peak GRFs at foot contact (from 60 to 140 m/min, Fa-p increased 0.15 to 0.4 N/BW, Fm-l increased 0.1 to 0.15 N/BW, Fvert

increased 1 to 1.5 N/BW). Discussion In first peak in GRF immediately after foot contact during fast walking such as 140 m/min, large variability especially in both Fa-p and Fm-l were observed. Inter-individual and intra-individual (right and left foot) differences in GRF frustration were also stressed. It was suggested that unstable dynamic balance was indicated especially at the early phase in double support during normal fast walking. EFFECTS OF INTENSIVE WHOLE-BODY-VIBRATION TRAINING ON PHYSICAL PERFORMANCE IN ADULTS WITH PARALYSIS: PILOT-STUDY

Yoon, J.I, Tsuji, T.I, Hotta, K.2, Saghaazadeh, M.I, Tanaka, K.I, Okura, T.I

1: University of Tsukuba, 2: Ibaraki Prefectural University of Health Science, Japan Introduction

With the rising number of strokes worldwide and the number of individuals left with disabilities after stroke, novel strategies to reduce disability, increase physical function and improve quality of life are of major importance. Recently, whole-body-vibration (WBV) has been gaining attention as a new physical training technique combining safety and effectiveness. With WBV one can expect the same effects of strength training without imposing heavy weights or executing dynamic actions. WBV training (WBVT) is an intervention that can address these challenges when trying to improve physical function in stroke patients; however, to the best of our knowledge, no study has been performed demonstrating definitive outcomes for WBVT. This study examines the effect of a 12-month WBVT program on the physical performance and range of motion (ROM) of the upper-limbs in a middle-aged Japanese man following a stroke. Method The subject was a 62-year-old man who had a stroke 12 months previously that paralyzed his right side. He participated in the WBVT program once weekly for 52 weeks. Sessions during weeks 1-24 included 10 min of massage, 5 min stretching and 20 min cool down with massage. Sessions in weeks 25-52 consisted of 5 min warm-up, 20 min weight-bearing strength training and 25 min cool down with massage. All aspects of the session were performed on the POWER PLATE® (POWER PLATE, London, UK) at a frequency of 30-40 Hz and a vibration amplitude of 2.5 mm. We used the Simple Test for Evaluating Hand Function (STEF), Brunnstrom recovery stage for ROM, and timed up-and go (TUG), grip strength and one-leg balance with eyes open (OBE) to evaluate physical performance. We tested at baseline, week 20 and week 52 as follow up. However, the subject was proficient in STEF and ROM at the week 20 testing and follow up testing included only those for physical performance. Result The subject improved in 8 items of physical performance. From baseline to 20 weeks, STEF and ROM increased from 38 to 69 points, shoulder flexion from 85 to 115 degrees, shoulder external rotation from -5 to 15 degrees, horizontal flexion from 80 to 100 degrees and shoulder horizontal extension from -35 to 0 degrees, respectively. Moreover, from baseline to week 20 and to week 52, TUG improved from 8.94 s to 7.28 s to 6.34 s, grip strength from 10.4 kg to 23.5 kg to 30.4 kg and OBE from 3.43 s to 17.41 s to 40.41 s, respectively. Conclusion A once weekly, 52-week WBV exercise program was shown to be safe in a middle-aged Japanese man suffering from stroke. In addition, our data suggest that a WBVT program can improve ROM and physical performance.

THE EFFECTS OF KINESIO TAPING ON PAIN, FUNCTION, GAIT AND NEUROMUSCULAR CONTROL IN PATIENTS WITH KNEE OSTEOARTHRITIS: A RANDOMIZED, PLACEBO-CONTROLLED STUDY

Rahlf, A.L., Zech, A.

University Hamburg

Introduction Knee osteoarthritis is one of the most frequent musculoskeletal disorders of elderly people (Felson, 1990). The conservative treatment of osteoarthritis with kinesio taping has gained increasing attention in recent years. However, current evidence on the effectiveness of kinesio tape is limited due inconsistent findings (Morris et al. 2013; William et al., 2012). The objective of this study was to determine the effects of kinesio taping on pain, function, gait and neuromuscular control concerning patients with knee osteoarthritis. Methods 45 Patients (58.6±14.3 years) with a clinical and radiographic diagnosis of knee osteoarthritis were randomized in a kinesio tape, placebo tape and control group. The treatment period in the kinesio and placebo tape group consisted of three consecutive days. All participants completed pre- and post-tests and one interim test directly after receiving the tape in order to assess pain, stiffness and physical function (Western Ontario and Mac Master Universities Osteoarthritis Index = WOMAC), functional balance (balance error scoring systems = BESS), gait speed (10 m walking test) and maximum isometric quadriceps strength. Differences between the groups were analyzed by using repeated measures ANOVA. Results At baseline, there were no statistically significant differences between groups. Significant group by time interactions were found for the WOMAC-Score ($p=0.016$). Post hoc comparisons revealed significantly greater improvements in kinesio group (-1.1 ± 0.7 pts.) at post-tests compared to the placebo (-0.4 ± 0.6 pts.) and control group (-0.4 ± 0.6 pts.). Significant time effects but no group by time interactions were found for the walking test ($p=0.008$) and the BESS score ($p=0.011$). Discussion The results showed that kinesio taping increased physical function significantly in osteoarthritis patients. This implies that kinesio taping might be an effective measure for the conservative treatment of knee osteoarthritis. However, due to the small sample size in this study and lack of further trials, more research is needed on this issue. References Felson, D.T. (1990). Introduction: Volume based (endurance) respiratory training is less used technique than strength (power) training. The aim of our study was to demonstrate the impact of 4 weeks intense volume based respiratory training on the ventilatory parameters and exercise performance. Methodology: Group of 8 physiotherapists well educated in respiratory mechanics underwent exercise test followed by 4 weeks of volume based respiratory training using SpiroTiger device. There was no change in their physical activity before and during the training period. The exercise test protocol was a step test performed on bicycle ergometer started on 1W/kg, with each step increment 0.25W/kg until the exhaustion. Each step lasted 6 min to ensure stabilization of physiological reactions. The respiratory training protocol was based on the recommendation of the manufacturer, and each person trained 3 times a week 20-30 min. Spirometry (FVC, FEV1 and PEF), and dynamic physiological parameters (heart rate, VO2 consumption, ventilation, tidal volume and breathing frequency) were collected

continually during the test. To assure the comparable data between both pre and post training, the calculations were taken at the same load as an approximate figure from the last 30 sec the highest achieved step. Results: 4 weeks of training had a positive impact at all measured spirometry parameters. All measured parameters were improved: FVC +11%, $p < 0,005$, FEV1 +12%, $p < 0,01$, PEF +9%, $p < 0,01$. Physiology measures of ventilatory parameters measured during the exercise also showed a statistically significant improvement: ventilation 17%, $p < 0,01$, tidal volume 13% $p < 0,005$, while breathing rate did not statistically change. Also max achieved heart rate remained identical. Maximum oxygen consumption at the highest achieved step also increased significantly +12% $p < 0,005$. Discussion: Our findings demonstrated, that volume based respiratory training alone can improve static and dynamic ventilatory parameters after 4 weeks of intense respiratory training. It also improves the oxygen consumption. Heart rate and breathing rate were not affected, so the whole impact came from the improvement of respiratory system. There is significant amount of data published about resistance and obstructive training with mixed results on measurable parameters. Our finding brought a results from a novel training technique based on volume rather than strengthening the respiratory muscles. References: Shoemaker MJ, Cardiopulm Phys Ther J. 2009 Sep;20(3):5-15. ASSOCIATION BETWEEN RATE OF TORQUE DEVELOPMENT AND GAIT SPEED IN AMBULATORY POST-STROKE PATIENTS

Shimose, R.1,2, Matsunaga, A.2, Hoshi, T.1, Hori, K.1, Enomoto, T.1, Shibata, K.1, Sakota, Y.1, Otsuka, T.1, Adachi, S.1, Ichinosawa, Y.2, Shimizu, S.2, Sakamoto, M.2, Suzuki, M.2, Yona, M.3, Muro, M.

Introduction Rate of torque development (RTD), which can be derived from the average slope of the torque-time curve in the early phase of rising muscle force, is a valuable parameter for assessing the ability to perform rapid and forceful movements in trained athletes, elderly, and/or disabled people. Although gait speed is reportedly associated with the severity of paresis, standing balance, and muscle strength of unaffected lower limbs, only a few studies have assessed RTD of affected lower limbs in order to identify factors that reduce gait speed in post-stroke patients. In this study, we aimed to investigate the association between RTD of affected lower limbs and gait speed in ambulatory post-stroke patients. Methods Fourteen stroke patients (mean age, 65 \pm 10 years) who had received inpatient rehabilitation therapy for at least one month after stroke were enrolled in this study. Exclusion criteria were dementia, low vision, higher brain dysfunction, orthopedic disease, and requiring assistance and/or devices while level walking. Clinical characteristics including age, sex, stroke type, and affected side were collected. Maximal gait speed over 10 m of level walking was measured within one month after stroke. Patients were also asked to pedal a recumbent cycle ergometer (Strength Ergo 240, Japan) as fast and forcefully as possible at a constant rate of 40 rpm. Peak torque (PT) and RTD of unaffected and affected lower limbs were calculated based on the torque-time curve from torque onset to 200 ms. Differences in PT and RTD between unaffected and affected limbs were assessed using the Wilcoxon signed rank test. Moreover, relationships between PT and RTD and maximal gait speed were assessed by Spearman's rank correlation coefficient. Results PT and RTD of affected limbs were significantly lower compared to those of unaffected limbs (respectively, $P < 0.01$). PT ($r = 0.64$, $p < 0.05$) and RTD ($r = 0.62$, $p < 0.05$) of affected limbs were significantly correlated with maximal gait speed. Conclusion (Discussion) Gait speed is a useful predictor of independent and practical walking in post-stroke patients. Our findings suggest that gait speed is associated with RTD and PT of affected lower limbs, and is important for improving gait speed to increase rapid force production of affected lower limbs in ambulatory post-stroke patients. MOTOR ABILITY AFTER ISCHEMIC STROKE

Yoshida, H.M.1, Kishimoto, S.T.1, Analha, G.O.1, Lima, F.O.2, Li, L.M.2, Fernandes, P.T.1

State University of Campinas

Introduction Stroke is one of the most common diseases in the world, representing the third position of mortality(1). World Health Organization(5) estimated that, annually, 15 million people suffer their first stroke, and 5 million die and another 5 million has permanent impairment. European Stroke Organization indicates stroke as the most cause of long term disability in Europe(2). Therefore, motor impairment is one of most common deficit after ischemic stroke and it is estimated that 80% of patients remain with some motor impairment. Objective Identify the motor impairment in post stroke adult patients. Methods We evaluated patients with first anterior circulation ischemic stroke, both gender and adults. Motor function was evaluated by Fugl-Meyer Motor Scale (FMMS)(3). The motor domain includes movement, coordination and reflex action. Each domain contains multiple items, each scored on a 3-point ordinal scale (0 = cannot perform, 1 = performs partially, 2 = performs fully). The motor score ranges from 0 (hemiplegia) to a maximum of 100 points (normal motor performance), divided into 66 points for the Upper Extremity (UE) and 34 points for the Lower Extremity (LE). Similarly, there is a maximum of 24 points for Sensation (SE), 14 points for Sitting and Standing (SS). Results We performed the evaluation in 117 patients (68 men; 61 \pm 14 years; 61 had a left sided ischemic stroke). The subjects present the following motor ability score: UE 54.88 (\pm 17.94); LE 29.16 (\pm 7.83); For UE + LE the group presented 84.05 (\pm 24.52); SS 10.84 (\pm 3.67); SE 21.93 (\pm 4.93). Total score was 116.82 (\pm 30.57). Conclusion Some studies had shown that 76% of post stroke survivors had weakness on UE(4). Our results confirm this data and support that most of our subjects has considerable motor deficit in UE motor performance. LE impairment in our patients could indicate difficulties to execute task such as walk. In this study, our patients also reported difficulties in execute daily activities as a result of motor impairment. We also highlight need of future studies in order to verify co-morbidities associated to motor impairment such as depressive symptoms and cognition. References 1.American Heart Association. MO-PM14 PH Fatigue

EFFECTS OF PRIOR EXERCISE ABOVE CRITICAL POWER ON MUSCLE FATIGUE

Helal, L.C.A.S.1, Souza, K.M.1, De-Lucas, R.D.1, Nascimento, P.C.1, Guglielmo, L.G.A.1, Denadai, B.S.2

1: UFSC (Florianópolis, Brazil), 2: UNESP (Rio Claro, Brazil)

Introduction The physiological nature of anaerobic work capacity (AWC) has received little consideration in comparison to critical power (CP). Therefore, the aim of this study was to analyze the influence of prior exercise performed at different work rates above CP (with the same AWC rate depletion) on muscle fatigue during a subsequent isokinetic cycling sprint. **Methods** Fifteen healthy male subjects (mean \pm SD; age, 26.0 ± 3.5 years; weight, 76.6 ± 10.4 kg; height, 178.2 ± 7.6 cm) volunteered to participate in this study. Each subject performed the following testing stages: 1) a ramp incremental test (25 W/min) to measure maximal oxygen uptake ($\dot{V}O_{2\max}$) and maximal power output (P_{\max}); 2) a 5-s all-out isokinetic sprint test at 120-rpm to measure cycling peak torque in control condition (TCON); 3) four constant work rate tests performed to exhaustion (over a range of times between 2 and 12 min) for CP and AWC determination; and 4) two constant work rate tests, each at work rate set to deplete 70% AWC (the time integral of the work rate above CP consuming 70% of AWC) either 3-min or 10-min, followed immediately by a 5-s all-out isokinetic sprint test at 120-rpm to measure cycling peak torque in the experimental conditions (TEXP3min and TEXP10min). Peak torque was considered as the average of the peak torque for each leg in all conditions. For comparisons, one-way repeated measure ANOVA followed by Bonferroni's paired t-test was used. The level of significance was set at $p < 0.05$. **Results** The $\dot{V}O_{2\max}$ and P_{\max} were 3.71 ± 0.49 L.min⁻¹ and 322 ± 26 W, respectively. The CP and AWC were 207 ± 17 W ($r^2 = 0.99 \pm 0.01$; SEE = 3.9 ± 2.7 W; $64.3 \pm 2.7\%$ P_{\max}) and 21.3 ± 4.2 kJ, respectively. The constant work rate tests, which were set to deplete 70% AWC (14.9 ± 3.0 kJ) in 3 min and 10 min, were performed at 289 ± 25 W ($89.8 \pm 2.9\%$ P_{\max}) and 231 ± 19 W ($71.9 \pm 2.2\%$ P_{\max}), respectively. TEXP3min (108.4 ± 19.8 Nm) and TEXP10min (112.1 ± 23.0 Nm) decreased significantly ($F = 19.68$; $p < 0.001$) in the same magnitude ($p = 0.46$) in comparison to TCON (135.5 ± 20.2 Nm). **Discussion** The result of the present study is consistent with the idea that AWC is depleted at a rate that bears some proportionality to the magnitude of the work rate requirement above CP (Fukuba et al., 2003; Jones et al., 2010). We conclude that prior exercise above CP produces a similar level of muscle fatigue independent of the work rate performed when AWC is depleted at the same rate. **References** Fukuba Y, Miura A, Endo M, Kan A, Yanagawa K, Whipp BJ (2003). *Med Sci Sports Exerc*, 35 (8), 1413-1418. EFFECT OF MUSCLE-DAMAGING ECCENTRIC EXERCISE WITH REDUCED MUSCLE GLYCOGEN ON PLASMA INTERLEUKIN-6 AND NEUROMUSCULAR FUNCTION

Willems, M.E.T., Myers, S.D., Gavin, J.P.

University of Chichester

Introduction Exercise-induced muscle damage from eccentric contractions is characterized by neuromuscular dysfunction and inflammation typified by an elevated interleukin-6 (IL-6) response. The IL-6 response is also related to glycogen availability (Pedersen and Febbraio, 2008). We examined whether muscle-damaging eccentric exercise with low muscle glycogen would result in higher IL-6 levels and larger neuromuscular dysfunction. **Methods** Twelve men [age 23 ± 4 years, height 179 ± 5 cm, body mass 77 ± 10 kg, $\dot{V}O_{2\max}$ 54.3 ± 9.1 mL.kg⁻¹.min⁻¹, mean \pm SD] participated with normal sleep quality/patterns (3.9 ± 0.9 score on the Pittsburgh Sleep Quality Index indicating no confounding effect on IL-6 levels). Neuromuscular function and IL-6 were measured before and after 1) a glycogen-reducing cycling protocol (~ 75 rpm for 10 min at 50% $\dot{V}O_{2\max}$; then 60% $\dot{V}O_{2\max}$ until exhaustion; time-to-exhaustion 95 ± 13 min) in an evening session and 2) downhill running under two conditions [normal glycogen (NORM) or with reduced glycogen (RED)] ($\sim 12\%$ at individual lactate threshold speed [12.1 ± 1.1 km.h⁻¹] for level running) the following morning in a fasted state, with recovery examined up to 48 h. Plasma was analysed in duplicate using IL-6 Quantikine high-sensitivity ELISA kits (R&D Systems Europe Ltd, Abingdon, UK). Neuromuscular function of m.quadriceps femoris was quantified by isometric maximal voluntary force (iMVC), low (20 Hz) and high (50 Hz) frequency forces using surface electrical stimulation, and low frequency fatigue. Two-way repeated measures ANOVA and pre-planned paired samples t-tests were used. Significance accepted at $P < 0.05$. **Results** Isometric maximal voluntary force was reduced by similar amounts immediately after eccentric exercise (24.6% (NORM) and 27.7% (RED), $P < 0.05$). During recovery, iMVC was reduced up to 48 h with no difference between conditions. For both conditions, 20 Hz and 50 Hz force was reduced for 48 h by similar amounts for each frequency. The change in low frequency fatigue was greater for the NORM condition immediately ($P = 0.02$) and 48 h ($P = 0.03$) after eccentric exercise. Following the glycogen-reducing cycling protocol, IL-6 was increased (8.10 ± 3.05 pg.mL⁻¹, $P < 0.01$). Plasma IL-6 immediately after eccentric exercise (NORM: 4.32 ± 3.17 pg.mL⁻¹; RED: 4.49 ± 2.92 pg.mL⁻¹) and at 12, 24 and 48 h were not different between conditions. **Discussion** Muscle-damaging eccentric exercise with low muscle glycogen exacerbated low-frequency fatigue, but had no effect on plasma IL-6 responses. Such exercise appears to have a greater peripheral contribution to force loss in early recovery. **References** Pedersen BK, Febbraio MA. (2008). *Physiol Rev*. 88(4), 1379-406. INFLUENCE OF VOLUNTARY HYPERVENTILATION DURING HYPOXIA ON EXECUTIVE FUNCTION AND PREFRONTAL CORTICAL ACTIVITY: AN EXPERIMENTAL MODEL FOR HYPOXIA CENTRAL FATIGUE WITH EXERCISE

Genta, O., Kazuki, H., Kazuya, S., Kyeongho, B., Hideaki, S.

University of Tsukuba

Introduction Hypoxic exercise impairs executive function as evidenced in cognitive functions such as selective attention, cognitive flexibility and processing speed associated with higher brain centers. This may be due to hypoxemia caused by hyperventilation during exercise (Ando et al., 2010). Hypoxemia, caused by apnea/hypoventilation after hyperventilation, leads to a decline in cerebral oxygenation and executive function (Van Diest et al., 2000). However, the neural mechanisms behind this decline are unclear. Since the left dorsolateral prefrontal cortex (DLPFC) plays a crucial role in executive functions, it is hypothesized that the cognitive decline due to hyperventilation is

due to decreased activity in the left DLPFC. We thus aim to clarify the underlying neural mechanisms of hyperventilation-induced declines in executive function by using multichannel functional near-infrared spectroscopy (fNIRS), in order to establish an experimental model examining hypoxia central fatigue with exercise. Methods Fourteen healthy participants performed a color-word Stroop task (CWST), consisting of incongruent and neutral conditions, both before and 15 minutes after 10 minutes of voluntary hyperventilation under hypoxic (13% O₂) conditions. All subjects were monitored during voluntary hyperventilation to ensure that their end-tidal CO₂ (ETCO₂), an indicator of PaCO₂, was lower than 23 mmHg, their ventilatory volume was 50 L/min and respiration rate was 60 breaths/min. Cognitive performance was assessed based on reaction time (RT) for the CWST. Brain activity was monitored using fNIRS during the CWST. fNIRS probes were positioned to cover the left DLPFC (Yanagisawa et al., 2010). Change in oxy-Hb concentration was used as an indication of brain activity. The difference between conditions (incongruent-neutral) was calculated as RTinterference to determine executive control. To determine expired gas, arterial oxygen saturation (SpO₂) was measured. Results and Discussion All subjects performed voluntary hyperventilation, SpO₂ decreased following voluntary hyperventilation. There were significant interactions between RTinterference: voluntary hyperventilation lead to increased RTinterference compared with normal breath. There were significant interactions of oxy-Hb of the left DLPFC: voluntary hyperventilation decreased left DLPFC activity compared with normal breath. These results suggest that hypoxemia elicited by hyperventilation is associated with cerebral hypoxia, which may cause a decline in task-related prefrontal activity. This could be an experimental model for exercise-induced central fatigue. References Ando S, Yamada Y, Kokubu M. (2010). Journal of Applied Physiology, 108, 1210-1216. BIOLOGICAL, PERCEPTUAL AND NEUROMUSCULAR RESPONSES TO AN INTERNATIONAL JUNIOR RUGBY UNION MATCH: HOW ARE THEY RELATED TO MATCH ACTIVITY?

Lacome, M.1, Piscione, J.1, Van Lierde, F.2, Hager, J.P.1, Dine, G.2

1: FFR (Marcoussis, France), 2: IBT (Troyes, France)

Introduction The Rugby Union Junior (U20) World Championship is a high challenging competition in which each team can play 5 matches in 21 days. The adaptation of the recovery and training load of players is essential and an assessment of the individual player fatigue following match may help to optimize this regulation. The purpose of this study was thus to monitor plasma creatine kinase ([CK]), neuromuscular and perceptual responses to an international junior match and to analyse their respective relationship with match activity. Methods Fifteen international junior rugby union players (97.2±14.3 kg 187±9 cm) took part to the study. GPS and notational data were used to describe individual match activity. [CK] was measured using capillary blood sample respectively 6h before and 1, 12, 24 and 48h post match. A wellbeing questionnaire (Hooper et al., 1995) was completed respectively 36h before and 12, 36 and 60h after the match. Countermovement jump performance (CMJ height) was assessed respectively 36h before and 36 and 60h after the match. Results [CK] increased significantly from 259.3 ± 286.9 U.L-1 to 1023.5 ± 1065.4 U.L-1 24h post match (P<0.001; ES = 1.72) and remained significantly higher 48h post match (p<0.001; ES = 0.69). Wellbeing score decreased significantly from 23.1 ± 2.2 to 19.0 ± 3.6 12h post match (P<0.001; ES = 1.29) but was not significantly different 36h post match. CMJ height was significantly lower 36h post match (P<0.05; ES = 0.20) but not 60h post match. There was a large relationship between the maximal values of CK observed post match, expressed in percentage of the pre match value (Δ [CK]%), and the number of impacts sustained during the match ($r = 0.62$; P<0.05). A large relationship between Δ [CK]% and the number of high intensity static activities was also observed ($r = 0.53$; P<0.05). The variation in wellbeing score between pre match values and 36h post match values (Wellbeing%) was largely associated with the running distance ($r = -0.56$; P<0.05) and the number of high intensity actions measured with GPS ($r = -0.59$; P<0.05). Conclusion This study was the first to examine the physiological, neuromuscular and perceptual responses to an international junior rugby union match and their relationships with match activity. Even if wellbeing score returned to baseline value 36h post match, neuromuscular function was still lower 36h post match. Moreover, [CK] was increased for 48h post match, which may indicate that muscle recovery was not complete 2 days after the match. Questions remain concerning the time course of recovery over a rugby union junior world championship with a match every four days. References Hooper SL, Mackinnon LT. (1995). THE IMPACT OF AEROBIC FITNESS STATUS ON THE PHYSIOLOGICAL RESPONSES TO INCREMENTAL RAMP EXERCISE

Boone, J., Celie, B., Bourgois, J.

Ghent University

Introduction The capacity to adjust to changes in metabolic demand is an important aspect of exercise (in)tolerance in healthy subjects and patients. The purpose of this study is to obtain insight into the impact of aerobic fitness level on pulmonary VO₂ response, muscle activation and deoxygenation by means of surface electromyography (EMG) and near-infrared spectroscopy (NIRS), respectively in response to incremental ramp exercise, characterized by a continuous and linear increase in work rate. Methods Sixtyfour male subjects performed incremental ramp cycle exercise (20-35 Watt.min-1) until exhaustion, starting from a baseline work rate of 50 Watt for three minutes. VO₂ was expressed as a function of work rate and the slope of the VO₂/WR-relationship below and above the gas exchange threshold was calculated (S1VO₂ and S2VO₂). Deoxy[Hb+Mb] was normalized with the deoxy[Hb+Mb] at baseline cycling set at 0% and the highest deoxy[Hb+Mb] set at 100%. The deoxy[Hb+Mb] response was modeled by means of a sigmoid function and the slope of the sigmoid d and the c/d-point (the work rate where 50% of the amplitude in deoxy[Hb+Mb] is reached) were determined. IEMG was expressed relative to the iEMG signal in response to a maximal voluntary contraction (%MVC) and set out as a function of work rate. The slope of the iEMG/WR-relationship for the same work rate domain as for VO₂ was calculated (S1EMG and S2EMG). The above mentioned parameters were correlated with VO₂peak to express the impact of aerobic fitness status on the physiological responses to ramp exercise. Results The mean VO₂peak was 52.5±6.4 ml.min-1.kg-1 (range: 39.8-66.7 ml.min-1.kg-1). The mean S1VO₂ and S2VO₂ were respectively 9.6±0.2 ml.min-1.Watt-1 (range 9.1-10.1 ml.min-1.Watt-1) and 10.0±0.3 ml.min-1.Watt-1 (range 9.3-10.7 ml.min-1.Watt-1) and were not correlated to VO₂peak ($r = 0.27$ and $r = 0.13$ respectively; P>0.05). The mean S1EMG and S2EMG were respectively 0.099±0.009 %Watt-1 (range: 0.078-0.122 %Watt-1) and 0.156±0.006 %Watt-1 (range 0.143-0.166 %Watt-1) and were not correlated with VO₂peak ($r = 0.13$ and $r = 0.09$ respectively, P>0.05). The slope of the sigmoid (d) was 0.072±0.010 %WRpeak-1 (range 0.052-0.091 %WRpeak-1) and the c/d point was 52.6 ± 3.3 %WRpeak (range 45.5-60.4 %WRpeak). Both d and c/d were significantly (P<0.01 and P<0.001, respectively) positively correlated to VO₂peak ($r = 0.44$ and $r = 0.84$, respectively). Conclusion The present study shows the although aerobic fitness status has no impact on pulmonary VO₂ and muscle fiber recruitment, the pattern of deoxy[Hb+Mb], which can be considered as a reflection of the dynamic relationship between O₂ supply and O₂ demand, is altered (i.e., a delayed increase in O₂ extraction with a higher aerobic fitness status) in response to ramp exercise. THE EFFECT OF A SIX-WEEK WHOLE BODY VIBRATION TRAINING PROTOCOL ON THE PHYSICAL CAPACITIES AND FATIGABILITY OF OVERWEIGHT WOMEN

Serresse, S., Zory, R., Boudreau Larivière, C.
Laurentian University

Introduction Whole body vibration (WBV) is a relatively new training technique that can improve fatigability by increasing strength and can potentially enhance adherence to exercise programs as this type of training is considered low intensity 1. The aim of this study was to examine the effects of a 6-week WBV training program on the physical capacities and fatigability of overweight women. **Methods** Female participants with body fat percentages (BF %) ranging from 30-35% were separated into 2 groups; control (CON; n=10) or whole body vibration (VIB; n=14). The study design consisted of a 6-week WBV training regimen (30 Hz and low amplitude (2mm)) preceded (sessions 1 and 2) and followed (sessions 3 and 4) by 2 testing sessions. During testing sessions 1 and 3, the basal metabolic rate (BMR), body composition, Wingate, squat (SJ) and countermovement (CMJ) jumps and fatigue perception (FSS, MFI and SHARP questionnaires) were assessed. Isokinetic and muscle fatigue tests were performed during sessions 2 and 4. WBV training sessions lasted 30 minutes and entailed 15 sets of 1-minute timed squats followed by 1-minute rest and were performed 3 times a week. The VIB group performed their exercises on the power Plate® pro 6. The CON group performed the same exercises without vibration. Following a normality test, repeated measures ANOVA was used to analyse the effect of the WBV training program. **Results** The results revealed that the 6-week training regimen significantly decreased body fat mass and BF % in both groups with no differences between groups but had no other effect on body composition or BMR. Training did not improve leg power as measured using the Wingate or vertical jumps (SJ and CMJ) for both groups. The Wingate test did show a decrease in the fatigue index for both groups. Unexpectedly, a decrease in strength was found in extension phase during eccentric contractions (120°/s) and in flexion phase during concentric contractions (120°/s and 180°/s) for the VIB group. Fatigue perception measured using a multidimensional approach and fatigue rate represented by regression slopes were unchanged in both groups. **Discussion** The aim of this investigation was to evaluate the effect of a 6-week WBV training regimen on body composition, neuromuscular and physiological effects in overweight women. This study demonstrates that WBV training at 30 Hz and 2mm amplitude has a very limited impact on the physical capacities and fatigability in our sample of overweight women. Higher intensity vibration parameters may be required to elicit beneficial changes in this population of women. **References** 1 Torvinen, Saila, et al. (2002) Clinical physiology and functional imaging 22.2: 145-152. Contact sx_serresse@laurentian.ca

CHANGES IN MUSCLE HARDNESS ASSESSED BY ULTRASOUND ELASTOGRAPHY AFTER REPEATED ECCENTRIC EXERCISE

Lau, W.Y.1, Blazeovich, A.J.1, Newton, M.2, Inami, T.1, Wu, S.S.1, Nosaka, K.1
1:Edith Cowan University (Australia), 2: Murdoch University (Australia)

Introduction After performing eccentric exercise, muscles become weak, sore and stiff. Murayama et al. (1) used a pressure method in which the force required to deform the upper arm was measured, to examine changes in muscle hardness after elbow flexor eccentric exercise, and reported approximately 30% increases in hardness at 4 and 5 days post-exercise. Recently, ultrasound elastography has been used to assess muscle hardness, and Niitsu et al. (2) reported that muscle hardness increased immediately after, peaked at 2 days and decreased at 4 days after 3 sets of 15 elbow flexor eccentric contractions. However, no previous study has compared between the first and second bouts for changes in muscle hardness to investigate whether the magnitude of muscle damage affects the changes. The present study tested the hypothesis that the changes in muscle hardness would be smaller after the second than the first bout. **Methods** Ten untrained men (22-28 y) performed two exercise bouts consisting of 10 sets of 6 maximal isokinetic eccentric contractions of the elbow flexors with the non-dominant arm separated by 4 weeks. During each eccentric contraction, the elbow joint was forcibly extended from a flexed (60°) to a fully extended (0°) position. Changes in maximal voluntary isometric contraction strength (MVC), range of motion (ROM), muscle soreness (by visual analog scale; VAS), ultrasound echo intensity and muscle hardness (by real-time ultrasound elastography: RTE) before, immediately after, and 1-5 days after exercise were compared between bouts by two-way repeated measures ANOVA. **Results** Compared with the first bout, changes in MVC, ROM, VAS and echo intensity were smaller ($P < 0.05$) after the second bout, showing the typical repeated bout effect. Compared with the subdermal adipose tissue, muscles were softer before exercise, but became harder at 3-5 days post-exercise. The magnitude of the increase in muscle hardness was greater after the first bout than the second by 30-55%, and brachialis became harder than biceps brachii after exercise. **Discussion** The results suggest that muscles become harder after eccentric exercise when the magnitude of muscle damage is greater, and the changes after the repeated bout was minimum. It seemed that the increased hardness after eccentric exercise was associated with inflammation of muscle/connective tissue, since a correlation ($r = 0.89$; $P < 0.05$) was found between the magnitude of increase in muscle hardness and echo intensity. The changes in muscle hardness assessed by RTE appear to be comparable to those shown by the pressure method (1). **Reference** 1. Murayama et al. (2002) Eur J Appl Physiol. 82:361-7. 2. MO-BN04 BM Balance & Stability

THE AGE DIFFERENCE ON THE RELIABILITY WHILE MEASURING POSTURAL SWAY WITH QUIET STANDING

Lo, P.Y.1, Su, B.L.2, Hong, J.Y.2, Lin, N.H.2, Yan, C.W.2, Guo, L.Y.1
1: Kaohsiung Medical University, 2: National Sun Yat-Sen University

Introduction Reliability reflects measurement consistency and the degree to which an instrument is free from the concurrent variance of measurements while performing during different sessions, days or raters. When looking at reliability, we see minimal studies that compare the reliability of age differences in postural sway measurements even though many studies find significantly greater postural sway in the elder population than compared to the younger cohort. Investigation of this age difference is important for choosing variables to

represent their postural sway improvement in order to determine the intervention outcome. The aim of this study is to investigate whether different test-retest reliabilities of postural sway variables, calculated from center of pressure (COP), will have the age effect. Methods Forty healthy subjects were recruited (twenty young adults: 20.1 ± 1.3 yr, and twenty elders: 68.8 ± 3.1 yr). In this study, a self-designed force plate was constructed of four dynamometers to measure the vertical force. Participants were asked to stand upright on the force plate. We collected data for 40 seconds in both open-eyed and close-eyed double leg stance conditions. Test-retest reliability was examined by the intra-class correlation coefficients (ICCs). Results The ICCs for test-retest reliability of the antero-posterior average velocity (V-AP) and medio-lateral average velocity (V-ML) of COP were 0.92-0.98 (excellent) in the older and 0.85-0.92 (excellent) in the younger groups. For the variables of the antero-posterior mean distance (MD-AP) of COP, the ICCs of the younger group (0.50-0.61, fair to good) were lower than the older (0.92-0.93, excellent). In contrast, the ICCs values for the medio-lateral mean distance (MD-ML) of COP in the younger (0.80-0.81, excellent) were higher than the older (0.38-0.55, fair to good). Discussion The age effect is present in the reliability of postural sway measurements where MD-AP was better in the older group and MD-ML was better in the younger group. This study also showed the reliability of the V-AP, and the V-ML to be better than MD-AP and MD-ML regardless of age. The results were similar to findings of past studies (Golriz et al., 2012; Swanenburg et al., 2008). Conclusion When using postural sway improvement for detecting an intervention outcome, it will be more beneficial to choose COP velocity domain variables, i.e. V-AP or V-ML. However, when using the COP distance domain variable it will be better to choose the MD-AP for the elder population and MD-ML for the younger. Reference Golriz S, Hebert JJ, Foreman KB, Walker BF. THE COMPARISON OF BALANCE ABILITIES OF NOVICE, MID-LEVEL AND ELITE ARCHERS DURING ARROW SHOOTING

Yenigelen Simsek, D.

Anadolu University

Introduction Archery is a good example of a sport where balance is required to achieve high scores. (Hrysomallis, 2011). The aim of this study was to compare the differences in ground reaction forces between novice, mid-level and elite archers during arrow shooting. Methods Twenty-seven archers (group I: elite archers (EA): n=9, group II: mid-level archers (MLA): n=9, group III: novice archers (NA): n=9) volunteered to participate to the current study. The archery level have divided in to three groups (elite archers > 1200, mid-level 1100-1200, novice archers <1100) according to their FITA scores. Anterior-posterior (fy) and Medio-lateral (fx) force and center of pressure (COP) sway values during the successful shots towards the goal from a distance of 18 m have been analyzed. During measurement 600x400x100 mm 'Kistler (Germany) 9281EA' force platform have used. Force data sampled at 2000 Hz and normalized according to body weight. ANOVA test has been applied to determine the ground reaction force differences that emerge throughout the implementation of the arrow shot techniques of the elite, mid-level and novice archers and Tukey-W test as the PostHoc test has been chosen to present from which group the differences stem. Results The highest sway values have been demonstrated by novice archers (fy range value = 0,0495; fx= 0,0524) as compared with elite (fy range value = 0,036; fx=0,376) and mid-level archers (fy range value = 0,0404; fx= 0,0430). Mid-level archers have shown least sway. On the other hand elite archer's sway strategy was different than both archery groups. Just after a sharp increase, they have reached a plateau on than continue swaying on anterior-posterior directions. Discussion In general, the results of these studies revealed that balance point projection of archers, in terms of the area they occupy during shooting, the elite archers showed an sway towards right or left sides, but the amount of sway towards front and back was relatively less. It was observed from current and the other study's that as the performance level decreased the movements towards front and back increased. This situation is thought to be a factor decreasing the score at the target. It can be derived from these results that as the archers get experienced through technical development and shooting trainings postural sway rates at fx and fy sides will decrease. The experienced archers were observed to manage to stabilize their postures better even at the last seconds of shooting. In order to train archers in the case of keep balance just before arrow release instantaneous visual force feedback training including fx, fy and COP sway values could be recommended.

A DANCING INTERVENTION IMPROVES LOCAL DYNAMIC STABILITY IN ELDERLY INDIVIDUALS

Hamacher, D., Hamacher, D., Schega, S.

Otto-von-Guericke-Universität Magdeburg

Introduction Lower local dynamic stability (lds) of human walking is associated with risk of falling (Bruijn et al., 2013) which in turn is associated with reduced cognitive functions (Ijmker and Lamothe, 2012). As dancing implies high demands on (and therewith trains) executive functions as well as motor control (Bläsing et al., 2012), it might increase lds and, hence, risk of falling. Since it is not sufficiently investigated how lds develops in the course of a cognitive-motor intervention, the randomized controlled trial aims to investigate whether an additional cognitive demand, which is incorporated in an exercise intervention (6-months dancing programme), affects lds in elderly individuals. Methods 32 elderly subjects were randomly assigned to either a health-related exercise group (age=68.9±3.0 years) or a dancing group (age=67.9±3.9 years). Prior to and after the according intervention, the participants walked for 5 minutes a level hallway up and down. Then, lds of 3 dimensional angular velocity data of trunk trajectories was calculated (Rosenstein et al., 1993). The data was analysed by a blind observer using two-way repeated measures ANOVA. Results Regarding lds of trunk movements, an interaction effect in favour of the dancing group has been observed ($F_{1,30} = 5,436$; $p = .026$; $\eta^2 = 0.146$). Discussion Our data indicates that a dancing programme (which combines cognitive and motor efforts) increases lds of walking in a higher extent than a conventional health related exercise intervention did. The improvements observed in the dancing group are presumable due to the motor-cognitive dual-task character of dancing. We therefore suggest that a music-based multitask exercise might be an efficient fall prevention programme and recommend its implementation in senior centres. THE BOUNDING LIMITS OF CENTER-OF-PRESSURE VELOCITY AS A HALLMARK FEATURE OF CHANGES IN CONTROL POSTURAL STRATEGIES IN OLDER HEMODIALYSIS PATIENTS

Deschamps, T.1, Paris, A.2, Hristea, D.2, Magnard, J.1

University of Nantes

1: Lab « Motricité, Interactions, Performance » (E.A 4334), University of Nantes (France), 2: Dialysis Unit, ECHO Nantes Dialysis Association (France). Introduction Accident falls in older patients with end stage renal diseases (ESRD) undergoing hemodialysis (HD) were found to be higher than the non-dialysed elderly population, affecting quality of life and physical function (Desmet et al., 2005). The present study examined the HD-related changes in postural sway in ESRD patients, as an objective hallmark of their functional abilities. We hypothesized that the primary effects of uraemia, but HD treatment and inactivity also, affected the postural control in HD patients leading to higher bounding limits of center-of-pressure (COP) velocity dynamics. Methods A total of 55 individuals volunteered to take part in this investigation, including 28 HD patients and 27 age- and body mass index-matched healthy participants HS (70.42 ± 13.69 years; 23.46 ± 4.67 kg/m²; vs. 73.62 ± 6.59 years; 25.09 ± 3.54 kg/m²). For all data collection of postural sway, the participants were asked to maintain quiet stance on force platform. The test consisted of two trials of quiet stance, with eyes open and eyes closed. COP parameters were mean and standard deviation (SD) of position, velocity and average absolute maximal velocity (AAMV) in antero-posterior and medio-lateral directions. Results The analysis concerning all COP parameters revealed a significant main effect of group on velocity-based variables, evidencing mean ($p < 0.01$) and SD velocity ($p < 0.01$) and AAMV ($p < 0.05$) increased for HD patients. For example, the thresholds' values that bound the dynamics of COP movement speed (as estimated by computing the AAMV in the antero-posterior direction with eyes open) are significantly higher in HD patients (mean 22.84 ± 10.85 mm/s) than those in HS (mean 14.84 ± 7.53 mm/s) ($p < 0.01$; $\eta^2 = 0.16$). Besides analyses for many COP position variables showed that postural sway was not significantly different between groups, except for the SD position in medio-lateral axis ($p < 0.05$). Discussion The current findings identified the bounding limits of COP velocity as an objective hallmark feature of HD-related changes in postural sway. This point is of special interest for clinical balance assessment in order to examine the effects of long-term targeted intradialytic exercise programs on functional performances. The assessment of this active control of COP velocity dynamics can be also useful for early detection of increased fall risk in HD patients (Deschamps et al., 2014) References Desmet C, Beguin C, Swine C, Jadoul M. TRUNK STABILITY, MUSCULAR FITNESS AND SPORT PERFORMANCE LEVEL IN COMPETITIVE JUDOKAS

López Valenciano, A., Barbado, D., Juan Recio, C., Montero Carretero, C., Dieën, J.H.V., Vera Garcia, F.J.

UNIVERSIDAD MIGUEL HERNANDEZ DE ELCHE

INTRODUCTION The development of the ability to stabilize the trunk/core may improve the performance of a judoka through improvement of body balance control and optimization of force transmission from the lower extremities to the upper limbs. However, to our knowledge, evidence on relationship between trunk stability and level of athletic performance in judo is lacking. The aim of this study was to compare trunk stability and trunk muscular fitness between national and international level judokas. METHODS Twenty-five competitive judokas (8 international and 17 national level judokas) took part in this study. A battery of static and dynamic tests was performed to measure trunk balancing while sitting on stable and unstable seats placed on a force plate (Kistler 9286A). Postural and dynamic sway were assessed by analyzing the mean radial displacement of the centre of pressure (COP). Sudden and unexpected trunk loads in anterior, posterior and lateral directions, were applied to the thorax by a pneumatic mechanism, while the participant was seated with the pelvis fixed. Trunk angular displacement was measured and the damping and stiffness coefficients of the trunk were calculated from the first 110 ms of data after loading. An isokinetic test was used to assess trunk muscle fitness, which consisted of 4 trials of 15 maximal flexion-extension exertions at 120°/s (ROM = 50°). Absolute and relative peak torque and maximum work were calculated to assess trunk muscular strength, and the endurance ratio, maximum work ratio and final fatigue ratio were calculated to assess muscular endurance. RESULTS International level judokas showed lower trunk angular displacement and higher damping after anterior directed loading, and higher relative and absolute peak torque and relative maximum work during maximal extension exertions, than national level judokas. DISCUSSION Trunk response to sudden perturbations and trunk extensor strength measures were different between national and international level judokas. Trunk stability against loading may be determinant of high performance in judo, as it may help competitive judokas to keep balance during defensive and offensive techniques. In addition, trunk extensor strength, rather than trunk flexor strength, appears to be related to high performance in judo. EFFECT OF SPORT SPECIALIZATION IN JUDO AND KAYAK ON TRUNK STABILITY

Barbado, D.1, Juan Recio, C.1, López Valenciano, A.1, Elvira, J.L.L.1, Dieën, J.H.V.2, Vera Garcia, F.J.1

1Sports Research Centre, Miguel Hernandez University of Elche; 2MOVE Research Institute Amsterdam, VU University Amsterdam

Effect of sport specialization in judo and kayak on trunk stability Introduction: Trunk/core stability is considered an important determinant of athletic performance in sports with large demands on balance control (van Dieën et al., 2012). However, studies on the effect of specialization in sports with these demands on trunk stability are lacking. The aim of this study was to compare trunk stability measures between judokas, kayakers and recreational athletes. Methods: 25 competitive judokas, 10 competitive kayakers and 36 recreational athletes took part in this study. A battery of static and dynamic tests was performed to measure trunk balancing while sitting on stable and unstable seats placed on a force plate (Kistler 9286A). Postural and dynamic sway were assessed by analyzing the mean radial displacement of the centre of pressure (COP). Sudden and unexpected trunk loads in anterior, posterior and lateral directions, were applied to the thorax by a pneumatic mechanism while the subject was seated with the pelvis fixed. Trunk angular displacement was measured and the damping and stiffness coefficients of the trunk were calculated from the first 110 ms of data after perturbation. Results: Judo athletes showed higher trunk stiffness and lower angular displacement after lateral loading than recreationally trained individuals ($p < 0.05$). Kayakers showed lower mean radial displacements of the COP than judokas and recreational athletes, especially in dynamic balance tasks on the unstable seat ($p < 0.05$). Discussion: Judokas' trunk response after lateral loading and Kayakers' high trunk balance control while sitting may be related to the specific exertions they do regularly while training and competing, i.e.: judokas undergo rapid lateral and rotational loads in upright stance during defensive and offensive techniques, and Kayakers must maintain balance in the kayak to reduce hydrodynamic friction while kayaking. Therefore, sport specific tests appear to be necessary to properly characterize trunk stability in competitive athletes. INVESTIGATION OF SUBJECT INDEPENDENT MOVEMENT PARAMETERS IN PROFESSIONAL POOL BILLIARD

Kornfeind, P.1, Baca, A.1, Kuzdas, D.1, Gollnhuber, G.2, Neumann, M.2

1: Faculty of Sport Science, University of Vienna (Vienna, Austria), 2: Austrian Pool-Billiard Association (Carinthia, Austria)

INTRODUCTION The object of the game is to strike the white cue ball into the colored balls and then subsequently pocket them, finishing with the 9-ball. For the specific task of hitting the white ball with the cue stick, elite players show wide fluctuations in their movement patterns when playing the same given tasks. However, the purpose of this study is to find subject independent movement parameters determining a successful shot technique in order to develop general principles for coaches and youth players. Furthermore these results may help coaches and scientists to gain their understandings of the structure of such a complex movement and more important to identify essential details. All measurements have been realized during an international tournament in St. Johann (Salzburg, Austria). **METHODS** A group of 22 elite players performed 18 predefined tasks comprising breaks, follow-, draw- and stop-shots while their 3D kinematics (upper body and cue), the longitudinal accelerations of the cue stick and foot pressure were collected. Each predefined position of the balls has been previously marked on the table's cloth to guarantee identical conditions for all participants. All players had to succeed in one given task within three attempts and they were allowed to use their own sports equipment (shooting cue, break cue). Kinematics were captured at 250 Hz by a motion analysis system comprising 8 cameras (Vicon, Oxford) whereas the signal of the accelerometer, mounted on the butt cap of the cue, was recorded with 5 kHz. In addition, a Pedar-X system (Novel, Munich) was electrically triggered and recorded the changes in balance at 50 Hz during the performed tasks. Segment angles were calculated using an adapted upper body model (golem) in Nexus and the 3D motion was visualized in Polygon. For data analysis, three cue position events (back position, ball impact and front position) were defined in all trials and a group of kinematic parameters in combination with the accelerometer data has been selected for evaluation. **RESULTS** Although data analysis is still in progress, preliminary results show in spite of high fluctuations that the average cue stick motion is basically non-accelerated ($0.003g \pm 0.038$) at ball impact for all of the tasks except for the breaks ($0.378g \pm 0.022$). The control sequence of the upper extremities (shoulder-, elbow- and wrist-angles) for the given tasks showed only small variations while during shot preparation, two different player types could be distinguished. Subject dependent movements were found in the ROM of the wrist joint, especially for the abduction/adduction of the hand segment. **DISCUSSION** First results are encouraging and imply that beside individual shot techniques also some general movement parameters exist. Despite the high number of DOF in the input configuration the tested pool billiard players achieved very similar outcomes of success even though movement strategies varied. **CONTACT** philipp.kornfeind@univie.ac.at

NEUROMUSCULAR AND KINEMATIC BEHAVIOUR IN RESPONSE TO EXTERNALLY APPLIED PERTURBATION – EFFECT OF DIRECTION, AMPLITUDE AND VELOCITY

Freyler, K., Ritzmann, R., Gollhofer, A.

University of Freiburg

Introduction Reactive balance training (RBT) is based on the mechanical interference of postural equilibrium via externally applied perturbations of the support surface. Research shows that RBT can provide improved rehabilitation and performance outcomes to counteract postural dysfunctions (Lurie et al. 2013). To detect most effective training conditions, the effect of various perturbation determinants on kinematic behavior and underlying neuromuscular mechanisms need to be understood. The aim of this study was to examine the effect of three perturbation determinants on neuromuscular activity, centre of pressure (COP) performance and joint kinematics. **Methods** In 20 subjects, COP displacement (COPd) and velocity (COPv), ankle, knee and hip joint excursions as well as electromyographic (EMG) responses of the soleus, tibialis anterior, peroneus longus and gluteus medius in monopodal stance were analysed with respect to i) the perturbation direction (anterior; posterior; medial; lateral), ii) amplitude (2; 3; 4cm) and iii) velocity (1,1; 1,8m/s-1) during random translations of the support surface. EMG data were analysed regarding the reflex phases short- (SLR), medium- (MLR) and long-latency response (LLR). **Results** i) For each direction of the perturbation, COPd shifted towards the opposite direction, joint angles deflected according to each direction and EMG responses appeared according to the respective direction. ii) With increasing perturbation amplitude, COPd ($p < 0.05$), COPv ($p < 0.05$), joint excursions ($p < 0.05$) and EMG responses in LLR ($p < 0.05$) increased progressively. iii) With increasing perturbation velocity, COPd ($p < 0.05$), COPv ($p < 0.05$), joint excursions ($p < 0.05$) and EMG responses in SLR, MLR and LLR ($p < 0.05$) augmented. **Discussion** Increased perturbation amplitudes and velocities led to enhanced kinematic responses accompanied by an enhancement in neuromuscular activation profiles for specific reflex phases. Thorough analysis revealed that neuromuscular reflex control during perturbed stance in the early reflex phases (SLR, MLR) is responsive to the perturbation velocity but not to the perturbation amplitude. This finding is supposed to be associated with the muscle spindle sensitivity, which generates responses in regard to the stretch acceleration (Gollhofer & Rapp 1993). Enhanced EMG responses in LLR observed with increased perturbation amplitudes, however, support the perception of supraspinal control (Taube et al. 2006). Outcomes revealed in this study should be considered when creating RBT regimens, to define specific recommendations for the most efficient training purposes. **References** Gollhofer A & Rapp W. EFFECTS OF AGE ON INHIBITION AND FACILITATION IN THE PRIMARY MOTOR CORTEX DURING STANDING

Négyesi, J.1, Hortobágyi, T.2,3, Papegaaij, S.2

1 Semmelweis University (Budapest, Hungary), 2 RUG, University Medical Center Groningen (Groningen, the Netherlands), 3 Newcastle University (Newcastle upon Tyne, United Kingdom)

Introduction Although recent studies point to the involvement of M1 in postural control (Tokuno et al., 2009), it is unknown if age modifies M1 inhibitory and facilitatory circuits controlling posture. We examined the effects of age on the involvement of M1 in the control of human standing. **Methods** Eleven young (age 23 ± 2.6 years, range 20-29, 6 men) and eleven old adults (age 64 ± 4.3 years, range 60-76, 8 men) received single and paired pulse transcranial magnetic brain stimulation while they stood with or without support on a force platform. During free standing, participants were standing naturally upright. During supported standing, participants gently leaned against a wooden board at chest level to remove the need for the nervous system to control sway. Motor evoked potentials (MEPs) were recorded from the soleus muscle. Interstimulus intervals of 2.5 and 13 ms were used to assess short-interval intracortical inhibition (SICI) and intra-

cortical inhibition (ICF), respectively. Results Age did not affect SICl ($p = 0.208$) but it was lower during free (34% inhibition) than during supported standing (50% inhibition) ($p = 0.023$). Age and conditions did not affect ICF ($p = 0.661$, $p = 0.250$). Although the motor threshold was similar in the two age groups ($p = 0.474$), the amplitude of the test MEP was 90% higher in the old compared with the young group ($p = 0.017$). The test MEP was not different between conditions ($p = 0.087$). There was no age by condition interaction (test MEP: $p = 0.930$, SICl: $p = 0.961$, ICF: $p = 0.366$). To determine whether differences in background EMG could have caused the condition effect in SICl, we performed a correlation analysis. The difference in background EMG between condition did not correlate with the difference in SICl between conditions ($r = 0.071$, $p = 0.754$). Discussion This is the first study showing a posture-related modulation in SICl, suggesting the involvement of M1 inhibitory circuits in the control of human standing. However, age does not seem to affect this modulation. Therefore, the age-related changes in postural control cannot be attributed to differences in modulation of SICl during normal standing. From these data we cannot determine if increase in spinal and/or supraspinal excitability mediates the age-related increase in corticospinal excitability. Additional experiments will extend these preliminary data by examining responses to peripheral nerve stimulation and correlate nerve stimulation and the TMS responses with the force platform-derived behavioral data. PROLYL HYDROXYLASE DOMAIN 2 DEFICIENCY INDUCES MUSCLE FIBER TYPE CONVERSION

Shin, J.C., Nunomiya, A., Kitajima, Y., Dan, T., Miyata, T., Nagatomi, R.

Tohoku University Graduate school of medicine

Introduction Hypoxic training or exposure to hypoxic condition has been known to improve exercise performance; however, the effect of hypoxic training remains largely unanswered. In particular, the alteration of skeletal muscle fiber type by hypoxic condition has not been elucidated, even though skeletal muscle fiber type composition is a crucial factor for muscle endurance, strength, and energy metabolism. Under hypoxia, hypoxia-inducible factor-1 (HIF-1) is stabilized by Prolyl hydroxylase domain 2 (PHD2) in response to low oxygen level within a cell (G-H Fong et al., 2008). Stabilized HIF-1 triggers the activation of various target genes involving angiogenesis and erythropoiesis (Eduarne Berra et al., 2006). Moreover, induction of vascular formation by stabilization of HIF-1 may play a pivotal role in the formation of oxidative muscle fibers. Thus, we hypothesized that Phd2 deficiency elicits muscle fiber type transition toward oxidative fiber type via new vascular formation. **Method** We employed Phd2 tamoxifen driven Cre-loxp system to generate a mouse in which Phd2 gene will be deleted upon activation of calcium-dependent recombinase (Cre). Tamoxifen administration for consecutive 7 days was performed to delete Phd2 gene. All muscles were isolated at 6 week after tamoxifen administration. The proportion of slow fiber and capillary density were measured by immunostaining using frozen muscle section. Protein expression was detected by western blot analysis. **Results** Phd2 deletion demonstrated an increased hemoglobin concentration, RBC counts, and hematocrit. The proportion of slow fiber type was significantly increased in the soleus (control 35.8% vs Phd2 cKO 47%, $p < 0.05$) and gastrocnemius (Total number of slow fibers : control 54 vs Phd2 cKO 127, $p < 0.05$) muscle of Phd2 deficiency mice. In addition, capillary density in gastrocnemius was increased in Phd2 cKO mice. Also, the protein level of calcineurin A was increased in gastrocnemius of Phd2 deficiency mice. **Discussion** The present data indicated that Phd2 conditional knockout successfully induced a marked change in the RBC count, Hb concentration. Furthermore, Phd2 deficiency enhanced oxidative fiber type in soleus and gastrocnemius muscle, and expression of calcineurin A, which is important in regulating fiber type switching (Stephanie A. Parsons et al., 2003), may contribute to the formation of slow fiber type. **Reference** 1. G-H Fong, K Takeda. *Cell Death and Differentiation* 15, 635–641, 2008. 2. DOES STABILIZED HYPOXIC RESPONSE FAVOR THE EFFECT OF ENDURANCE TRAINING?

Nunomiya, A., Shin, J.C., Kitajima, Y., Dan, T., Miyata, T., Nagatomi, R.

Tohoku University

Introduction Recently, altitude training has widely been accepted by elite athletes as an efficient way to improve endurance capacity. One of the indices for the effect of altitude training is considered to be increases in red blood cell counts, hematocrit or hemoglobin concentration induced by hypoxic response (Lavigne et al., 1997). There is, however, still an on-going debate as to whether hypoxic response per se may improve endurance capacity or not. The key factor of hypoxic response is hypoxia inducible factor (HIF), consisting of two subunits: an oxygen-regulated HIF- α subunit (HIF-1 α , 2 α , 3 α) and a constitutively stable HIF- β subunit. Under normoxia, HIF- α subunit undergoes hydroxylation by prolyl hydroxylase domains (PHDs) and is rapidly degraded by 26S proteasome (Berra et al., 2003). In order to examine whether stabilized HIF activity may favor endurance capacity, we generated a conditional knockout (cKO) mouse of Phd2, the main PHD isoform for the control of HIF- α degradation. **Methods** Because Phd2 knockout is embryonic lethal (Takeda et al., 2007), estrogen receptor (ER) agonist-induced Phd2 cKO mouse using Cre-loxP system was used. Three days after tamoxifen, an estrogen-agonist, endurance test using a rodent treadmill was performed. Phd2 cKO mice and control mice were then divided into training and non-training group. The mice in the training group underwent 4-week endurance training on a rodent treadmill. After training, all mice of both groups were tested for their endurance capacity and were sacrificed for blood and tissue examination. **Results** Phd2 cKO mice exhibited marked increases in hematocrit (control: 47.8 ± 0.5 , and cKO: 76.9 ± 1.1 %, $p < 0.01$), hemoglobin concentration (control: 16 ± 0.3 , and cKO: 23 ± 0.7 g/dl, $p < 0.01$) and RBC counts (in $10^2/\mu\text{l}$; control: 986.4 ± 13.8 , and cKO: 1445.6 ± 93.7 , $p < 0.01$). Endurance time of trained mice of both cKO and control were significantly improved (Δ endurance time (sec.); control: 1650.25 ± 543.37 , $p < 0.05$, and cKO: 2516.86 ± 726.37 , $p < 0.01$), and the improvement was significantly different between control and Phd2 cKO mice ($p < 0.05$). **Discussion** Tamoxifen-treated Phd2 cKO mice elicited a marked change in the blood component by PHD2 deletion, due to HIF-1 stabilization and the following transcriptional activation involving hematopoiesis and angiogenesis. Moreover, a contribution of hematological change on the 4-week training effect was observed. Consequently, our data suggest that Phd2 deficiency improved the training effect. **References** Levine BD and J Stray-

ENDURANCE TRAINING REDUCES HIGH-FAT DIET-INDUCED UP-REGULATION OF APOPTOTIC SIGNALING IN VISCERAL ADIPOSE TISSUE FROM OBESE ANIMALS

Rocha Rodrigues, S., Beleza, J., Gonçalves, I.O., Passos, E., Ascensão, A., Magalhães, J.

Faculty of sports- University of Porto

Introduction Obesity-induced adipocyte cell death dependency of cyclophilin D (CyD) modulatory function has been reported. Therefore we aimed to analyze the effects of endurance training (ET), used as therapeutic strategy, on Bax, Bcl-2 and CyD protein in epididymal adipose tissue from rats submitted to high-fat diet (HFD)-induced obesity. **Methods** Male Sprague-Dawley were assigned into sedentary (SED) and ET groups fed with two isocaloric diets, a standard and HFD (35% or 70% fat-derived Kcal, respectively) as follows: SED35, ET35, SED70, and ET70. After 9 weeks of hypercaloric diet regimens, ET-animals were submitted to 8-wks on treadmill while maintained dietary treatments. Epididymal fat pads were excised and used to determine Bax, Bcl-2 and CyD protein levels by western blot. **Results** Animals fed with HFD exhibited a significant increase in body weight and visceral adiposity compared with those fed with standard diet. Moreover, HFD increased Bax and decreased Bcl-2 protein levels (SED70 vs. SED35), thereby increased Bax/Bcl-2 ratio in epididymal fat depot. CyD protein levels increased in animals fed with HFD. Eight weeks of ET significantly decreased body weight and visceral adiposity in both groups. A pronounced ET effect was also observed by increases in heart/body weight ratio and skeletal muscle citrate synthase activity. Moreover, ET35 showed an increase of Bcl-2 protein levels compared with SED35. In addition, ET70 showed a decreased in Bax protein levels and a decreased Bax/Bcl-2 ratio compared with sedentary counterparts (ET70 vs. SED70). We also found that ET attenuated HFD-induced upregulation of CyD protein levels. A significant correlation were found between Bax/Bcl-2 ratio and CyD protein levels. **Discussion** Our results suggest that 8 weeks of ET reduced HFD-induced upregulation of pro-apoptotic protein and CyD protein levels in epididymal fat depot from rats submitted to long-standing diet-induced obesity. EFFECTS OF CYCLING AND SMALL-SIDED GAMES ON PROTEIN CONTENT AND MRNA EXPRESSION ASSOCIATED WITH PH REGULATION

Bishop, D., Mendham, A.E., Duffield, R., Coutts, A.J., Marino, F., Boyko, A., McAinch, A.

Victoria University

Introduction Small-sided games (SSG) training has been associated with greater motivation and compliance compared with continuous aerobic exercise (2). SSG training has also been associated with positive adaptations on measures shown to influence glucose regulation and insulin sensitivity, which are either comparable to, or better than, continuous, aerobic exercise training (1, 2). However, there are no published data directly examining the efficacy of SSG training for improving factors associated with skeletal muscle pH regulation. **Methods** Part A. Thirty-three sedentary men were randomly assigned to a CYC (n=11), SSG (n=11), or control group (CON, n=11). Participants in the exercise groups trained 3 d.wk⁻¹ for 8 weeks, while control participants maintained normal activity and dietary patterns. Pre- and post-intervention testing included a graded exercise test and a resting muscle biopsy. Western blotting was used to quantify the content of skeletal muscle proteins involved in muscle pH regulation (i.e., MCT1, MCT4, NBCe1, NHE, CD147). Part B. Nine sedentary men participated in 2 x 40 min exercise conditions (CYC and SSG) following a randomized, cross-over design. Muscle samples were collected at rest, 30 and 240 min post-exercise for the analysis of the mRNA content of the proteins measured in Part A. **Results** Part A. Post training, there were increases in NHE (30-80%), MCT1 (40-50%), and MCT4 (60-90%), but not NBCe1 or CD147; there were no significant differences between CYC and SSG for any of the proteins. Part B. The mRNA content of MCT4 was significantly increased post-exercise for both CYC and SSG, with no difference between conditions. The mRNA content of the other measured proteins was not significantly altered by either of the two exercise conditions. **Discussion** This study shows that both CYC and SSG were similarly effective at raising the content of some of the proteins important for skeletal muscle pH regulation. This suggests that intermittent exercise training, such as SSG, can be an effective alternative to continuous cycling for improving skeletal muscle pH regulation. As previously reported by others, training-induced changes in protein content were not always matched by acute, exercise-induced changes in associated mRNA content. **References** 1. ENDURANCE TRAINING MITIGATES MITOCHONDRIAL ALTERATIONS-INDUCED BY A HIGH-FAT DIET IN VISCERAL ADIPOSE TISSUE

Beleza, J.I, Rocha Rodrigues, S.I, Gonçalves, I.O.I, Passos, E.I, Ascensão, A.I, Magalhães, J.I

Faculty of Sport of University of Porto

Introduction Obesity-related modulation in visceral adipose tissue (VAT) mitochondria has been reported. However, the role of exercise against the modifications induced by high-fat diets (HFD) on VAT mitochondria is poorly understood. We aimed to analyze the influence of voluntary physical activity (VPA) and endurance training (ET) on markers of mitochondrial function and biogenesis in VAT from rats fed with a HFD-induced obesity. **Methods** Male Sprague-Dawley were assigned into sedentary (SED), VPA and ET groups fed with two isocaloric diets, a standard (SD) and HFD (35% or 70% fat-derived Kcal, respectively) as follows: SED35, VPA35, ET35, SED70, VPA70 and ET70 during 17 weeks. VPA-animals had free access to voluntary running wheel throughout the entire protocol. After 9 weeks of hypercaloric diet regimens, ET-animals were submitted to 8-wks maintaining dietary treatments. Epididymal fat pads were excised and used to determine subunits of the oxidative phosphorylation system (OXPHOS), mitochondrial transcriptional factor (TFAM) and peroxisome proliferator-activated receptor gamma co-activator 1-alpha (PGC-1α) protein levels. **Results** Animals fed with HFD showed an increase of body weight, visceral adiposity index (VAI) although with no alterations in spleen/body weight, an indicator of immune dysfunction or infection. HFD-animals showed a decrease of complexes IV and V protein levels vs. their counterparts. VPA decreased BW (VPA35 vs.SED35), VAI (VPA35 vs.SED35 and VPA70 vs.SED70), epididymal weight (VPA35 vs.SED35 and VPA70 vs.SED70), but had no significant effect on OXPHOS subunits levels. VPA tend to increase protein levels of TFAM and PGC-1α only in groups submitted to standard diet, although without statistical meaning. ET-8wks significantly decreased body weight and VAI in both groups. A pronounced ET effect was observed by increases in heart/body weight ratio and skeletal muscle citrate synthase. ET increased complex IV in both groups (ET35 vs.SED35 ET70

vs.SED70). ET35 showed an increase of complex V protein levels vs. SED group. We observed an increase of TFAM (ET35 vs.SED35; ET70 vs.SED70) and PGC-1 α (ET35 vs.SED35; ET70 vs.SED70) protein levels. Discussion Our results suggest that ET positively modulate the expression of several mitochondrial proteins in visceral adipose tissue in rats fed with a HFD. Contact Jorge_sousa_beleza@hotmail.com

THE EFFECT OF AEROBIC EXERCISE ON LIPOTOXICITY-INDUCED SKELETAL MUSCLE DAMAGE IN RAT

Park, J., Baek, K.

Pusan National University

Introduction Lipotoxicity has been shown in cultured skeletal muscle cells, whereas its functional consequences in vivo are unresolved. Moreover, effects of exercise on skeletal muscle damage induced by lipotoxicity are not known. Therefore, the purpose of this study was to investigate the effects of lipotoxicity on skeletal muscle in rat, and the effects of exercise on skeletal muscle damage induced by lipotoxicity. **Methods** The experiment was composed of 2 phases. In Phase-1, 35 rats were divided into 2 groups, normal diet group (ND, n=7) and high-fat diet group (HFD, n=28), to study the effects of lipotoxicity induced by high-fat diet on skeletal muscle. In Phase-2 (after 6 weeks), the HFD group was divided into 3 groups, exercise group (EXE, n=7), control group (CON, n=7), and diet adjusted group (DA, n=7), to study the effects of exercise on skeletal muscle damage induced by lipotoxicity. EXE and CON were on high-fat diet and DA group was on normal diet. Lipid accumulation in skeletal muscle was determined by Oil Red O staining method. To confirm apoptosis in skeletal muscle, cell regeneration, nucleus infiltration, and inflammation response were determined by Hematoxylin & Eosin staining, and PARP and Caspase-3 protein levels were determined by Western Blot analysis. **Results** In Phase-1, lipid accumulation in skeletal muscle of HFD group was higher than ND group. Apoptosis in skeletal muscle was also higher in HFD than ND group, which is confirmed by PARP and Caspase-3 protein expression levels. In Phase-2, lipid accumulation in skeletal muscle of CON group was higher than EXE and DA group. Cell regeneration was higher in EXE and DA group than CON group. Nucleus infiltration was lower in DA group than EXE and CON group. Inflammation response was higher in EXE than CON and DA group. Protein contents of cleaved PARP were higher CON than EXE and DA group. Relative muscle weight was not different between ND and HFD group, but was higher in EXE group than CON and DA group. **Conclusions** The data of this study show that lipid accumulation-induced lipotoxicity can result in muscle loss, but exercise and normal diet can attenuate the extents of apoptosis in skeletal muscle induced by lipotoxicity. These results suggest that exercise and balanced diet may provide a favorable environment to reduce a possibility of age-related sarcopenia or disuse-induced muscle atrophy. THE EFFECT OF ENDURANCE EXERCISE ON ENOS EXPRESSION IN ATHLETES

Drozdovska, S.1, Dosenko, V.2, Ilyin, V.1

NATIONAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORT OF UKRAINE

Introduction Nitric oxide, blood concentration of which is dependent on endothelial NO-synthase gene activity, has been shown play crucial role in adaptation processes to physical exercises. Several studies showed the increasing eNOS gene expression in cells of different tissues in response to physical exercise (Yang et al., 2002; Grijalva et al., 2008). Therefore, the aim of this study was to investigate the eNOS gene expressions level in blood cells of athletes specialized in different kinds of sport and changes of the level of eNOS mRNA under influence of physical exercises. **Methods** 20 underwater swimmers, 13 rowers and 10 sedentary men participated in the study. DNA was isolated from buccal epithelium. RNA was extracted from platelets and monocytes. T-786C polymorphism and eNOS gene expression were detected by Real Time PCR. For an assay of eNOS enzyme activity in platelets we used a fluorimetric detection system FCANOS-1 (Sigma). Physical load was provided by maximal incremental cycling test until the 'refusal' by ergometer «Concept II» (USA). **Results** Higher level of eNOS gene expression and eNOS enzyme activity are observed in athletes' platelets compared to people uninvolved in sports (20,8% fold and 22,8%, p<0,01 respectively). We found that the levels of eNOS mRNA of blood cells of athletes, adapted to the aerobic exercises in the rest was higher, than athletes adapted to the anaerobic exercises. eNOS mRNA of blood cells and NO - synthase activity in platelets were lower than in monocytes, as well as in the control group and athletes. Physical activity leads to the increase of the eNOS gene expression and NO - synthase activity in platelets and decrease in blood monocytes qualified athletes. Reducing T - alleles T-786 C polymorphism leads to decrease of eNOS gene expression level. **Discussion** Adaptation to physical exercise with various pathways of energy supply results in different in value changes of eNOS gene expression level in the rest. Therefore, eNOS affects the development of adaptation processes to physical exercise among qualified athletes. Apparently, high demand of NO during endurance exercises is related to its modifying effect on carbohydrates and oxygen consumption (McConnell et al., 2008;), and its influence on basal mitochondrial biogenesis in skeletal muscles (Wadley et al., 2007). **References** Yang, Ai-Lun; Tsai, Shaw-Jenq; Jiang, Meei Jyh; Jen, Chaoying J.; Chen, Hsiun-ing (2002) Journal of Biomedical Science, 9(2), 149. CIRCULATING MICRORNAS AFTER HIGH INTENSITY INTERVAL AND CONTINUOUS EXERCISE IN CHILDREN

Kilian, Y.1,2, Wehmeier, U.F.3, Mester, J.1,2, Hilberg, T.3, Sperlich, B.4

1,2: German Sport University Cologne, 3: Sports Medicine, University of Wuppertal, Germany, 4: Institute of Sports Science, University of Würzburg, Germany

Introduction In general, studies investigating the rapid changes in gene expression in response to acute exercise in children are sparse. miRNAs are small non-coding molecules playing an important role in gene silencing by acting as intracellular mediators of essential biological functions and some were shown to alter in response to physical exercise. Recently, miRNAs were detected in the bloodstream, giving the opportunity to measure gene-regulation minimal-invasively in children. Therefore, the aim of the study was to evaluate the impact of one session with high-intensity intervals (HIIT) and one session with low continuous intensity (HVT) on the expression of vascular regulating miRNAs. **Methods** Twelve healthy competitive young cyclists took part in this study (14.4 \pm 0.8 years; VO2max 58.8 \pm 8.9 ml/min/kg). HIIT consisted of 4x4 min intervals at 90-95% peak power output (PPO) separated by 3 min of active rest, the high volume training consisted of a constant load exercise for 90 min at 60% PPO. Capillary blood from the earlobe was collected under resting conditions, during and 0', 30', 60', 180' after exercise to determine miRNAs (-16, -21, -126), VEGF and VEGF mRNA. **Results** VEGF protein did not show any differences over time or between interventions, whereas VEGF mRNA significantly increased 0', 30', 60', 180' after HVT and 180' after HIIT. All miRNAs did not show significant changes neither between the interventions nor over time. However, small effect size for miR-21 after HIIT (η^2 = 0.157) and a small effect size for miR-16 (η^2 = 0.10) and miR-126 after HVT (η^2 = 0.169) were detected. **Conclu-**

sion The present study could not obtain a clear evidence of which kind of exercise intensity causes an endothelial-specific regulation of miRNAs. The expression of VEGF mRNA would tend to favor the HVT session. A 2.7 fold change in miR-126 during HVT support the results of the VEGF mRNA. Similar results for miR-126 were shown during four hours of cycling at 70 % VO₂max (Uhlmann, 2013). For miR-21 an inverse correlation of VO₂max was shown (Bye, 2013). In the present study the subjects all had high VO₂max values, which could explain the low expression of miR-21. Since the expression values (Ct-values) of the present miRNAs differed from those of adults one might speculate that differences in gene regulation are also reflected in the distinct response to acute exercise. MO-SH04 Psychology of Team Performance

THE EFFECT OF A 4-WEEK STATE TEAM HITTING TRAINING SCHEDULE ON SOFTBALL HITTING MECHANICS AND ITS INFLUENCE ON FEAR AND COMPETENCE

Walsh, A., Haff, G.G., Howard, B., Nimphius, S.

Edith Cowan University

Introduction In Australia, many of the tee ball coaches are volunteers with limited coaching experience, which may result in an inability to effectively prepare athletes to face a pitched ball. Youth pitching can be inaccurate and may invoke fear in the hitter (Martens, et al., 1984). Therefore, the aim of this study was to profile the changes of the fear of failure, sport anxiety, physical self-perception and physical importance and their interaction with the youth's ability to consistently demonstrate correct batting technique. **Methods** Four psychological questionnaires were administered in identical order pre- and post- training schedule; the Physical Self Perception Profile, Physical Importance Profile, Sport Anxiety Scale and Fear of Failure. 11 female participants (age: 13.36 ± 0.81 yrs) with at least one year of playing experience in tee ball, baseball or softball attended a four-week training schedule. Participants completed five soft toss warm up swings and then each participant completed 20 swings with the instruction to "hit the ball up the middle" while hitting a ball tossed from five metres away. Bats were self-selected (Escamilla, et al., 2009). Swing competency was analysed using a baseball hitting scale (Walsh, 2013). Paired t-tests and regression analysis were used to analyse the data. Significance was set at a α level of $p \leq 0.05$. **Results** Significant differences were observed between hitting scores pre- and post-training, ($p = 0.031$), demonstrating that four weeks of training could significantly improve hitting performance. Regression analysis showed the best predictor of hitting performance was Physical Importance Profile with $p = 0.04$ and $R^2 = 0.38$. **Discussion** Key finding of this study was that batting performance can be improved following four weeks of training which included, batting against live pitching and front side toss. Interaction between hitting scores and sports anxiety scale, physical importance profile and physical self-perception profile show a negative trend, which suggests increased hitting technique resulted in lowering of anxiety, perception and importance of the hitting task, but increased the fear of failure experienced by the subjects. There was 38% shared variance between the Physical importance profile and batting performance. **References:** Martens, R., Rivkin, F., Bump, L. HOW ENTITATIVITY AND TEAM IDENTIFICATION AFFECTS PERCEPTION OF TEAM MEMBERS COMPETENCE

Guraj, K.

University of Warsaw

Introduction: One of the most common though yet not completely resolved issues in team sports is the influence of game location. The biggest research so far has been made by Carron and Courneya (1992) who presented a model consisting of 4 crucial factors standing behind the home advantage phenomenon. Not many studies, however, have been focusing on the social aspect of the competition and the way it affects the teams. The aim of this study is therefore to look at the competition as a fight we vs. them, a situation where a positive group identity is being threatened and examine how does this affect the way players perceive the teams, their skills and how does team identification contribute to those processes. **Methods:** A questionnaire study was conducted in a repeated measures design with 3 conditions included – control (at practice) and 2 experimental (home and away). We examined responses from 34 male elite volleyball and basketball players from Polish first division. **Variables assessed:** both competing teams' entitativity, overall competence perception, specific skills perception, team identification, perceived control over events. **Results:** Own team entitativity turned out to be significantly higher than the opponents' no matter the condition. However, when playing home the effect was the strongest. The evaluation of team competence increased equally in both competing conditions but this tendency applied only when it was being automatic (overall competence perception). When analytical thinking was being activated (specific skills perception), the effect disappeared and the evaluation became stable. Team identification level turned out to be the reason for those differences. The more the players were identifying with their team, the more likely they were to underestimate their skills during practice and overestimate them while competing. **Conclusion/Discussion:** The study didn't show many game location related effects. However, it has shown how important the conditions (practice vs. competition) can be for the players when it comes to self-competence evaluation and what big of a role the level of identification with their own team plays. Paradoxically, those findings suggest that high level of team identification among players may actually be more of a hindrance than an advantage as it makes players' competence perception more unstable and may result in them feeling more threatened by the opponents and playing worse. Therefore, further research on how big of an impact it actually has on the final performance is a must. **Selected references:** Mullen, B., Brown, R., Smith C. (1992). *Eur. J. of Soc. THE EFFECTS OF A BRIEF HYPNOSIS INTERVENTION ON SELF-CONFIDENCE IN PROFESSIONAL TEAM HANDBALL PLAYERS

Rathschlag, M.1, Lind, E.2, Kennedy, G.3, Morris, T.3

German Sport University Cologne

Introduction Modern practices of hypnosis have occurred most commonly in the fields of medicine, dentistry, and psychology. However, the implementation of hypnosis into the field of sport psychology is still undeveloped and there are only a few studies in this research field (e.g. Barker, Jones, & Greenless, 2010; Pates, Cummings, & Maynard, 2002). The aim of the study was to increase our understanding whether a hypnosis intervention can help athletes to enhance their self-confidence. **Methods** Participants were selected from a professional team handball team in Germany (n = 18). A pretest-posttest follow-up design with repeated measures was used. The players were randomly assigned to either a hypnosis (n = 9) or a progressive muscle relaxation group (n = 9). All participants undertook four training sessions (of either hypnosis or progressive muscle relaxation) in between pretest (baseline) and the posttest data collection. All participants completed the self-confidence subscale of the CSAI-2, the SSCI and the TCSI at both times of measurements. **Results** The results showed a significant main effect for time of measurement in the SSCI ($F(1,16) = 5.355, p < .036$) and also in the CSAI-2 ($F(1,16) = 3.788, p < .048$). There were no significant main effects for group and no significant interactions in the different scales. **Discussion** Results indicated that both a hypnosis intervention and a progressive muscle relaxation can help athletes to enhance their state self-confidence. Further studies can investigate the temporal stability of this effect over a longer period. **References** Barker JB, Jones MV, Greenless I (2013). J Sports & Exercise Psychology, 32, 243-252. PROBLEM SOLVING APPROACHES OF HIGH SCHOOL STUDENTS EXERCISING REGULARLY IN SPORT TEAMS

Senduran, F., Amman, T., Donuk, B., Erdogan, M.

Marmara University

Introduction Schools take on an important task for raising young generations and providing that they gain problem solving skill. The students gain new experiences in physical education lessons and with sport team activities. The more children have new experiences, the richer information they gather and they also discover new tools for problem solving (Thorton, 1998). In this study, the effect of regular sport activities on the solution approaches performed for solving the problem by high school students when they encountered the said problem, was analyzed. **Method** 600 high school students participated in the study. Problem-Solving Inventory (PSI) (Heppner & Petersen, 1982) was used to evaluate problem solving solutions of the students. Athlete students were selected from the students who took charge in school teams, exercised for 6 days in a week provided that this exercise did not exceed 1,5 hours and who also participated in competitions. Mann-Whitney U test which is non-parametric test was used to examine two samples (athlete & non-athlete). **Results** According to findings which were obtained, a significant difference was found among self-confident approach values of athlete and non-athlete students ($U=45,0, p=0,008$). A significant difference was observed among assessor approach values of athlete and non-athlete students ($U=46,2, p=0,033$). Athlete students believed that they would solve the problem that they encountered. Besides, athlete students preferred using systematic method while solving a problem and making decision more often than those who were not athlete and of the same age. **Discussion** The students who did sport regularly were more self confident than those who did not do sport regularly and of the same age when they encountered a problem and they evaluated phase of solving problem and results that they obtained more carefully than the students who did not do sport regularly and of the same age. Baumann (1994) stated that it should be paid attention to creative thinking in physical education lesson and especially in gymnastics lesson. Baumann also states that the students reveal their aesthetical characteristics and creativity in physical education lesson. Benson (1995) emphasized that problem solving is an intellectual skill which can be learnt and developed with experiences. According to results of the study, it can be said that athlete students who do regular sport and exercise at high schools are more effective problem solvers than the students who are not athlete and in the same age group. **References** Baumann, S. SPORT COMMITMENT AND PARTICIPATION IN MASTERS SWIMMERS: THE INFLUENCE OF COACH AND TEAMMATES

Santi, G., Bruton, A., Pietrantonio, L., Mellalieu, S.

University of Bologna

Introduction Contemporary theories of sport commitment (e.g., Wilson et al., 2004) suggest the type of commitment displayed (i.e., functional vs. obligatory) has differential effects on sport participation. This study investigated how coach and teammates influence masters athletes' sport commitment, and the effect of functional and obligatory commitment on participation in masters swimming. **Methods** The sample consisted of 523 masters swimmers (330 male and 193 female) aged between 22 and 83 years ($M = 39.00, SD = 10.42$). A bi-dimensional commitment scale (Young & Medic, 2011) was used to measure commitment dimensions and perceived influence from social agents. Structural Equation Modeling analysis was conducted in order to evaluate the influence of social agents on functional and obligatory commitment, and the predictive capabilities of the two types of commitment toward sport participation. **Results** The final model ($\chi^2=350.4(176)$; $NFI=0.95$; $IFI=0.97$; $CFI=0.97$; $RMSEA=0.04$ [90%; $CI=0.04-0.05$]) revealed support provided by coach ($\beta = .15$) and teammates ($\beta = .37$) increased functional commitment, constraints from these social agents determined higher obligatory commitment ($\beta = .20$ coach; $\beta = .31$ teammates), and coach constraints negatively impacted functional commitment ($\beta = -.19$). In addition, both commitment types predicted training participation, with functional commitment increasing participation in team training sessions ($\beta = .16$), and obligatory commitment increasing the hours of individual training ($\beta = .10$). **Discussion** The findings suggest that social agents play an important role predicting commitment in masters swimming. Specifically, both coaches and teammates should demonstrate a supportive attitude towards athletes in order to promote the will to participate in team training. Additionally, pressures from teammates have no effect on an individual's desire to participate within a group and indirectly increase the hours of individual training. Finally, coaches should avoid inducing pressures towards the athlete, as this indirectly decreases hours spent with the team and increases hours of individual training. **References** Wilson, P. M., Rodgers, W. M., Carpenter, P. J., Hall, C., Hardy, J., & Fraser, S. N. (2004). The relationship between commitment and exercise behavior. Psychology of Sport and Exercise, 5, 405-421. Young, B. W., & Medic, N. (2011). Examining social influences on the sport commitment of masters swimmers. Psychology of Sport and Exercise, 12, 168-175.

HOW DO TEAM SPORTS COACHES DEBRIEF THEIR PLAYERS IN ELITE SPORTS?

Macquet, A.C.1, Ferrand, C.3, Stanton, N.3

Introduction Debriefing is both a process, namely the way debriefing is prepared and transmitted to players, and a product, namely the message transmitted to players. It has potential positive outcomes on learning, motivation, confidence, emotional recovery, and reflective practice. To date, there are few studies on debriefing in sport. The present study aimed to explore the process used by staff to prepare and transmit debriefing in elite team sports as well as explore the content of debriefing. **Method** Nine national coaches of basketball, volleyball, handball, field and ice hockey volunteered to participate in the study. Data collection involved semi-structured interviews with each participant separately. Coaches were asked to explain how they prepared and transmitted their debriefings to players in major competitions. Data processing involved inductive and deductive analysis of verbal reports. **Results** Results showed that debriefing consisted of two parts: preparing for the game assessment, and transmitting the game assessment and fostering players' involvement in the following match. Preparing for the game assessment involved: (a) preparation of video material (i.e., recovering the video of the match and sequencing it); (b) assessment of own team's game (i.e., strengths and weaknesses, efficiency of game plan and game plan implementation, performance statistics, possible causes of achievements and failures, areas for improvement); (c) development of presentation material (i.e., most meaningful video sequences, players' feelings and analysis); and (d) division of labor. Transmitting the game assessment and fostering players' involvement in the following match comprised: (a) encouraging players to analyze their own game and transmitting assessments of the game (i.e., efficiency of game plan implementation, areas for improvement, taking into account players' attention capabilities); (b) fostering players' involvement in the following match (i.e., stressing the work done, boosting players' confidence and motivation, managing substitutes' frustration and players' roles, turning the page on the game and think about recovery and following match). **Discussion** Results suggest that debriefing involves tactical as well as psychological work. Tactical work relates to the work done. Psychological work consists of players' attitudes, commitment and motivation. They are both influenced by what went well and badly in the past in order to highlight what needs to be done in the immediate future. Results also suggest that the work of debriefing was divided according to staff and players' roles, competencies and experience. Results have been used to improve communication between the coach and players and enhance team performance. Contact anne-claire.macquet@insep.fr

SPORT COMMENTARY EFFECTS ON SPECTATORS' VIEWS OF WHO WINS

Myers, T.1, Balmer, N.2, Rehman, M.1, Strotmeyer, S.3

1 Newman University, 2 University College London, 3 University of Pittsburgh

Introduction Many sporting events are viewed on television or other visual media, and away from the actual competition. Understanding factors that impact on spectators' views of officials' decisions is important for a number of stakeholders in sports including athletes, coaches, officials, promoters and media companies. There have been limited studies looking at the effects of how a commentator's own beliefs influence spectators' perceptions of outcomes. As such, the aim of this study was to determine if audio commentary discussing the action in a sporting competition influences viewers' perceptions of who they felt won. **Methods** An opportunity sample of 565 participants (worldwide) participated in an online experiment and were randomly assigned to one of three conditions, each involving watching a 15-minute online video of the same Muay Thai fight: Condition 1, the fight was presented with a commentary supporting the boxer in the red corner, with the commentator highlighting their techniques; condition 2, participants watched the fight with commentary supporting the boxer in the blue corner, with the commentator highlighting their techniques; condition 3, involved participants watching the bout with no commentary. After watching the bout, participants were asked for their opinion of whom they felt won the bout (their choices were red win, blue win or draw). A chi-square analysis compared choice of winner by commentary condition. Adjusted standardised residuals were used to determine the impact of the three commentary conditions on the choices of the winner. **Results** The commentary condition had a statistically significant effect on which boxer participants' thought won the fight ($\chi^2=77.49$, $p<.001$, Cramer's $V=2.62$). An examination of the cell frequencies and adjusted residuals for each condition suggested when listening to the pro red commentary 80.5% of participants thought red won, 15.7% thought blue won, and 3.8% awarded the fight a draw. In the pro blue commentary 50.6% of participants thought blue won, 37.2% thought red won and 12.2% awarded a draw. **Discussion** The results suggest that the nature of the commentary had a significant impact on participants' choice of winner. By highlighting specific action during the fight, the commentator appeared to be able to influence spectators' perception of the outcome. The findings support previous literature that suggests commentary functions to shape the viewing experience (e.g., Comisky, Bryant, & Zillmann, 1977; Sullivan, 1991). The commentary directed participants' attention to specific action and this may have resulted in them missing the equally effective action by the other competitor. Alternatively, the commentator's perceived authority and knowledge may have influenced participant choice in a more general sense, suggesting social psychological factors played a major role. **References** Comisky P, Bryant J, Zillmann, D. (1977). J Commu 27 150-154 Sullivan, D.B. (1991). J Broadcasting 35 (4) 487-504.

A STUDY ON THE RESOURCEFULNESS LEVEL OF TEACHER CANDIDATES WHO HAVE BEEN STUDYING IN PHYSICAL EDUCATION AND SPORTS COLLEGE

Nergiz, S., Eraslan, M., Erdogan, B.S., Filiz, K., Caliskan, E., Yarali, D.

Mediterranean University

Introduction The aim of this study is to examine the Learned Intensity Levels of prospective teachers of physical education and sports College. **Method** The Research Group contains 112 male and 89 female ($\text{age} = 21.89 \pm 1.631$) in total 200 prospective teachers from Selçuk University physical education and sports college. In order to determine a conclusion on Learned Resourcefulness level, "Learned Resourcefulness Scale" has been used as the methodology which is developed by Rosenbaum (1980) and adopted to Turkish by Dağ (1991) and the Turkish version has been used in some studies in Turkey. For the interpretation of the data, the Kolmogorov-Smirnov test, one way anova test and to determine the difference between the groups Tukey test have been applied. The significance was $P < 0.05$. **Results** In terms of gender variables the difference between the average levels of scores of the Learned Resourcefulness Scale is not significant [t value = 0.461 $P=0.645 > 0.05$]. As a result of this study; in terms of the gender variables no difference has been demonstrated. **Discussion** Rosenbaum (1990), claims that Learned Resourcefulness gained from the environment around individuals regardless their gender. The findings of this study are consistency with this opinion. Moreover Zausniewski, Chung, Chang and Krafcik (2002) illustrated the parallel conclusion that depending on the gender. **References** Zausniewski, J. A., Chung, C., Chang, H. J., & Krafcik, K. PRE- AND POST-SEASON PERSONAL AND CONTEXTUAL FACTORS IN YOUTH SOCCER

Santos, A.J., Carvalho, H.M., Diogo, F., Gonçalves, C.E.

University of Coimbra

Sport practice has potential to promote youth positive development. The bioecological theory of (Bronfenbrenner, 1999) gives importance to the person and the relation established with the surrounding environment. The enjoyment in sport is important for adhesion and maintenance. Not all sport experiences are positive, being possible that the pressure for results lead to improper feelings and behaviors. The development assets model (Benson, 1998) is based a large study of factors related to positive developmental and successful adulthood. This model provides a guideline for preventive factors promotion rather than correctional or negative ones. The present study aims to: a) analyze the sources of enjoyment, attitudes and developmental assets of youth soccer athletes; b) analyze the effects of sport involvement during a season on the sources of enjoyment, attitudes and developmental assets. The male athletes (n=135) aged 12-18 (M=15.68, SD=1.63) answered to Sources of Enjoyment in Youth Sport Questionnaire, Sport Attitudes Questionnaire and Developmental Assets Profile at season beginning and end. The athletes are from the major teams (under 15, under 17, under 19) from three clubs (professional, rural area amateur, urban area amateur) previous analyzed. It was performed a multilevel analysis. The magnitude in changes was modest. The season has negative effects in cheating, commitment, effort expenditure and commitment to learning. There is contextual effects on support, family and community assets. In the sources of enjoyment were observe major differences between contexts with professional club athletes presenting lower levels. This study confirms that a sport environment with support and caring can promote the enjoyment and positive moral decisions and diminish the negative outcomes. There were verified differences according to the context in the positive factors of sport attitudes. This study rise the concern with the negative effects of sport on youth development. The implementation of sport programs, mainly in professional clubs, should pay attention to the youth needs of nurturing, supporting and opportunities to achieve a positive adulthood.

THE GROUP COMPOSITION PROBLEM IN PHYSICAL EDUCATION.

Bom, L., Fonseca, M.M.R., Mira, J.T., Carreiro da Costa, F.

ULHT Universidade Lusofona

Introduction Physical Education (PE) has distinctive features among other curricular disciplines, namely social interaction contents, either group or dyadic activities. Such specific PE disciplinary contents include team sports, group gymnastics, dance and athletic relays (group), or badminton, judo and dance (dual). To learn these activities, students are involved in problematic situations, cooperative and competitive. The "selection of the learning task" and the situation design are "critical decisions" (Rink, 1999, p. 160). Deciding group composition to practice learning tasks is a crucial pedagogical problem in a context of class diversity (abilities, gender, motivation, etc). The teacher must solve this problem in every PE practice when the opportunity to learn depends on teammate's behaviors. That is the case of PE group and dyadic practices where interactive contingencies are intrinsic conditions to learn tactical or choreographic contents. Therefore, group composition is an important instructional option, not only a decision related only to class management and climate, nor a generic and vague long-term education aim. Methods First, we interviewed 47 PE teachers following class observation, in 15 secondary schools. The objective was to identify specific options and pedagogical orientations regarding group composition. Then, we interviewed 28 experienced teachers. Each interviewee reviewed the transcript. We designed and tested a written questionnaire based on content analysis. A sample of 37 practicum supervisors and 25 first year students from a two-year Physical Education Teacher Education master program answered this form. Results Teachers in this sample considered gender as an ability and motivational factor, not a grouping criterion per se. We identified two clear pedagogical options: mixed ability and level grouping. Same-ability grouping was a main option of teachers with an analytic sport instruction orientation. This option was coherent with concept of ability as a natural entity, contrasting with a concept of ability as potential or process. Teachers with a potential or processes ability concept showed the tendency to prefer mixed ability grouping. The «expert teachers» preferred mixed ability groups but made flexible options according to specific content, student learning pace and objectives. The teachers following a fixed rule during the school year typically preferred level grouping. PE students (first year master course) were clearly different from teachers in two options: changing groups during the unit and in the same lesson; letting pupils choose their teammates. PHYSICAL EDUCATION PARTICIPATION AND LEISURE-TIME PHYSICAL ACTIVITY INFLUENCED BY PE TEACHERS, FAMILY AND FRIENDS: PERCEIVED AUTONOMY SUPPORT SCALE IN EXERCISE SETTING

Soos, I.1, Hamar, P.2, Ling, J.1, Boros Balint, I.3, Simonek, J.4, Dizmatsek, I.2, Hagger, M.S.5

1 University of Sunderland, UK, 2 Semmelweis University, Budapest, Hungary, 3 Babes-Bolyai University, Romania, 4 Constantine de Philosophier University, Slovakia, 5 Curtin University, Perth, Australia

Background There has been a shift from a skill-related to a health-related focus in both physical education (PE) and physical activity (PA) in the new EU countries compared to the era before they joined the European Union. Aims The aim of this study was to identify which social agents (family, friends, PE teacher) had the most influence on autonomy support of young people's physical activity behaviour in three

new EU member countries and an existing member country. Method Participants (N = 1129; mean age = 15.1 years, SD = 1.7) completed the Perceived Autonomy Support Scale in Exercise Setting (PASSSES Hagger et al. 2007) from 4 countries (Hungary, Romania, Slovakia, UK). They were required to indicate the level of perceived autonomy support provided by PE teachers in PE lessons, and family and friends for doing PA in their free-time. Participants' perceived behavioural control and autonomous motivation for PA were also measured. Results Of the four countries, British students perceived the most autonomy support from PE teachers and Hungarian counterparts from family and friends. Hungarian students showed the highest intention to pursue regular PA in the next 4 weeks, and they were followed by British students. However, 4 weeks later British students reported that they had completed the most physical activity participation followed by Hungarian students. Discussion Our findings support the extended trans-contextual model of motivation for health-related physical activity developed by Hagger et al. (2009). The influence of perceived autonomy support from peers and parents are important on perceived behavioural control along with PE teachers' unique effect on leisure-time autonomous motivation. For future research, enjoyment and exercise motivation should be considered as other significant contributing factors to physical activity behaviour control. SPORT SOCIALIZATION IN A DIGITAL AGE: SPORT GAMES AND SPORT IDENTITY

Pot, N., van der Kamp, J., van Hilvoorde, I.

VU University Amsterdam

In the present digital era, playing computer games is often regarded as a threat to participating in sports. However, with the introduction of game computers with body-motion controls (e.g., Nintendo Wii or Microsoft Kinect) playing sport games are hypothesised to contribute to sport participation, given specific circumstances. The present study was aimed at investigating the purported relationship between playing sport games and sport participation from a philosophical, psychological and pedagogical point of view. The first part of this study is a philosophical discussion about the concepts of physical activity and sports in relation to sport games. This centres on the question whether playing a sport game on a motion sensitive computer can be regarded as a sport or is mere physical activity. The circumstances under which sport games can be considered sports are investigated. Hence, the consequences for the potential role that sport games can play in increasing sport participation levels are discussed. Second, we investigated the circumstances under which playing a golf game contributed to the formation of a sport identity. One-hundred and twenty first year high school students participated in this study. They were divided in four groups: Group 1 received eight weeks of golf training on a golf course, group 2 received indoor golf training in a gymnastics hall, group 3 received indoor golf training on Microsoft Kinect computers and group 4 was a control group who received no golf training. The sport identity, game-identity, background characteristics and enjoyment of the lessons were measured by means of a survey before and after the eight weeks of training. In addition, golf skills were assessed pre and post training. Preliminary results show that the development of the sport identity is related to background characteristics of the participants, as well as contextual characteristics during the golf game and golf skills. Finally, we investigated how motion sensitive computers can be integrated in the PE context in a pedagogically responsible way. Qualitative data showed the conditions under which PE teachers experienced the added value of motion sensitive computers during their classes. The study shows that sport games can indeed play a role in sport socialisation, given specific circumstances. Furthermore, the study gives insight in the possible role that sport games can play in sport socialisation in a pedagogical context.

ACTIVE WORKSTATIONS TO FIGHT SEDENTARY BEHAVIOUR: A SYSTEMATIC REVIEW

Torbeyns, T., Meeusen, R.

Vrije Universiteit Brussel

Background The impact of active workstations has been studied in several settings and several outcomes have been investigated. However, the effects on health, work performance, quality of life, etc. have never been systematically reviewed. Objective To evaluate the existing literature about active workstations and the possible positive health and work performance effects. Data sources We searched the electronic databases PubMed and Web of Science (until September 23, 2013). Search terms included active workstation, standing workstation, standing desk, stand up workstation, stand up desk, walking workstation, treadmill workstation, treadmill desk, cycling workstation, bike desk, health, quality of life, cognition, computer performance, absenteeism, productivity, academic achievement, cognitive decline, and independent living. In addition, we searched the reference lists of relevant published articles. Study selection Randomised controlled trials and quasi-experiments, investigating the introduction of active workstations in humans were included. We did not accept studies combining the introduction of active workstations with other interventions, nor observational studies. Outcomes concerning health, energy expenditure, cognition, quality of life and work performance were included. Results We included 29 studies of which 5 longitudinal studies in school-aged children, 9 longitudinal and 15 non-longitudinal studies in adults. Fourteen investigated standing desks, 14 walking desks, and 1 a cycling workstation. General findings are decreased sitting time, increased energy expenditure, a positive effect on several health markers, no detrimental effect on work performance, no acute effect on cognitive function and no straightforward findings concerning computer task performance. Conclusions The implementation of active workstations might contribute to improving people's health and physical activity level. The effect of the use of these active workstations on cognition and applied work tasks such as computer task performance needs further investigation before conclusions can be made. Another aspect that needs further investigation is the implementation of the different active workstations in all age-groups. Contact Tine.Torbeyns@vub.ac.be

RELATIONSHIP BETWEEN BODY COMPOSITION AND ANAEROBIC PERFORMANCE IN YOUNG BRAZILIAN SOCCER PLAYERS

Sousa, S., Rodrigues, E.Q., Cintra Filho, D.A.

Londrina State University

Body composition and anaerobic performance are very important for performance in soccer game, but what the relationship between body composition variables and anaerobic performance? The aim of this study was to investigate relationship between body composition variables and anaerobic performance in young Brazilian soccer players. Methods: 13 soccer players (age 13.4 ± 0.6 ; body mass 53.4 ± 10.7 kg; 1.62 ± 11 cm height). They were evaluated by two analysis, in the first day Analysis of body composition (Bone Densitometry – DEXA), the variables: muscle mass full body (MM), muscle mass lower limb (MMLL), bone mass full body (BM), bone mass lower limb (BMLL) and fat mass full body (FM). On the second day, anaerobic performance Wingate test protocol (Mastrangelo et al., 2004) consisted 5-minute warmup, a 5-minute rest interval. Resistance to pedaling was based on body mass (BM) by (0,075 kg of resistance per kilogram of BM). Wingate test consisted 30-second sprint and the variables were calculated by software Ergometric 6.0, the variables: peak absolute power (PAP), relative peak power (RPP), mean absolute power (MAP), relative mean power (RMP) and fatigue index (FI). Statistical analysis was performed by the Shapiro-Wilk test, and correlation was assessed using the Pearson test. SPSS 20.0. Results: Relationship were found between PAP x MM 0,675 ($p < 0,05$), PAP x MMLL 0,583 ($p < 0,05$), PAP x BM 0,674 ($p < 0,05$), MAP x MM 0,720 ($p < 0,01$), MAP x MMLL 0,675 ($p < 0,05$), MAP x BM 0,746 ($p < 0,01$), FI x FM -0,576 ($p < 0,05$). Discussion: The study showed relationships between body composition and anaerobic performance in young soccer players. Sousa, Rodrigues and Cintra-Filho (2013) confirmed relationship between body composition and anaerobic performance in young soccer players. Mercier et al (1992) showed relationships between anthropometric variables and anaerobic power performance, the authors mentioned that during growth there is increased muscle, bone and fat mass. Conclusion: We conclude that there are relationship between body composition and anaerobic performance in young Brazilian soccer players. SPEED AND POWER ABILITIES OF YOUNG GERMAN SOCCER TALENTS RECRUITED FOR NATIONAL DEVELOPMENT TRAINING CENTER

Reer, R., Stein, D., Wellmann, K., Schroeder, J., Braumann, K.M.

University of Hamburg

Introduction In addition to aerobic endurance, speed and power are generally the deciding conditioning factors in successful soccer performance. Only limited information is available that is associated with professionally organized development of young soccer players (1,2,3). Methods The speed and sprinting power (SP) was determined via a series of 5 x 30 m utilizing double-light system (Start: 1 m back from the first light and self-selected start time, with 1:30 min break between individual sprints). The jumping power was determined via standard squat jump (SJ) and counter movement jump (CMJ) using force plate (3 CMJ per test). All testing was conducted before the beginning of the soccer season on a track surface in the training center. The variables of interest were the best times measured during 0-5m (SP-5m) and 0-30m (SP-30m) as well as maximal jump height in SJ und CMJ. Results The measured variables reveal that the power and speed of young soccer players were associated with age dependent differences (SP-5m: U16 (0.97 ± 0.06 s), U17 (0.95 ± 0.04 s), U19 (0.94 ± 0.04 s), U23 (0.93 ± 0.05 s); SP-30m: U16 (4.23 ± 0.2 s), U17 (4.13 ± 0.1 s), U19 (4.07 ± 0.1 s), U23 (4.03 ± 0.1 s); SJ: U16 (31.6 ± 3.9 cm), U17 (32.1 ± 4.4 cm), U19 (33.9 ± 3.7 cm), U23 (35.7 ± 3.9 cm); CMJ: U16 (33.0 ± 4.0 cm), U17 (33.7 ± 3.9 cm), U19 (36.3 ± 3.9 cm), U23 (37.8 ± 3.6 cm)). Discussion The results of our investigation suggest that young soccer players of our development talent team in soccer center showed continued and consistent improvement in selected physiological variables of speed and power that improves with advancing age. The major factors responsible for improvement appear to be longer attention span and physical development and maturity associated with aging. ANALYSIS OF YO-YO INTERMITTENT RECOVERY TEST, FUNCTIONAL MOVEMENT AND BODY COMPOSITION IN ELITE-LEVEL MALE PROFESSIONAL FOOTBALL PLAYERS

Zalai, D.1,2, Losada, P.2, Horvath, P.2, Kovacs, I.2, Varga, P.P.2, Varszegi, J.2

1: Semmelweis University (Budapest, Hungary), 2: Ferenc Puskás Football Academy (Felcsút, Hungary)

Introduction Physical performance is a very complex subject in football. Football is characterized by high intensity intermittent capacity, changes in directions – acceleration-deceleration combination - and the quick recovery between actions during a 90-minute match. The ability of core performance and quality of functional movement are crucial roles in professional football performance. The body composition is also a key factor in the physical make-up of football players (Sutton, 2009). The aims of the study were to (1) analyse the players ability in relation to high intensity exercise capacity, (2) to examine the quality of functional movement patterns, and (3) to assess multi-complex body composition. Methods The athletes (N=25) were tested by Yo-Yo Intermittent Recovery Test Level 1 (YYIR1), that evaluates the players football specific intermittent capacity (Bangsbo, 2008). Additionally we used Functional Movement Screen™ (FMS) system, that determined the joints mobility and stability function, core performance, quality of functional movements, and identified athletes functional asymmetries in movement patterns that are considered to be the most significant risk factors for non-contact injury (Kiesel, 2007). The

global and segmental body composition was assessed by using the multi-frequency bioimpedance analyser (Inbody 720). Results We have found differences between the players (mean \pm SD age=24,32 \pm 5,8yrs, height=183,8 \pm 6,02 cm, weight=81,01 \pm 7,82 kg) YYIRI performances ($p<0,05$) and segmental body composition ($p<0,05$) by players football specific positions. Correlations were determined between FMS and body composition parameters using Pearson product correlation coefficients ($p<0,05$). The average \pm SD score regarding FMS was 15,16 \pm 1,8 points. Discussion There are many standards contributing to high level of football capabilities. It is fundamental to establish the key factors of physical performance and certain aspects of the injury potential, in order to determine the individuals players performance during the game. References Bangsbo J, Iain FM, Krstrup P. (2008). Sports Med., 38, 37-51. Kiesel K, Plisky P, Voight ML. (2007). North Am J Sports Phys Ther., 3, 147-158. Sutton L, Scott M, Wallace J, Reilly T. FUNCTIONAL MOVEMENT SCREEN TEST DURING A SOCCER GAME IN YOUNG PLAYERS

Cavaggioni, L., Trecroci, A., Millefanti, A., Alberti, G.

University of Milan

INTRODUCTION During a soccer match there are many physiological and sport specific parameters that changes from the beginning to the end. It seems that in young soccer players, as well as in adults, there are differences between role position in terms of distance covered, sprinting and high intensity (HI) actions, which are lower in the second half, but with similar HR values. Also specific technique ability is affected, in fact there is a decline of short passing abilities. Many quantitative factors may be involved during a match, however there are few studies related to qualitative aspects and their development during a game. The purpose is to provide available data about using and examining the effect of a match on general quality of movement in young football players. **METHODS** Eight male regional-level football players (15 \pm 1 yrs, 57 \pm 2 kg, 169 \pm 1.5 cm, 20 \pm 1 kg/m²) were recruited. Functional Movement Screen (FMS) underwent to all players in order to obtain an evaluation of the general quality of movement before and after an official game. FMS consisted on deep squat-in line lunge-hurdle step-shoulder mobility-active straight leg raise-push up and rotary stability. Due to the rank-order nature of the data, Wilcoxon Signed Rank test were used to examine differences in the FMS scores. **RESULTS** Pre to post differences in the movement patterns were pointed out by FMS single scores: All players performed worse on deep squat, in line lunge, active straight leg raise and rotary stability compared to the beginning of the match ($p<0,05$). Significant differences were reported also in the composite score: 61.9 pre Vs. 51 post match. Regional level soccer players showed different quality in the squatting, the lunging, the hip mobility and dynamic motor control patterns. **CONCLUSIONS** Young players can exhibit different qualities of functional movement during a 70 minutes match. After the game subjects were less balanced during multi-directional movements, presented minor motor control and poor hips mobility. This could be attributed to the match related fatigue which limit not only specific-technical or physiological parameters, but also the execution of basic movement patterns. For a football player, for whom is important to be in balance, to be strong, to have body control and flexibility, indeed the FMS could be an easy strategy to evaluate the quality of movement during the growth period or to introduce specific exercises after training, especially when they are tired. **REFERENCES** 1. EFFECTS OF TRAINING IN INTERMEDIATE ALTITUDE BY TWO NATIONAL U20 CONCACAF SOCCER TEAMS

Ventura Franco, P.

Universidad del Fútbol y Ciencias del Deporte

1: University Football and Sports Science (UFD) Hidalgo Mexico. 2: Center for Medical Excellence of Altitude (CEMA) Introduction. Science seeks to explain the physiological changes that occur in athletes in response to different altitudes. The aim of this study was to measure the effect of training in an altitude of 2520 meters above sea level, from biomedical test applied to the U 20 football teams; who prepared for U20 qualification world cup. Methods. A comparative of the results of study 1) hemoglobin (Hb) and red blood cells, 2) to establish Electrocardiogram adaptation anaerobic to aerobic sport, 3) score of Lake Louise, which assesses the degree of illness of AMS (Acute Mountain Sickness). Classified according to score: MAM MILD: 1 to 3 points. MAM MODERATE: 4 to 6 points, MAM GRAVE: 7 points or more. Including 20 players from two U20 selections, one from an average altitude of 1300 meters above sea level (Team 1) and another from sea level (Team 2). Results. 18 players from Team 1 with mean age of 18.8 \pm 0.61, with an average initial (hb) with respect to the final (hb) not present significance ($p = 0.38$), similar result was presented at the level of red blood cells ($p = 0.50$). According to the index of initial Chignon 13 players presented leveled systems, 4 with predominantly anaerobic and 1 aerobic dominance. At the end we found 8, 10 and 0 players respectively. The Lake Louise tests only 2 players show MAM mild and one moderate. Team 2 was evaluated ($n = 20$), with a mean age of 18.9 \pm 0.9, and an initial average (hb) level of 14.6 and 15.9 at the end the difference was significant ($p = 0.0023$). The number of erythrocytes cells at the training period incremented from 4947.0 to 5553.5 ($p = 0.01$); The Chignon index showed 18 players with leveled anaerobic systems, and one with anaerobic aerobic dominance, which was modified to 9, 6 and 5 respectively. The Lake Louise test 10 days after the stay detected 10 players with MAM Mild and MAM 6 moderate the rest showed no alteration. Discussion. According to the above it was shown that for the Team 2 coming from sea level, was sufficient 10 days to improve (hb) levels. Also it showed more evident acute mountain sickness, although none of the athletes presented severely. Regarding the rate anaerobic – aerobic the adaptation was more evident in the athletes from Team 1. Bibliography. Gómez. Montaner BH JR Rivilla ML E. Romo Da Silva ME (2011). AEROBIC WORK CAPACITIES ON 12 MIN RUNNING TEST AND YO-YO INTERMITTENT RECOVERY TESTS IN COLLEGIATE MALE SOCCER PLAYERS.

Teshima, T., Ohno, S., Hosoda, M., Tsunoda, N.

Kokushikan University

Purpose The purpose of this study was to clarify aerobic work capacities on 12 min running test and Yo-Yo intermittent recovery test in collegiate male soccer players. **Methods** Eighty-nine collegiate soccer players were participated in this study. Subjects were classified into two competitive level as played official game group (Regular) and did not play official game group (Non-regular), and also, their players were classified for five positional categories (FW: forward, SH: Side half and CH: Center half as a mid-fielder, SB: Side back and CH: Center

back as a defender). Subjects were performed 12 min running test (12MR, Cooper, 1968) and Yo-Yo intermittent recovery test level 1 (Yo-Yo IR1) and level 2 (Yo-Yo IR2, Bangsbo, J. and Mohr, M., 2012). Comparison between Regular and Non-regular was analyzed unpaired t-test. Positional category differences were analyzed by one-way ANOVA with Bonferroni-Dunn multiple comparisons post hoc test. Results Running distance of 12MR(3098.3±192.1m), Yo-Yo IR1(2888.5±478.1m) and IR2 (1276.4 ± 345.8) were obtained in all the subjects, and it's distance were longer than previous reports. Running distance of 12MR was significantly correlated to the running distance of Yo-Yo IR1 ($r=0.560$, $p<0.05$) and Yo-Yo IR2 ($r=0.608$, $p<0.05$) in collegiate soccer players. Regular(12MR:3315.5±106.5m, Yo-Yo IR2: 1513.8±279.7m) was significantly longer distance than Non-regular (12MR: 3134.1±179.1m, Yo-Yo IR2: 1200.6±274.4m) in all the tests. In positional category, SB(1487.5±324.7m) was longest running distance compared with other positions (CB: 1248.9±321.9m, SH: 1402.4±300.5m, CH:1195.0±255.8m) on Yo-Yo IR2. Discussion Result of aerobic performance on Yo-Yo IR2 differed by competitive level and positional category than that of Yo-Yo IR1 and 12MR in collegiate male soccer players. From these findings, it seems that Yo-Yo IR2 more reflect to aerobic work capacity than other two tests in collegiate male soccer players. References Bangsbo, J., Mohr, M. MO-BN05 Neuromuscular Performance

JOINT POWER CONTRIBUTION DURING JUMPING AND SIDECUTTING IN YOUNG FEMALE ELITE HANDBALL PLAYERS

Bencke, J., Lauridsen, H.B., Sørensen, R.S., Aagaard, P., Zebis, M.K.

Copenhagen University Hospital, Hvidovre

Introduction One game-changing parameter in handball is explosive power during jumping or sidcutting. In order to improve game performance, more knowledge about the physical demands of the different joints and muscle groups during sports specific movements may help trainers to implement specific exercises for enhancing performance in these movements. The aim of this study was to describe the kinematics and kinetics of the ankle, knee and hip joint during jumping and sidcutting, and investigate their relation to optimal performance. **Methods** 54 young female handball players (16.8 yrs, SD: 1.3) were recruited from Danish national youth teams. Three-dimensional movement analysis was used to investigate maximal counter movement jumping (CMJ) and individual sidcutting maneuvers. Maximal flexion ROM of the knee and hip joint was obtained, and eccentric and concentric joint power of the ankle, knee and hip joints were assessed to describe the performance demands imposed on the different joints. In sidcutting, optimal movement performance may be characterized by a high sagittal approach velocity that is translated into a high transverse velocity during a short ground contact. Thus, sidcutting performance was evaluated by the sum of sagittal approach velocity and transverse take-off velocity, divided by ground contact time. For CMJ, jump height was chosen as dependent parameter. Backwards multiple regression analyses were then used to investigate joint power production as primary determinant of CMJ height, and velocity change during sidcutting, respectively. **Results** During CMJ maximal knee and hip flexion reached 92 (12) and 97 degrees (9), respectively (0° deg=full extension). During sidcutting, maximal flexion angles were 55 (6) and 52 degrees (11) for the knee and hip joints, respectively. Multiple regression analyses showed that concentric knee joint power was the only determinant of CMJ height (adjusted R²: 0.44, $\beta=0.67$, $p<0.001$). Sidcutting performance was determined by concentric ankle joint power only (adjusted R²: 0.21, $\beta=0.47$, $p=0.001$). **Conclusions** Different muscle groups appeared to be determinants of movement performance in different handball specific movements. While vertical jumping mainly depended on knee joint power, peak concentric ankle joint power was the main determinant of sidcutting performance. Consequently, specific power training of the plantar flexors should be employed to improve sidcutting in handball, while power training of the knee extensors would expect to improve vertical jump performance.

HEART RATE VARIABILITY PERFORM AFTER AN EXERCISE OF POWER WITH MUSCULAR OPTIMAL LOAD

Bermejo, J.L., Huertas, F., Ballester, R., Palma, V., Maestre, C., Pablos, C.

Universidad Católica de Valencia

Introduction: Overall, the autonomic nervous system (ANS) is divided into two main branches, the parasympathetic and sympathetic, that during exercise participates in the control. This study aims to analyze HRV during and after recovery from performing strength exercises, to establish the relationship between changes in HRV and physical work in a short period of time. **Method and Design:** 17 soldiers of the Spanish Army (age = 33.7 ± 4.5), underwent assessment of HRV at rest and during tests, recorded through the Polar RS 800. The HRV signal is analyzed in time and frequency domains. Participants were tested on two sessions. Session 1: Incremental load test to determine the load linked to Pmax and 1-repetition maximum (1RM). Session 2 (48-72h rest): Six sets of repetitions until failure with three power loads: 1. Loading 15% lower than Pmax, 2. Burden related to Pmax and 3. Loading 15% higher than Pmax. Then after 15 min of recovery is recording again. **Results:** In practice the values of SDNN, RMSD, pNN50, LF, HF and LF / HF were: [48.57 (18.18) 37.45 (21.36) 13.05 (12.15), 79 82 (8.95) 20.18 (8.95) 4.92 (2.41) ms], respectively. In the recovery period SDNN values, RMSD, pNN50, LF, HF and LF / HF were: [51.01 (21.73) 38.75 (24.83) 15.22 (16.63), 82.64 (8.64) 17.36 (8.64) 6.16 (3.20) ms] respectively. Effort vs Recovery: significant increase of LF / HF ($p = .002$) and LF ($p = .007$) and decreased HF ($p = .007$). **Discussion:** According to the results obtained by Rezk et al.(3) work overload causes an increase in LF component and HF decreases according to the intensity of the exercise performed, which agrees with the results obtained in our study and in turn, indicates an increase of SNS and a decrease in the parasympathetic nervous system (PNS). As Heffernan(1) notes our data show that after the completion of resistance exercise, the cardiac sympathetic modulation is high, while the parasympathetic modulation remains low. Moreover, there is variation in sympathetic activity in the recovery phase, usually showing higher values than at rest, which should result in an increase in the LF / HF ratio(2). **References** (1)Heffernan K., Kelly E., Collier S., Fernhall B. FUNCTIONAL PLASTICITY MECHANISMS OF SPINAL CIRCUITRY OF LUMBOSACRAL ENLARGEMENT IN ATHLETES

Andriyanova, E., Lanskaya, O.

Velikiye Luki State Academy of Physical Education and Sports

Introduction The spinal cord of mammals demonstrates considerable plasticity, which occurs even in mature individuals. Plastic changes, arising in the spinal cord locally, modulate spinal circuitry to better match movements to task demands as a result of sports training. **Methods** and subjects 18 non-athletes, 13 basketball-players and 13 ski-racers (aged 18-22) were involved into the investigation. We used the technique of registration of posterior root-muscle reflexes (PRM-reflexes) (Minassian K. et al., 2007) which were evoked by percutaneous surface electric spinal cord stimulation at the lumbosacral levels (T11-L3). These responses are equivalents of the H-reflex. There were investigated PRM-reflex thresholds and maximal amplitudes of bilateral biceps femoris, medial head of gastrocnemius, soleus and flexor digitorum brevis muscles. **Results** In basketball-players, as well as in ski-racers, PRM-reflexes thresholds of all the studied muscles at all the studied levels of stimulation were lower, and the maximal amplitudes were higher, than received in the group of the individuals not adapted for sports. However, only in the ski-racers significant differences of these parameters were revealed in comparison with the non-trained group. The thresholds of PRM-reflexes, registered at T11-L3 level stimulation, in the qualified basketball-players were higher, and their maximum amplitudes were lower, than in the ski-racers. In some cases significant differences were revealed. It testifies that, in general, athletes have higher reflex excitability of spinal alpha-motoneurons of the hip, shin and foot muscles in comparison with non-trained individuals. In their turn, the ski-racers surpass basketball-players in this characteristic. **Discussion** Athletes, adapted to enduring cyclic work of moderate power (e.g. ski-racers), are characterized by considerable strengthening of reflex function of lumbosacral neural structures, innervating skeletal muscles of the lower extremities, in comparison with the athletes adapted to loadings of variable power with mixed structure movements (e.g. basketball-players). **References** Minassian K., Persy I., Rattay F., Dimitrijevic M.R., Hofer C., Kern H. Posterior root-muscle reflexes elicited by transcutaneous stimulation of the human lumbosacral cord// *Muscle Nerve*. 2007 Mar;35(3):327-36.

BRAIN-DERIVED NEUROTROPHIC FACTOR CONCENTRATIONS AFTER EXERCISE IN WHEELCHAIR RUGBY ATHLETES

Zeller, S., Abel, T., Strüder, H.K.

German Sports University Cologne

PURPOSE: The purpose of this study was to investigate the influence of a graded exercise test (GXT) of wheelchair rugby athletes with a tetraplegic spinal cord injury (SCI) on acute changes in serum concentrations of brain-derived neurotrophic factor (BDNF). BDNF plays a major role in terms of neurogenesis and neuroplasticity and can be increased by physical activity (Knaepen et al., 2010). Rojas Vega et al. (2008) demonstrated increasing BDNF values after moderate handcycling activities in paraplegic athletes. **METHODS:** Nine male elite wheelchair rugby athletes (age: 30.7 ± 3.77 years; height: 180 ± 0.05 cm; weight: 76.7 ± 7.33 kg; wheelchair rugby since 4.11 ± 3.33 years) with a tetraplegic SCI (C5-C7) were recruited for this study. The subjects completed a graded exercise test (GXT) with an initial load of 10 W increased by 10 W every two minutes until exhaustion. Venous blood samples were taken at rest and following the GXT. BDNF concentration was measured using an enzyme immunoassay ELISA kit. In addition blood lactate concentration (mmol/l), oxygen uptake ($\dot{V}O_2$, absolute [l/min] and relative [ml/kg/min]), respiratory quotient (RQ) and heart rate (HR [b/min]) were measured. **RESULTS:** At rest the BDNF concentration was 39.30 ± 24.88 ng/ml and after the GXT 56.54 ± 25.45 ng/ml. Here, no significant differences could be found. The subjects completed the incremental stage test while reaching a maximal power of 73.33 ± 24.49 W. According to this maximal power peak HR was 126.9 ± 23.57 b/min and maximal lactate concentration 5.1 ± 1.74 mmol/l. The peak $\dot{V}O_{2\max}$ of 1.52 ± 0.64 l/min (19.8 ± 8.35 ml/kg/min) was found during a maximal RER of 1.01 ± 0.07 . **CONCLUSIONS:** There is no positive influence of a GXT for wheelchair rugby athletes with a tetraplegic SCI on serum BDNF concentration. Effects of physical activity in terms of increased BDNF levels for humans without a spinal cord injury and for paraplegic athletes depend on exercise intensity and duration (Rojas Vega et al., 2008; Zoladz & Pilc, 2010). In comparison to able-bodied subjects the current BDNF concentrations at rest were about 5-8-fold higher. According to these results further studies should examine the possible increase of BDNF levels in tetraplegic spinal cord injured subjects at different types, durations and intensities of exercise. **References:** Knaepen, K., Goekint, M., Heyman, E. 14:00 - 15:00**Mini-Orals****MO-PM17 TT Endurance Exercise 1****PHYSIOLOGICAL AND BIOMECHANICAL EFFECTS OF AN ULTRA-LONG MOUNTAIN BIKE RACE OF 4600KM: A CASE STUDY**

MORIO, C., ANDROUET, P., GUEGUEN, N.

Oxylane Research

Introduction Ultra-endurance running were increasing interest nowadays, competitively and scientifically (Millet 2011). Although cycling was widely studied, little was known on ultra-endurance cycling efforts, especially in mountain bike (MTB) cycling. The present case study investigated the effects of an ultra-long MTB race on physiological and biomechanical parameters of pedalling. **Methods** JD (male, 1.63m, 63kg, 33 years-old) participated in two sessions of measures 1 week before, 1 week after and 6 weeks after a 4 600 km of orienteering and self-supported MTB race (Tour Divide) with 61 km of cumulative elevation. Session 1 consisted in an incremental cadence maximal test (Deakin et al 2011) on a MTB home trainer with SRM powermeter and Fitmate Pro gas analyser. Maximal oxygen consumption ($\dot{V}O_{2\max}$), aerobic power output (MAP) and rate of perceived exertion (RPEmax) were measured. Session 2 consisted in pedalling techniques measurement with Powertec force pedals at two cadences (70rpm-90rpm) and two power outputs (150W-250W). Index of

effectiveness (IE) was calculated with effective (FE) and ineffective (FU) forces. Results As the present focused on a case study, only descriptive results were presented and discussed. JD finished the race in 22 days and 16 hours including 12 days 11 hours on his bike and 10 days 5 hours of rest. He cycled 200±49km/day. Initial JD's VO₂max and MAP were 61.8mL/min/kg and 285W, respectively. One week after the race, both parameters dropped to 57.9mL/min/kg and 267W. After the recovery phase only VO₂max came back to its initial level of 62mL/min/kg whereas MAP stayed at a low level of 266W. After the race, the applied FE on the pedals increased during the pushing phase for all cadence and power conditions except for 70rpm at 245W. For this specific condition, no change was observed after the race, therewith FE was reduced after the recovery period. IE showed obviously inversed trends. Discussion Results during the one week post sessions showed that the race induced a chronic fatigue. The recovery showed a reduce efficiency of cycling compared to initial level that might be due to either detraining or adaptation to submaximal effort. The FE increase during the pushing phase might reveal a greater turns in muscle activation in order to prevent long term fatigue (Dorel et al 2009). This would need further investigation including EMG pattern measurements. The lack of change in 70rpm at 245W after the race suggested that it could be JD's preferred technique. Indeed, the commuting cycling performed by JD during the recovery phase might explain the lower FE at this specific cadence and power output. References Deakin GB, Davie AJ, Zhou S. INFLUENCE OF HYPEROXIA IN THE RECOVERY DURING DOUBLE POLING INTERVALS.

Zinner, C.1, Sperlich, B.2, Hauser, A.3, Born, D.2, Wehrlin, J.P.3, Holmberg, H.C.1

Mid Sweden University, Östersund, Sweden

1: Swedish Winter Sports Research Centre, Department of Health Sciences, Mid Sweden University, Östersund, Sweden 2: Department of Sport Science, Julius-Maximilians-University Würzburg, Germany 3: Swiss Federal Institute of Sport, Section for Elite Sport, Magglingen, Switzerland Introduction In the last years only a few studies focused on the use of hyperoxia during recovery between bouts of high-intensity exercise and the physiological responses. The limited studies devoted to this practice provide inconsistent results. Therefore, the aim of this study was if using hyperoxia during double poling exercise will help to recover better during normoxic or hypoxic conditions. Methods Ten male endurance athletes (25.3±4.1 yrs; 179.2±4.5 cm; 74.2±3.4 kg) performed three interventions, with 3x3min intervals on a double-poling ergometer with 3min recovery, in randomized and single-blind order. One trial was conducted in normoxic conditions (NO) with a FiO₂=0.21 during the intervals and the recovery (NONO). During the 2nd trial a FiO₂=1.00 was applied during the recovery (NOHE) and during the 3rd trial the intervals were conducted under hypoxic conditions (FiO₂=0.165) (HO) and hyperoxia (HE) was applied during recovery (HOHE). During the intervals the mean power output (P_{mean}) was determined. Further blood lactate concentration and blood PO₂ was determined after each interval. For the determination of the tissue saturation index (TSI) of the m. triceps brachii NIRS was used. Results During the recoveries with hyperoxia PO₂ was significantly higher compared to the other interventions (P<0.01). During the NOHE-intervention P_{mean} did not decrease significantly from the 1st to the 3rd interval. During the two other interventions P_{mean} of the 1st interval was significantly higher compared to the 2nd and 3rd interval (P<0.01). Lactate concentration showed no differences between the interventions HOHE and NONO. In NOHE lactate values were lower after the 2nd and 3rd interval compared to the other interventions. There were no significant differences in the TSI between the interventions. Discussion An application of hyperoxia increases the diffusion of O₂ to the mitochondria and therefore O₂ delivery to the muscles during exercise. We could show that application of HE during recovery in normoxia increases the recovery and therefore performance in subsequent 2nd and 3rd 3min interval wasn't significantly decreased. In the intervention during which the intervals were performed in hypoxia the hyperoxia during the recovery was not sufficient to achieve a full recovery and similar power outputs in the 2nd and 3rd interval. Although, we couldn't find any differences in the TSI between the interventions. Contact ch.zinner@gmx.de

URINARY STEROID PROFILE ANALYSIS IN IRONMAN TRIATHLETES

Olcina, G., Marcos, M., Crespo, C., Muñoz, D., Maynar, M., Timón, R.

Sport Sciences Faculty, University of Extremadura

Introduction High volume exercise provokes physiological stress and it causes changes in hormonal metabolism (Timon et al., 2007). However, there is controversy on this biological response. The aim of this study was to determine variations in the urinary steroid profile in humans after performing an ultra-endurance race: Ironman triathlon. Methods Study sample was formed by 15 male triathletes. They participated in Ironman European Championships, Frankfurt (Germany). Finish times ranged between 9:08:15 and 11:40:10. Three urine samples were collected: (i) first morning urine, (ii) first urine after the event and (iii) 24 hours after the event. Gas chromatography-mass spectrometry technique was used to detect and quantify urinary steroid profile. SPSS 19.0 was used for statistical analysis, Kolmogorov-Smirnov and Levene test to study data distribution and variance homogeneity and repeated measures analysis for data analysis. Results Androstosterone (3297.80±756.83 ng/ml to 2154.26±1375.38 ng/ml; p=0.013), DHEA (478.00±192.12 ng/ml to 326.50±159.64 ng/ml; p=0.017), epitestosterone (137.04±44.22 ng/ml to 77.59±45.71 ng/ml; p=0.033) and beta-stradiol (59.36±11.74 ng/ml to 41.67±10.59 ng/ml; p=0.025) values significantly decreased after the event. Also urinary values of DHEA significantly decreased 24 hours after finished the event (478.00±192.12 ng/ml to 321.10±140.03 ng/ml; p=0.009). However, cortisol (200.38±56.60 ng/ml to 257.10±74.00 ng/ml; p=0.044) and tetrahydrocortisol (238.65±81.55 ng/ml to 289.62±77.13 ng/ml; p=0.034) values increased after event and both remained elevated at 24 hours. Ratios between anabolic / catabolic hormones also decreased significantly after Ironman competition (p<0.05). Discussion Steroid profile was modified in accordance with previous studies (Neubauer et al., 2008). Androgens excretion and their metabolites decreased in urine after the Ironman due to disturbances caused by stress in hypothalamic-pituitary axis. This should be for retaining androgens to improve recovery process. Urinary cortisol values increased after exercise by a significant stress induced by an activation of adrenal gland due to physiological demands of the ironman competition. Androgen/corticosteroids ratios decreased in similar way as previous results found by our research group (Timón et al., 2007). It indicates an increase in catabolic status of triathletes at least 24h after the event. References Neubauer O, König D, Wagner K H. RELATIONSHIP BETWEEN AEROBIC AND ANAEROBIC CAPACITY AND CYCLING TIME TRIALS

Schwindling, S., Skorski, S., Hammes, D., Meyer, T.

Saarland University

Introduction: Cyclists can maintain high velocities during a 40 km race and are still able to perform a great endspurt (Abbiss & Laursen, 2008). It can be assumed that this requires aerobic endurance capacity and a good anaerobic capacity. Both properties can be measured using standardized laboratory tests (e. g. VO₂max, lactate thresholds, 30-s anaerobic Wingate test (WIN)). However, studies analysing the relationship between those "classic" cycling tests and actual TT performance are still missing. Hence, the aim of the current study was to determine the relationship between aerobic as well as anaerobic parameters and the 40 km TT performance. **Methods:** 23 male cyclists (28.8±7.6y) participated in the study. Subjects completed a flat 40 km TT, a WIN and a graded cycling test until exhaustion (GXT) in this order. Individual anaerobic threshold (IAT) as well as VO₂max were determined from the GXT. All tests were conducted on one day with 2 h rest in-between and were performed on participants' own bicycle (installed to a Cycplus2 ergometer). Coefficients of correlation between test results were determined using Pearson's regression test. Additionally, to find the best combination of variables predicting TT performance and determining which percentage of TT results can be explained by results from the other tests, a multiple regression analysis with stepwise inclusion was carried out. **Results:** Overall TT performance was 65.7±3.5min with an average power output (P) of 236±38 W. Significant correlations of TT were found with GXT maximum P (P_{max}, $r=-0.83$) and IAT ($r=-0.78$). When related to body weight, correlations for P_{max} and IAT were still significant, yet lower ($r=-0.63$ and $r=-0.74$, respectively). No significant correlations were found between TT and VO₂max ($r=-0.37$) and results from WIN (P_{max}: $r=-0.03$; P_{mean}: $r=-0.29$). Multiple regression revealed the highest coefficient of determination for the estimation of TT when P_{max} and body weight were combined in one equation ($R^2=0.73$, SEE=312s, F=28.8). **Discussion:** The results suggest that the P_{max} in an incremental cycling test is the best predictor for performance in a 40km TT. In combination with the body weight approximately 73% of TT performance can be explained. Furthermore, in trained cyclists absolute power output seems to be a better predictor than VO₂max and power output in relation to body weight. This is not surprising given that body weight can be fully invested into power output whereas it is carried by the bicycle frame. Results of the Wingate test do not seem to be relevant predictors for TT performance, possibly because endspurt does not influence overall performance relevantly enough. **References:** Abbiss CR, Laursen PB (2008). *Sports Med*, 38(3), 239-52. DETERMINANTS OF TIME TRIAL PERFORMANCE IN TRAINED CYCLISTS

van der Zwaard, S., de Ruiter, C.J., Jaspers, R.T., de Haan, A., de Koning, J.J.

Vrije Universiteit

MOVE research institute Amsterdam, VU (Amsterdam, Netherlands). **Background:** Optimizing cycling performance in short and long distance time trials sets different requirements in peak power and endurance capacity within athletes. **Purpose:** As a first step, we aimed to explore determinants of time trial performance in trained cyclists. For 6 time trials (0.5 – 40km), we determined to what extent time trial performance was related to mean power output in the time trial (P_{mean}), weight, training volume, gross efficiency (GE), maximal oxygen uptake (VO₂max) and maximal power output (P_{max}), the latter obtained with an incremental test. **Methods:** Nineteen trained male cyclists completed a maximal incremental test and 6 time trials (0.5, 1, 2, 4, 15, and 40km) with the instruction to finish as fast as possible. Linear regression analyses were performed to assess the relationship between finish times in relatively short and long time trials. For every time trial, Pearson's correlation coefficients were calculated between time trial performance (defined as inverted finish time) and P_{mean}, weight, training volume, GE, VO₂max and P_{max}. Subjects averaged a training volume of 12 ± 4.6 h/wk. **Results:** Finish times of long time trials (15 and 40km) were strongly related ($R^2 = 0.67$, $p<0.01$), as well as time on short time trials (0.5 and 1km, $R^2 = 0.49$, $p<0.01$). However, performance on shortest and longest time trials was not related ($R^2 = 0.05$). P_{mean} was highly related to performance for most time trials ($r = 0.99$), but only moderate for short time trials ($r = 0.44-0.64$). Weight was poorly related ($r = -0.28-0.19$) and training volume poorly or even negatively related to time trial performance ($r = -0.53-0.04$). GE poorly attributed to performance ($r = -0.03-0.35$). In addition, VO₂max and P_{max} were both poorly related to the shortest time trial performance ($r = 0.10$, $r = 0.18$) and moderately for other trials ($r = 0.50-0.65$). **Conclusion:** This study shows that performances in short time trials (associated with peak power) and long time trials (associated with endurance capacity) were not related, which is in line with the concept that performances of different duration set other physiological requirements. Subsequently, time trial performance was highly related to P_{mean}, moderately related to VO₂max and P_{max} and poorly related to weight, training volume and GE. Somewhat lower correlations with P_{mean} and short time trial performance may be due to pacing strategies. Note that in this study, VO₂max (which is commonly used as marker of endurance capacity) relates only moderately to endurance performance. We conclude that future research should investigate other physiological variables (e.g. muscle fiber type and/or mitochondrial density) and pacing strategies as determinants of time trial performance. EFFECTS OF MATCHED VOLUME HIGH-INTENSITY INTERVAL TRAINING ON AEROBIC CAPACITY AND METABOLIC RESPONSES IN ACTIVE MEN

Lee, C.L.1, Cheng, C.F.2, Hsu, W.C.3

1: National Sun Yat-sen University (Kaohsiung, Taiwan) 2: National Taiwan Normal University (Taipei, Taiwan) 3: University of Taipei (Taipei, Taiwan)

Introduction: High-intensity interval training (HIT) can be broadly defined as repeated bouts of sprint to moderate duration exercise (i.e., few seconds to several minutes) completed at an intensity that is greater than anaerobic threshold [1, 2]. Compared with sprint interval training (SIT), the aerobic interval training (AIT) may result in specific adaptations in cardiorespiratory fitness (e.g., peak oxygen uptake, VO₂peak) and blood metabolic profiles [1, 2]. These different responses might be attributed to the unequal training volume. Hence, this study examines the effects of matched volume in SIT and AIT on physiological responses during graded exercise test (GXT) in general population. **Methods:** Twenty-four recreationally active males were randomly (22±1 yrs, 177±7 cm, and 69±9 kg) assigned to one of three groups: AIT (8 × 60-s at 85-90% VO₂peak; 120-s recovery at 30% VO₂peak), SIT (48 × 10-s at 85-90% VO₂peak; 20-s recovery at 30% VO₂peak), or control group (CON). Before and after a 4-wks period (12 sessions), participants performed GXT on a cycle ergometer to assess the VO₂peak and ventilatory responses. Blood lactate and glucose concentrations were measured before and after GXT. Blood samples were drawn from antecubital vein before GXT to evaluate the lipid profiles and insulin levels. **Results:** The VO₂peak were significantly improved in SIT and AIT ($P < 0.05$), whereas no significant changes in carbohydrate ($P > 0.05$) and fat oxidation rates ($P = 0.06$) during GXT. Compared with CON, the AIT and SIT resulted in 16.8% and 13.3% increases in VO₂peak, respectively. Furthermore, only AIT

revealed a significant higher VO₂peak than that in CON. No significant difference in VO₂peak was observed between AIT and SIT at post-training, but pulmonary ventilation was greater in SIT. Although the blood lactate, blood glucose, total cholesterol, triglyceride and insulin concentrations were not different among the AIT, SIT and CON groups ($P > 0.05$), high-density lipoprotein cholesterol levels were significantly higher in AIT compared with CON at post-training ($P < 0.05$). Discussion: These findings could provide support for the improvements in VO₂peak after 4-wks of SIT or AIT, which is in line with other studies [1, 2]. Furthermore, the AIT might have more effective than SIT to improve aerobic capacity and attenuate the risks of cardiovascular diseases in sedentary individuals. Helgerud et al. [3] reported that the administration of HIT with longer intervals was superior to that with short intervals to increase maximal oxygen uptake. In conclusion, both AIT and SIT, the time-efficient exercise prescriptions, could be used to ameliorate aerobic capacity and cardiometabolic risks. This study was supported by a grant from National Science Council, Taiwan (NSC 102-2410-H-110-082). References: 1. Gibala MJ, McGee SL (2008). *Exerc Sport Sci Rev* 36(2), 58-63. 2. Kessler et al. ANALYSIS OF ENDURANCE TRAINING ON SELECTED BLOOD VALUES IN ADOLESCENTS REQUIRING DIALYSIS

Thys, S.1, Feldkötter, M.2, Hoppe, B.2, Schaar, B.3

1: GSUC (Cologne, Germany); 2: UCB (Bonn, Germany); 3: UFAF (Munich, Germany)

Introduction: Undergoing hemodialysis children and adolescents have a reduced physical capacity compared to children with a low or moderately severe chronic renal insufficiency. In the treatment of chronic kidney failure, performance is noticeably increased with the aid of recombinant erythropoietin (EPO). However, the relative concentrations of red blood cells and hemoglobin, as well as the morphology of the erythrocytes can also regularly be adjusted by sports activity. Since both interventions have a positive effect on the physiological performance, the following study aims to determine the effects of endurance training on hematocrit (HCT) and hemoglobin (HB) levels in contrast to the effect of EPO. Methodic: 7 subjects of different gender were included in the study (age: 16.43 ± 1.13 years; body height: 156 ± 13.18 cm; body weight: 50.26 ± 10.43 kg). EPO dosages were recorded. The study design was quasi-experimental with a waiting-control group in a pre-posttest design. The intervention included an endurance training for three times per week for 30-40 minutes, which was performed on an ergometer during the first two hours of dialysis. The following blood values were obtained: HB, HCT, glucose, phosphate, urea, creatinine, blood pH, base excess, calcium i.a.. Results: Two groups were formed. In the first group EPO dosage was not changed during course of the training intervention, in the second group the medication was modified. Referring to the performance level, measured in VO₂ peak and VO₂peak/kg, the subjects decreased with one exception. However, all the subjects kept or increased the wattage and duration. Discussion: Overvalued doses of EPO prevent an adaptation of the blood values by physical activity. Subjects, who were undervalued, can increase their HB and HCT values by physical activity. As outcome the amount of HB and HCT will equal the prescriptive limits or will even be slightly above. Therefore, the medication could be reduced in complying with an individualized intervention of endurance training by ergometer. MO-PM18 SM Epidemiology

INCIDENCE AND PREVALENCE OF RUNNING-RELATED INJURIES IN TRAIL-RUNNERS

Hespanhol Junior, L.C., van Mechelen, W., Verhagen, E.

EMGO+ Institute for Health and Care Research, VU University Medical Center, Amsterdam, The Netherlands

Introduction The injury risk of running is high with a prevalence and incidence of running-related injury (RRI) being about 50% and 10 RRIs/1,000 hours, respectively[1, 2]. It is postulated that the risk of injury is lower in trail running as compared to road or track. However, there are no studies about RRI in trail-runners to support this hypothesis. Therefore, the objective of this study was to determine the incidence and prevalence of RRI in trail-runners. Methods This prospective cohort study was part of the "Healthy Trails" project. A total of 181 trail-runners answered online surveys every fortnight during a follow-up period of 16 weeks. This survey contained questions about running exposure, health problems and required medical attention. Descriptive analyses were performed and the incidence of RRI was reported by RRIs/1,000 hours of running exposure (training and events). Results A total of 74.2% (n=141) of the participants were males. The mean age was 42.1 years (SD=9.2) and the BMI was 22.5 kg/m² (SD=2.0). During follow-up, the running exposure was on average 2.8 running sessions/week (SD=1.4), totalling 37.4 km/week (SD=23.2) in 3.9 hours/week (SD=2.7). A total of 74 participants reported 97 unique RRIs. The mean prevalence of RRI at each time point was 22.6% (SD=3.0). The incidence of RRI over the follow-up period was 7.91 RRIs/1,000 hours (95%CI 6.11 to 9.71). The incidence of RRI resulting in time-loss or required medical attention were 5.67 RRIs/1,000 hours (95%CI 4.14 to 7.19) and 2.14 RRIs/1,000 hours (95%CI 1.20 to 3.08), respectively. Discussion RRI rates in trail-runners appear to be lower than those reported in the literature for road-runners. Therefore, the hypothesis regarding trail-runners to be at decreased injury risk is supported by our data. Yet, the exposure in terms of kilometres and hours run is steep in trail-runners and most runners have over 5 years of running experience, indicating that trail-runners are a different population than road-runners. As such, injury prevention in trail-running is of equal importance. Due to the inherent differences in trail-running as opposed to road-running, future studies are required to gain more insight into the injury risk factors and mechanisms that underlie trail-running injuries. A FEASIBILITY STUDY DESIGN FOR THE PREVENTION OF LOWER LIMB INJURIES IN PETE STUDENTS FOLLOWING RE-AIM

Goossens, L., Cardon, G., Witvrouw, E., De Clercq, D.
Ghent University

Introduction Efficacy of a lower limb injury prevention program in PETE students has been proven in terms of injury risk and incidence rate (Goossens et al., 2014). To describe further implementation possibilities of this intervention, a feasibility study is requisite. Methods A lower limb injury prevention program in PETE students (S), consisting of an injury awareness program (theoretical course, posters, website, technical training) and application of active strategies (warm-up, cool-down, stretching, dynamic stabilization, functional strength, core stability) runs for 1 academic year. Teachers (T) were trained for application of the intervention during 1 theoretical-practical (TP) session. Retrospective injury registrations and pre-post questionnaires for change in behavioral attitudes and intentions, perceived behavioral control, intrinsic motivation, knowledge (T&S), intervention appreciation (T), self-reported behavior and subjective norm (S) will be taken. Teachers register application of active strategies weekly. Feasibility will be analyzed using the RE-AIM model. Results All 14 professional bachelor PETE trainings in Flanders were randomly allocated to the intervention (IG) or control group (CG). Four institutions of the IG agreed to participate, giving a reach on institutional level (IL) of 28.6%. On teacher level (TL) % of teachers whom attended the TP session and on student level (SL) % of students exposed to the program via educated teachers will constitute the reach. The reduction in injury risk and the change in behavioral attitudes, perceived behavioral control, intrinsic motivation, subjective norm and knowledge of students in IG compared to CG (IL) and the change in behavioral attitudes, perceived behavioral control, intrinsic motivation and knowledge of teachers in IG compared to CG (TL) will measure effectiveness. Adoption will be measured by % of teachers delivering the program and by their intervention appreciation (TL) and by % of students attending classes (SL). Implementation will be calculated by % of institutions making use of the awareness program (IL), by total amount of active strategy applications (TL) and by % of students that got in touch with the awareness program (SL). Maintenance will be expressed as % of institutions (IL) and teachers (TL) intending to implement a prevention program in the future and as % of students intending to execute the active prevention strategies regularly in the future (SL). Conclusion After completing this study, policy makers will have sufficient evidence based rationale, making a plea for the implementation of structured prevention of lower limb injuries in PETE training. INJURIES IN GERMAN ELITE MEN'S SOCCER – NO PAIN MORE GAIN!

Klein, C., Luig, P., Henke, T.
VBG, German Social Accident Insurance Institution for the administrative sector

INTRODUCTION: In Germany, soccer is the most popular sport, but particularly on professional level a sport with a very high injury incidence (approx. 18.4 inj. / 1000h). During the observation period more than 6,840 injuries within the 1st and 2nd league led to about 30,000 days of disability and medical costs of almost 4 million per season in average. The purpose of this study is to identify typical injury situations in professional men soccer and the illustration of resulting preventive measures. METHODS: The observation period focused on the season 2010/11, 11/12 and 12/13 of the two highest leagues in German men's soccer. To describe the sample of all professional soccer players who played at least once in a competitive match, soccer specific journals were consulted. Injury data including information about nature and severity of the injury were analysed. The footage was available via the media library of the German Soccer League. With the aid of a validated checklist 117 injuries were video analysed. Additionally 67 professional soccer coaches participated in an online survey concerning injuries and preventive approaches to increase compliance of the resulting measures. RESULTS: Throughout the observation period 78 % of all athletes got injured at least once. In average each player sustained 2.5 injuries per season. About two-thirds of the injuries concerned the lower limbs. Most of them were injuries of thighs (19.5 %), knees (16.0 %) and ankles (12.4 %). Knee injuries showed the highest severity leading to nearly 7,500 days of disability and 1.6 million medical costs per season. In case of thigh injuries prevalently chronic injuries were monitored as a result from overuse effects during the season. 93 % of non-contact injuries by pivoting were knee injuries resulting from lunges (39 %), own sliding tackles (31 %) or stopping - typically in combination with change of direction (23 %). Commonly contact injuries resulted from collisions (43 %) or kicks (35 %) of opposing players and pertain to knee (30 %) or ankle (23 %). In case of kicks, at time of injury the injured athlete mainly was running/sprinting (33 %) or in a shooting/passing motion (24 %). Collisions with opposing players often occurred after sliding tackles of the injured player (28 %). In most cases of contact injuries the injured player was in contact with the ground (70 %) at least with one foot (45 %) at the moment of injury. DISCUSSION: To reduce number of injuries and to increase performance level of the athletes, sport specific, applicable and acceptable prevention measures are necessary. Measured by the given injury situations preventive recommendations should focus on physical preparation and training approaches. One focus should aim at strengthening of the mechanical axis to reduce number of non-contact injuries. Beyond that return-to-play guidelines for common kind of injuries should be implemented to reduce number of re-injuries.

THE EPIDEMIOLOGY OF TABLE TENNIS INJURIES VIA I.R.I SPORT MEDICINE FEDERATION INJURY SURVEILLANCE SYSTEM OVER THREE YEARS.

Moradi Shahpar, F., Pourkazemi, L.A., Ebrahimi Varkiani, M., Alizadeh, M.H.
Sport Medicine Federation & University of Esfahan

Introduction Injury prevention is an important part of health care in sport. In order to plan a preventive measure, first the extent of the sport injury should be established[1]. Table tennis is an Olympic sport and is played professionally in Asia. As all sports, incurring injury in table tennis is unavoidable. Table tennis was one of the low risk of injury sports in the 37th Thailand National Games 2008[2]. While there is a few researches studying the injury profile in table tennis and due to the importance of injury identification in prevention, the present article proposed to study the profile of injuries in Iranian athletes presented to the sport medicine federation injury surveillance system. Methods A retrospective analysis was conducted of the data for Iranian table tennis players from the sport medicine federation injury surveillance system of Iran during one year of Persian calendar at 21st of March 2009 until 19th of March 2012. This system is operated to provide sport related injuries incurred by insured athletes participating in various sports from all provinces of Iran. The injury definition was any reportable events occurred as a result of participating in competition or practice, required medical attention by physician and resulted in restriction of the athlete's participation for at least one day beyond the injury. The type of injuries was not considered due to unavailability. All statistical analysis was done by the SPSS software (version 14). Results Among 56270 registered athletes (Male=36789 & Female=19481), 112 athletes with mean age of 32.46±14.35, presented 126 injuries (Male=111 & Female=15). The incidence rate of 2.23 per 1000 athletes registered (Male= 3.06 & Female= 0.76) was calculated. Addressing body regions, lower extremity (58.9%) followed by

upper extremity (27.4%) incurred most of injuries. Furthermore, the rate of 4.1 injury per 1000 registered athletes reported for young athletes aged 15-24 was higher than other ages. Concerning the body parts, knee (28.6%), ankle (12.7%) and wrist, hand and finger (12.7%) were the most common parts of injury. For about 77.8% of injuries occurred in training and the left in competition. Discussion The injury rate was 2.23 per 1000 registered athletes. It was lower than the rate reported in London Olympic Games 2012[3]. In consistence with most sports, risk of injury in male was higher than female. In conclusion, it seems that injury prevention programs should be provided on lower extremity, specially knee and ankle in both gender. The athletes aged 15-24 should be focused more as well. 1. APPRECIATION ORIENTED OPTIMIZATION OF AN INTRINSIC INTERVENTION FOR INJURY PREVENTION IN PHYSICAL EDUCATION TEACHERS

Vercruysse, S., De Clercq, D., Goossens, L., Haerens, L.

Ghent University

Introduction Physical Education (PE) teachers are at high risk of injuries because of the total package of physically active tasks (ref1), so injury prevention is needed. The content can be based on successful sports injury prevention programs (ref2) and compliance should be a concern (ref3). This study aimed to apply the cycle of implementation evaluation and optimization to develop an intrinsic injury prevention intervention for PE teachers, with the main focus on increasing teachers' appreciation. Also, if potential change in teachers' attitude, knowledge and behavior was measured. Methods Twenty PE teachers (13 men, 7 women; 42.1 ± 12.17 yrs) of 9 different schools in Flanders (Belgium) voluntarily participated. The intervention was spread over 2 afternoons: Training A (theory + practical part 1) and training B (practical part 2). Optimization of content and way of delivery was made by 2 main adjustments for A and one for B, based on feedback and suggestions obtained through appreciation questionnaires and focus group conversations (ref4). Appreciation was measured on a 5-point Likert scale immediately after a training, knowledge by multiple choice questions of the different prevention strategies, attitude per prevention strategy based on a sum score on three sets of questions, injury preventive behavior by weekly online registrations. Results and discussion After adjustments, overall appreciation for A improved from 4.2 to 4.5 ($p=0.009$). Main adaptations in the theoretical (e.g. using more intelligible words) and practical part (e.g. new structure of didactical posters) showed that optimization can be reached through the proposed method. While making B, suggestions given at the end of A were implemented already, resulting in no big changes of B. Only trunk muscular endurance tests were added, but no differences in appreciation were perceived. Attitude mostly changed after B and mainly towards lower leg stabilisation exercises ($p=0.032$), lower leg strength training ($p=0.007$), core stability ($p=0.041$) and correct performance of lower leg exercises ($p=0.029$). Dynamic stretching before a sport activity ($p=0.031$) and static stretching ($p=0.001$) improved from the beginning till the end of the intervention. Knowledge improved ($p<0.001$) from a score of 4.98 to 6.79 on 10. Weekly behavior scores showed a good compliance, despite a trend ($p=0.063$) of reduction towards the end of the intervention. Further analysis could investigate the relationship between appreciation and the changes in knowledge, attitudes and behavior. References 1 Sandmark H et al (1999). CIRCUMSTANCE OF INJURY OF CONCUSSION IN HIGH SCHOOL RUGBY PLAYER

Otomo, M., Fukubayashi, T.

waseda university

Introduction In recent years, concussion in sports has become recognized as a central issue in sports medicine in Europe and the United States. Although rugby athletes can sustain injuries to all body parts, concussions are the most common. In Japan, concussion occurs more often in high school rugby player. The purpose of this study was to examine the circumstance of injury concussion in high school rugby player. Methods Subjects were 103 high school rugby players (16.2 ± 1.8 years) in Japan. They visited the clinic and diagnosed with concussion in 22 days of investigation. In 22 days, 308 high schools came to rugby camp around the clinic. We investigated by interview format for symptoms and circumstances of injury concussion. Result Location of the clinic is in the surrounded by rugby ground of 108. Therefore, they took 1 hour 28 minutes \pm 42 minutes to visit clinic after injury concussion. 37% of participants had a history of concussion, and 63% of participants did not have a concussion history. And, participants did not have concussion history were younger than participants who had history of concussion ($p<0.01$). The situation at the time of injury, 98% of subjects hit their head (41% frontal region, 31% temporal region and 21% occipital region). In addition, participants of 71% were tackling player, 29% of participants were tackled player. Subject of 22% who had loss of consciousness, and had loss of memory was 77% of all subjects. The most common symptom of concussion was headache (82%). Conclusion Tackling is the phase of play that produces the highest proportion of injuries in this study. There were many participants who had a loss of memory than loss of consciousness. The most common symptom of concussion was headache. INCIDENCE AND CAUSES OF INJURIES AMONG WRESTLERS IN KOSOVO A 1-YEAR PROSPECTIVE STUDY

Haxhiu, B., Murtezani, A., Berisha, A., Gara, E., Zahiti, B.

University Clinical Center of Kosovo, University of Prishtina

Introduction: Although wrestling is worldwide sport, its nature results in high injury rates. Several studies have evaluated the incidence and risk factors for injuries among wrestlers, but there are still limited data. The purpose of this study was to assess the incidence and risk factors for injuries among elite senior wrestlers in freestyle wrestling in Kosovo. Methods: A prospective cohort study of 107 wrestlers from 7 different wrestling clubs was conducted during the year 2012/2013. A self-administered questionnaire, together with an information leaflet about the study was given to them. The questionnaire included individual characteristics: age, weight, height, body mass index, smoking habits (yes/no), athlete experience, and previous history of injury. Standard check off forms was used to collect related data on injuries including injury type, severity, location, and wrestling technique that led to the injury. Results: A total of 107 athletes sus-

tained 69 injuries. The overall injury rate was 5.8% per 1000 athlete-exposures. Competition had a significantly higher injury rate than practice. No serious and catastrophic injury was recorded. Most injuries in this study, 84.4%, were mild. Injured wrestlers were an average of 9 months older and had a 32% higher experience level than noninjured wrestlers. The knee, shoulder, and ankle were the most commonly injured regions. Sprains and strains were the most common injury types. The most common wrestling activities resulting in injury was the takedown position (72%). Age showed strong associations with injury. The main risk factors for injury among wrestlers were higher experience level (OR=3.5, 95% CI 1.9-6.2, $p<0.01$), as well as takedown position (OR=2.5, 95% CI 1.3-4.7, $p<0.01$), and age (OR=1.7, 95% CI 1.0-3.0, $p<0.01$). Discussion: The incidence of injuries among wrestler in our study is significantly high. The risk of injuries was enhanced by a wrestler's increased years of experience, takedown position and age. It can be reduced by preventive interventions, especially more physical training. Correct preparation for the game not only prevents poor performance, but might also reduce the incidence of injuries.

MO-PM19 TT Strength Training

EFFECTS OF CONCURRENT ENDURANCE AND CIRCUIT RESISTANCE TRAINING SEQUENCE ON AEROBIC AND ANAEROBIC POWER

MANIAZHAGU, D.

ALAGAPPA UNIVERSITY

EFFECTS OF CONCURRENT ENDURANCE AND CIRCUIT RESISTANCE TRAINING SEQUENCE ON AEROBIC AND ANAEROBIC POWER Introduction Physical training is exposing the organism to a training load or work stress of sufficient intensity, duration and frequency to produce a noticeable or measurable training effect, that is, to improve the functions for which training is aimed. The majority of concurrent training studies involving isoinertial strength training demonstrated an inhibition in strength development (Hennessy et al 1994, Kraemer et al 1995). The purpose of the study was to find out the effects of concurrent training and circuit resistance training sequence on aerobic and anaerobic power. Methods Fifty men students from Caussanel College of Arts and Science, Muthupettai, Ramanathapuram, Tamil nadu, India were selected at random as subjects. The age of the subjects was ranged from 18 to 22 years. The selected subjects were divided into five groups, viz, Group -1 those who underwent individualized circuit resistance training, Group - 2 those who underwent individualized endurance training, Group - 3 those who underwent circuit resistance training before endurance training, Group - 4 those who underwent circuit resistance training after endurance training and Group -5 was served as control Participants. The aerobic and anaerobic power was selected as dependent variables and tested with standardised test prior and immediately after the programme of twenty four weeks. Results Concurrent endurance training and circuit resistance training sequence have produced significant improvement on aerobic and anaerobic power of college men students. Discussion A number of studies have been conducted to investigate the possible interference effects of performing strength training and endurance training concurrently. Most have shown that concurrent strength and endurance training does in fact have deleterious effects on the development of strength or force production. Nelson et al. (1990) conducted a study on previously untrained subjects in which one group; strength trained 4 days/wk for 20 weeks while another group performed the same routine but also performed endurance on the same days. The results indicated that although both groups showed increases in force production, yet the strength-training group showed greater improvements. Kraemer et al. (1995) found the same results. References Hennessy, L.C and Watson, E.S. (1994). The interference effect of training for strength and endurance simultaneously. Journal of strength and conditioning Research, 8, 12 - 9. ACUTE EFFECT OF LOCAL VIBRATORY TRAINING ON BENCH PRESS PERFORMANCE

Timon, R., Collado Mateo, D., Camacho, M., Marcos, M., Olcina, G., Gusi, N.

Sport Sciences Faculty. University of Extremadura

Introduction Vibration training can improve muscle strength, power and performance (Marin et al, 2013). However, the effects of vibration depend on the method of application, amplitude and frequency of the vibration as well as the training level of the participants (Luo et al, 2005). The aim of this study was to determine if the vibration applied to the chest via hands has similar effects on bench press performance in recreational bodybuilders and non trained young subjects. **Methods** Nineteen participants (10 trained and 9 non trained) randomly performed two different trials on separate days. Each trial consisted of 1 set of bench press with a load of 75% 1RM to failure. One of trials was performed without vibration (control) and the other right after a 30-seconds vibration exposure (12Hz, 4mm) on a Galileo oscillating platform. Cinematic parameters (velocity and acceleration) through the set were monitored by a rotary encoder. Total repetitions, blood lactate and perceived exertion (OMNI test) were analyzed as well. **Results** In the non trained group, vibration exposure caused a significant increase in the mean velocity (from 0.36 ± 0.02 to 0.39 ± 0.03 m/s) and acceleration (from 0.75 ± 0.10 to 0.86 ± 0.09 m/s²) for the whole set, as well as a decrease in perceived exertion (from 8 ± 0.57 to 7.30 ± 0.47). No change in either lactate or total repetitions was observed. In the recreational bodybuilder group the vibration exposure did not cause any variation. **Discussion** This type of vibration for non trained subjects could facilitate the neuromuscular activation induced by an involuntary reflex contraction (Ritzmann et al, 2010), improving resistance performance in bench press. Several research on vibration exposure immediately before exercise has demonstrated similar results (Cormie et al, 2006; Marin et al, 2013). However, this vibration would cause no changes in recreational bodybuilders because they may have better fibre recruitment than non trained subjects when they lift heavy weights. **References** Cormie P, Deane RS, Triplett NT, McBride JM. 2006. EFFECTS OF PLYOMETRIC AND SPRINT TRAINING ON PHYSICAL AND TECHNICAL SKILL PERFORMANCE IN PUBERTAL SOCCER PLAYERS

Ferrete Caceres, C., Saez de Villarreal, E., Suarez Arrones, L., Requena, B., Haff, G.

UNIVERSITY OF PABLO DE OLAVIDE

Objective: To determine the influence of a short-term combined plyometric and sprint training within regular soccer practice on explosive and technical actions of pubertal soccer players during the in-season. **Design:** Fiftythree players were randomly assigned to 4 groups; control group (CG) (soccer training only), Slalom group (SlalomG) (plyometric+acceleration+dribbling), Shooting group (ShootG) (plyometric+acceleration+shooting) and combined group (CombG) (plyometric+acceleration+dribbling+shooting). All players trained four times per week for 120 minutes with the same soccer drills. **Method:** 10-m sprint, 10-m agility with and without ball, CMJ and Abalakov vertical jump, ball-shooting speed and Yo-Yo IE test were measured before and after training. The experimental groups followed a 9-week plyometric and sprint program (i.e., jumping, hurdling, bouncing, skipping, and footwork) implemented before the soccer training. **Results:** Baseline-training results showed no significant differences between the groups in any of the variables tested. No improvement was found in the control group, however, meaningful improvement was found in all variables in the experimental groups: CMJ (ES=0.4-0.9), Abalakov vertical jump (ES=0.6-1.2), 10-m sprint (ES=0.3-0.8), 10-m agility (ES=1.8-2.2) and ball-shooting speed (ES=0.7-1.6). **Conclusions:** A specific combined plyometric and sprint training within regular soccer practice improved explosive actions compared to conventional soccer training only. Therefore, the short-term combined program had a beneficial impact on explosive actions, such as sprinting, change of direction, jumping and ball-shooting speed which are important determinants of match-winning actions in soccer performance. Therefore, we propose modifications to current training methodology for pubertal soccer players to include combined plyometric and speed training for athlete preparation in this sport.

EFFECTS OF TWO DIFFERENT STRENGTH CIRCUIT SCHEMES ON MAXIMAL STRENGTH OF NORMAL TRAINED PEOPLE

Kreuzpointner, F., Eibl, F., Bernsau, J., Hahn, D.

Technische Universität München

Introduction Time is a very limiting factor for normal people who perform strength training. Comparing the effects of classical strength training (ST) and strength circuit training (CT) Alcaraz et al. (2011) showed that CT with a lower amount of training time is equal to ST. Thus CT seems to be a good alternative training scheme for gaining strength. The purpose of this study was to pursue that time saving idea and to compare a high intensity circuit scheme with a classical volume based circuit scheme. **Methods** Two groups (A and B) with similar training experience (te) participated in this study (A: n=12, y=27.7±4.3, height=1.81±0.1m, weight=76.2±13.2kg, te=2.4±1.7 d*wk⁻¹; B: n=12, y=26.2±4.4y, height=1.75±0.1m, weight=74.7±13.8kg, te=2.3±1.4 d*wk⁻¹). Training schemes of both groups had similar workloads, included 4 exercises (seated hamstring curl, chest press (no data available), leg extension and lat pull-down) and were performed on motor driven training devices (eGym GmbH, Munich, Germany). Scheme A: (concentric phase: 80% MVC, eccentric phase: 104% MVC, 15 repetitions and 1 set, resting time between exercises were 60s); Scheme B (concentric phase: 45% MVC, eccentric phase: 75% MVC, 12 repetitions and 2 sets, resting time between exercises were 70s and between sets 140s). The participants trained for 4 weeks with a frequency of three times per week with at least one day rest in between sessions. After a warm up (2 min rope skipping, 25 squats, 10 push-ups and 3 pull-ups) participants performed an MVC before every training session, which served for the evaluation of adaptation to training. The mean MVC of the first and the last two sessions were averaged to compensate outliers and were used for data analysis. ANOVA for repeated measures and Bonferroni post-hoc comparisons served for statistical analysis (p<0.05). **Results** For leg extension, seated hamstring curl and lat pull-down group A had a strength gain of 16% (137.9±40.0kg to 159.9±41.1kg), 14% (63.2±17.9kg to 73.0±21.6kg) and 8% (90.5±28.5kg to 97.3±29.4kg) whereas group B gained 38% (115.1±35.1kg to 158.3±35.2kg), 17% (53.5±21.5kg to 62.1±27.0kg) and 7% (91.2±38.1kg to 97.6±37.6kg) of MVC, respectively. There was a statistical significant enhancement within the maximum strength in both groups (p < .01), but no difference between groups. **Discussion** Under the manner of time, scheme A was superior to scheme B because it had the same effect for the muscle groups trained but took only half the time. For further understanding of the training effects it might be worth investigating whether scheme A or B trigger different structural and/or neural adaptations. Scheme A might be better for gaining strength without or only little hypertrophy due to the higher intensity than scheme B which is aimed at hypertrophy. **References** Alcaraz, P. E., et al. (2011). EFFECTS OF FULL AND PARTIAL RANGE OF MOTION TRAINING ON STRENGTH, POWER, AND BODY COMPOSITION CHANGES IN UNTRAINED MEN

Liu, G.L., Lee, H.Y., Zeng, Y.S., Liu, J.S., Chen, C.Y., Chuang, T.C., Ho, J.Y.

National Taiwan Normal University

Introduction Most coaches and researchers support the use of full range of motion (FRM) training, but there was some support for the use of partial range of motion (PRM) training. While PRM training has an advantage on force production, FRM training produces greater total work (Clark et al., 2008). Because intensity and training volume play important roles in muscular adaptations to resistance training, comparison of muscular adaptations between FRM and PRM training is warranted. Therefore, this study aimed to examine the effects of 8 weeks of FRM or PRM squat and bench press training on strength, power, and body composition in untrained men. **Method** After completion of strength testing, seventeen untrained college males (age 21.8 ± 1.6 years, height 173.1 ± 3.4 cm, weight 69.4 ± 9.4 kg) were matched up and assigned to FRM training group (n=8) or PRM training group (n=9). All subjects performed squat and bench press training 2-3 times per week for a total of 8 weeks (total 22 training sessions) at intensity of 10RM for 3 sets. FRM and PRM squat and bench press 10RM, counter movement jump (CMJ), seated medicine ball put, and body composition were measured before and after 8 weeks of training. **Results** After 8 weeks of training, significant increases in squat and bench press 10RM, power performance, and muscle mass were observed in both training groups (p < .05). While changes in FRM squat 10RM were significantly greater in FRM training group than PRM training group (39.6 ± 7.5% vs 25.7 ± 15.3%), changes in PRM squat and bench press 10RM were significantly greater in PRM training group than FRM training group (squat 40.0 ± 13.3% vs 20.0 ± 11.9%; bench press 28.6 ± 11.0% vs 15.3 ± 10.1%). In addition, changes in CMJ power were greater in PRM training group than FRM training group (9.7 ± 5.9% vs 4.7 ± 3.1%). However, there was no significant difference in muscle mass changes between two training groups. **Conclusion** Our findings indicate that both FRM and PRM training may

be adopted by untrained men to increase strength, power, and muscle mass. However, PRM training can induce greater gains in PRM squat and bench press 10RM and lower body power performance whereas FRM training can only induce greater gains in FRM squat 10RM. ACUTE MUSCLE DAMAGE DIFFERENCES BETWEEN LOW- AND HIGH-VOLUME IN STRENGTH EXERCISE

Pinto, M.D.1, Wilhelm, E.N.1,2, Ughini, C.V.1, Ruas, C.V.1, Pinto, R.S.1

1: UFRGS (Porto Alegre, Brazil), 2: Brunel University (London, UK)

Introduction Strength exercise volume may affect the acute muscle damage (MD) induced by exercise. A possible relationship between MD and chronic hypertrophy (Schonfeld, 2012) has been proposed, but to date no study has compared the acute effects of one and three sets (1-SET and 3-SET) on MD. Also, of particular relevance, is the knowledge about the time course of MD. Therefore, the aim of this study was to compare the effects of 1-SET and 3-SET on MD markers and time-course recovery in pectoralis major muscle. **Methods** Fifteen untrained men (23.0±2.1 years) performed strength exercise protocol (SEP) consisted of 1-SET or 3-SET of 12 repetitions bench press exercise at 65% of one repetition maximum. Three minutes of rest interval was given between sets in the 3-SET. Subjects performed randomly 1-SET or 3-SET of SEP separated by 2 weeks. Shoulder horizontal flexion isometric peak torque (IPT) was obtained by dynamometry of horizontal flexion. Muscle thickness (MT) and echointensity (EI) of clavicular and sternal portions of pectoralis major muscle were obtained by ultrasonography. Delayed onset muscle soreness (DOMS) was assessed by visual 100 mm analog scale. All measurements were made in the right side at pre, post, 24, 48, and 72 hours after SEP. A two-way repeated measures ANOVA was employed, and a one way ANOVA was used to identify differences between groups at specific time points when a significant time*group interaction was observed. An $\alpha \leq 0.05$ was adopted. **Results** All variables presented a significant time effect ($p \leq 0.05$). IPT returned to pre values after 48 h of SEP ($p > 0.05$) and sternocostal DOMS recovered only in 1-SET after 72h. No significant group effect was observed in IPT, MT, and clavicular portion EI ($p > 0.05$), while a significant higher DOMS values were observed in 3-SET in the clavicular and sternal portions (group effect, $p \leq 0.05$). Significant major effect was found in MT ($p \leq 0.05$) in 3-SET sternocostal portion group immediately after the SEP. Greater clavicular portion EI values were found in 3-SET immediately post SEP ($p \leq 0.05$), and DOMS of sternocostal portion was significantly greater in 3-SET at post 24h, 48 and 72 periods ($p \leq 0.05$). **Discussion** This study demonstrated that 3-SET tend to produce more MD than 1-SET protocol, although not all variables presented differences between groups (e.g. IPT). Of particular relevance is the IPT strength recovery time at 48 h after SEP, which returned to the pre values 2 days after the exercise session. The lack of recovery of MD variables in the end of the study period, in particular the 3-SET SEP, suggests that a greater recovery time is required for untrained men, even when a low volume SEP is performed. **References** Schonfeld (2012). OPTIMISATION OF STRENGTH TRAINING IN PRE-COMPETITION PERIOD IN ELITE FEMALE WRESTLERS

Iliev, I., Makaveev, R.

National Sports Academy - Sofia/Bulgaria

Introduction Many experts highlight the importance of the difference in the manifestations of the strength training in the structure of the specialized physical training of female wrestlers (Stanchev, 2013; Stanev 2011). At the same time, the methodology of strength training in female wrestling today can hardly be considered well-structured and complete. The purpose of this study was to determine the effect of 5 strength exercises involving the development of strength training and its preservation from phase 1 preparation period to phase 2 pre-competition period. Practical experience shows that by the end of the training period their strength training has reached a significantly high level which, however, cannot be maintained and diminishes quickly and significantly (Stanev, 2011). **Methods** Twenty-two elite female wrestlers (age: 21.4 ± 3.6 years; height: 163.7 ± 7.4 cm; weight: 55 ± 6.5). They were randomly divided in 11 wrestlers for the experimental group (EG) and 11 wrestlers for the control group (CG). EG training included 5 strength exercises for 10 weeks, 4 times a week during the preparation period and 3 times a week during the pre-competition period. The tests used were: 1.Standing long jump – cm; 2.Push-ups – repetition until failure; 3.Pull-ups – repetition until failure 4.Barbell turning – 1 repetition max/kg; 5.Barbell squats – 1 repetition max/kg. The SPSS version 21 package for mathematical and statistical analysis was used. **Results** Analysis of the results of the tests from the beginning of the preparation period reveals that the mean values of the two groups are relatively identical. The analysis of the mean results at the end of the pre-competition period shows progress in the results of EG in comparison to CG. Standing long jump CG 1,9945 cm < EG 2,0155 cm; Push-ups CG 25,6364 < EG 32,0909; Pull-ups CG 17,6364 < EG 19,0909; Barbell turning CG 47,7727 < EG 51,6364; Barbell squats CG 67,6364 < EG 71,4545. Five of the wrestlers from EG have better ratings in the competitions. **Discussion** Experiments in this field have turned into a reserve for improvement of the training process management and have led to a more effective development and preservation of the strength training in female wrestlers, and to better results in competitions. Wrestlers must train more often for strength by following a well-structured programme consistent with their individual needs. It is a prerequisite and a condition for enhancement of their achievements and for prevention of injuries, which in its turn leads to a logical increase in their opportunities for optimal rating in competitions. **References** Stanchev, N. THE EFFECTS OF CRASHED ICE INGESTION FOR ENDURANCE CYCLING PERFORMANCE IN HEAT ENVIRONMENT

Naito, T.

Kyushu University

Introduction Pre-cooling by crashed ice is effective for improving exercise performance compared with tap water¹⁾. However, there has not been study to determine whether both pre-cooling and water replacement are improved endurance cycling performance compared with cold water. The purpose of this study was to investigate the effects of crashed ice ingestion on thermoregulatory responses and endurance cycling time in the heat. **Methods** On two separate occasions, in a counterbalanced order, 9 healthy males (age = 23 ± 4 yr, height = 172.2 ± 5.0 cm, body mass = 64.0 ± 9.6 kg, maximal oxygen uptake ($\text{VO}_{2\text{max}}$) = 47.7 ± 8.7 ml/kg/min) ingested 7.5 g/kg of either crashed ice (0.5°C) or cold water (6°C) before exercise and 6.0 g/kg of same drink as pre-exercise during cycling to exhaustion at $60\%\text{VO}_{2\text{max}}$ in the heat environment (35°C , 30% relative humidity). Rectal temperature and skin temperature, HR, VO_2 , sweating rate, and ratings of thermal sensation and perceived exertion were measured. Heat storage was calculated using the formula of Adams et al.²⁾. **Results and Discussion** Running time was longer after crashed ice (50.0 ± 12.2 min) compared with cold water ingestion (42.2 ± 10.1 min). Before cycling performance, rectal temperature decreased $0.37 \pm 0.03^{\circ}\text{C}$ after crashed ice ingestion compared with $0.17 \pm 0.02^{\circ}\text{C}$ with cold water and remained lower for the first 30 min of exercise. After crashed ice ingestion, heat storage capacity increased (-7.61 ± 4.21 W/m²) compared with cold water (-2.18 ± 3.18 W/m²). However, rating of change occurring in rectal temperature during cycling performance did not reach significance. These results suggest that endurance cycling performance improved because of decreased rectal temperature and heat storage immediately before exercise compared with cold water ingestion. **Conclusions** Compared with cold water, both pre-cooling and water replacement by crashed ice ingestion dropped rectal temperature at pre-exercise and remained lower during exercise. Moreover, crashed ice ingestion increased endurance cycling time in the heat. As such, crashed ice ingestion may be an effective and practical pre-cooling and water replacement maneuver for athletes competing in heat environment. **References** 1) Ihsan M, Landers G, Brearley M, Peeling P (2010): Beneficial effects of ice ingestion as a precooling strategy on 40-km cycling time-trial performance. *Int. THE EFFECT OF ENVIRONMENTAL TEMPERATURE ON TIME MOTION CHARACTERISTICS OF SOCCER PLAYERS IN THE AUSTRALIAN A LEAGUE

Janse de Jonge, X.1, Nosek, P.1,2, Clark, A.1,2, Everett, K.1, Hillebrandt, H.1

1 The University of Newcastle, Australia 2 Central Coast Mariners Football Club, Australia

Sporting performance is understood to be negatively impacted in hot environments. In Australia the professional A League is played over the summer season. The size of the continent and the fact that some matches are played in New Zealand means that there is a large variation in environmental conditions between matches in the A League. This study aimed to examine the effect of environmental temperature on time-motion characteristics in a soccer team competing in the A League. Fifteen male soccer players (age 27 ± 5 yrs; body mass 81 ± 7 kg; height 183 ± 5 cm) from a professional soccer team volunteered for this project. They wore 5 Hz GPS units (MinimaxX, Catapult Innovations, Australia) during A League matches and 67 full game files were analysed for High Speed Activity (HSA) at >14.4 km/h, Low Speed Activity (LSA) at <14.4 km/h and total distance. Each half of the game was analysed and then divided into three equal periods for further analysis. The total number of match files was divided in half based on environmental temperature using the median split technique. Match files were excluded for the median temperature and to ensure equal distribution of the different playing positions resulting in 27 match files for each environmental condition. Mixed measures ANOVAs (with factor temperature and repeated measures for halves and the six periods) were performed. The mean temperature for the cool matches was 16°C (range 9-19) and for warm matches was 23°C (range 21-28). The ANOVAs for halves showed a significant decrease from first to second half for total and LSA distance and no significant interaction with temperature for any of the measures. For the six periods of the match a significant greater total, LSA and HSA distance was covered in the first period than all other periods, except for the first period of the second half for HSA. Furthermore an interaction between temperature and playing period was found for total and LSA distance with a significantly greater drop in both distances from the first to the fifth period in the warm condition compared to the cool condition. For HSA distance no significant interactions were found. The findings of this study suggest that regardless of environmental temperature soccer players cover the greatest total distance and LSA distance in the first half and especially in the first 15 minutes of the match. The environmental temperature had no effect on HSA distance, while total distance and LSA distance decreased more throughout the match in warm than in cool conditions. In conclusion, it appears that in warm environments soccer players are able to maintain similar high-intensity match-play as in cool conditions, at the expense of LSA.

WHAT HAPPENS IN THE BRAIN DURING RECOVERY FROM EXHAUSTIVE CYCLING IN THE HEAT?

De Pauw, K., Roelands, B., Vanparijs, J., Marušič, U., Tellez, H.F., Knaepen, K., Meeusen, R.

Vrije Universiteit Brussel

Introduction Accelerating the post-exercise recovery process beneficially influences subsequent exercise performance¹. Although the effect of different recovery interventions on physiological parameters is well investigated, the question remains how recovery influences brain functioning. Therefore, the neurotrophin brain-derived neurotrophic factor (BDNF) and the relative EEG power spectrum were analyzed at baseline and during the post-exercise recovery period. **Methods** After a maximal cycle test and familiarization trial, 9 trained male subjects (age: 22 ± 3 y; $\text{VO}_{2\text{max}}$: 62 ± 5 mL·kg⁻¹·min⁻¹) performed 3 experimental trials in 30°C . Each trial consisted of two exercise tasks separated by 1h. The first was a 60min constant load trial, followed by a 30min time-trial (TT1). Thereafter, active recovery (AR; cy-

cling at 80W), passive rest (PR) or cold water immersion (CWI; 15°C water) was applied for 15min. The second trial comprised a 12min time-trial (TT2). EEG was obtained at baseline, during recovery and before TT2. Blood samples were taken at baseline, before and after the recovery period. BDNF data (ELISA kit) were analyzed using ANOVA and paired t-tests. Power spectral data (discrete Fourier transform) were analyzed using Friedman and Wilcoxon tests. Results/Discussion After CWI subjects maintained high power outputs during TT2, whereas after AR and PR subjects gradually declined the power output after the onset of TT2. Exhaustive cycling in the heat significantly reduced β 1power at prefrontal electrodes ($P \leq 0.038$) indicating decreased state of activity in sensory and psychological information processing centers. Exercise as a physiological stressor increased β 2power at central electrodes ($P \leq 0.028$) and FC1, FC2 and Cz ($P \leq 0.086$). AR and PR did not elicit any significant electrocortical alteration. CWI increased β 1power at Fz - F4 ($P \leq 0.038$), and FP1 - FP2 ($P \leq 0.086$). The rest period after CWI decreased β 2power at Cz ($P = 0.028$), and FC1, FC2, C3 and C4 ($P \leq 0.086$) back to pre-exercise levels. Exhaustive cycling significantly increased BDNF by 51.5% ($P < 0.001$; baseline: 19.9 ± 6.8 ng/mL; post-exercise: 29.6 ± 10.4 ng/mL). CWI significantly decreased BDNF compared to post-exercise ($P = 0.007$; -39.9%), whereas AR showed a trend towards reduced BDNF ($P = 0.095$; -25.2%) and PR showed no change ($P = 0.834$; +3.2%). Conclusion CWI beneficially influences the second cycling bout. CWI not only rapidly normalizes physiological parameters and serum BDNF levels, but also restores exercise-induced altered brain rhythms to rest levels. Reference IVersey NG, et al. THE EFFECT OF GLUTAMINE ON INTESTINAL HEAT SHOCK PROTEIN-72 EXPRESSION AND INTESTINAL PERMEABILITY FOLLOWING EXHAUSTIVE RUNNING

Ong, M.L.Y., Ruell, P.A., Rooney, K.B., Thompson, M.W.

The University of Sydney

Introduction Glutamine is an enhancer of heat shock protein-72 (HSP72) expression for protein refolding of cell membrane necessary for intestinal cells integrity. Prolonged exercise in the heat decreases splanchnic blood flow which may increase intestinal permeability and trigger systemic inflammation associated with exertional heat stroke. This study examined firstly whether orally administered glutamine induce the cell protective HSP72 expression in the subdivisions of the intestine and secondly whether the increased HSP72 expression correlated with reduced intestinal permeability following exhaustive running in the heat. Methods Sprague-Dawley rats were supplemented with alanyl-glutamine (GLU, 0.2g/kg body weight) or placebo (PLA, water) for 5 consecutive days and then subjected to running till exhaustion in hot (HOT, 30°C) and neutral (NEU, 20°C) conditions. Body weight loss and running duration were recorded. Following running, rats were immediately gavaged with 4 kDa FITC-dextran (FD-4) for measure of plasma intestinal permeability. At terminal procedure, cardiac blood samples were collected and segments of duodenum, jejunum, ileum and colon tissues were analysed for HSP72 by enzymatic-immuno assay. Results The running distance were significantly longer in NEU group irrespective of supplement intervention ($p < 0.05$). HSP72 concentrations increased in all intestinal segments of GLU-HOT group compared to all other groups but were not significant. Colon HSP72 concentrations in all groups were highest compared to other intestinal segments ($P < 0.05$). The plasma FD-4 were not correlated with the highest increase in intestinal HSP72 of GLU-HOT group although there was a correlation with ileum HSP72 ($P < 0.05$). Glutamine however does not significantly induce HSP72 in all intestinal subdivisions of non-exercising control rats. Discussion Our results indicated that glutamine did not sufficiently increase the intestinal HSP72 response and therefore was not associated with reduced intestinal permeability. A further glutamine dose-response study may be required to support our results (Ehrenfried et al., 1995; Wischmeyer et al., 1997). References Ehrenfried, JA, Chen, J, Li, J, Mark Evers, B. (1995). CHANGES OF URINE VOLUME AND SUBJECTIVE MICTURITION DURING AQUABICS

WADA, T.1, KAKUTANI, N.2, MIYAMOTO, M.3, WATANABE, Y.1, KREMENIK, M.J.4, ONODERA, S.4

1 Graduate School, Kawasaki University of Medical Welfare, 2 Ray Sports Club Okayama, 3 Saiseikai Fitness and Culture Club, 4 Kawasaki University of Medical Welfare

Purpose: The purpose of this study was to investigate the effects of aquabics on urine volume, subjective micturition, Rating of Perceived Exertion (RPE), heart rate, blood pressure and rectal temperature. Methods: Nine healthy male subjects volunteered for this study. Each subject signed an informed consent form. The study was conducted in an indoor pool facility at K University, in 2013. This study consisted of two experimental conditions : the land trial (L) and the water trial (W). The water level was set to the xiphoid. Subjects participated in both conditions on different days. Measurement items were urine volume, subjective micturition, Rating of Perceived Exertion (RPE), heart rate, blood pressure (SBP: Systolic Blood Pressure / DBP: Diastolic Blood Pressure) and rectal temperature. The water temperature was 30 degrees Celsius. Both conditions began with 30 minutes in a sitting posture on land. Then, for the next 45 minutes, the W condition performed aquabics while the L condition performed aerobics. Finally, for the last 30 minutes, both conditions were back on land in a sitting posture. Results and Discussion: Urine volume and subjective micturition after immersion in the W condition were both higher than that of L ($p < 0.05$). RPE at immersion, recovery at 5 minutes and recovery at 10 minutes in the W condition was higher than that of L ($p < 0.05$). Heart rate at immersion in the W condition was lower than that of L ($p < 0.05$). Rectal temperature between block 2 and at 10 minutes in the W condition was lower than that of L ($p < 0.05$). SBP between immersion and at 10 minutes in the W condition was lower than that of L ($p < 0.05$). DBP between immersion and at 10 minutes in the W condition was lower than that of L ($p < 0.05$). Previous studies demonstrated that due to the responses of the physical characterization in water differed from those on land. Venous return increases in water and urine formation rises and then diuretic effect increases. Compared with in land exercise, the loss of body fluid is increasing by urine in water exercise. These things suggest increased urine volume and subjective micturition. Conclusion: 1) Urine volume and subjective micturition increases through inundation in water. 2) Urine volume decreases with progress at each time of recovery. 3) Urine volume increases athletic strength at the time of exercise more in water than on land.

ICE SLURRY INGESTION REDUCES FACIAL SKIN TEMPERATURES IN A WARM ENVIRONMENT.

Sumire, O., Xin Yan, Z., Hiroshi, H.

Hiroshima University

Introduction Recently, the internal body cooling by ice slurry ingestion attracts attention. As ice slurries were ingested through the mouth, it is possible that consumption resulted in conductive cooling of the facial skin and blood (Siegel et al., 2012). However, previous studies did not measure the changes of facial skin temperature by ice slurry ingestion. Therefore, the purpose of this study was to investigate the effects of ice slurry ingestion on facial skin temperature and thermal sensation. Methods Eight male subjects ingested either 7.5 g/kg ice

slurry (-1°C ; ICE) or cold sports drink (4°C ; COOL) or warm sports drink (37°C ; CON) for 15 min in a warm environment (30°C , 80% relative humidity). Then, they kept rest for 1 hour. As the physiological index, rectal temperature (Tre), mean skin temperature (Tsk), forehead skin temperature (Thead), heart rate (HR), a nude body mass, and urine specific gravity were measured. Subjective thermal sensation (TS) was measured at 5 min intervals throughout the experiment. Results In the ICE, Tre significantly reduced compared with CON and COOL (vs CON: from 5min to 30min, vs COOL: from 5 min to 30 min, $p < 0.05$). The degradation amount of Tre was significantly larger than that of CON and COOL (ICE: $0.53 \pm 0.19^{\circ}\text{C}$, CON: $0.07 \pm 0.18^{\circ}\text{C}$, COOL: $0.22 \pm 0.19^{\circ}\text{C}$, $p < 0.05$). Thead was significantly reduced compared with CON and COOL (vs CON: from 0 min to 15 min, vs COOL: from 0 min to 10 min, $p < 0.05$). The degradation amount of Thead was significantly larger than that of CON and COOL (ICE: $0.33 \pm 0.16^{\circ}\text{C}$, CON: $-0.23 \pm 0.30^{\circ}\text{C}$, COOL: $-0.30 \pm 0.30^{\circ}\text{C}$, $p < 0.05$). TS of ICE was significantly lower than that of CON and COOL (vs CON: from -10 min to 35 min, vs COOL: from -10 min to 5 min, $p < 0.05$). TS correlated with Tre and Thead (Tre: $r = 0.394$, Thead: $r = 0.396$, $p < 0.05$). Discussion Ice slurry ingestion significantly reduced Thead compared with warm or cold drink ingestion. Because the ice slurry was ingested through the mouth, it is possible that consumption resulted in conductive cooling of the facial skin and blood (Siegel et al., 2012). Therefore, it is assumed that the reduction of facial skin temperature reflects the reduction of brain temperature. In the present study, we firstly observed the reduction of Thead which reflects brain temperature by ice slurry ingestion. We suggest that ice slurry ingestion may reduce brain temperature by reducing facial skin temperature. References Siegel R et al. (2012). J Sports Sci 30(2): 155-165.

EFFECTS OF EXERCISE IN THE MORNING ON EXERCISE PERFORMANCE IN THE EVENING

NISHIMURA, K., NAGASAKI, K., YAMAGUCHI, H., YOSHIOKA, A., TAMARI, Y., ONODERA, S., TAKAMOTO, N.

Hirashima Institute of Technology

Aim: This study aimed to determine the effects of exercise in the morning on exercise performance, such as capacity for aerobic exercise and maximum anaerobic exercise power in the evening. Method: The study included 14 healthy Japanese men, and they provided written informed consent before participation. After resting supine for 10 min, each subject performed the Japan Fitness Test between 05:00 p.m. and 07:00 p.m. This study was performed under 2 conditions: the exercise (E) condition and the control (C) condition, and each condition was simulated on a different day. The E condition involved performing cycling exercises for 30 min at 08:30 a.m. The exercise intensity was adjusted to 40% of maximum oxygen uptake. In the C condition, the participants did not perform exercise in the morning. The fitness test was performed in the same order for both conditions. All subjects went to bed at 11:00 p.m. and awoke at 07:00 a.m. on each experimental day. Each subject ate breakfast at 07:30 a.m. and lunch at 12:30 p.m. under both conditions. The order of the 2 conditions was random, and the duration between the conditions was 1 week. Results and Discussion: Resting before the fitness test, heart rate and double product were significantly higher under the E condition than the C condition. The blood pressure, oral temperature, and ln HF, an index of cardiac parasympathetic nervous system modulation, of the participants were not compared between the E and C conditions. The 20-m shuttle run, an index of capacity for aerobic exercise, and maximum anaerobic exercise power were significantly higher under the E condition than the C condition. The results of other fitness tests, such as grip strength, sit-ups, sit and reach, standing long jump, and 50-m run, were not compared between the 2 conditions. The total fitness score was significantly higher under the E condition than the C condition. These results might have occurred owing changes in the circadian rhythm caused by exercise in the morning and pre-exercise effects. Previous studies have reported that daily rhythm in humans was regulated by exercise in the morning, and also the exercise performance was enhanced by pre-exercise. The data suggest that exercise in the morning is an effective conditioning and training method for the sports athletes. In conclusion, exercise performance, such as capacity for aerobic exercise, and maximum anaerobic exercise power in the evening is improved by exercise in the morning.

PHYSIOLOGICAL RESPONSES TO COLD WATER IMMERSION APNEA AFTER SHORT INTENSIVE EXERCISE

Konstantinidou, S.I, Mpeintaris, N.I, Soultanakis, H.I

1: National Kapodistrian University of Athens (Athens, Greece)

Introduction Diving response in humans is activated through apnea and aggravated with face immersion in cold water. Long and mild exercise on an ergometer preceding apnea intensifies the diving response (Andersson et al., 2002). This study aimed at identifying the impact of short-intensive exercise on the diving response and its potential interaction with the cold shock response. Methods Ten swimmers formed both the experimental and the control group performing one apnea with face immersion in cold water ($10 \pm 1.05^{\circ}\text{C}$) after rest (AAR), and another apnea after exercise (AAE). Subjects were asked to perform a 3-minute walk on a treadmill at a pre-estimated speed and elevation starting at 55% of their VO_2max for the first minute, at 75% for the second and at 85% for the last minute. Their heart rate was measured continuously. Blood samples were taken at rest and after the two apneas and analyzed through i-Stat automatic analyzer (Abbott Point of Care Inc., U.S.A.). Arterial blood pressure was measured at rest and after the two apneas. Results One way ANOVA for repeated measures was applied for data analysis ($p=0.05$). Heart rate dropped significantly from rest ($81.00 \pm 5.60\text{bpm}$) to AAR (64.40 ± 4.61) whereas at AAE increased (118.60 ± 5.00) and the differences were statistically significant. Systolic blood pressure increased from rest ($12.4 \pm 0.28\text{ mmHg}$) to AAR (13.8 ± 0.20) and after AAE (17.9 ± 0.59). All changes were statistically significant. Lactic acid (La^+) increased from rest ($1.04 \pm 0.22\text{mmol/L}$) to AAR (1.228 ± 0.22) and after AAE (4.977 ± 0.84). All changes were statistically significant. The pH changes from rest (7.354 ± 0.010) to AAR (7.387 ± 0.008) and after AAE (7.290 ± 0.012) were statistically significant. Total blood carbon dioxide (TCO_2) dropped significantly from rest ($30.30 \pm 0.61\text{mmol/L}$) to only after the AAE condition (26.40 ± 1.20). Similarly, bicarbonate (HCO_3) dropped significantly from resting values ($28.8 \pm 0.54\text{mmol/L}$) to AAE (25.06 ± 1.09). Finally, apnea after exercise was reduced with an average time of 11.2 seconds (± 3.6). Discussion The statistically significant fall in the heart rate with apnea AAR, confirms the activation of the diving reflex in the absence of exercise. Blood pressure and heart rate statistically significant increases at AAE, suggest that the cold shock after short intensive exercise attenuated the diving reflex's impact. This was also evident by the drop of TCO_2 and HCO_3 , and the inability of the participants to maintain apnea with immersion for 40 s as with AAR. To the best of our knowledge, this is the first study demonstrating the cardio respiratory and blood gas responses to cold water immersion apnea after short intensive exercise. 14:00 - 15:00**Mini-Orals****MO-PM21 HF Physical Activity in Children 2****PROJECT PANK: RATIONALE, DESIGN AND BASELINE RESULTS OF A MULTIDISCIPLINARY SCHOOL-BASED INTERVENTION IN CHILDREN WITH CARDIOVASCULAR AND METABOLIC RISK FACTORS. A RANDOMIZED CONTROLLED TRIAL.**

Batalau, R.1,2, Cruz, J.1,2, Gonçalves, P.2, Cabrita, P.2, Guerreiro, T.2, Santos, M.1, Gonçalves, R.1,2, Leal, J.1,2, Palmeira, A.2,3

Lusófona University

Introduction Atherosclerosis begins in youth and is related to the presence of cardiovascular and metabolic risk factors (CMRF): age, gender, nutrition, physical inactivity, cardiorespiratory fitness (CF), blood pressure (BP), lipids and overweight/obesity. There is strong evidence showing that schools should include nutrition and physical activity (PA) in the curriculum. However, few school-based studies measured physical and clinical outcomes, some of them reporting no changes. Project PANK (PA and Nutrition for Kids) is a multidisciplinary school-based intervention to improve many variables associated with CMRF: BMI, waist circumference (WC), waist-height ratio (WHR), BP, PA, CF, nutrition, sedentary behavior (SB) and blood variables (glucose, total cholesterol (TC), HDL-C, LDL-C), and triglycerides (TG) among Portuguese children. This study reports the PANK baseline data. **Methods** The main variables were objectively measured. The CF through the 20m shuttle run test; SB and PA by accelerometers (GT3X) for 7 consecutive days and blood variables after an overnight fast. The other variables were assessed using standardized procedures. Participants (N=77, aged 7-10 years) were recruited after a cross-sectional study and allocated by intervention or control group. The inclusion criteria were the presence of, at least, one variable associated with the development of CMRF. Overweight and obesity condition were the main inclusion criteria. **Results** The Spearman's rho revealed a statistically significant inverse relationship between CF and levels of TG ($\rho = -.53, p < .001$), as well as, CF and TC ($\rho = -.25, p = .036$). The length of time spent in sedentary behaviors was inversely correlated with moderate ($\rho = -.38, p = .001$) and vigorous PA ($\rho = -.32, p = .005$). The length of time spent in moderate ($\rho = .27, p = .018$) and vigorous PA ($\rho = .33, p = .004$) were positively correlated with CF. Obese children had higher values of fasting glucose ($t = 2.05, p = .044$), WC ($t = 7.17, p < .001$), and WHR ($t = 6.457, p < .001$), when compared to overweight children. **Discussion** These results justify the importance of school-based interventions to promote the reversion of overweight/obesity conditions and to decrease abdominal fat. Additionally, it seems to be equally important the increase of moderate/vigorous PA to improve CF in order to control blood variables. Project PANK focus on these factors in a comprehensive, multi-component and significant curriculum in nutrition and PA programs, taught by trained experts, and a parental component. MAY BE USED THE WHOLE BODY BIOIMPEDANCE METHOD LIKE A TOOL FOR AN ASSESSMENT OF CHILDREN'S OVERWEIGHT AND OBESITY?

Bunc, V., Hráský, P., Skalská, M.

Faculty of P.E. and Sports Charles University

Introduction Increases in childhood overweight and obesity have emphasized the importance of accurate and accessible body composition assessment, especially in monitoring prevention and treatment effort. According to latest data collected in the Czech Republic the increase of children's overweight and obesity during the last four years (2008-2013) is about 12% and the similar trend has been reported in other EU countries participating in this project and thus we deem important to develop efficient policy tools (eg. systematic education curricula) for obesity management. Bioimpedance analysis (BIA) seems to be one of the simple, safe, and inexpensive method for assessment of body composition in pediatric subjects. **Methods** Seven-thousand-two hundred twenty four children aged 6-14 years (3925 – 54,9% boys, and 3224 – 45,1% girls) were evaluated BC by mono frequency and multi-frequency bioimpedance analyser by using of adapted prediction equation for Czech children. The measurement itself was performed using the multi-frequency BIA analyzer BIA 2000 M, in a tetrapolar configuration of electrodes on the right side of the body in a lying position. The arrangement of the electrodes followed the manufacturer's recommendations. The apparatus measures total impedance, i.e. allows determining its capacity and resistance components. In The hydration state was controlled 8 hours before the laboratory evaluation in all subjects. **Results** The mean value of %BF in all boys was $19.79 \pm 2.37\%$, and the same in girls was $22.18 \pm 4.51\%$. In age of 6 years we found in group of boys the mean %BF $22.4 \pm 4.1\%$, the $8.0 \pm 1.0\%$ of boys was obese and $15.0 \pm 3.1\%$ boys was overweight, in girls of the same age we found $24.5 \pm 4.0\%$, $8.0 \pm 1.5\%$ and $16.0 \pm 2.1\%$, the same data in boys of age 14 years were $18.0 \pm 2.8\%$, $11.0 \pm 2.0\%$, $19.0 \pm 3.0\%$, and the same in girls $21.4 \pm 3.0\%$, $12.0 \pm 1.7\%$, $19.5 \pm 2.0\%$. Linear regression analysis showed a significant positive relationship between %BF measured and BMI; $\%BF(\%) = 0.921 \cdot BMI(kg.m^{-2}) - 4.292$, $r = 0.858$, $r^2 = 0.736$, $SEE = 1.22\%$ in boys, and in girls; $\%BF(\%) = 1.284 \cdot BMI(kg.m^{-2}) - 6.906$, $r = 0.903$, $r^2 = 0.815$, $SEE = 1.05\%$, $p < 0.0001$ in both cases. **Conclusions** The BIA method is a useful method for detecting BC in children and may be declared like a precise tool for measuring of BC in epidemiological studies in children. The decisive role for this using of this method plays the population oriented prediction equation and subject's hydration state. The study was implemented with support from Research Grant of Czech Ministry of Education MSM 0021620864 and Grant of Charles University P38.

LONGITUDINAL STUDY ON THE EFFECTS OF SPORTS CLUB PARTICIPATION IN YOUNG CHILDREN ON BMI, COGNITIVE AND MOTOR PERFORMANCE

Augste, C.

University of Augsburg

Introduction Physical activity in children has been reported to have health benefits, such as prevention of obesity, and advantages in cognitive and motor performance (Jiménez-Pavón et al., 2010; Keele & Fox, 2009; Sacchetti et al., 2013). Most of this information, however, is based on cross-sectional studies. The aim of this study was therefore to conduct a longitudinal investigation of the persistent effects of sports club participation in young children. **Methods** 112 children performed three motor tasks (standing long jump, bidirectional jumping, balancing backwards on a 6 cm wide beam) and a cognitive task (man-drawing-test) before school entry (age = 69.3 months, SD =

4.1, 55 female) and at the end of grade 2 (age= 98.1 months, SD = 3.7). Additionally, their body mass index (BMI) was determined. The raw data of the motor tasks and the man-drawing test were transformed into gender and age specific normalized data. In a parental questionnaire sports club activities of the preschool children were recorded. For statistical analysis (t-tests) the children were split into two groups based on their participation in sport club activities (non-participants vs those participating once or more per week). Results 55.4 % of the preschool children were already training in sports clubs at least once per week. These children performed significantly better than the non-participants in the standing long jump ($T = -2.540$; $df = 110$, $p = .012$), while their balancing nearly reached significance ($T = -1.974$; $df = 110$; $p = .051$). Their other outcomes were slightly better than for the non-participants, but these differences did not reach significance. The testing at grade 2 showed that the active group had a significantly lower BMI ($T = 2.313$; $df = 110$, $p = .023$) and performed better than the non-participants in standing long jump ($T = -2.288$; $df = 110$, $p = .024$) and balancing ($T = -4.388$; $df = 110$, $p < .001$). Bidirectional jumping nearly reached significance ($T = -1.975$, $df = 110$; $p = .051$), while no difference between the groups was found in the man-drawing-test ($T = -.340$; $df = 110$; $p = .735$). Discussion Our findings suggest that participation in sports club activities from preschool age results in greater improvements in motor performance and a lower BMI throughout the first two years of school compared to non-participants. Despite physical education (PE) being compulsory in the German school system, it appears that the addition of sports club participation outside school has a positive effect on motor performance. It could be suggested that PE content and/or duration needs to improve to benefit children who are not involved in sports club activities outside of school. Another option may be to start PE in preschool. References Jiménez-Pavón D, Kelly J, Reilly JJ (2010). *Int J Pediatr Obes*, 5(1), 3–18. EFFECTS OF SCHOOL-BASED EXERCISE AND NUTRITION PROGRAM ON OBESITY PREVALENCE AND BODY FAT IN OVERWEIGHT CHILDREN

Coelho, E., Moreira, M., Fonseca, S., Monteiro, D., Mourão, I.
University of Trás-os-Montes and Alto Douro

Introduction: Childhood obesity has doubled in children and tripled in adolescents in the past 30 years (NCHS, 2012). School plays an important role in prevent childhood obesity; through promote a healthy eating and an active lifestyle. The aim of this study was to assess the impact of school-based exercise and nutritional interventions on children's body mass index and body fat percentage. Methods: The office for "Childhood Development Promotion" developed a nutrition school program (during the first semester) and an exercise program (during the second semester) throughout the school year 2012/13, and followed 50 overweight children (32 girls and 22 boys, 8.41 ± 1.12 years old) from Vila Real, Portugal. In three different moments, the weight and height was collected to calculate BMI, and the cutoffs of Cole et al. (2000) to estimate obesity. The bioelectrical impedance analysis (TANITA) was used to predict the percentage of body fat. T-test and Wilcoxon test were used to compare data. Results: At the end of the program was observed a significant reduction on BMI ($p=0.000$) and on percentage of body fat ($p=0.006$), nevertheless between the first to the second evaluation, the BMI ($p=0.003$) increased significantly. The intervention program was effective in reducing body fat ($p=0.012$) and in obesity prevalence ($p=0.001$). Discussion: The results allowed us to conclude that the decrease of energy intake is not enough to face childhood obesity. The caloric intake restriction should be combined with physical activity in way to decrease energy balance. References Cole TJ, Bellizzi MC, Flegal KM, Dietz WH. (2000). COMPLIANCE OF DAILY PHYSICAL ACTIVITY RECOMMENDATIONS AND ABDOMINAL OBESITY IN PRESCHOOL CHILDREN

Silva dos Santos, S., Santos, A., Mota, J., Vale, S.
Faculty of sport

Aim: Abdominal obesity, a status of excessive accumulation of both central subcutaneous and visceral fat, has emerged as an main predictor for metabolic complications and adverse health effects. Waist-height ratio (WHR) is simple, yet effective, surrogate measures of abdominal obesity and may be good predictor of cardiovascular disease risk in children. The aims of this study were to analyze the association between compliance of daily PA recommendations and Waist-height ratio (WHR) in a sample of preschool children. Methods: This study comprised 704 preschool children, aged from 3 to 6 years old. WHR was calculated as the ratio of waist (cm) and height (cm) and cutoff of 0.5 was used to define abdominal obesity ($WHR \geq 0.5$ - higher risk). PA was measured during 7 consecutive days using the GTIM ActiGraph accelerometer and ≥ 800 cpm cutoff was used. Results: Using the WHR, the prevalence abdominal obesity was 56.7% and 40.7% for girls and boys, respectively. Girls that not met the $\geq 3h$ TPA guideline were associated with higher WHR (OR: 1.7; IC: 1.0 - 2.8). No other statistically significant associations were found. Conclusions: There is an association with low levels of TPA and abdominal obesity among pre-school girls. Further longitudinal studies are needed to confirm this data.

THE PHYSIOLOGICAL RESPONSE OF SPORT CLIMBING IN CHILDREN

Panackova, M., Balas, J., Bunc, V.
Charles University

Introduction The aim of the study was to assess the physiological response of sport climbing in children. Methods Twenty five children (aged 8–12 years) participated in the study (boys: weight 30.0 ± 5.8 kg and height 134.3 ± 8.9 cm; girls: weight 33.1 ± 9.3 kg and height 138.1 ± 10.4 cm). All children undertook a climb at a vertical route and twelve of them at a slightly overhanging route. Both routes were climbed with a self-selected speed. Portable gas analyser was used to assess the physiological response during the climbs. Furthermore, the time spent by climbing was registered during the 8 following week's period in all children. Results The peak oxygen consumption at the vertical route was 39.8 ± 4.6 ml•kg⁻¹•min⁻¹ in boys and 37.1 ± 4.3 ml•kg⁻¹•min⁻¹ in girls. The time of climbing was similar in boys and in girls (3.6 ± 0.8 min, 3.7 ± 1.1 min respective). The peak oxygen consumption was slightly higher at the overhanging than at the vertical route (42.9 ± 2.3 ml•kg⁻¹•min⁻¹ in boys; 40.5 ± 5.6 ml•kg⁻¹•min⁻¹ in girls). The boys climbed faster (4.3 ± 0.9 min) than the girls (5.2 ± 0.1 min). The average time spent by climbing in the training session during the 8 weeks period was 11.3 ± 4.3 min. Discussion/Conclusion The school-aged children and youth should accumulate 60 min of physical activity on a daily basis (Pate et al. 1995), preferentially during intermittent and short bouts (Janssen, 2007). Although the climbing is an activity with a high aerobic component, the

total time spent by climbing in climbing schools during 60 minutes of training does not provide a sufficient stimulus to fulfil the recommendation for aerobic fitness. BODY COMPOSITION CHANGES OVER SECONDARY SCHOOL ON FEMALE ADOLESCENTS

Bezerra, P.1,2, Silva, B.1, Fernandes, F.1, Rodrigues, T.M.1, Costa, N.M.C.1

1: Viana do Castelo Polytechnic Institute (IPVC), 2: Research Centre in Sports Sciences, Health Sciences and Human Development (CIDESD)

Introduction The concerns with the body image, size and shape are common among adolescents. Any changing or body dissatisfaction may promote different behaviors with evident risks for health. This is particularly common in female adolescents. The aim of this study was to investigate the body composition changes over the secondary school years, in female adolescents. **Methods** Two hundred and forty female adolescents (16.4 ± 1.1 yrs, 57.7 ± 9.4 Kg, 1.62 ± 0.56 m, BMI = 22.1 ± 3.4) were recruited from Viana do Castelo. The subjects were assessed on weight, height, and both whole body and segment fat mass (FATm) and free fat mass (FFM) as percent of body composition (Tanita BC-408), over two years (Y1 and Y2). T-pair test was used to assess the differences over the time. Pearson coefficient of correlation was used to examine the association between variables. The significance was set at $p < 0.05$. The Human Research Ethics Committee of the Institute approved testing procedures. **Results** Weight, height and BMI increased from Y1 to Y2 ($t=4.68$ to 7.09 , $p<0.001$). FATm showed changes in whole body (Y2, 17.1 ± 6.9 ; Y1, 15.8 ± 6.0 , $t=6-17$, $p<0.001$) and trunk (Y2, 8.2 ± 4.3 , Y1, $t=6.9 \pm 3.2$, $p<0.001$) but not in segments, over the time. In relation to FFM, it was found significant increments in whole body and all segments ($t=2.83$ to 12.43 , $p<0.05$ to $p<0.001$) but significant decrements in trunk region ($t=-5.96$, $p<0.001$). Strong correlations were found between whole body and segments in both FATm and FFM, on Y1, Y2, and on changes over the time ($r=0.68$ to 0.91 , $p<0.001$). **Discussion** Despite having significant increments on weight, height and BMI from Y1 to Y2, the changes on body composition do not follow the same path. In fact, the FATm increases in both whole body and trunk, while FFM increases in whole body and segments. The changes over the time seem to be consistent as shown by the strong correlations found on Y1, Y2 and on differences from Y1 to Y2.

INFLUENCE OF SCREEN- RELATED BEHAVIOR ON MOTOR DEVELOPMENT OF ADOLESCENTS - A LONGITUDINAL STUDY

Albrecht, C.1, Worth, A.1, Schlack, R.3, Oberger, J.1, Schmidt, S.2, Schlenker, L.2, Bös, K.2

1: University of Education Karlsruhe (GER), 2: KIT (GER) 3: RKI Berlin (GER)

Introduction Opportunities for sedentary behaviors during leisure time have increased for young people (Salmon et al., 2011). However, there are only few studies that specifically examine associations of screen-related behavior (SRB) with motor performance (MP). It is unknown whether SRB in adolescents influences the longitudinal development of MP. The purpose of these analyses is to investigate, whether inter-individual changes in MP in adolescents/young adults over time depend on SRB. **Methods** We tested MP during a 6-year interval in a representative, nationwide sample of 4,528 (t0)/ 5,290 (t1) German children/adolescents (4 to 23 years) (KiGGS and MoMo-study). MP was assessed by MoMo-test-profile (11 test items) (Bös et al., 2009). The present study examines $n=572$ study subjects (14-17 years at t0 and 20-23 years at t1). Four MP items were selected (gross motor coordination: jumping sideways (sw), balancing backwards (bw); condition: standing (st.) long jump, push-ups). SRB was captured with three items for daily use of television, pc/internet and video gaming at t0 and t1. A sum score of total screen time was calculated and trichotomized: low to moderate SRB: 0-2.9 h/day; high SRB: 3.0-4.9 h/day; extreme high SRB: up to 5 h/day). Using rmANOVAs, we examined the influence of SRB group membership on MP development. **Results** We found significant differences in MP level at t0 according to SRB time for the push-ups (group: $F_{2, 525} = 13.20$, $p < .01$, $\eta^2 = .05$) and st. long-jump (group: $F_{2, 533} = 4.28$, $p < .05$, $\eta^2 = .02$). The rmANOVA revealed significant differences in MP development from t0 to t1 according to SRB time for push-ups (time*group: $F_{2, 525} = 9.37$, $p < .01$, $\eta^2 = .03$), st. long jump (time*group: $F_{2, 533} = 14.32$, $p < .01$, $\eta^2 = .05$), jumping sw (time*group: $F_{2, 532} = 3.41$, $p < .05$, $\eta^2 = .01$) and balancing bw (time*group: $F_{2, 533} = 4.80$, $p < .01$, $\eta^2 = .02$). Adolescents with low to moderate SRB time over 6-year interval show a higher increase of MP from t0 to t1. **Discussion** Development of MP from t0 to t1 differs significantly among adolescents according SRB time in gross motor coordination tasks and conditional-determined tasks. Meeting moderate to vigorous physical activity guidelines has found to be a prerequisite for age-appropriate MP (Bös et al., 2009). Our results indicate that it might also be important to limit the time spent with SRB in adolescence to achieve higher levels of MP in young adulthood. **References** Bös, K., Worth, A., Oppel, E. Introduction Protecting children from starting to smoke is an important UK Government public health priority (Department of Health, 2011). Evidence suggests that participation in physical activity (PA) can be protective against smoking initiation. Therefore we developed a novel intervention - SmokeFree Sports (SFS) - that aimed to utilise PA as a tool to prevent smoking. The purpose of this study was to evaluate the impact of a school-based SFS intervention on children's perceptions towards smoking. **Methods** A controlled-trial was conducted among Year 5 children ($n=1097$; 49% boys, Age Mean= 9.5 ± 0.3) in 43 primary schools across the North West of England between October 2012 and May 2013. Schools were clustered into intervention ($n=32$) and comparison groups ($n=11$). Intervention components included a three hour workshop for teachers and external sports coaches, delivery of five activity sessions (multi-activity, dance x 2, football x 2) and a school assembly with a Great Britain athlete. To assess children's smoking-related attitudes, cigarette refusal self-efficacy and intentions to smoke, a questionnaire was completed at baseline and post-intervention. After controlling for family and friends smoking status, intervention effects were explored using logistic regression and ANCOVA. Qualitative data was also collected through focus groups and interviews with children and coaches/teachers, respectively. **Results** Compared to children at comparison schools, children that participated in the intervention were more likely to believe that: 1) it is not safe to smoke for a year or two (RR= 1.2, $P<0.01$); 2) it is difficult to quit (RR= 1.5, $P<0.05$); 3) second-hand smoke is harmful to you (RR= 1.2, $P<0.01$), 4) smoking effects sport performance (RR= 1.6, $P<0.01$) and 5) makes 'no difference' to weight control (RR=2.0, $P<0.01$). No intervention effects were observed for cigarette refusal self-efficacy ($P=.20$) or intentions to smoke ($P=.45$). Qualitative data revealed that the intervention components made children more determined not to smoke

and resolute in their abstinence, whilst awareness of smoking factors had increased. Discussion SFS had a positive impact on children's attitudes toward smoking. Whilst smoking-related self-efficacy and intentions did not change significantly, they were high for both groups at baseline, suggesting a possible ceiling effect. To determine the long-term effects of SFS and therefore the efficacy of PA as a smoking prevention strategy, a 12 month follow-up is planned. References Department of Health (2011). SEASON CHANGES IN PHYSICAL PERFORMANCE OF YOUTH ELITE MALE NATIONAL TEAM HANDBALL PLAYERS

Póvoas, S.1,2, Sampaio, J.1,3, Gomes, I.1,2, Lopes, M.2, Gonçalves, B.3, Marques, M.1,4

Maia University Institute - ISMAI

Introduction The training of elite handball players should comprise exercises aiming at improving the ability to maintain a high exercise intensity (1,2). Consequently, evaluations should be performed to determine how players are coping with these demands throughout the season. The purpose of this study was to analyse the effects of training and competition during an entire season on the anthropometric and physical profile of elite male youth national team handball players. **Methods** Seventeen elite male handball players (under-18) from the Portuguese national team were evaluated at three time points throughout the season (pre-season (T0), competitive period (T1) and immediately before participating in international national teams competitions (T2)). The players performed the Yo-Yo Intermittent Endurance Test–level 2 (YYIE2), the countermovement jump (CMJ), a straight sprint test (5, 10 and 30 m), three sprint tests with changes of direction: forward running (COD), forward/backward running (COD F/B), defensive sideways movements (COD Def), and the running–based anaerobic sprint test (RAST) (for ref.'s see 1). **Results** Performance in the YYIE2 increased significantly from T0 to T1 and to T2 time points, and from T1 to T2 in the CMJ, although decreased in the sprint tests from T1 to T2 ($p \leq 0.05$). A decrease was also shown in COD F/B and COD Def tests from T1 to T2 ($p < 0.00$). There were no significant changes in the anthropometric profile, except for a decrease in fat mass percentage ($p = 0.05$). **Discussion** Accordingly to previous studies (3), the results show that training and competition induce alterations in physical performance during a season. Training sessions and competitive matches favourably modified specific endurance and power-related abilities throughout the season. The neuromuscular demands of the specific pattern of handball movements and actions did not positively influence COD performance throughout the season in this age group. Since COD movements are required in top elite handball players (1,2), these results suggest that the ability to perform acceleration-deceleration movements, which in turn are associated to eccentric muscle contractions, should be improved in youth players. **References** 1.Póvoas, S. et al. MO-SH06 Sportmarketing & Consumersatisfaction

THE QUALITY PERCEPTION OF 2012 WORLD INDOOR ATHLETICS CHAMPIONSHIPS

Şimşek, K.

Anadolu University

Introduction Event quality has been surveyed in terms of not only marketing (Dale et al., 2005;) but also operational by researches (Getz et al., 2001). All general impressions related to consumption experience determine the perceptions about event quality. Getz (2005) emphasizes that it is necessary that sport event quality has been conceptualized as a mix of various programs and processes of service delivery. Sportive struggle, atmosphere of the facility, the other consumers and other privileges sold during the event affect the delivery service quality in Recreation and Sport (Kelley and Turley, 2001). **Methods** In this research, the scale named "Quality Perception of Event" has been used as data collection tool developed by Ko, Zhang, Cattani ve Pastore (2011). Dimensions composing the scale have been compared according to the demographical features of sample group to determine the views of spectators about quality perception of World Indoor Athletics Championships (T-Testi, ANOVA). **Results** According to obtained results, it has been found out that most of the scale dimensions which have been used to determine the quality of World Indoor Athletics Championships have important differences in terms of demographical features of the sample group. The most prominent finding in the research is that the environment dimension which is one of the dimensions determining event quality has significant differences in all comparisons made in terms of demographical features. **Discussion** Every tool is different from each other, nevertheless; there are some similarities and repeated issues in researches of Recreation and Sport Industries due to varieties of dimensions and service quality which researches desire to measure. It is necessary to make more researches in order to create a valid and reliable service quality model for spectator sports. Dale B, Iwaarden JV, Wiele TVD, Williams R. THE TURKISH ADAPTATION OF RECREATIVE CONSUMER'S SATISFACTION SCALE

Şimşek, K.Y.1, Mercanoğlu, A.O.2

Anadolu University Faculty of Sport Sciences

Introduction Knowing in details in the making a decision process behavioral effects of individuals who provide recreational consumption with the aim of utilizing their free time is really important to keep free time consumer. The aim of study of consumer's behaviors is being able to understand the behavior after buying the product or getting the service (Cronin, 2000). **Methods** The aim of this study is adapting the scale called Recreative Consumer's Satisfaction Scale which was developed by Alexandris and Palialia (1999) into Turkish. In the direction of this aim, the tests of content validity, convex validity, separation/ external validity, and structural validity were done by apply-

ing to the individuals who utilize their free time in the socio-cultural, sportive and artistic facilities which belong to Eskişehir Municipality. It was benefited from the analyzes of Material Total Correlation (material values between 0,39 and 0,80) and Cronbach Alfa which are internal coefficient about the reliability of the scale. It was also benefited from corroborative analyzes with the intention of examine the accuracy of the five dimension structure which was decided in the result of explanatory factor analyze. Results According to the analyze of the explanatory factor in the study, the number of the factors which appeared support the number of the factor in the original scale and its structure. It was determined that Cronbach alfa value of the factors is between 0.721 and 0.900. At the end of the corroborative factor analyze which was done, it was found that $\chi^2=268.17$, $df=125$ $\chi^2/df=2,14$, $p=.000<.001$; RMSEA= .69 (acceptable); SRMR= .054 (acceptable); NFI=.96 (good adaptation); NNFI=.97 (good adaptation); CFI=.97 (good adaptation); AGFI=.85 (acceptable) and GFI=.89; (unacceptable). It can be said that the items which are in question are compatible with the five dimension structure. The correlation among the structures which form Recreative Consumer Satisfaction scale changes between 0,365 and 0, 624. It was found out that the lowest material total point correlation value of the scale called as Recreative Consumer Satisfaction is $r = 0,218$ and the highest one is $r = 0.744$. In all the items of the scale, positive and significant correlation ($p<01$) was determined. Discussion In this study which aimed at determining validity and reliability of the Recreative Consumer Satisfaction scale in Turkish language and culture, it can be come through that it was reached to a valid and reliable scale so it was achieved the goal of the study. , References Alexandris, K., & Palialia, E. (1999). Measuring customer satisfaction in fitness centres in Greece: an exploratory study. *Managing Leisure*, 4(4), 218-228. Cronin Jr, J. J., Brady, M. K., & Hult, G. T. M. (2000). THE VALIDITY AND RELIABILITY STUDY OF THE SCALE OF SERVICE QUALITY IN RECREATIONAL SPORT

Çevik, H., Şimşek, K.

Anadolu University, Faculty of Sport Science

Introduction Many researchers mention that SERVQUAL has a lot of theoretical and practical lacks for many industries. SERVQUAL that is used in the recreation and sport industry is insufficient in this field and it is needed additional researches about this model. Thus, researches focus on the specific service quality items, dimensions and developing elements of the recreation and sport industry. This situation causes the adaptation studies on previous models and emergence of new models designed to measure the particular service qualities in recreation sport industry (Ott, 2008). Methods In this research, it is aimed to study of validity and reliability of the scale of service quality in recreational sport, developed by Ko and Pastore (2005). The sample of the research is composed of 301 tourists, 167 males (55.8 %) and 134 females (44.2 %), selected from two five-star hotels which are located in Antalya using the convenience sampling method. Content validity, convergent validity, external validity and construct validity of the scale have been tested. It has benefited from Cronbach Alpha which is internal consistency coefficients related to the validity of scale and item-total correlation analyses. Results Explanatory factor analysis applies to determine construct validity of the scale revealed a construct with five factors and forty-one items. Internal consistency reliability coefficient for the whole study was found 0.944. The findings showed that internal consistency reliability of factor items had an item/total correlation coefficient ranging between 0,43 and 0,66. Discussion It can be reached a conclusion that this instrument has validity and reliability in this study aimed to determine the validity and reliability in Turkish language and culture of the instrument which is named Scale of Service Quality in Recreational Sport. DETERMINING THE CONSUMER'S SATISFACTION LEVEL IN THE FACILITIES WHERE LEISURE ACTIVITIES ARE ARRANGED IN PUBLIC CORPORATION: ESKİŞEHİR MUNICIPALITY SAMPLE

Şimşek, K.Y.1, Özfidan, S.2

anadolu university

Introduction Out of basic needs of public, generating and dedicating the facilities and places where provide the opportunity and possibility of utilizing their monotonous and stabile time; provide relaxing in their leisure time are among the primary duties of Municipalities (Ağılönü and Mengütay, 2009). Today and in the future local managers' one of the most important duties is keeping the public interest in socio cultural, sportive and artistic leisure activities. The main way of keeping this interest is about meeting the leisure consumer's needs and expects. Methods In this study, general scanning model which is one the descriptive research methods and descriptive statistic model were used. Within the research, 'Recreative Consumer Satisfaction Scale' which Alexandris and Palialia (1999) developed with the aim of determining the satisfaction level which the recreation consumers who benefit from socio cultural, sportive and artistic facilities in Eskişehir Municipality perceive from the facilities. Within Eskişehir Municipality, t test and single direction variance analysis (ANOVA) were used in order to determine age, occupation, level of education and gender difference of sample group, with the aim of determine the satisfaction level which recreation consumers who benefit from socio cultural, sportive and artistic facilities in Eskişehir Municipality perceive from the facilities. Results When the results which were obtained at the end of the study were analyzed, a significant difference was ascertained according to gender in all the dimensions which form recreative consumer satisfaction. When the study results which were obtained according to education level were analyzed, people who have primary school education level express more positive opinion than the other groups in the facilities/services and health/fitness dimensions. In the comparison which was done according to group of occupation, it was determined that the level of satisfaction which students obtain from facilities/services is higher than the other occupation groups Discussion When the body of literature about service quality is analyzed, the findings that state service concept is multi-dimensional and hierarchic are encountered and it is scientists' common view. In the industry of sports and recreation, researchers formed unique service quality dimensions while they were developing special scales. While every tool and scale is unique, some repeated issues and similarities compose in the studies in this industry because of variety of dimensions and service quality which scientists want to measure. More researches must be done in order to be able to form a valid and reliable service quality modal in sports which are spectators oriented. References Alexandris, K., & Palialia, E. (1999). BRAND LOYALTY AND SPORTS PRODUCTS BRAND PREFERENCES OF STUDENTS ATTENDING

Gumus, N., Çelik, V.O.

Anadolu University Faculty of Sport Sciences

Introduction The companies aiming to meet the expectations of their customers try to establish brand loyalty by investing on their brands both to be permanent in the related markets and to be superior to their rivals. The aim of this study is to determine the presence of brand loyalty for sports products brands and to explore the factors positively or negatively affecting brand loyalty as well as the importance placed on the brands. **Method** The population of the current study is the students attending Anadolu University Faculty of Sport Sciences. The sampling includes a total of 369 students. In order to determine brand loyalty and brand preferences of the students for sports products, a scale developed by Çiftçi (2006) was administered. SPSS program was used for the analysis of the data obtained; namely variance and factor analysis. **Results** Of the students, 126 (34.1%) stated that they prefer Adidas brand for sneakers and 170 (46.1%) for tracksuits. Similarly, 154 students (41.7 %) chose Adidas for t-shirts. In general, the favorite brand for sports products was found to be Adidas with a percentage of (44.4%). While a majority of students (54.5%) reported "brand credibility" as "very important", 33.3 % stated "a catchy logo" as "important". According to exploratory factor analysis, all the sub-scales stated in the scale developed by Çiftçi (2006) were found to be valid for that study. Significant differences were found in these sub-scales among the groups for various variables ($p < 0.05$). **Discussion** The results of the current study show that students take the following factors into consideration while preferring the sports products they will use; the prestige due to the use of the product, brand familiarity and an easy-to-remember name etc. However; the visibility of the brand label is not considered important by students. The following factors are also important while students buy a sports product: not frequent changes in prices, having the same price in every shop, option of payment by credit card and the availability of other easy payment methods. Finally, students state that the following factors are also influential in their sports brand preferences: high quality that meets the expectations; model and product variety, interesting and attractive design, high quality fabric, and the satisfaction with the other products of the brand. **References** Çiftçi, S. RELATIONSHIP QUALITY DIMENSIONS BETWEEN SOCCER CLUBS AND FANS

Kose, H., Argan, M.

Graduate School of Health Sciences

In sport industry, unfortunately, sport organizations are disconnected with their fans; thus, sport marketers and researchers have advocated a fundamental shift in sport marketing from a traditional exchange paradigm to a relationship paradigm (Kim, 2008; Kim and Trail, 2011) to have effective, successful and long-term relationships with their fans. This new phenomenon is called "relationship quality". RQ is the degree of appropriateness of a relationship to fulfill the needs of customers associated with relationship (Hennig-Thurau and Klee, 1997) and describes the structure that creates identity and warmth between organization and customers (Fournier, 1998). So, sport clubs that want to have effective, successful and long-term relationship with their fans, the quality of the relationship must be high. Unfortunately, there are not many studies about relationship quality on sports. So the aim of the study is to reveal the dimensions of relationship quality between sport clubs and fans. For this purpose the researchers used a 28-item scale instrument along with 5 items for demographics (age, gender, occupation, education level and monthly household income) to assess constructs of relationship quality dimensions. The sample comprised of sport fans of four popular teams Turkish Super League (Besiktas, Eskişehirspor, Fenerbahçe and Galatasaray) who watch their teams' games at the stadium or via television and buy their teams' licensed merchandise. A total of 712 usable responses were deemed usable for analysis. In order to analyze the data and to assess the validity of the scale, an exploratory factor analysis (EFA) was applied. For the variables, Kaiser-Meyer Olkin (KMO) was .93, indicating that the sample was adequate for factor analysis (Kaiser, 1974). According to the principal axis analysis, five factors had an eigen value equal to or greater than 1.0 (Kaiser, 1960), explaining a total of % 68.2 of the variance. These five factors were termed: "trust and loyalty", "identity and intimacy", "love", "customization" and "relational satisfaction". For all the constructs factor analysis displayed high loadings for the items and all five constructs met the criterion that a factor loading should be equal to or greater than 0.45. Consequently, sport club managers and marketers first should care the needs and wants of their fans. Then to have long-term and successful relationships with them they should care about relationship quality dimensions to make their fans loyal to the team and satisfied fans from the relationship. Thus, the results of the study can be interest of sport managers and sport marketers. Because identifying and understanding relationship quality dimensions between soccer clubs and fans is a key consideration for sport managers and marketers when designing a marketing strategy.

14:00 - 15:00**Mini-Orals****MO-BN06 Physical Education, Motor Skills & Dance****AN INTERVENTION TO INCREASE FUNDAMENTAL MOVEMENT SKILL MASTERY IN PRIMARY SCHOOL CHILDREN.**

Bryant, E., Birch, S.L., Duncan, M.J., James, R.S.

Coventry University

Background: FMS have been identified as an important prerequisite for physical activity (PA) participation (Cowley et al. 2010). **Aim:** The aim of this study was to identify if a multi-skilled intervention could improve FMS level, PA participation and weight status in primary school children. **Method:** The intervention group had a sample of 165 children aged 8-11 years old (mean 8.3 ± 0.4 years) of which 82 children were also the control group. The intervention was 60 minutes a week for 6 weeks which consisted of multi-skilled circuits to improve each individual FMS. Children were measured on the following methods at baseline, post intervention and at a six week follow up. Children were video recorded performing eight FMS (run, hop, gallop, catch, kick, throw, jump and balance) which were later analysed using the Process Orient Checklist to produce a % mastery of the FMS (NSW DoH, 2000). PA was measured using a four day pe-

dometer step count reading. Body fat % was measured using tricep and medial calf skinfold measurements and BMI was calculated from height and mass. Ethical approval and parental informed consent were gained prior to research commencing. Data were analysed via a repeated measure ANOVA with bonferroni post hoc analysis. Results: Children significantly improved in all eight FMS from baseline to post intervention by 40% and at the six week follow up by 41% ($p < .05$). The hop and jump improved significantly from post intervention to the six week follow up ($p < .05$). The control group significantly improved in 6 out of the 8 skills ($p < .05$) by 18% (catch and kick did not significantly improve). PA levels significantly increased in the post intervention and in the six week follow up ($p < .05$). The control group did not significantly increase PA levels ($p > .05$). BMI and BF% did not significantly change in the intervention or control group. Discussion: The intervention has highlighted that FMS can be taught and learnt, in turn having a positive effect on PA level. The children in the intervention group were teaching children from the control group in the playground everything they were learning in the intervention sessions. Thus, offering an explanation to why the control group also significantly improved. This information should be used to advocate the importance of teaching FMS in primary schools to enhance PA participation, which not only promotes maintenance of a healthy weight status, but will aid in health related fitness and mental well being. Cowely et al. (2010) BMJ, 44, 11-12. DoH (2000) NSW Dept Ed and Training, 16.

FUNDAMENTAL MOTOR SKILL PROFICIENCY OF SINGAPOREAN CHILDREN AT LOWER PRIMARY SCHOOL LEVEL

Mukherjee, S., Lye, C.T.J., Saunders, J., Coolds, W., Nonis, K.P.

National Institute of Education, Nanyang Technological University, Singapore

Introduction Fundamental motor skill (FMS) proficiency is a significant contributory factor for children's physical, cognitive and social development and provides the foundation for an active lifestyle in the long-term. Physical education (PE) is an integral part of the curriculum in Singapore primary schools. However, there are apparently no published reports on level of FMS proficiency in the Singapore primary school children. The objective of this study was to determine the FMS proficiency of Singaporean Children at the lower primary school level. **Methods** The FMS proficiency of Singapore primary school children at primary-1 and primary-3 levels was measured. The Test of Gross Motor Development (TGMD-2) was used as the test of gross motor skills for the participants (Ulrich 2000). The TGMD-2 comprises of 12 fundamental movement skills grouped into two subtests: (a) locomotor subtest and (b) object control subtest. All performances were videotaped and rated by the same researcher. Results 120 primary-1 (60 boys, 60 girls; mean age: 6.70 ± 0.25 years) and 120 primary-3 (60 boys, 60 girls; mean age: 9.15 ± 0.29 years) participated in the study. The mean gross motor quotient (GMQ) of the primary-1 children was 82.3 ± 9.66 . This was equivalent to the percentile ranking of 12.4. Majority of the participants were in the below average (35.8%) or poor (39.2%) category for overall proficiency and none of the participants were rated superior or very superior for overall FMS proficiency. The mean gross motor quotient (GMQ) of the primary-3 children was 78.8 ± 9.16 . This was equivalent to the percentile ranking of 7.9. Majority of the participants were in the below average (33.9%) or poor (40.3%) category for overall proficiency. 10.5% of the children were in average category and none of the participants were rated superior or very superior for overall FMS proficiency. For both the levels, there was no significant effect for gender for overall FMS, locomotor and object control proficiency. **Discussion** The main finding of this study was that the Singaporean children at the lower primary age group have a relatively low degree of FMS proficiency that is inferior to the TGMD-2 normative samples. The FMS proficiency scores were also lower than that reported in another recent study on Asian children (Pang & Fong, 2009). This study provides valuable data for the development of normative reference for FMS proficiency in Singaporean children and provides the comparison benchmark for future studies. Given that FMS competency has strong interactions with perceptions of motor competence and health-related fitness to predict physical activity and subsequent obesity from childhood to adulthood, this study serves to inform the policy on physical education curriculum in schools for development of appropriate strategies to promote movement proficiency development during early childhood years. **References:** Ulrich, B.D. (2000). Test of gross motor development (2nd Ed.) Austin, TX: Pro-ed Inc. Pang, AW., Fong, DT. (2009). Res Sports Med, 17, 125-144.

RELIABILITY OF MABC-2 FOR PRESCHOOL CHILDREN

Serbetar, I., Loftnesnes, J.M.

Faculty of Teacher Education Zagreb

RELIABILITY OF MABC-2 FOR PRESCHOOL CHILDREN **Introduction** Motor competence is capacity of child to successfully perform everyday motor task and/or to confidently participate in movement activities and sports. Early acquisition of fundamental motor skills may be useful for later building of complex motor skills and also to create healthy habit of participation in physical activities. One of the most widely used instruments for evaluation of motor competence is Movement Assessment Battery for Children - Second Edition (MABC-2; Henderson, Sugden & Barnett, 2007). This study is aimed to assess some reliability measures of MABC-2 performed on Croatian preschool children. **Methods** Participants in this study were 182 preschool children (93 boys, 89 girls) aged 3-6 from several kindergarten in north west Croatia. The Movement Assessment Battery for Children - Second Edition (MABC-2; Henderson, Sugden & Barnett, 2007) is divided in three age ranges and contains eight motor item in each range. Items are related to manual dexterity, ball skills and balance. Separate standardized scores with adequate percentile values can be established for each test part and for total score. Children were assessed by graduate students trained by first author. Test-retest assessment was performed within a 3 week. **Results and discussion** The intra-class coefficients (ICC) were computed twice, first on standardized measures and they were as follows: posting coins, .76; threading beads, .78; drawing, .83; catching beanbag, .70; throwing beanbag, .77; one leg balance, .85; walking heels raised, .76; jumping on mats, .66. The ICC coefficient for whole test was .78. Standard errors of measurement (SEM) ranged from 1.11 to 1.80. ICC's were also computed for raw scores and that allowed estimation of SEM as the indicator of measurement error expressed in same unit as the original measure. ICC for the raw scores of throwing was .72, all the others raw scores ICC were between .80 and .87. The highest measurement error expressed as independent of units of measurement was found for the threading beads and lowest one was found for jumping on mats. In present study, good to excellent overall reliability was found, which is comparable to other studies, for example Chow and Henderson (2003) or to the reliability data cited in manuals. **References** Henderson, S.E., Sugden, D.A., & Barnett, A.L. (2007). Movement Assessment Battery for Children-2 examiner's manual. London, UK: The Psychological Corporation. Chow S.M, Henderson S.E. (2003). Interrater and test-retest reliability of the Movement Assessment Battery for Chinese preschool children. Am J Occup Ther 57(5):574-7. Contact [ivan.serbetar@ufzg.hr]

MOTOR COORDINATION, BODY MASS INDEX, AND SPORT PARTICIPATION IN 6-11 YEARS OLD CHILDREN

Giuriato, M., La Torre, A., Caumo, A., Pugliese, L.

University of Milan

Introduction. Motor coordination (MC) in childhood plays a crucial role in the physical and psychological health in childhood and even throughout the lifespan. Nevertheless a decline in MC among children and an increase in child obesity have been reported. The aim of this study was to examine the MC level in 6-11 years old Italian children and its relationship with BMI and sport participation. **Methods.** A sample of 240 Italian children of both gender participated in the study. Participants were divided into three groups according to age and school grade: 1° grade (G1) (n=90, range=6-7 years; h=1.23±0.05 m; w=24.9±3.9 kg); 3° grade (G3) (n=66, range=8-9 years; h=1.34±0.05 m; w=32.3±5.3 kg); 5° grade (G5) (n=86, range=10-11 years; h=1.47±0.06 m; w=40.2±8.1 kg). Motor coordination was assessed through the Körperkoordinationstest für Kinder (KTK). Cut off points for BMI in childhood were used to categorize the participants as underweight (UW), normal (NW), overweight (OW) and obese (OB). Physical activity (PA) of the parents was evaluated with a questionnaire (IPAQ) with attached a dichotomous question about the participation in organized sport activities of their children. **Results.** A significant decrease of MQ was found from G1 to G5 (G1, 99.7±7.4; G3, 90±6.65, G5, 84.6±7.4). As for BMI, results showed an increase of OW and OB children from G1 (OW=11%; OB=1%) to G3 (OW=32%; OB=3%) and G5 (OW=29%; OB=9%). A significant association was found between BMI and MQ. OW and OB categories had an MQ value significantly lower than NW and UW (93.55±11.35 vs 86.2±8.9). As for PA, a significant association was found between parents IPAQ and children MQ. Parents with a high level of PA have children with higher MQ (93.4±10) respect to parents with a low level of PA (88.7±9.1). No difference in MQ and BMI was found between children involved in organized sport activities and children not involved. **Discussion.** These data confirm a significant decrease in MC over the years together with an alarming increase in child obesity. Relationship between parents PA and children MQ suggest that family environment could have great influence in MC. The inconsistent relationship between BMI and MC and sport activity suggest that children probably don't achieve a sufficient stimulus during their organized activity. In conclusion, efforts should be made in order to face the decline in MC, to promote healthy eating habits and adequate levels of physical activities. **References** Cole T, et al. MOTOR FITNESS SCORES AND CORRELATES OF MOTOR FITNESS IN PRIMARY SCHOOL CHILDREN IN THE NETHERLANDS

Collard, D.1, Verhagen, E.2, van Mechelen, W.2, Chinapaw, M.2

(1) Mulier institute, Utrecht, The Netherlands (2) EMGO+ institute for Health and Care Research, Amsterdam, The Netherlands

INTRODUCTION To engage in various physical activities, sports and games children need motor skill competence. In 2010 a study in Dutch primary school children showed that muscular strength, speed/agility, coordination and flexibility, were declined over 26 years (2006-1980) (Runhaar et al., 2010). The objective of this study is to give insight into the level of scores on MOPER fitness test in primary school children. To indicate which children perform low on the MOPER fitness test elements this study examine the cross-sectional relationship between different child characteristics and strength, speed/agility, flexibility and coordination. **METHODS** To identify correlates of motor fitness secondary data analyses were performed on the baseline data of the iPlay-study. The iPlay-study collected data of 2.208 children (9-12 years), on among others MOPER fitness test scores, BMI, membership of a sport club, sport frequency per week, sport experience, outdoor play frequency per week and demographic variables. The motor performance fitness test scores were converted into age and gender-specific z-scores. Multivariable multilevel regression analyses were performed to determine correlates of strength, coordination, speed/agility, flexibility and overall motor fitness. **RESULTS** The mean (sd) age of the children was 10.7 (0.8) years (n=1967). Seventeen percent of the children were overweight. 51 percent of the children who were member of a sport club participate two or three times a week in sport. About one third of the children participated six or seven times a week in leisure time physical activities. Furthermore results showed that boys perform slightly better on strength and speed/agility test. However, girls perform better on flexibility, coordination and trunk/leg strength. Furthermore, the frequency of sport and leisure time physical activity is positive associated with motor fitness. A strong negative association was found between being overweight and motor fitness. **DISCUSSION** Children with overweight and children who are less physically active are at greater risk for poor skill and health related physical fitness components such as speed, agility, coordination, muscular strength and flexibility. Interventions must especially focus on those two groups to improve skill and health related fitness components. **REFERENCES** Runhaar J., Collard D.C.M., Singh A.S., Kemper H.C. van Mechelen W. and Chinapaw M.J.M. EVALUATION OF MOTOR SKILLS TRAINING IN PHYSICAL EDUCATION; RESEARCH RESULTS IN THE SWEDISH BUNKEFLO PROJECT

Ericsson, I.

Malmö University

Introduction Fundamental motor skills may be an important factor in motivation for being physically active and being able to participate in social physical play. The aim was to study relationships between physical activity and school performance in perspective of results found in the Swedish Bunkelflo project, also called the Pediatric Osteoporosis Prevention (POP) study. Another aim was to evaluate the model for motor skills training used in the project, the Motor skills as Ground for Learning (MUGI) model – (in Swedish: Motorisk Utveckling som Grund för Inläring) (Ericsson, 2008). **Methods** All pupils (n=220) at two compulsory schools in a middle class area in Sweden were studied from school year 1 to 9. The control group had the school's regular PEH two lessons (90 min) per week. An intervention group had Physical Education and Health (PEH) on the schedule five lessons (225 min) per week and also, when needed, one extra hour of motor training per week according to the MUGI model (Ericsson, 2008). **Results** Both boys and girls improved significantly in motor skills and the differences between them decreased with extended physical activity and MUGI motor training in school. Significantly higher grades in PEH were found in the intervention than in the control group and there were no pupil without a grade in the subject, whereas almost 4% of the pupils in the control group did not receive a grade in PEH. There was a larger proportion of pupils in the intervention than in the control group (96% versus 89%) that reached qualification to upper secondary school and significant correlations were found between motor skills and sum of grades in evaluated subjects (Ericsson & Karlsson, 2012). **Conclusion** The MUGI model for motor skills training was found to be useful as a pedagogic model for improving motor skills (balance/bilateral coordination and eye-hand coordination) in school pupils. The school has good potentials in stimulating all pupils' development of motor skills, but two lessons of PEH per week are

not enough. The link between motor competence, physical and psychological health needs to be examined further. References Ericsson, I. (2008). THE SELF IMAGE. COMPARISON OF YOUNG, PARENT AND OBJECTIVE REALITY

Lucchetti, C., Nart, A., Catella, F., Biancalana, V.

School of Motor Sciences. Carlo Bo University of Urbino

Introduction During teenage boys change their corporeality in a strong way. Recent studies showed postural observation is very important in this age to prevent skeletal muscle disorders (Epstein et al., 1995). Regular physical activity is fundamental to improve health and wellness at any ages. The present study's target was to take over how teenagers feel their posture in comparison to the parents's one and to objective observation. Method 148 students were recruited (77 F, 71 M) mean age 11,8 years (between 11,1 and 12,1). Boys filled out the questionnaire for description of his own posture (Questionario Descrizione della Propria Postura -Q- DPP) while parents the questionnaire for description of their child's posture (Q-DPP). Both evaluated posture, flexibility, physical structure, symmetry, coordination, physical activity carried, worthy and life style. We used Podia XP to have a picture of boys's posture; Normes AFP 85 to evaluate BMI, shoulders's symmetry and other. Results The relationship between Parents/Children questionnaire (Q-DPP/Q-DPP) showed good statistical significance in 8 variables: flexibility ($r = .396$ $p < .005$); physical structure ($r = .600$ $p < .005$); symmetry ($r = .290$ $p < .005$); coordination ($r = .373$ $p < .005$); physical activity carried ($r = .402$ $p < .005$); worthy ($r = .320$ $p < .005$); life style ($r = .321$ $p < .005$). The relationship objective/subjective values (Parents/Children) showed good statistical significance in BMI/physical structure ($r = .642$ $p < .005$ / $r = .666$ $p < .005$); BMI/ physical activity carried ($r = .269$ $p < .005$); torso's tilt angle/flexibility reported by Parents/Children ($r = .324$ $p < .005$ / $r = .252$ $p < .005$); torso's tilt angle/posture reported by Children ($r = .162$ $p < .005$); torso's tilt angle/physical structure reported by Children ($r = .179$ $p < .005$). Discussion Results showed Boys have little awareness of their posture. Parents don't pay attention their Children's posture. It is very important to educate students at movement to better deal with body's changes in teens. References Carraro A., Scarpa S., Ventura L., (2010). A METHOD TO INDICATE THE VALUE OF DANCE IN THE EDUCATION CONTENT OF PHYSICAL EDUCATION: A COMPARISON BETWEEN JAPAN AND KOREA

Park, K.1, Murata, Y.1, Yamazaki, A.2

1:University of Tsukuba (Japan), 2: Shizuoka University (Japan)

Introduction Generally, dance is included in the art or physical education (PE) subject curriculum. Education content and methods vary depending on the subject in which dance is included. When it is included in PE, the continual debate on dance as art or PE rages on. Thus, the value of including dance in PE must be highlighted. The objective of this research is to investigate the indication method for the existence value of dance in PE by examining and comparing cases of dance in PE in Japan and Korea. Methods The main subject of this study was a guide to the national and PE curriculum in Japan and Korea. Supplementary subjects included published textbooks and guide materials conforming to the curriculum. In addition, interviews were conducted with three specialists who participated in curriculum revision in Japan and Korea. Results The content of PE in Japan was developed with a focus on "exercise domain and events." Dance is currently included in PE as an independent domain: "expressive activity field and dance." Dance forms with different characteristics, including "expression and creative dance, folk dance, and rhythm dance" are suggested in the content outline. In contrast, PE content in Korea was developed with a focus on "the value of physical activity." Here, dance is an elective activity in the "expression activity" domain. Various indication methods such as expressive sports (such as rhythm gymnastics) and many dance genres are suggested as education content. Discussion Dance is included in PE in both Japan and Korea. However, the domain to which dance is assigned and its education content differs between the two countries. This difference is caused by variation in the method to indicate the value of dance in PE. In Japan, dance is categorized in a single domain, and the characteristics of dance are clearly defined so that they differ from other exercise domains. Furthermore, the fundamental characteristics of dance are taught through three forms relevant to education, rather than through a diverse range of dance forms. On the other hand, in Korea, dance is not categorized as a domain with its own distinctive characteristics. Rather, the focus is on the characteristics dance (value of expression and creative activities) shares with other exercise domains, which indicates the value of dance. Conversely, the difference in the positioning of dance in education can be attributed to the two countries' different methods for PE content development. The value of dance must be highlighted in PE. This research proposes the value of dance in PE, recommends content depending on the objective of PE, and highlights the relationship to be maintained with other PE activities. IMPLEMENTATION AND STAGING FROM THE PERSPECTIVE OF OBSERVING MOVEMENT, AS INTERPRETED FROM DANCE TEACHERS' LANGUAGE

Yamazaki, A.1, Murata, Y.2, Park, K.2

1: Shizuoka University (Japan), 2: University of Tsukuba (Japan)

Introduction In 2012, dance became a required course for the second year of Japanese junior high school. As a result, P.E. teachers throughout the country are now involved in dance class. However, most teachers—men in particular—have little experience with dance and therefore report difficulty in teaching. This study focuses on differences in meaning of the instructional language used by experienced and inexperienced teachers to show the implementation and points of view on the teaching of specific movements and the evaluation of student movements when teaching improvised dance. We hope that the study will provide easy-to-understand teaching materials for inexperienced teachers. Method Our previous research presented 10 instructors' perspectives regarding movement, that is movement quality, to move greatly, to use all body, change of area, change of time, change of force, varieties of movement, moving sequence,

originality, identification with a material. Using these perspectives as source material, here we verify the Japanese National Curriculum for Creative Dance Skill, identifying perspectives regarding movement and diagramming their stages. The results of our classification were verified by a university dance teacher and a researcher. Results The previous research found no significant difference between experienced and inexperienced teachers for the perspectives regarding movements to use all body and change of area, indicating that these are easily visualized movements that are readily grasped by inexperienced teachers. This contrasts with movements change of force and varieties of movement, which are difficult to visualize and for which significant differences were seen, namely that experienced teachers were able to deliver continuous and instantaneous assessments and evaluations. These results indicate a development of teaching skill in which perspectives regarding movement are positioned in stages. Discussion This study thus suggests that providing inexperienced teachers access to the instructional perspectives of experienced teachers, will diversify the significant differences in interpretation of the instructional material between the two groups and broaden the types of movements in the instructional materials. Differences between experienced and inexperienced teachers furthermore suggest that staging the perspectives on viewing movement can provide an index for measuring the process of transformation from an inexperienced teacher to an experienced one. MO-SH07 Sport & Motivation

USING DIFFERENT INDICES OF CHANGE TO UNDERSTAND ACHIEVEMENT MOTIVATION IN PHYSICAL EDUCATION

Warburton, V.E., Spray, C.M.

University of East Anglia and Loughborough University

Introduction Understanding how pupils' motivation changes over time and the factors associated with such changes are key to developing feasible practical interventions to ensure young people have positive experiences in school Physical Education (PE) that can transcend physical activity contexts. However, the index of change used to examine the temporal patterns of motivation can influence the conclusions drawn and therefore employing multiple indices of change at both the sample- and individual-level are required to fully understand the dynamics of motivational processes in achievement contexts. **Methods** We report data from two longitudinal studies that have examined pupils' achievement motivation in physical education across the transition from primary-secondary school and during Key Stage 3 of secondary school. In study one, 140 primary school pupils completed measures of entity and incremental beliefs and approach-avoidance goals on four occasions during a 12-month period which included a transition to Year 7 of secondary school. In study two, 511 pupils in Years, 7, 8 and 9, completed measures of incremental and entity beliefs, and approach-avoidance goals on four occasions, over a 9-month period. We examined changes in achievement goal adoption and the association of implicit theories of ability through using three different indices of change, i.e. sample-level analyses, individual-level change (relative change index) and ipsative continuity. **Results** Across the two studies, the sample-level analyses revealed a decline in pupils' achievement goal adoption; whereas the individual-level and ipsative analyses suggested that most pupils evidenced stability rather than change in their achievement goal adoption. All analyses indicated that implicit theories of ability predicted change in achievement goal adoption. The individual-level analyses also revealed a group of pupils in both studies who evidenced change in their achievement goal adoption, and that for some of these pupils it was an increase in MApp goal adoption. **Discussion** Assessing different indices of change appears to be important for providing a more complete understanding of the dynamics of motivational processes. Implicit theories of ability appear to be important for understanding change in achievement goal adoption. In the individual-level analyses, it was encouraging to find that some pupils showed positive change in their achievement goal adoption. Implications for future research, such as identifying the characteristics and factors associated with adaptive changes in motivation, will be discussed. Contact v.warburton@uea.ac.uk

GOAL ORIENTATION, INTRINSIC MOTIVATION AND EXERTED EFFORT

Mehus, I., Sæther, S.A.

Norwegian University of Science and Technology

Introduction Researchers have found that task orientation is positively related to intentions towards physical activity and exerted effort, (Duda & Hall, 2001). However, Mehus (2013) found that ego orientation had a positive impact on effort in a highly competitive environment, whereas task orientation had no impact. This is a follow up study of Mehus (2013), investigating how intrinsic motivation impacts the relationship between goal orientation and exerted effort. **Methods** Participants (N=135) were students taking part in an introductory course in Sport Science. The mean age of the participants was 21 years, and 51.9% were female. To measure effort, participants were required to run around a volleyball court for three minutes, demanding two full stops for each lap. Total distance served as a measure of effort/aerobic fitness. VPA was measured using an Actigraph GT1M accelerometer (Actigraph LLC, Pensacola, FL, USA). Students were instructed to wear the monitor for 6 consecutive days. Dispositional goal orientations were measured using the Perception of Success Questionnaire (POSQ; Roberts, Treasure & Balague, 1998). Intrinsic motivation was measured using the Behavioral Regulation in Exercise Questionnaire (BREQ-2; Markland & Tobin, 2004). **Results** The regression model explained 48.7% of the variance in effort/physical fitness (adjusted R²), and turned out statistically significant. Except for age, all independent variables were statistically significant (p<.05). The model was checked for non-linearity and interaction effects. An interesting interaction effect was found between VPA and intrinsic motivation, indicating that students high in intrinsic motivation and VPA had a lower score on effort compared to students low in intrinsic motivation and high VPA. The interaction effect was included in the final model, explaining 50.7%, $F(7, 134)=20.72, p<.001$. **Discussion** Because men run faster than women in this sample, gender is the independent variable explaining the highest amount of variation in effort. However, controlling for gender also reveal that ego orientation, intrinsic motivation and VPA have a positive impact on effort, whereas task orientation has a negative impact on effort. Results are discussed within the theoretical framework of AGT and SDT. **References**

IS STRESS A POTENTIAL MECHANISM IN A MOTIVATIONAL FIT-SITUATION?

Schwab, S.

German Sports University Cologne

Introduction People show better performance and higher motivation in a regulatory fit-situation both in motor and cognitive tasks (Keller & Bless, 2006; Plessner, Unkelbach, Memmert, Baltes & Kolb, 2009). This regulatory fit means that the task requirement and the chronic, regulatory focus (promotion or prevention) of a person match up (Higgins, 2000). The aim of this study was to test the effect of stress as a possible mechanism in a motivational fit- and non-fit-situation. Therefore, a theoretical framework for the interaction between motivation and the crucial role that stress plays in this context will be presented. **Methods** Sixty four male college students ($M = 24.29$, $SD = 3.123$) took part in Experiment 1 and ten male and fourteen female college students ($M = 21.63$, $SD = 1.740$) participated in Experiment 2. With the help of the questionnaire regarding the chronic, regulatory focus (Keller & Bless, 2006) the type of self regulation was measured. After an appropriate instruction (promotion or prevention) the participants solved ten mazes. Physiological stress, determined via α -amylase in saliva (Rohleder, Nater, Wolf, Ehler, & Kirschbaum, 2004), was quantified before the manipulation, directly after the mazes and another five minutes later. **Results** There were significant differences both at the difference scores from measuring point one to measuring point two, $t(1,58) = -2.540$, $p < .05$, and as well at the difference scores from measuring point one to measuring point three, $t(1,58) = -2.278$, $p < .05$ (Experiment 1). Experiment 2 could replicate these findings. Both male and female participants showed a decreased stress activity under a fit-condition and an increased stress activity under a non-fit-condition. **Discussion** Our findings are a first attempt for the possibility that there are differences in neuroendocrine stress markers dependent on whether or not participants are in a fit-situation with a reduction of stress activity due to experiencing regulatory fit. **References** Higgins ET. ANALYZING THE CORRELATION OF MOTIVATIONAL CLIMATE AND ACHIEVEMENT GOALS OF AMATEUR FOOTBALL PLAYERS

Bal, E.1, Sahin, A.2, Erdogan, B.S.2, Eraslan, M.2, Baykose, N.3

1:AU(Antalya,Turkey), 2:MAEU(Burdur,Turkey), 3:SU(Konya,Turkey)

Introduction The purpose of this study was to analyze the correlation of motivational climate and achievement goals in the sample of amateur football players. **Methods** Research groups included 239 football players taking part actively as amateurs in football clubs in Antalya and Mugla, 194 of whom were men and 45 of whom were women (age=21,19 + 3,938). Task and Ego Orientation in Sport Questionnaire, which was developed by Duda, 1989 depending on Nicholls' Perceived Competence Based Developmental Theory and examined by Toros, 2004 in terms of validity – reliability, and Perceived Motivational Climate in Sport Questionnaire- PMCSQ, which was developed by Walling and his friends 1993 and examined by Toros, 2001 in terms of validity – reliability were used to reach the purpose of this study. Significance level $P < 0,05$ was obtained by using Kolmogorov-Smirnov test, Mann-Whitney U, Kruskal Wallis Test, Pearson Correlation during the process of data's analysis and interpretation. SPSS (Statistical package for social sciences) was used to find and examine the data. **Result** As a result positive and linear correlation between sub dimensions of motivational climate and achievement goals of proficiency was obtained. Performance correlation ($r=429$), duty correlation ($r=468$), and ego correlation ($r=385$) were concluded. $P < 0.01$ **Discussion** As a result of this study while a difference was identified in sub dimension of ego correlation in terms of gender, statistically no difference was observed in sub dimensions of proficiency, performance and duty correlations. Based on the points average it was resulted that in comparison the men, the women had got higher averages in both sub dimensions of achievement goals. Significant difference between the achievement goals of the boys and girls was obtained in the research done by Duda (1989) on the athletes doing sports as individuals or with teams in high school and university. According to the study's result while women have more tendency to duty, men have more tendency to ego. On the other hand intermediate correlation in a positive way was obtained between motivational climate and achievement goal. **Reference** Duda, J. L. THE DEVELOPMENT OF SELF-REGULATORY SKILLS IN YOUTH: THE SIGNIFICANCE OF SPORTS AND ACADEMICS

Jonker, L.1,2, Elferink Gemser, M.T.1,3, Tromp, E.J.Y.1, Baker, J.4, Visscher, C.1

1: UMCG, RUG (Groningen, The Netherlands), 2: KNVB (Zeist, The Netherlands) 3: HAN (Nijmegen, The Netherlands) 4: York U (Toronto, Canada)

Introduction Self-regulatory skills (metacognitive and motivational) are associated with success in sports and academia (Jonker et al., 2010) and encompass an individual's capacity to control their learning process (Zimmerman, 2006). **Methods** We assessed the development of four metacognitive (planning, self-monitoring, evaluation, reflection) and two motivational (effort, self-efficacy) skills in youth (aged 12-17 years) using multilevel modelling of longitudinal data (Snijders & Bosker, 2000). The effects of sport (competitive level and number of training hours) and academic (academic level and repeating class) data on this development were considered among 428 elite athletes, 140 regional athletes and 54 non-athletes, taking age and gender into account. **Results** The results showed that athletes who trained more had higher self-regulatory scores with their scores increasing over time ($p < .05$). Effort served as an exception as a decrease in scores was observed over time. The strong association between training hours and self-regulatory skills suggests that sport settings are

suitable venues for the development of these skills. Furthermore, we found that reflection and effort were more strongly associated with competitive level, and self-monitoring and self-efficacy with academic level. Discussion So, for elite youth athletes striving to attain senior elite status, reflection and effort seemed most valuable by outscoring their regional and non-athletic peers and their scores increasing with age. On the other hand, self-monitoring and self-efficacy seemed important aspects for success in students which is in line with prior research (Lan, 2005; Välijärvi & Sahlberg, 2008). Greater attention to the development of self-regulatory skills through sport and educational experiences will not only inform our understanding of the development of exceptional athletes and student but will assist in the creation of more effective interventions to promote positive development in all youth. CONGRUENCE BETWEEN COACH AND ATHLETE PERCEPTIONS OF AUTONOMY SUPPORT AND GOAL STRUCTURE ACROSS TRAINING AND COMPETITION IN INDIVIDUAL AND TEAM SPORTS

van de Pol, P.1, Kavussanu, M.2, Geurts, S.1, Kompier, M.1

1 Radboud University Nijmegen, The Netherlands; 2 University of Birmingham, Birmingham, UK.

Introduction: Two central aspects that shape the coaching environment in sport are 'goal structure' and 'autonomy support'. However, the extent to which a coaching environment facilitates adaptive motivational patterns in sport may depend on the degree of congruence (vs. incongruence) between coach and athlete perceptions of this environment. In addition, the manner in which coaches and athletes perceive the coaching environment may depend on the distinction between training and competition contexts and the type of sport in which athletes participate (i.e., individual or team sports). The purpose of this study was to examine congruence between coach and athlete perceptions of autonomy support and goal structure across context and sport type. Method: Participants were individual- (n = 145) and team-sport (n = 203) athletes and their coaches (n = 15), who completed questionnaires measuring perceptions of goal structure (i.e., task and ego) and autonomy support (i.e., interest in athlete's input and praise for autonomous behaviour) in training and competition. We examined our study purpose with Multilevel Modeling. Results: Coach perceptions of autonomy support (i.e., interest and praise) and task goal structure were higher than corresponding athlete perceptions, in both contexts and sport types. In addition, for autonomy interest, incongruence in individual sports was higher in competition than in training, whereas, in team sports, incongruence in autonomy interest did not depend on context. For autonomy praise and task goal structure, incongruence in individual sports was higher in training than in competition, whereas in team sports, incongruence in these aspects of the coaching environment did not depend on context. Coaches and athletes' perceptions of ego goal structure did not differ from each other. Conclusion: The results of this study indicate that congruence between coach and athlete perceptions of autonomy support and goal structure may depend on context and/or sport type. Hence, the present findings highlight the importance of making the distinction between training and competition, and individual and team sports, when examining motivational processes in sport.

PROMOTING WELL-BEING AND A HEALTHY LIFESTYLE THROUGH SATISFACTION OF BASIC PSYCHOLOGICAL NEEDS IN YOUTH FOOTBALL: A LONGITUDINAL STUDY

Fabra, P., González, L., Tomás, I., Aienza, F., Castillo, I., Balaguer, I.

Research Group of Sport Psychology, University of Valencia

Introduction Basic psychological needs theory (BPNT; Deci & Ryan, 2000) holds that an autonomy supportive coaching interpersonal style facilitates well-being and health through satisfaction of basic psychological needs. According to the postulates of BPNT, the objective of this study was to examine whether perceptions of coach autonomy support predicted players' needs satisfaction and, in turn, their life satisfaction and healthier lifestyle over the course of a competitive football season. Method 597 Spanish young footballers (M=12.58±0.54 years) completed the Spanish version (Balaguer, Castillo, & Duda, 2008) of the Sport Climate Questionnaire (<http://www.psych.rochester.edu/SDT/>), the Perceived Autonomy Scale (Reinboth & Duda, 2006), the Perceived Competence subscale from the Intrinsic Motivation Inventory (McAuley, Duncan, & Tammen, 1989), the Acceptance subscale of the Need for Relatedness Scale (Richer & Vallerand, 1998), the Satisfaction with Life Scale (Diener, Emmons, Larsen, & Griffin, 1985) and the Health Behaviour in School Children (Wold, 1995) at the beginning and at the end of a football season. Results Results of SEM indicated that, at the beginning (T1) and at the end (T2) of the season, players' perceptions of coach autonomy support positively predicted players' need satisfaction (T1 $\beta = .55$; T2 $\beta = .39$), which positively predicted players' life satisfaction (T1 $\beta = .44$; T2 $\beta = .28$). We found that in all the cases, the study variables in T1 acted as positive predictors of the same variables in T2 (autonomy support $\beta = .61$; needs satisfaction $\beta = .46$; life satisfaction $\beta = .45$). Finally, players' life satisfaction in T2 negatively predicted players' use of tobacco ($\beta = -.13$), alcohol ($\beta = -.14$) and unhealthy food intake in T2 ($\beta = -.10$). Discussion This longitudinal study supports BPNT postulates and emphasizes the importance of an autonomy supportive interpersonal style by coaches within youth sport in order to promote their athletes' psychological welfare and to prevent engagement in risky health behaviours. IMPORTANCE AND RELATIONSHIP BETWEEN THE BASIC PSYCHOLOGICAL NEEDS AND THE "REFLECTION" IN ELITE ACADEMY SOCCER PLAYERS

Chamorro, J.L., Sánchez Miguel, P.A., Leo, F.M., Sánchez Oliva, D., Amado, D., González Ponce, I., Pulido, J.J.

University of Extremadura

Introduction Self-determination Theory (SDT; Deci Ryan, 1985, 2000; Ryan Deci, 2000) is a motivational theoretical framework, and lies in a continuum of self-determination. The SDT explains three factors that can facilitate self-determined motivation, called basic psychological needs (BPN): autonomy, competence and relatedness with the others. On the other hand, the term 'reflection' is included within the theory of self-regulated learning of Zimmerman's (2006, 2008). Self-regulated learning gives explanation to the progression in learning tasks. Toering (2010) used this model into the soccer field and showed that the variable 'reflection' would be in the middle of the self-regulation model of learning for young elite soccer players. The objective of this study was to identify the relationship between motivation, through

the satisfaction of BPN, and the learning process, through the variable 'reflection', as well as test the influences regarding a crucial stage for athletes such as transition to the elite sport. Methods Participants were 478 soccer players, ranging in age from 16 to 19 years old ($M=17.45$; $SD=.71$) belonging to the maximum Spanish under-18 division clubs. The instruments used were as follows: autonomy satisfaction by Standage, Duda & Ntoumanis (2005); competence satisfaction from McAuley, Duncan, Tammern, (1989); relatedness satisfaction of Richer & Vallerand (1998) and, for measuring reflection, the scale of 'reflection' by Peltier et al. (2006). Results Firstly, bivariate correlation analysis showed significant positive correlation between 'reflection' and the three basic psychological needs ($P < .01$). Secondly, linear regression analysis revealed that the three basic psychological needs emerged as predictors of reflection. The model has a $R^2=.433$, $R^2=.182$ and significance level under .001. The three basic psychological needs significantly predict the 'reflection' under .01 and $\beta=.09$ for autonomy, $\beta=.161$ for the competence and $\beta=.191$ for the relatedness. Discussion This study showed how in the field of sport and, and particularly in soccer, motivation, through the BPN satisfaction (Ryan Deci, 2000), and self-regulation learning, through the 'reflection' (Toering 2010) were not only related to each other, but it is important to note that working the BPN in soccer, we can influence the learning process of the different variables that influences on sport performance, aspects crucial for the development and adaptation into elite sport. ESC PROJECT: THE INFLUENCE OF STRANGERS IN PHYSICAL ACTIVITY PROMOTION. A RANDOMIZED PILOT TRIAL

Gonçalves, R.1,2, Duarte, A.1, Batalau, R.1,2, Cruz, J.1,2, Leal, J.1, Palmeira, A.2,3

Lusophone University of Humanities and Technologies

Introduction Notwithstanding the wide spread knowledge about the multiple health benefits associated with regular physical activity (PA), physical inactivity is worrisome and was recently nominated the fourth leading risk factor for global mortality (1). Therefore, programs that promote behavior changes towards PA seem warranted. A rising number of studies have been emerging from Deci and Ryan's Self-Determination Theory with interventions targeting health behavior change (2). Recent research shows that exercise motivation can be 'contagious' (3). Hence, the main purpose of this pilot study, which was built to test the procedures of a larger trial, was to analyze the association between social contagion through strangers and PA and sedentary behavior (SB) levels. Methods A randomized pilot trial was designed, with 16 adults (18-64 years), both genders, with four groups (4 participants each): group 1, primed with a promotional brochure about PA e SB; group 2, primed with strangers doing PA; group 3, primed with strangers in SB; control group, exposed to video about healthy nutrition. Participants PA and SB were measured objectively by accelerometers ActiGraph (GT3X) for seven consecutive days, using a 10-second epoch, before and after the intervention. Cases were included if they had at least two valid days for each wearing week. A valid day had to contain at least 10 valid hours. Data was examined by analysis of variance (ANOVA) with repeated measures. Results We found a marginally significant increase in all groups between pre-test and post-test for SB ($F=4.37$, $p=.059$). Pre-test and post-test PA differences were not found on moderate ($F=.06$, $p=.814$) and vigorous ($F=.56$, $p=.468$) intensities. Significant decreases were found on light ($F=12.21$, $p=.004$) and lifestyle ($F=9.63$, $p=.009$) PA intensities. No differences were found between control and intervention groups. Discussion The pilot data seems to indicate that strangers doing PA or in SB do not promote the social contagion for PA and SB in adults. However, this data is preliminary data and more research is in progress. References 1. WHO. Global Recommendations on Physical Activity for Health. Geneva: WHO Press. 2010. 2. IS-PM02 Control of skeletal muscle mass with ageing: Effects of exercise, inactivity and inflammation *

INFLAMMATION: FRIEND OR FOE OF SKELETAL MUSCLE?

Kjaer, M.

Bispebjerg Hospital

Inflammation covers a broad spectrum from intensely diseased patients with inflammatory conditions, to more moderate low-grade inflammation due to e.g. aging. In younger individuals, inflammatory conditions seem to be important post-exercise training, and inhibition of inflammation can diminish the exercise induced rise in myofibrillar protein synthesis, satellite cell activation or connective tissue protein synthesis. Degree of inflammation slowly increases with aging, but can be counteracted by physical training, so similar to cardiovascular and muscle volume capacity life-long training can "rejuvenate" you in regards to inflammation by 30-50 years. In elderly, it seems that counteracting the inflammatory state can have beneficial effects in regards to muscle loss in relation to inactivity, and be encouraging in terms of muscle growth response to heavy resistance training. So, inflammation can be both friend and foe at different time-points in life.

IMPACT OF INACTIVITY ON MUSCULOSKELETAL HEALTH IN AGEING

Greenhaff, P.

University of Nottingham

Musculoskeletal deterioration with age results in frailty and immobility and is a major public health problem. Indeed, it is projected that the healthcare of the very elderly will account for an increasing proportion of future health budgets across the EU. While men and women of all ages, socio-economic groups, and ethnicities are reported to be healthier if they remain active, and despite a large body of data

demonstrating positive effects of exercise in elderly people, the number of older people engaging in meaningful amounts of physical activity appears to be surprisingly small (~50% of adults >60 yrs in Europe are failing to meet government recommended physical activity guidelines). Importantly, while specific exercise guidelines have been formulated for older people, these recommendations appear not to be based on quantified, evidence-based studies demonstrating improvement or maintenance of metabolic and physiological function in skeletal muscle. Preserving musculoskeletal health in ageing will be best realised by attaining a clear understanding of mechanisms driving the loss of muscle mass and quality. This lecture will therefore focus on the role of inactivity, amongst other drivers such as obesity and inflammation, as a major determinant of muscle mass loss and quality with ageing. In particular, the presentation will consider the physiological and molecular drivers of musculoskeletal deterioration associated with inactivity, and will present evidence to support the contention that inactivity and/or exposure to acute episodes of complete inactivity (immobilization) will exacerbate musculoskeletal ageing, and particularly when combined with other burdens (such as acute inflammation).

MAINTAINING MUSCLE MASS IN OLD AGE: EXERCISE, NUTRITION OR DRUGS?

Greig, C.A.

University of Birmingham

Sarcopenia is an inevitable consequence of advancing age. The repercussions of a declining muscle mass and function are serious if functionally important thresholds for physical independence are crossed. This usually occurs around the eighth/ ninth decades of life but much earlier in the presence of disease and much later in the presence of sustained physical activity (PA). Although sarcopenia is of complex aetiology, contributory factors may include habitual sedentarism and/or deficits in the responsiveness of muscle protein synthesis to the main drivers of muscle anabolism, namely PA and feeding, a phenomenon known as anabolic resistance. Interventions to maintain muscle mass in older people are a major priority and would be expected to result in both decreased healthcare costs and improved physical independence and quality of life. However, there are challenges: Although the most effective therapeutic treatment for sarcopenia is PA (specifically, resistance exercise training-RET), the evidence for a direct, functionally relevant hypertrophic effect of PA in older people (women in particular) is actually weak. Even when PA/ nutrition interventions are combined, for example, as in studies of RET plus protein/ essential amino acid supplementation, (a practice which results in an additive effect on muscle protein synthesis in younger adults), the resultant reported changes in muscle mass and function are contradictory although in older adults over 70 y there would appear to be little benefit compared with RET alone. That said, there are as yet relatively under-researched intervention strategies (timing and distribution of protein/ essential amino acid supplementation) bearing potential utility in improving responsiveness to PA in older age. Furthermore a number of nutraceuticals, for example, omega-3 fatty acids, beta-hydroxy-beta-methyl-butyrate and vitamin D3 have been identified with the potential also to enhance responsiveness to PA. Given the challenges to promotion of participation in PA by older adults, but encouraged by recent advances in our knowledge of how muscle mass is regulated at a molecular/ cellular level, there is much interest in the potential for pharmacological treatment of sarcopenia. The track record to date for pharmacological interventions, particularly in otherwise healthy older people, is limited. A number of novel agents with potentially therapeutic effects such as selective androgen receptor modulators (SARMs), angiotensin converting enzyme (ACE) inhibitors and activin-receptor type IIB (ActRIIB) inhibitors are currently in clinical trials. Exercise, Nutrition or Drugs? Rather than consider these 'treatments' separately, there is a case for multi-modal intervention strategies designed to optimize muscle responsiveness, maintain muscle mass and combat sarcopenia in older people.

IS-BN01 Maximizing wheeling performance! *

MAXIMIZING WHEELING PERFORMANCE! WHEELCHAIR TRAINING: WHAT IS THE IDEAL STRATEGY AND PROGRAMME?

Goosey Tolfrey, V.

Loughborough University

Although the locomotion for daily wheelchair ambulation and sports involves a repetitive cyclic movement pattern which may be considered similar to that of cycling, running, or swimming, the training principles are not directly transferrable. The wheelchair athlete uses a considerably smaller amount of muscle mass which is dependent upon their disability and/or functional capacity. Generally the higher the spinal cord injury (SCI) the greater the functional impairment. For wheelchair athletes, who regularly take part in competitive sports this intriguing complex model continues with noticeable hypertrophy in the upper extremities and muscle atrophy below the level of the lesion. The main issue for the coach is with the scheduling of recovery sessions and with the selection of the most suitable tools to monitor the volume of training, as repetitive upper-limb movements are associated with shoulder complaints and degeneration. That said, regardless of disability, from a physical foundation, it is imperative to develop and/or maintain the components of fitness, and there is strong evidence to suggest that wheelchair athletes gain similar training adaptations to the able-bodied (AB) through aerobic and anaerobic conditioning. In order to develop and implement safe and effective training programmes an understanding of the nature and onset of the physical disability and indeed the exercise modality is essential. This presentation will focus on the wheelchair athlete to illustrate the differences and similarities between Olympic and Paralympic sports knowledge via four key areas; i) describe a selection of the key training modalities available to the wheelchair athlete; ii) discuss how the training prescription for the AB may be challenged in terms of its use for wheelchair athletes; iii) discuss how the tools for quantifying training load can be applied; and iv) conclude with whether an ideal upper extremity training strategy actually exists for wheelchair athletes. The presentation will provide examples of the most common training modes for the wheelchair athlete (i.e., arm crank ergometry, hand-cycling, over-ground and/or ergometer based wheelchair propulsion). I will discuss how going back to basics for exercise prescription (using RPE) may be just as effective as using sophisticated technological measures such as power meters. The presentation aims to address to a broad audience interested in wheelchair propulsion in general but especially in Paralympic sports.

FITTING THE WHEELCHAIR TO THE ATHLETE

van-der-Woude, L., de-Groot, S.

University of Groningen, University Medical Center Groningen

Upper body exercise capacity is considerably lower compared to lower body capacities, simply due to the lower muscle mass, and the more complex functional anatomy of the shoulder and wrist complexes. In addition, the upper body is often less trained and skilled in wheeled mobility and sports-specific tasks. In the context of optimum wheelchair sports performance and considering the limited physical resources and the concomitant upper body vulnerability, optimization of the individual wheelchair-user combination is crucial. Other than optimizing sports-specific work capacity and reducing mechanical losses from the wheelchair, this involves the detailed fine-tuning of the wheelchair to the user, i.e. the ergonomics of the wheelchair-athlete interface (Mason et al 2013). Fitting the final details of the wheelchair to the individual athlete is highly specialized, yet little documented, work and dominated by unique skills of the manufacturer or the sports wheelchair specialist. This skilled knowledge is to a large extent linked to the person of the AT specialist and hardly founded in congruent scientific theory (van Breukelen 2013). The scientific work done on the ergonomics of sports wheelchair fitting gives us different, yet somewhat limited leads towards optimization, based on a set of diverse often lab-based studies with variable groups of subjects, often able-bodied (Mason et al 2013). Self-evident elements like propulsion mechanism, seat height/position, handrim size, tube diameter and profile, and wheel camber have been dealt with in small sample experiments, using diverse methodologies. The major developments in wheelchair design, posture and fitting over the past 50yrs were empirically-based athlete and small industry-driven innovations (Sports 'n Spokes), followed by a limited research evidence. With the help of the power balance model, different elements of the wheelchair-user combination can be evaluated in a combined framework of biomechanical and exercise physiological theories. The use of wheelchair and sport-specific measurement technologies, e.g. instrumented wheels with ambulant physiology and motion sensor technology, both in lab and field-based experiments, allows evaluating individual performance characteristics in dependence of wheelchair design and fitting. In a standardized repeated measures design this can help the individual athlete reach maximum performance (De Groot et al 2014), assuming knowledgeable support staff. THE PERFECT WHEELCHAIR

Vaslin, P.

Blaise Pascal University - Clermont University

Introduction Instead of giving a list of definitive assertions, this lecture will rather try to answer the question: 'Does the perfect manual wheelchair (MWC) exist?' Sport MWC can be compared to each other from their wheeling performance, their stability, their manoeuvrability and the materials used for their construction. From the studies that have evaluated these criteria, it is possible to list the features needed by different sport MWC. Material & Methods Wheeling performance of a manual wheelchair depends on several factors that have been experimentally evaluated in scientific and clinical conditions (van der Woude et al. 1986, Kwarcia et al. 2009, Sauret et al. 2012). Static stability depends on numerous factors that have been studied in various experimental conditions (Cooper et al. 1994, Kirby & Dupuis 1999) but have not yet been gathered into a complete mechanical model (Tomlinson 2000). Manoeuvrability can be defined as the MWC properties to tilt easily backwards and to turn quickly on the spot. Whereas the first one has been indirectly evaluated (Kirby & Dupuis 1999), the second one has been rarely studied (Chénier et al. 2014). Like in most instrumented sports, building materials of sport MWC have evolved from wood to composite materials, which have different mechanical properties that can enhance sport MWC features. Results Wheeling performance depends on wheels radii, vertical loads on the wheels, fore-aft distribution of the total load, and rolling resistance parameters. Static stability depends on the position of the centre of mass (COM) of the {User+MWC} system with respect to front and rear wheels axles, the distribution of the total mass between front and rear wheels, and wheels radii. Manoeuvrability: The User's and the system COM should be located near the middle of rear wheels centres and MWC wheelbase should be reduced. Materials used in sports MWC present advantages and drawbacks with respect to the aims and constraints of sport practices. Discussion Although 'The perfect wheelchair' does not yet exist, several mechanical parameters presented and analysed here can be looked for, combined and enhanced on specific MWC designed for a particular sport practice, in order to allow the User to achieve the best performance. 15:00 - 16:30**Invited symposia****IS-PM01 Asthma in the athletes *****MECHANISMS OF ASTHMA DEVELOPMENT IN ELITE ATHLETES**

Carlsen, K.H.

Oslo University Hospital; University of Oslo and Norwegian School of Sport Sciences

Asthma is often found in endurance athletes with epithelial damage reported as first step in asthma development (1-3). Airways inflammation increases after a competitive season (4) contributing to BHR of endurance athletes (5). Athletes are exposed to environmental pollution during performance (6). Increased parasympathetic tone is observed in endurance athletes (7), with the following hypothesis of athlete's asthma proposed (8): With daily training and frequent competitions with increased ventilation, damage occurs to the respiratory epithelium, probably as first step in asthma development. Due to daily training sessions with increased ventilation, healing is delayed. Inflammation, neutrophilic or eosinophilic, dependent upon atopic phenotype occurs with BHR and airway symptoms. Also, endurance training increases parasympathetic activity and bronchial tone, contributing to increased BHR. Also, some sports are performed in envi-

ronments with exposures as cold air inhaled by winter athletes, organic chlorine compounds in swimming pools, ultrafine particles in ice and traffic air pollution for cyclists. Thus many stimuli contribute to increased BHR, increased airways inflammation and bronchoconstrictor tone. Thus BHR and asthma symptoms may occur, measured objectively by bronchial responsiveness, such as metacholine bronchial challenge or tests for exercise induced asthma. 1. ASTHMA IN ATHLETES

Bonsignore, M.

University of Palermo

Asthma in athletes does not prevent excellence in performance, as shown by several asthmatic Olympic medallists in both winter and summer sports. However, treatment of the disease may interfere with the life of the athletes, since some of the drugs used to manage asthma are forbidden by doping legislation or require strict medical assessment for prescription in athletes. As for diagnosis, classic allergic asthma may be more frequent in summer sports athletes due to increased allergen exposure during intense exercise. Some athletes show asthma with specific sport-related features, the best known examples being ski asthma and asthma in swimmers, which show clinical and pathological alterations believed to be triggered by environmental factors rather than allergen exposure. In addition, many athletes report exercise-induced respiratory symptoms without any evidence of alterations when challenged in the laboratory, or may develop exercise-induced bronchoconstriction possibly secondary to insufficient conditioning of inspired air during intense effort without being asthmatics according to the usual medical definition. In our laboratory, we have studied both airway cell composition and bronchial reactivity in amateur runners. Our studies in nonasthmatic athletes have shown that endurance exercise causes mild, self-limited inflammation associated with damage of bronchial epithelial cells. In addition, such changes are not associated with increased bronchial reactivity. On the contrary, bronchial reactivity tends to decrease with moderate training in both normal subjects and asthmatic patients. Unfortunately, data on airway cells in elite athletes are still limited. Overall, volume and intensity of exercise appear important modulating factors of airway cell and reactivity. Recent data point to subtle changes in immune function caused by intense exercise, which may adversely affect both systemic and airway responses.

DIAGNOSIS AND TREATMENT OF ASTHMA IN ATHLETES

Backer, V.

Bispebjerg University hospital

Asthma is frequently found among elite athletes performing endurance sports such as swimming, rowing and cross-country skiing. Asthma is characterised by respiratory symptoms during both rest and exercise, airway inflammation as well as AHR to multiple agents. Although these athletes often report symptoms while exercising, they seldom have symptoms at rest. Shortness of breath during exercise could be caused by asthma, but other conditions and diseases might induce exercise-induced respiratory symptoms, e.g. low physical fitness, laryngeal disorders, hyperventilation syndrome, and cardiac illnesses too. Although laryngeal disorders induce inspiratory shortness of breath, often during exercise, these disorders are frequently misclassified as asthma in elite athletes. Moreover, compared with non-athletic, asthmatic individuals, elite athletes have been shown to have a different distribution of airway inflammation and unequal response to bronchial provocative test. Elite athletes should undergo comprehensive assessment to confirm an asthma diagnosis and determine its degree of severity. Treatment should be as for any other asthmatic individual, including the use of beta2-agonist, inhaled steroid and leukotrien-antagonist, due the asthma severity classified in the guidelines. It should, however, be noted that daily use of beta-agonists could expose elite athletes to the risk of developing tolerance towards these drugs. Use of beta2-agonist should be replaced with daily inhaled corticosteroid treatment, the most important treatment of exercise-induced asthma. All treating physicians should be aware of the doping aspects. Systemic beta2-agonist intake is strictly prohibited, whereas inhaled treatment is allowed in therapeutic doses when asthma is documented and dispensation has been granted when needed.

OP-PM01 Muscle Protein Synthesis & Balance

RELATIONSHIPS BETWEEN LONG-TERM MUSCLE PROTEIN SYNTHESIS AND HYPERTROPHY IN RESPONSE TO RESISTANCE EXERCISE TRAINING: A NOVEL D2O TRACER APPROACH

Brook, M.S., Wilkinson, D.J., Franchi, M., Narici, M.V., Szewczyk, N.S., Greenhaff, P.L., Smith, K., Atherton, P.J.

University of Nottingham

Introduction: Muscle hypertrophy in response to resistance exercise training (RET) is underpinned by cumulative post-exercise increases in muscle protein synthesis (MPS). Many recommendations for optimizing hypertrophy have been derived from the use of short-term (e.g. <5h) stable isotope tracer measurements e.g. designation of optimal exercise paradigms, nutrient quantity/timing/composition. However,

er, such acute measures have poor predictive capacity for hypertrophy (1). Here, we developed a D2O tracer approach to quantify long-term MPS and explore links between "real-life" MPS and muscle mass/function in response to RET. Methods: 8 (23±1y) men undertook 6-wks unilateral RET: 6×8 reps, 75%-1RM 3/wk-1 (i.e. one leg untrained (UT) time-control and contralateral RET leg) with MVC and 1-RM assessed to progress training loads. DXA scans (0/6-wk) and Vastus lateralis (VL) ultrasound measures were taken at 0/3/6-wk. After bilateral baseline VL biopsies, subjects consumed 150 ml D2O (70-Atom%) and then 50ml/wk-1 to maintain a pseudo steady-state. Saliva was collected to monitor body water enrichment via TC/EA-IRMS and bilateral VL biopsies taken at 3/6-wk to assess MPS via GC-Pyrolysis-IRMS, where: $MPS = (\% / d) = -\ln((1 - [APEA]_0 / [APEA]_t) / t) \times 100$ (2). Paired t-tests or 1-way ANOVA were applied as appropriate with $P < 0.05$ considered significant. Results: After 6-wks RET, 1-RM increased: $54 \pm 3\text{Kg}$ to $72 \pm 6\text{Kg}$ ($P < 0.01$) as did MVC at all joint angles e.g. 229 ± 24 to $290 \pm 25\text{Nm}$ at 60° ($P < 0.01$). DXA-derived increases in quadriceps mass 0-6-wks: 5782 ± 273 to 6017 ± 324 ($P < 0.05$) were accompanied by increases in VL thickness: ($+9 \pm 2\%$ and $13 \pm 2\%$), fascicle length ($6 \pm 2\%$ and $6 \pm 2\%$) and pennation angle ($8 \pm 3\%$ and $9 \pm 2\%$), at 3 and 6-wks, respectively (all $P < 0.05$). None of these changes in the RET leg differed 3 vs. 6-wks, while in the UT leg, both mass and functional parameters remained unchanged from baseline. MPS remained constant in the UT leg: $1.25 \pm 0.06\% \cdot d^{-1}$, $1.29 \pm 0.06\% \cdot d^{-1}$, and $1.29 \pm 0.07\% \cdot d^{-1}$ 0-3, 3-6 and 0-6-wks, respectively. In contrast, the RET leg exhibited greater MPS 0-3 ($1.51 \pm 0.09\% \cdot d^{-1}$; $P < 0.05$ vs. UT) but not 3-6 ($1.15 \pm 0.14\% \cdot d^{-1}$) or 0-6-wks ($1.36 \pm 0.06\% \cdot d^{-1}$), consistent with geometric adaptations tailing off after 3-wks RET. Discussion: Consistent with previous work (3), our data show muscle remodeling to be most active during the early stages of RET. Since this was also reflected in long-term measures of MPS, application of the D2O tracer heralds great promise e.g. for predicting muscle hypertrophy responses and for more objectively assessing effective strategies to maximize hypertrophy/mitigate atrophy. 1. Churchward-Venne et al. PLoS One, 2014 in press 2. Wilkinson et al. AJP 2013 in press 3. Seynnes et al. JAP 2007 Jan;102(1):368-73

NEUROMUSCULAR ELECTRICAL STIMULATION PREVENTS SKELETAL MUSCLE FIBER ATROPHY IN FULLY-SEDATED ICU PATIENTS

Dirks, M.L.

Maastricht University Medical Centre + (MUMC+)

BACKGROUND: Fully-sedated patients, being treated in the Intensive Care Unit (ICU), experience substantial skeletal muscle loss. As a consequence, their survival and an eventual recovery after awakening are compromised. Neuromuscular electrical stimulation (NMES) represents a successful strategy to alleviate muscle loss in healthy subjects during a period of immobilization or in patients during a period of bed-rest. **AIM:** To investigate the efficacy of twice-daily NMES to alleviate muscle loss in fully-sedated ICU patients. **METHODS:** Six fully-sedated patients admitted for acute critical illness ($n=3$ males, $n=3$ females; age 63 ± 6 y; APACHE score (a severity-of-disease score and predictor of mortality): 29 ± 2) were included. One leg was subjected to NMES (40 min per session) of the quadriceps muscle twice daily for a period of 7 ± 1 d while the other leg acted as the non-stimulated control (CON). Directly before the first NMES session and on the day after the final session, muscle biopsies were collected from both legs to assess muscle fiber-type specific cross-sectional area (CSA) and myocellular characteristics. Furthermore, the phosphorylation status of key proteins involved in the regulation of muscle protein synthesis was assessed, and the mRNA expression of selected genes involved in muscle protein breakdown was measured. **RESULTS:** In the CON leg, muscle fiber CSA had decreased by 16 ± 9 and $24 \pm 7\%$ in type I and II fibers, respectively ($P < 0.05$). In contrast, no decline in either type I or type II muscle fiber CSA was observed in the stimulated (NMES) leg. No differences were observed in muscle fiber type specific myonuclear content, myonuclear domain size or satellite cell content between legs or over time. The phosphorylation state of Akt and P70S6K did not change over time or between legs. However, NMES increased mTOR phosphorylation by 19% when compared to baseline values ($P < 0.05$), whereas no changes were observed in the CON leg. Furthermore, mRNA expression of key genes involved in muscle protein breakdown either declined (FOXO1; $P < 0.05$) or remained unchanged (MAFBx and MuRF1) following the intervention, with no differences between the CON and NMES leg. **CONCLUSION:** NMES represents an effective and feasible interventional strategy to prevent skeletal muscle wasting in critically ill, comatose patients. NMES can be applied to offset negative consequences of muscle wasting and, as such, may increase survival and improve subsequent rehabilitation.

LEUCINE ENRICHED PROTEIN FEEDING DOES NOT IMPAIR EXERCISE-INDUCED LIPID OXIDATION: IMPLICATIONS FOR TRAINING IN CARBOHYDRATE RESTRICTED STATES

Impey, S.G.1, Owens, D.J.1, Bartlett, J.D.1, Smith, K.2, Close, G.L.1, Morton, J.P.1

1: Liverpool John Moores, 2: University of Nottingham

Introduction Training with reduced carbohydrate (CHO) availability augments skeletal muscle oxidative adaptations, an effect that may be mediated via free fatty acid (FFA) signalling (Hawley and Morton, 2014). However, a negative effect of CHO restriction during training is increased skeletal muscle protein breakdown (Howarth et al. 2010). A potential solution to overcome the latter is increased protein provision (especially leucine rich protein) so as to promote protein synthesis (Churchward-Venne et al. 2013) though this strategy may be limited in that elevated insulin associated with protein feeding may actually attenuate lipolysis thereby negating FFA mediated signalling. The aim of the present study was therefore to test the hypothesis that leucine enriched protein feeding enhances circulating amino acid availability but does not impair lipid oxidation during exercise despite elevated insulin levels. **Method** Nine male cyclists performed 2 hours of cycling at 70% $\dot{V}O_{2\text{peak}}$ in fasted conditions (PLACEBO) or having consumed a whey protein isolate solution (WHEY) or a leucine enriched protein gel (GEL), administered as 20g 1 hour before, 10 g/h during and 20 g thirty minutes after exercise. Total leucine administration was 11.4 g and 4.6 in GEL and WHEY, respectively. Primary and secondary outcome variables were plasma FFA availability and rates of lipid oxidation during exercise, respectively. Results Mean plasma leucine concentrations during the 5 h collection period were elevated in GEL ($P = 0.001$) compared with WHEY and PLACEBO (375 ± 100 , 272 ± 51 , $146 \pm 14 \mu\text{mol} \cdot \text{L}^{-1}$ respectively). No differences ($P = 0.153$) in plasma FFA (WHEY 0.53 ± 0.30 , GEL 0.45 ± 0.25 , PLACEBO 0.65 ± 0.30 , $\text{mmol} \cdot \text{L}^{-1}$) were apparent between trials during exercise, despite elevated ($P = 0.001$) insulin in WHEY and GEL compared with PLACEBO (38 ± 16 , 35 ± 16 , $22 \pm 11 \text{pmol} \cdot \text{L}^{-1}$ respectively). Accordingly, whole body rates of lipid (WHEY 0.37 ± 0.26 , GEL 0.36 ± 0.24 , PLACEBO $0.34 \pm 0.24 \text{g} \cdot \text{min}^{-1}$) oxidation were not different ($P = 0.955$) between conditions. Discussion Leucine enriched protein feeding does not impair FFA availability or whole body rates of lipid oxidation during exercise. Data have practical applications for those athletes who deliberately train in CHO restricted states given that high leucine availability promotes protein synthesis and that high rates of lipid oxidation is one of the main aims of CHO restriction. BASAL AND POST-PRANDIAL PROTEIN SYNTHESIS RATES ARE NOT IMPAIRED IN OLDER TYPE 2 DIABETES PATIENTS WHEN COMPARED WITH HEALTHY AGE-MATCHED CONTROLS

Kouw, I., Gorissen, S.H.M., Burd, N.A., Cermak, N.M., Gijsen, A.P., van Kranenburg, J., van Loon, L.J.C.
Maastricht University

Introduction: The progressive loss of skeletal muscle mass that occurs with aging seems to be accelerated in a type 2 diabetic state (Leenders et al., 2013). This may be attributed to impairments in basal and/or post-prandial protein metabolism. The present study tested the hypothesis that the whole body and muscle protein synthetic response to the ingestion of a meal-like amount of dietary protein is reduced in type 2 diabetic elderly when compared with age-matched, normoglycemic controls. **Methods:** Twelve healthy, normoglycemic elderly males (CON) and twelve age-matched type 2 diabetes patients (DM) participated in the current experiment. Primed continuous intravenous infusions with L-[ring-2H5]-phenylalanine were combined with the ingestion of 20 g specifically produced intrinsically L-[1-13C]-phenylalanine labeled dietary protein. Blood and muscle samples were taken at regular intervals to assess whole body amino acid kinetics and muscle protein synthesis rates in the postabsorptive and postprandial state. **Results:** Plasma insulin concentrations increased significantly following protein ingestion in both groups, with a greater increase in the DM compared with CON group ($P < 0.001$). Exogenous phenylalanine appearance rates increased following protein ingestion in both groups ($P < 0.001$), with no differences between groups. Whole body protein synthesis rates increased from 0.57 ± 0.02 to 0.63 ± 0.02 μmol phenylalanine-kg $^{-1}$ -min $^{-1}$ (CON) and from 0.55 ± 0.01 to 0.59 ± 0.014 μmol phenylalanine-kg $^{-1}$ -min $^{-1}$ (DM) in the post-absorptive to post-prandial state ($P < 0.001$), with no differences between groups. Postprandial muscle protein accretion and muscle protein synthesis rates are presently being assessed by determining the incorporation of L-[1-13C]-phenylalanine and L-[ring-2H5]-phenylalanine into muscle protein in the collected muscle biopsy samples. **Discussion:** Following protein ingestion, diet-derived plasma amino acid availability and whole body protein synthesis rates did not differ between elderly individuals with type 2 diabetes and age-matched, normoglycemic controls. We conclude that basal and post-prandial (whole-body) protein synthesis rates are not reduced in a type 2 diabetic state.

FISH OIL SUPPLEMENTATION ALTERS P70S6K1 ACTIVITY IN RESPONSE TO RESISTANCE EXERCISE AND PROTEIN FEEDING WITHOUT INFLUENCING MYOFIBRILLAR PROTEIN SYNTHESIS IN HUMANS

McGlory, C.1, Wardle, S.L.1, Macnaughton, L.S.M.1, Scott, F.1, Witard, O.C.1, Dick, J.1, Bell, J.G.1, Phillips, S.M.2, Hamilton, D.L.1, Galloway, S.D.R.1, Tipton, K.D.1

INTRODUCTION n-3 PUFA-enriched fish oil (FO) supplementation potentiates muscle protein synthesis (MPS) and mTOR-p70S6K1 phosphorylation in response to a hyperaminoacidemic-hyperinsulinemic infusion. However, whether FO supplementation potentiates MPS and kinase activity in response to protein ingestion or when protein ingestion is combined with resistance exercise (RE) remains unknown. Thus, the aim of this study was to address these questions. **METHODS** In a randomised design, 20 healthy males (age: 23 ± 0.6 y; body mass 83 ± 2 kg; > 6 mo RE training) were separated into two groups then supplemented with 5g.d $^{-1}$ of either FO or coconut oil control (CO) for 8 wks. After supplementation, participants performed a bout of unilateral RE followed by ingestion of 30g of whey protein. Skeletal muscle biopsies were obtained before and after (REST) supplementation as well as from both legs post RE (POST EX; POST REST) and 3h post RE plus protein ingestion (3h POST EXFED; 3h POST FED) for assessment of changes in lipid composition, MPS using L-[ring-13C6]-phenylalanine and kinase activity using (γ -32P) ATP (McGlory et al., in press). **RESULTS** In response to supplementation the skeletal muscle n-3 PUFA composition was significantly increased in the FO group (5.53 ± 0.30 to $11.16 \pm 0.45\%$ of total fatty acids) but was unchanged in the CO group. Supplementation significantly decreased panPKB activity at REST in the FO group (12.5 ± 2.6 to 8.2 ± 1.6 mU/mg) but not the CO group. There was a significant increase from REST at POST EX for panPKB (17.0 ± 2.0 to 27.7 ± 5.7 mU/mg) and AMPK α 2 (3.6 ± 0.6 to 9.8 ± 1.2 mU/mg) activity in the CO group but not in the FO group. At 3h POST EXFED there was a significant increase in p70S6K1 activity from REST in the CO group only (5.6 ± 1.4 to 12.2 ± 2.1 $\mu\text{U/mg}$). In response to RE plus protein ingestion MPS was significantly elevated above REST in both the FO (0.025 ± 0.002 to 0.091 ± 0.003 %h $^{-1}$) and CO (0.024 ± 0.001 to 0.077 ± 0.06 %h $^{-1}$) groups but there was no effect of supplementation. In response to protein ingestion alone there was a significant increase in MPS in both groups above REST (0.025 ± 0.002 to 0.076 ± 0.051 %h $^{-1}$ [FO]; 0.024 ± 0.001 to 0.056 ± 0.005 %h $^{-1}$ [CO]) but no effect of supplementation. **DISCUSSION** These data highlight that 8 wk of n-3 PUFA-enriched fish oil supplementation alters p70S6K1 activity in response to RE plus protein ingestion without influencing MPS. **REFERENCES** McGlory C, et al. HIGH-INTENSITY CYCLING PERFORMED PRIOR TO RESISTANCE EXERCISE DOES NOT INFLUENCE MTORC1-SIGNALING AND THE RATE OF MUSCLE PROTEIN SYNTHESIS IN THE TRICEPS BRACHII

Moberg, M., Apró, W., Ekblom, B., Blomstrand, E.

The Åstrand Laboratory

Introduction Endurance exercise can influence strength training adaptations when performed concurrently, with both inhibition (Kreamer 1995) and augmentation (Lundberg 2012) of muscular hypertrophy being reported. Our lab has set out to conduct a series of studies to examine the influence of endurance exercise on the acute stimulatory effect of resistance exercise on anabolic processes. In the present study, the effect of endurance exercise on a previously inactive muscle was investigated. The aim was to examine the influence of resistance exercise on mTORC1-signaling and rate of protein synthesis in the triceps brachii muscle with or without preceding intervals of high-intensity cycling. **Methods** Eight trained males performed, in a randomized fashion, two sessions of heavy resistance exercise (RE) with the triceps muscles, where one session was preceded by intervals of high-intensity cycling (E+RE), 5 x 4 min at 85% of VO $_2$ peak. Mixed muscle protein fractional synthetic rate (FSR) was measured at rest, prior to exercise, and during a 3 hour recovery period following exercise by continuous infusion of L-[ring-13C6] phenylalanine. Muscle biopsies from the triceps brachii was collected twice at rest separated by three hours, directly after resistance exercise and following 90 and 180 min of recovery. Signalling in the mTORC1- and AMPK-pathway was assessed using western blot technique. **Results** The same amount of work with regard to load, total number of repetitions and total time under tension was performed in the two trials. Muscle protein FSR increased from 0.050 ± 0.006 %/h at rest to 0.078 ± 0.008 and 0.082 ± 0.0016 %/h following E+RE and RE, respectively, with no difference between trials. Phosphorylation (P) of AMPK T172 was increased by 45-65% directly after exercise, similarly in both conditions, and regressed to a level approx. 20% lower than baseline following 180 min of recovery. P-mTOR S2448 was increased 76 and 108% above rest directly after the E+RE and RE, respectively, and remained elevated in both trials during the entire recovery period. P-eEF2 T56 was 20-36% higher directly after exercise but fell to a level that was 30-36% lower than pre-exercise and remained reduced during the entire recovery, with no difference between trials. **Conclu-**

sion High-intensity endurance cycling does not influence the acute stimulation of anabolic signalling and muscle protein synthesis in the triceps brachii following resistance exercise. MUSCLE-SPECIFIC HYPERTROPHY OF SYNERGISTIC MUSCLES IN COMPETITIVE CYCLISTS

Ema, R.^{1,2}, Wakahara, T.³, Yanaka, T.¹, Konda, S.¹, Kanehisa, H.⁴, Kawakami, Y.¹

1: Waseda University (Tokorozawa, Japan) 2: JSPS Research Fellow (Japan) 3: Doshisha University (Kyotanabe, Japan) 4: National Institute of Fitness and Sports in KANOYA (Kanoya, Japan)

Introduction It has been shown that joint power at the hip and knee contributes to pedaling power (Elmer et al. 2011), suggesting that muscles around the two joints are the major power source of a pedaling motion. However, detailed knowledge of cycling training-induced muscular hypertrophy is scarce. Our study (Ema et al. in press) suggested that the training with simultaneous extensions of the knee and hip joints induces muscle-specific hypertrophy of the quadriceps femoris (vasti increase in volume whereas the rectus femoris does not). A similar hypertrophic response associated with the difference in the anatomical features (biarticular or monoarticular nature) has been observed among the triceps brachii as a result of multijoint dumbbell press training (Wakahara et al. 2013). Based on these findings, it was hypothesized that 1) regular training of competitive cycling induces muscle-specific hypertrophy of hip and knee synergistic muscles, and 2) the muscle-specificity in hypertrophic responses is related to the difference in the anatomical features of these muscles. We tested these hypotheses with a longitudinal observation of competitive cyclists. **Methods** T1-weighted magnetic resonance images (slice thickness: 1 cm) of the trunk and thigh were obtained from 12 varsity cyclists (10 males, 2 females; experience: 0.1 - 10.7 yr) twice (6 months in-between; cycling training: 15 hours per week on average). From the images, the volumes of each muscle of the quadriceps femoris, hamstring and psoas major were determined. **Results and Discussion** A two-way analysis of variance showed a significant time x muscle interaction for the muscle volume ($P < 0.001$). The regular training of competitive cycling induced significant gains in the volumes of the vastus lateralis ($4.0 \pm 2.4\%$), vastus medialis ($2.9 \pm 1.9\%$), vastus intermedius ($3.2 \pm 2.8\%$), biceps femoris short head ($3.1 \pm 3.1\%$), semitendinosus ($3.0 \pm 3.5\%$) and psoas major ($4.8 \pm 2.8\%$). On the other hand, the volumes of the rectus femoris, biceps femoris long head and semimembranosus remained unchanged. These results support the first and partly the second hypothesis. It is suggested that the muscle-specificity in hypertrophic responses to the competitive cycling training is linked to the differences in the number of joints that the muscles cross, with one exception in the hamstring. **References** Elmer SJ, Barratt PR, Korff T, Martin JC. INTER-DANCER DIFFERENCE IN MUSCLE ACTIVITIES AT JOINT PHASE TRANSITION DURING TIPTOE STANDING IN CLASSICAL BALLET

Tanabe, H.

Kyoto University

Introduction We have previously demonstrated the joint coordination of entire trial length during tiptoe standing for ballet dancers. However, it is necessary to investigate the temporal change of muscle activities and accompanying phase transition to reveal the neuromuscular mechanism underlying the joint fluctuation during standing. Thus, we aimed to investigate the contributions of muscle activities to the adjacent joints' phase transitions during tiptoe standing in ballet dancers. **Methods** Seven female ballet dancers performed tiptoe standing with three kinds of ballet specific foot positions (1st, 5th, and 6th positions) for 10s, during which kinematics data of metatarsophalangeal (MP), ankle, knee, and hip and surface electromyograms (EMG) over 12 lower limb muscles were recorded. Next, we calculated the phase difference between adjacent joints' angular displacements in sagittal plane (that is, MP-ankle (M-A), ankle-knee (A-K), knee-hip (K-H)) by Hilbert transformation and detected the time when each phase difference changes from in- to anti- phase (A) or from anti- to in- phase (B). We created a phase distribution map and also numbered the phase transition across each 10s trial. Then we computed the cross-correlation between the phase difference and EMG data at the detected time of phase transition. Mean values of cross-correlation for all events during each foot position were calculated for each participant, joint pair, and the phase transition pattern (A or B). We focused on its peak of lag > 100 ms to detect the muscle activities prior to phase transitions. **Results** The M-A and A-K phase difference were distributed around 0 or 2π (however it varied more widely for ankle-knee phase). On the other hand, K-H phase difference did not show specific tendency. The mean number of phase transition during 10s trial was [1st, 5th, and 6th position] = [8.79, 10.89, 5.93], [9.86, 11.29, 10.43], and [11.57, 7.07, 9.36] times for M-A, A-K, K-H coordination, respectively. The peak and its lag of cross-correlation between phase transition and EMG was dependent on the dancers and leg positions. For example, MP-ankle phase transition from anti to in-phase during 1st position was generated by the activation of five muscles around these joints for dancer 5. Also, knee-hip phase transition during 6th position had no relationship with muscle activation or attenuation for dancer 7. **Discussion** Our results showed that distal joint coordination tended to have in-phase fluctuations and that the phase transition tended to increase when uncustomed position (6th position is not frequently used in ballet). Also, phase transitions in ballet dancers' joint coordination were mostly accompanied by muscle activations or attenuation. The muscle activities that affect the phase transition and the time lag between them were dancer-specific. In this study, it was suggested that phase transition between adjacent joints' angular displacements could be generated by dancer-specific predictive muscle activities or attenuation.

AGE-RELATED DECREASE IN POSTURAL CONTROL IS RELATED TO DIFFERENT MODULATION IN MOTOR CORTICAL INHIBITION BETWEEN POSTURAL TASKS

Papegaaij, S.1, Taube, W.2, Hogenhout, M.1, Baudry, S.3, Hortobágyi, T.1,4

(1) University of Groningen, University Medical Center Groningen, (2) University of Fribourg, (3) Université Libre de Bruxelles, (4) Northumbria University

Background Although recent studies point to the involvement of the primary motor cortex in postural control, it is unknown if age-related changes in motor cortical circuits play a role in impaired postural control. We examined the interaction between age and postural task difficulty in cortical excitability as indexed by transcranial magnetic brain stimulation-evoked short-interval intracortical inhibition (SICI) and intracortical facilitation (ICF) during standing. **Methods** Eleven young adults (22.6 ± 1.1 years) and twelve old adults (67.8 ± 4.3 years) received single and paired pulses delivered by transcranial magnetic brain stimulation while they stood on a rigid platform or foam, with the eyes open or closed. Motor evoked potentials (MEPs) were recorded from the tibialis anterior muscle. Interstimulus intervals of 2.5 and 13 ms were used to assess SICI and ICF, respectively. **Results** There was an overall age-related 43% reduction in SICI ($p = 0.001$). SICI lessened with increased task difficulty in old (31%) but not in young (1%) adults (condition \times group interaction, $p = 0.049$). This reduction was associated with increases in center of pressure velocity when the support surface was altered ($r = -0.648$, $p = 0.043$). Age and conditions did not affect ICF ($p = 0.527$, $p = 0.325$). **Conclusions** This study extends the literature reporting on the age-related reductions in cortical inhibition during manual tasks by demonstrating similar reductions in cortical inhibition during postural tasks. Moreover, it demonstrates that motor cortical circuits control upright posture differently in old vs. young adults. Future experiments will clarify whether this difference in control mediates impaired postural control or serves as a compensatory mechanism to counteract postural instability in old age.

DOES METABOLITE ACCUMULATION PER SE ENHANCE EXERCISE-INDUCED MUSCLE HYPERTROPHY?

Madarambe, H., Nakada, S., Ohta, T., Ishii, N.

The University of Tokyo

Introduction Metabolic stress has been considered one of the primary factors in exercise-induced muscle hypertrophy, because many studies show greater muscle hypertrophy after a period of resistance training with greater production and/or accumulation of metabolites (Schoenfeld, 2013); however, its mechanism has not been elucidated. Given that metabolite accumulation has a causal relationship with additional hypertrophy, it still remains unclear whether the additional hypertrophy is caused by metabolite accumulation per se or by an interaction between metabolite accumulation and concomitant muscle contractions. In addition, since metabolite accumulation causes endocrine responses via muscle metaboreflex (Inagaki et al., 2011), it is uncertain whether its hypertrophic effect, if any, is local or systemic. We therefore aimed to investigate whether metabolite accumulation per se enhances exercise-induced muscle hypertrophy. **Methods** Eight men completed an 8-wk resistance exercise (RE) program for knee extensor muscles. In order to accumulate metabolites after the exercise, blood flow restriction was applied after (not during) the exercise (post-exercise blood flow restriction, PEBFR). Employing a within-subject design, one limb was subjected to RE + PEBFR, whereas the contralateral limb to RE only. On each exercise session, subjects performed 3 sets of unilateral knee extension exercise at 70% of 1RM for RE limb first, and then performed 3 sets for RE + PEBFR limb. Immediately after the exercise session, the proximal portion of the RE + PEBFR limb was compressed with an air-pressure cuff for 5 min. Muscle thickness (MTH) and 1RM of knee extensors were measured before and after the 8-wk intervention period. The data were analyzed with a two-factor (condition \times time) repeated measures ANOVA. **Results** There were significant main effects of time but no condition \times time interactions for MTH and 1RM. MTH and 1RM increased significantly after the 8-wk intervention period independent of the condition. **Discussion** Applying PEBFR had no additional effect on muscle hypertrophy, indicating that metabolite accumulation per se does not enhance exercise-induced muscle hypertrophy. This result suggests the following possibilities: (a) no causal relationship would exist between metabolite accumulation and exercise-induced muscle hypertrophy, or (b) an interaction would exist between metabolite accumulation and muscle contractions; concomitant muscle contractions are essential for metabolite accumulation to cause additional hypertrophy, or (c) hypertrophic effect of metabolite accumulation, if any, would not be local but systemic. **References** Inagaki Y, Madarambe H, Neya M, Ishii N. INJURIES TO PROFESSIONAL AND AMATEUR KICKBOXING CONTESTANTS

Lystad, R.P.

Macquarie University

Introduction Kickboxing, in the wider sense of the term, is a group of predominantly Japanese, South-East Asian, and Western full-contact combat sports that allow both kicking and punching from a standing position. Despite its popularity, there appears to be a scarcity of published data elucidating the injury epidemiology in both professional and amateur kickboxing contestants. Thus, the objectives of this study were to: determine the injury incidence, describe the injury pattern, and identify potential risk factors for injury. **Methods** Data describing all fight outcomes and injuries sustained during professional and amateur kickboxing contests over a 13-year period (ie, from January 2000 to December 2013, inclusive) were obtained from the official records of the Nevada State Athletic Commission in the United States. The injury incidence rate (IIR) was calculated both per 1000 exposures and per 1000 exposure-minutes using standard methods. Injuries were classified according to the Orchard Sports Injury Classification System, version 10, and presented as proportions by anatomical region and type of injury. Rate ratios (RR) were calculated with 95% confidence intervals (CI) to identify potential risk factors. **Results** The sample consisted of 448 unique fighters competing across 51 events, 906 exposures, 8265 exposure-minutes, and 355 injuries. The mean age of the fighters was 29.1 years (sd 5.4; range 15-48). The overall IIR were 391.8 (95%CI 352.1-434.8) per 1000 exposures and 43.0 (95%CI 38.6-47.7) per 1000 exposure-minutes. The most commonly injured anatomical regions were the head (57.3%) and lower extremity (26.6%), while the most common types of injury were laceration (71.5%) and fracture (20.0%). Professional fighters were two and half times more likely to get injured compared to amateurs (RR 2.54, 95%CI 1.40-4.59), while losing fighters were three and half times more likely to get injured compared to winners (RR 3.47, 95%CI 2.70-4.47). **Discussion** This study revealed an IIR that was greater than previous reports of injuries in kickboxing (Zazryn et al, 2003), as well as in other popular combat sports such as mixed martial arts (Lystad et al, 2014). The proportion of head injuries in kickboxing is comparable to that than in professional boxing, but greater than that in other combat sports. The scarcity of epidemiologic data in kickboxing, especially in regard to the severity of injuries, underscores the urgent need for more research, whereupon evidence-informed decisions concerning the sport can be made. **References** Lystad RP, Gregory K,

DOES PRE-EXERCISE STATIC STRETCH INDUCES TO ACUTE IMPAIRMENTS ON THE PEAK TORQUE? AN EVIDENCE-BASED SYSTEMATIC REVIEW AND META-ANALYSIS

Andrade, R.I, Cervaens, M.I, Pereira, R.I,2, Viana, R.I, Amaral, L.I

1- University of Fernando Pessoa; 2- Clínica Espregueira Mendes - FIFA Medical Centre of Excellence - Clínica do Dragão;

Introduction: Stretching before exercise or sports practice is a common procedure. Furthermore, stretching seems to be something mandatory upon the generalized certainty it only brings positive effects. In fact, some evidence indicate that static stretching (SS) before exercise, prevents injuries (e.g., muscle strains; McHugh et al., 2010), but not all injuries (Thacker et al., 2004). Thus, pre-exercise static stretching is a growing controversy fact among the exercise and sports professionals. Therefore, the aim of this meta-analysis was to determine the acute effects of pre-exercise SS on isokinetic concentric/eccentric peak torque of lower limbs, at both slow and fast velocities. **Methods:** Systematic review in Pubmed and EBSCO (SPORTDiscus) to identify studies that assessed the effect of static stretching before exercise on peak torque, published between 2011 and 2013. The key-words used were: static stretch; static stretching; acute stretch; acute stretching; passive stretch; peak torque; with the logic operators (AND, OR). The level of evidence was assessed by Oxford Center for Evidence-Based Medicine (CEBM) scale and the methodological quality by Newcastle-Ottawa Scale (NOS). The statistical analysis used in this study was inverse variance with random effects by measuring the mean difference effect. **Results:** A total of 4 articles that studied the acute effects of pre-exercise SS on peak torque were identified. Altogether 446 individuals were included in this meta-analysis, with a respective mean difference of -5.27 [95% Confidence Interval: -9.02, -1.52; $p = 0.006$], however only on 30°/s and 120°/s eccentric and concentric peak torque showed a significant negative acute effect. The methodological quality had a mean score 7.8 ± 1.1 and the level of evidence was 2b according to NOS and CEBM, respectively. **Discussion:** This systematic review and meta-analysis provides scientific evidence of the last 3 years and showed that pre-exercise SS induced significant impairments on the peak torque, revealing a negative acute effect on muscular performance of the lower limb. Results of our meta-analytic systematic review are in line with the conclusions of several research studies that also referred a decline on the sports performance (Rubini et al., 2007; McHugh et al., 2010; Behm et al., 2011). We recommend avoiding pre-exercise SS in order to minimize the possibilities of impairments. **References** Behm et al.(2011) *Eur J Appl Physiol*, 111(11), 2633-2651. McHugh et al. OP-PM02 Alternative Exercise Training

SATELLITE CELL AND MYONUCLEAR RESPONSE TO BLOOD FLOW RESTRICTED RESISTANCE EXERCISE

Løvstad, A.1, Bjørnsen, T.2, Dalen, T.1, Paulsen, P.1, Raastad, T.1, Benestad, H.4, Wernbom, M.3

1: Norwegian School of Sport Sciences (Oslo, Norway), 2: University of Agder (Kristiansand, Norway), 3: University of Gothenburg (Gothenburg, Sweden), 4: University of Oslo (Oslo, Norway)

Introduction In a recent study Nielsen et al.,- (2012) reported that short term high frequency blood flow restricted resistance exercise (BFRRE, 21 sessions in 3 week) at 20% of 1 repetition maximum (1RM) resulted in a 150-300 % increases in satellite cells (SC) and a ~30- % increase in myonuclear number. However, the SC and myonuclear responses appeared to plateau already after one week of training and it may be speculated that a rest period can reset the responsiveness of the system after the initial training response. Thus, the purpose of the present study was to investigate the SC and myonuclear responses to two blocks of high frequency BFRRE interspersed by 10 days of rest. **Methods** Ten participants completed fourteen BFRRE sessions divided into two blocks of seven sessions in five days, separated by a 10-day rest period. The exercise protocol consisted of four sets to voluntary failure (30 seconds rest between sets) using unilateral knee extensions at 20% of 1RM. Both legs were exercised with partial blood flow restriction induced by a pressure cuff (100 mmHg; men, 90 mmHg; women). Muscle biopsies were sampled from m. vastus lateralis at baseline, four times during and two times post intervention. The muscle tissue were cut in 8 µm thick sections and stained against SC (NCAM + Laminin), myonuclei (DAPI) and fiber type (SC71+ dystrophin). Fluorescence microscope was used to quantify SC and myonuclei. **Results** No significant changes were found in the number of myonuclei in type 1 and 2 fibers after the first week of training, but after the last training block a significant increase was observed in both type 1 and 2 fibers ($28 \pm 29\%$ and $28 \pm 31\%$ respectively, $p=0.02$). No significant changes were found in the number of satellite cells in type 1 and 2 fibers after the first week of training. After the last training block a significant increase was observed in type 1 ($102 \pm 48\%$, $p<0.01$), but not in type II fibers ($26 \pm 62\%$, $p=0.35$). The mean fiber cross sectional area of type 1 and 2 fibers was unaltered after the first training block, and showed non-significant increases of $19 \pm 23\%$ ($p=0.06$) and $15 \pm 27\%$ ($p=0.2$), respectively, after the second training block. **Discussion** Although the exercise was performed similarly to Nielsen et al., (2012), both the absolute changes and the time line for the observed changes were very different in our study. Nevertheless the rest period may have been important for the late SC, myonuclear and fiber area response. **In conclusion**, myonuclear number increased significantly for both type 1 and 2 fibers in response to BFRRE. However, only type 1 fibers showed a significant increase in SC. **References** Nielsen JL, Aagaard P, Bech RD, Nygaard T, Hvid LG, Wernbom M, Suetta C and Frandsen U. STRENGTH TRAINING IMPROVES RUNNING AND CYCLING PERFORMANCE

Vikmoen, O.1, Rønnestad, B.R.1, Ellefsen, S.1, Raastad, T.2

1:Lillehammer University College 2:Norwegian School of Sports Sciences

Introduction Equivocal findings exist on the effect of adding strength training (S) to endurance training on running and cycling performance (1-4). However, the effect of S on running and cycling in the same athletes has not been investigated. Thus, the present study investigated the effects of S on running and cycling performance and muscle fiber composition in duathletes. **Methods** Nineteen females (33 ± 8 years, 64 ± 7 kg, $\text{VO}_{2\text{max}}$ cycling: 54 ± 3 ml·kg⁻¹·min⁻¹, $\text{VO}_{2\text{max}}$ running: 53 ± 3 ml·kg⁻¹·min⁻¹) were randomly assigned to either usual endurance training combined with S (E+S, n=11) or to usual endurance training only (E, n=8). The S consisted of four lower body exercises [3x4-10 repetition maximum (RM)] twice a week for 12 wk. Running and cycling performance was evaluated by a 5-min all-out test after a prolonged period of submaximal work (1.5 h at 60% of V_{max} in running and 3 h at 45% of W_{max} in cycling). Muscle biopsies from m. vastus lateralis were analyzed for muscle fiber composition by immunohistochemistry. **Results** There were no differences between the groups at baseline. E+S increased 1RM in leg press more than E ($39 \pm 19\%$ vs. $6 \pm 9\%$, $p < 0.01$). Body mass was reduced in E ($1.4 \pm 1.2\%$, $p < 0.01$), with no change in E+S. E+S increased body mass adjusted mean power output in the 5-min all-out cycling test by $7 \pm 5\%$ ($p < 0.01$) while no change occurred in E. Effect size (ES) analyses revealed a moderate effect on percent performance improvements of E+S vs E (ES=0.62). In the 5 min running test E+S improved the running distance more than E ($5 \pm 6\%$ vs. $-1 \pm 5\%$, $p = 0.05$, ES= 0.95). E+S reduced VO_2 during the last hour of the prolonged cycling ($-3 \pm 4\%$, $p = 0.04$) while no changes occurred in E with a moderate effect of E+S vs. E at 180 min (ES=1.10). No changes occurred in VO_2 during the prolonged running. The proportion of fibers positive for IIA and IIX myosin heavy chain was reduced from $9 \pm 7\%$ to 0% in E+S ($p = 0.01$) with a concomitant increase in type IIA fibers ($39 \pm 13\%$ to $51 \pm 10\%$, ($p = 0.01$). No changes occurred in E. The correlation between change in all-out performance and change in IIA fibers was $r = -0.54$ ($p = 0.03$) in cycling and $r = -0.51$ in running ($p = 0.04$). **Discussion** The main finding was that adding S to usual endurance training in female athletes improved all-out performance after prolonged submaximal work in both cycling and running. This seems to be related to reduction in type IIA muscle fibers. In addition E+S reduced VO_2 during the last hour of prolonged cycling. These findings are in agreement with studies in both cycling (1) and running (3) but contradict other studies (2, 4). **References** 1. Aagaard et al., SJMSS, 2011; 21:298-307 2. EFFECTS OF TRADITIONAL AND RESISTED SPRINT TRAINING IN HIGHLY TRAINED, FEMALE TEAM HANDBALL PLAYERS

Luteberget, L., Raastad, T., Seynnes, O., Spencer, M.

Norwegian School of Sport Sciences

Effects of traditional and resisted sprint training in highly trained, female team handball players **Introduction** Resisted sprint training (RST) is a method often used to improve acceleration, an important factor for performance in handball. The objective of RST is to elicit a greater neuromuscular activation and to enhance the recruitment of fast twitch fibres. A load of 12-13 % of body mass is suggested as an optimal load (1). Studies report conflicting results regarding the effectiveness of RST. However, the current knowledge suggests that the effect of RST exceeds traditional sprint training (TST) in short sprints (5-10 m). In addition, ultrasound-based data indicate that fascicle length positively correlates with sprint performance (2), but evidence concerning changes in muscle architecture following sprint training is lacking. The aim of this study was to compare the effects of RST versus TST, upon sprint performance, and to determine whether these effects were reflected in muscle architectural measurements. **Method** A group of semi-professional female handball players (n=18) was assigned to either RST group (sled towing, with 12.4 ± 0.2 % of body mass) or TST group matched on 10-m sprint performance. The participants completed two sprint sessions per week for 10 weeks. Sessions included 10-m and 20-m sprints, with a total sprint distance of 240-280 m per session, equal for both groups. Sprint tests (10-m and 30-m), vertical and horizontal jumps, 20-m shuttle run test and muscle architecture were performed pre- and post-training. **Results** Beneficial effects were found in 30-m sprint for both groups (TST= -0.31 ± 0.19 s, RST= -0.16 ± 0.13 s; mean \pm 90% CI), with a moderate effect size between groups (ES=0.85). Only TST had a beneficial effect on 10-m time (-0.04 ± 0.04 s, ES=0.51). Pennation angle decreased in both groups, resulting in a small effect on fascicle length (5.3 ± 3.9 %, ES=0.26 and 4.0 ± 2.1 %, ES=0.46 for TST and RST, respectively). Both groups obtained a small effect size for agility performance (TST=0.46 and RST=0.28). **Discussion** Sprint training appears to be effective in enhancing short distance (10-30m) sprints in female handball players, and TST appears to be more effective than RST. The load suggested in previous studies as optimal for RST, may not apply for female athletes. The effect on fascicle length is similar for both groups, yet small in magnitude. This possibly suggests a velocity-specific adaptation to sprint training, present in concurrently training athletes. Specific agility training is advisable to have a better effect on agility performance. **References** 1. West DJ, Cunningham DJ, Bracken RM, et al. (2013) J Strength Cond Res. 27, 1014-1018 2. EXERCISE TRAINING REDUCES THE FREQUENCY OF MENOPAUSAL HOT FLUSHES BY IMPROVING THERMOREGULATORY CONTROL

Bailey, T.G., Low, D.A., Aziz, N., Cable, N.T., Jones, H.

Liverpool John Moores University

Introduction Menopausal hot flushes (HF) occur due to a reduction in oestrogen causing thermoregulatory dysfunction. A HF consists of a feeling of intense heat, skin reddening, cutaneous vasodilation (CVC) and profuse sweating. This coincides with dramatic changes in heart rate, blood pressure and reduced brain blood flow (Lucas et al., 2013). Exercise training enhances thermoregulatory efficiency in sweating and CVC responses to changes in core temperature (T_{c}) (Ichinose et al., 2009). Also, exercise training enhances brain blood flow (Murrell et al., 2013). Our aim was to determine if improving thermoregulatory control with exercise training would alleviate HF. We hypothesised that exercise training reduces HF frequency via improving sweat-rate (SR) and CVC efficiency to increases in T_{c} , and enhanced vascular function and brain blood flow. **Methods** Symptomatic postmenopausal females (n=16) completed a 7-day HF questionnaire and underwent a passive heat stress in a water-perfused suit (48°C) to obtain T_{c} thresholds and sensitivities for SR (capacitance hygrometry) and CVC (laser Doppler flowmetry). Middle cerebral artery velocity (MCAv; transcranial Doppler) was measured throughout the heat stress, brachial artery flow-mediated dilation (FMD) and cardiorespiratory fitness were also assessed. Females then underwent supervised exercise-training or no training for 16 weeks and all measurements were repeated. Data were analysed using linear mixed models and presented as mean \pm SD. **Results** Weekly HF-frequency reduced [63 ± 22 to 26 ± 13] following exercise training compared to no change in control [45 ± 5 to 46 ± 17 , $P = 0.01$]. Basal T_{c} was reduced by $0.13 \pm 0.14^{\circ}\text{C}$ following exercise training vs. $0.03 \pm 0.12^{\circ}\text{C}$ in control

[$P=0.04$]. The T_c threshold for SR [$0.22\pm0.14^\circ\text{C}$, $P=0.008$] and CVC [$0.22\pm0.09^\circ\text{C}$, $P=0.02$] occurred earlier following exercise training compared with no change in control [$0.05\pm0.11^\circ\text{C}$ and $0.02\pm0.14^\circ\text{C}$]. SR sensitivity was higher with exercise training [$0.26\pm0.23\text{ mg}\cdot\text{min}^{-1}\cdot\text{cm}^{-2}\cdot^\circ\text{C}^{-1}$] vs. no change in control [$0.07\pm0.28\text{ mg}\cdot\text{min}^{-1}\cdot\text{cm}^{-2}\cdot^\circ\text{C}^{-1}$, $P=0.05$]. MCAv decreased during heat stress [$P=0.000$], however MCAv was $4.5\pm1.6\text{ cm/s}$ higher during heating following exercise training, compared to no change in control [$-2.1\pm2.8\text{ cm/s}$, $P=0.000$]. Fitness [$4.4\pm1.9\text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ vs. $1.0\pm2.4\text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$; $P=0.001$] and FMD [$3.6\pm2.0\%$ vs. $0.6\pm1.9\%$; $P=0.004$] improved with exercise training compared to no changes in control. Conclusions These novel findings indicate that exercise training reduces the frequency of HF by improving thermoregulatory responsiveness to an increase in T_c . These responses are mediated through enhanced sweating and vascular conductance in the cutaneous and cerebral circulations. These findings have implications for the non-pharmacological treatment of symptomatic postmenopausal women with exercise training. 1. Ichinose T et al. (2009). *Exp Phys* 94, 90-102 2. Lucas R et al. RELATIONSHIP BETWEEN RELATIVE AGE, ANTHROPOMETRY, MATURITY AND MOTOR SKILLS IN YOUNG ALPINE SKI RACERS COMPARED TO PUPILS OF THE SAME AGE

Müller, L., Hildebrandt, C., Raschner, C.

University of Innsbruck

Introduction A relative age effect (RAE) consists of an over-representation of athletes born early in a selection year. It was shown to be present in ski racing at all age categories (Müller et al., 2012). The causal mechanisms for its existence still remain unclear; due to the high demands of physical abilities in ski racing, the consideration of the influence of biological maturation on the RAE seems to be important. **Methods** 139 pupils (10-14 years) were investigated; 53 (31♂, 22♀) of them of a ski boarding school and 86 (46♂, 40♀) of a secondary modern school of the same region (a new approach in RAE research, to include a comparison group of non-athletes). Anthropometric measurements, 6 physical performance tests and the estimation of the maturity status and consequently the calculation of the age at peak height velocity (A-PHV) (Malina et al., 2012) were carried out and the birth months (divided into four quarters) were examined. ANOVA was used to evaluate differences in anthropometrics, physical performance and A-PHV between the pupils born in the single relative age (RA) quarters. Correlations between the physical performance and the A-PHV were assessed. Significance was set at $p<0.05$. **Results** The ski racers born in the four quarters did not differ in anthropometrics and physical performance; however, they differed significantly ($p=0.02$; $F=3.59$) in the A-PHV with lower values for relatively older athletes. The pupils of the control group did not differ in any variable. The ski racers were highly significant better in all physical performance tests. A significant correlation was shown between the A-PHV and the agility test ($p<0.001$; $r=-0.45$), the core strength test ($p=0.036$; $r=0.3$) and the counter movement jump ($p=0.049$; $r=0.27$) within the group of the ski racers and between the A-PHV and the core strength test ($p=0.005$; $r=0.3$) and the drop jump ($p=0.047$; $r=-0.22$) within the comparison group. **Discussion** The ski racers born in the four quarters differed significantly in the A-PHV with lower values for relative older athletes, which means that they are more mature and accelerated compared to the relatively younger ski racers. This is in line with studies for example in soccer, where the maturity status significantly correlated with RA. Interestingly, this was not shown for the comparison group, which indicates that biological maturation correlates with the RA only in alpine ski racers. The superiority of the ski racers in physical performance underlines the importance of these skills in ski racing. **References** Müller L, Raschner C, Kornel E, Hildebrandt C, Bacik M, Kröll J, Müller E. Invited symposia

IS-SH01 FEPSAC symposium - Knowing what we want tomorrow in order to prepare for it today: Career development and transitions of talented, elite and retired athletes

A DEVELOPMENTAL AND HOLISTIC PERSPECTIVE ON THE CAREER OF ELITE AND RETIRED ATHLETES

Wylleman, P., Reints, A.

Vrije Universiteit Brussel

While different studies have listed reasons as to why elite athletes retire from elite sport and how these may influence the quality of the post-athletic career (Alfermann & Stambulova, 2007), researchers have largely neglected the decision-making process which is at the basis of athletic retirement. Using the developmental model of transitions faced by athletes (Wylleman & Reints, 2011) and the Push Pull Anti-push Anti-pull framework (Fernandez, Stephan, & Fouquereau, 2006), this study investigated the factors influencing the decision making process amongst 24 Flemish former elite athletes to retire or to postpone retirement. Using interviews, results revealed that former athletes' decision-making process was influenced by positive and negative factors within the athletic career as well as by positive and negative factors within the post athletic career. It was concluded that the decision to retire from sport was characterised by taking into consideration different pro's and con's of being engaged in an athletic career, which confirms the idea that retiring from sport can be seen as 'multifaceted, complex, and individual'.

THE ROLE OF WELL-BEING FORECASTS IN ELITE SPORT RETIREMENT PLANNING AND DECISION MAKING, AND POST-RETIREMENT LIFE ADJUSTMENT

Sanchez, X., Scheibe, S.

University of Groningen

People often make predictions about their affective experience and life satisfaction in response to future events, such as changing jobs or retiring. Such forecasts of future well-being have been identified as an important determinant of decision-making, influencing all kind of decisions. In elite sport, athletes shall plan when to retire and how best to prepare for that transition out of sport sufficiently long before they actually retire. In the present study, we examined whether those athletes who do prepare for life after sport differ from those who

don't in their forecasted well-being after retirement. Elite athletes were asked to complete measures of emotional wellbeing and life satisfaction (social, financial and work areas) in relation to two periods of their life: present (current) and expected (forecast: one year into retirement). Higher life satisfaction forecasts in the social and financial areas were observed amongst the athletes who were not preparing for life after sport. Time to (expected) retirement also influenced planning in addition to well-being forecasts; precisely, athletes who thought would not retire within the next three years were not currently preparing for their working life after sport. We discuss the role that well-being forecasts may play in elite athletes' sport retirement both in their planning of the transition out of sport during their actual sporting career and their future post-sporting career life adjustment.

EVIDENCE-BASED INTERVENTION PROGRAMMES ADDRESSING AFFECTIVE FORECASTING ERRORS IN ELITE SPORT RETIREMENT

Lavallee, D.

University of Stirling

Several career transitions programmes for athletes have been developed in countries around the world recently, based on the belief that intervention at the organisational level can be a useful means for facilitating the career transition process. These programmes vary in their focus from educating athletes on lifestyle management to helping others cope with various forms of sport transitions such as making the transition from junior-to-senior level. Research suggests that accurate (affective) forecasting can play a key role in athletes' decision-making and post-retirement life quality. This presentation will focus on research with Olympic-level athletes from the UK, US and Canada. In this study participants were asked to make predictions on how they would feel about their retirement three months before and nine months after the Olympic Games they retired after. Results suggested athletes tended to under-estimate the amount of preparation required for their life after sport. Recommendations for interventions programmes will be discussed.

OP-SH01 Sports Policy and Statistics

ATTACKING AND DEFENSIVE STYLES OF PLAY IN ELITE SOCCER

Fernandez Navarro, J.1,2, Ford, P.R.1, Scott, M.1, Fradua, L.2, Zubillaga, A.3, McRobert, A.P.1

1: LJMU (Liverpool, UK), 2: UGR (Granada, Spain), 3: UPV/EHU (Vitoria-Gasteiz, Spain)

Introduction Soccer teams use different styles of play or strategies in competition (Tenga et al., 2003). However, performance indicators associated with attacking and defending styles of play have not been clearly defined. The aim of this study was to use factor analysis to define and categorise the different styles of play used in elite soccer and determine the performance indicators that contribute to them. Methods Ninety-seven matches, involving 37 different teams from 1st Spanish La Liga and the English Premier League (2006-2007 and 2010-2011) were monitored using a multiple-camera match analysis system (Amisco Pro®, version 1.0.2, Nice, France). Nineteen attacking (14) and defending (5) performance indicators were measured. Factor analysis using principal component analysis (PCA) was conducted on the 19 performance indicators with orthogonal rotation (varimax). This technique allows the grouping of performance indicators into a few factors that represent the styles of play. In addition, each team's specific way of playing can be categorised by describing their score for each factor. Results The Kaiser-Meyer-Olkin measure verified the sampling adequacy for the analysis (KMO = .53). Six factors extracted in the factor analysis explained 84.91% of the variance. Factor 1 explained the largest variance (27.8%). Two opposing styles of play were associated with each factor based on a positive or negative score. The attacking styles of play determined were: direct or possession, crossing or no crossing, wide possession or narrow possession, and fast progression of possession or slow progression of possession. In contrast, the defensive styles of play were: applying pressure/regaining the ball in wide areas or applying pressure/regaining the ball in central areas, and low pressure or high pressure. The six factors described 12 different ways that teams played (8 attacking and 4 defending). Discussion Factor analysis revealed the different styles of play used in elite soccer and the performance indicators that contribute to them. A team's score on each factor demonstrated their dependence on a style of play (Pollard et al., 1988). For example, one English team's way of playing was to use the direct, no crossing, narrow and fast progression styles of play in attack. In defence they used a low pressure but applied pressure in central areas to regain the ball. The implications are that training can be designed to improve the performance indicators associated with the team's styles of play or prepare them to face the styles of play of upcoming opponent's. A NEW TOOL FOR MEASURING ANTI-DOPING ATTITUDES IN ELITE ATHLETES: THE ANTI-DOPING PROGRAMME EVALUATION QUESTIONNAIRE

Lamberti, N.1, Malagoni, A.M.1,2, Felisatti, M.1, Caracciolo, S.1, Resch, N.2, Litmanen, H.2, Dal Follo, D.2, Jeannier, P.2, Zhukovskaja, L.2, Carrabre, J.E.2, Manfredini, F.1,2

1. University of Ferrara; 2. International Biathlon Union

Background The international federations, which have progressively strengthened the anti-doping programs, with new duties for athletes, lack any feedback in terms of acceptance and satisfaction of the anti-doping actions from athletes themselves. The project aimed i) to develop, an anonymous self-administered tool measuring elite athletes' attitudes on international anti-doping interventions, and ii) as first implementation, to survey anti-doping attitudes among top biathletes. Methods In the absence of available literature, relevant topics and items were identified. The preliminary English version of the anti-doping program evaluation questionnaire (APPROVE) was developed, translated (German, Russian and Italian) and distributed during an international biathlon event to a sample group for validation. The questionnaire's final structure was determined by factor analysis. Construct validity was explored by correlation with a single item of satisfaction and also internal consistency and test-retest reliability were evaluated. A cross-sectional evaluation of the anti-doping atti-

tude among elite biathletes was performed by administering APPROVE final validated version. Results Sixty-two subjects participated in the validation phase. The final version of APPROVE included: i) a Demographics section, ii) an Awareness section measuring respondents' knowledge of the anti-doping rules, and iii) an Anti-doping attitude section, including four 9-item domains (Safety, Confidence, Acceptance and Satisfaction) exploring athletes' perceived protection against cheating, confidence in competition fairness, acceptance of and satisfaction with anti-doping actions. APPROVE had construct validity, good internal consistency and significant-acceptable test-retest reliability. Two hundred forty-four biathletes participated in the survey (44.4% of response rate) with the Awareness score insufficient for 9% of them. A positive attitude was observed (ADOPT score: 64.9), with good-excellent scores for 74% of the athletes. The score domains were significantly lower for Safety (58.2) and higher for Satisfaction (70.8). Conclusions APPROVE, not being a sport specific questionnaire, allows a multi-faceted evaluation of the anti-doping attitude in sport and of the impact of anti-doping strategies on athletes. Its first implementation among top biathletes outlines a positive attitude towards the present anti-doping interventions, and the willing to accept the related restrictions to be protected against cheating. VARIABILITY AND PREDICTABILITY OF PERFORMANCE TIMES OF ELITE ALPINE SKIERS

Spencer, M.1, Reid, R.2, Gilgien, M.1, Hopkins, W.G.3

Norwegian School of Sports Sciences

1: Norwegian School of Sports Sciences, Oslo, Norway; 2: Norwegian Ski Federation, Oslo, Norway; 3: AUT University, Auckland, New Zealand Introduction The variability in performance of elite athletes between competitions provides useful information for research on factors affecting medal-winning performance. The aim of this study was to estimate the variability of performance of alpine skiers in international competitions. Methods Official race times and course information for men's and women's downhill, super G, giant slalom and slalom in World Cup competitions from seasons 2001-2013 were downloaded from fis-ski.com. In analyses of the top 30 athletes from each race there were 93-113 athletes competing in up to 26-64 races at 12-31 venues. In analyses restricted to the annual top-10 athletes there were 40-55 athletes in up to 41-73 races. A linear mixed model of log-transformed race times for each event provided estimates of within-athlete race-to-race variability (expressed as a coefficient of variation, CV) after adjustment for differences in mean race time arising from race terrain and snow conditions. Predictability of performance was expressed as an intraclass correlation representing the mean correlation between pairs of races within seasons. Results Within-athlete race-to-race variability in performance time was similar for men and women in the various events for top-30 athletes (CV of 0.54-0.73%) and for annual top-10 athletes (0.57-0.76%). Predictability of performance for men and women for top-30 athletes was low to moderate (correlations of 0.18-0.27 and 0.28-0.43, respectively), and poor to low for top-10 athletes (0.04-0.10 and 0.11-0.30). Discussion The race-to-race variability of the best alpine skiers is similar to that of elite skeleton athletes, another sport where speed is determined partly by gravity (Bullock et al., 2009). The variability is approximately half that of endurance sports such as cross-country skiing (Spencer et al., 2014). Estimates of the smallest worthwhile performance enhancement (0.3x within-athlete variability) will assist researchers investigating factors affecting performance of elite skiers. A COMPARISON OF CLASSIC AND SKATE CROSS-COUNTRY SKIING IN VARYING TERRAIN EMPLOYED BY MALE AND FEMALE WORLD-CLASS SKIERS

Bolger, C., Hegge, A.M.1, Kocbach, J.2, Sandbakk, Ø.1

1 NTNU, Trondheim, Norway; 2 Christian Michelsen Research, Bergen, Norway

Introduction Cross-country skiing evolved from the single classical style to two separate techniques, classic and skate. Skiers train to perform both styles on similar tracks with varying terrain. Extensive sprint race analyses have been done, whereas distance races have been examined to a less extent and no previous study has directly compared the skating and classic techniques during actual competitions. Therefore, the present study compared speed and heart rate profiles of world-class skiers during an international competition on varying terrain in the skating and classical technique. From here, we analyzed possible differences between classic and skate, and the magnitude of gender differences. Methods Four male and five female world-class cross-country skiers from the Norwegian national team participated in individual time-trials of 15 (men) and 10 km (women) on two consecutive days with comparable conditions on the same course for classic and skate. The skiers' heart rate and location were continuously monitored by a Garmin GPS monitor, and integrated with a calibrated standard track profile. Time, speed and heart rate for uphill, flat, downhill and turn sections of the overall races and on each consecutive 5 km lap were determined. Results The average speed was 10 and 9% higher in skating than in classic for men and women, respectively; with corresponding numbers of 12 and 11% for uphill, 7 and 13% for flat and 2 and 1.5% for downhill terrain. Men were 9, 11 and 4% faster than women on uphill, flat and downhill terrain in classic and 11, 6 and 5% in skating. On average, heart rate increased by approximately 10 bpm during ~1.5 min uphill skiing and was relatively stable throughout the flat sections in both techniques. There was a trend towards greater heart rate decreases during the downhill sections for classic compared to skating. Conclusion For the first time, the current study compared the speed and heart rate profiles during international skating and classic competitions in elite cross-country skiers. The ~10% difference between techniques for both genders was slightly less than expected; men showed greatest differences in uphill terrain, whereas women tended to have the greatest differences on the flat. The effect of terrain on gender differences may be associated with differences in the upper and lower limb distribution. Uphill skating and flat classic skiing are thought to have the most effective poling, whereas flat terrain in skating allows women to utilize the legs more. There were modest differences in downhill sections between techniques and gender. However, heart rate decreased less during skating downhill, which might be associated with leg contribution from the skating push-offs in this terrain.

THE IMPORTANCE OF PRIVACY IN PROVIDING WHEREABOUTS FOR DUTCH ELITE ATHLETES

De Hon, O.1, Valkenburg, D.2, Van Hilvoorde, I.2

1: Anti-Doping Authority Netherlands (Capelle aan den IJssel, The Netherlands), 2: Faculty of Human Movement Sciences, VU University (Amsterdam, The Netherlands)

Introduction To improve anti-doping efforts in sports, the World Anti-Doping Agency (WADA) introduced regulations for providing athletes' whereabouts. Because the success of this system depends on the co-operation and compliance of athletes, the perspective of elite athletes is important. This paper answers the following research questions: What is the perspective of Dutch elite athletes on the current whereabouts system in general and how important is their privacy in providing whereabouts in particular? In addition, this study explores

how far the whereabouts system can be developed in the future. Are athletes willing to accept greater invasions of their privacy in order to reduce administrative effort and whereabouts failures? Method A structured questionnaire was completed by 129 Dutch elite athletes registered in a national or international testing pool, which represents a 26% response rate. Results Almost all respondents stated that it is important that elite sport is free of doping and most athletes thought the whereabouts system is important in both detecting and preventing the use of doping. Just 20% of the athletes stated that they never forget to change their whereabouts and over 70% of the respondents were at least sometimes afraid to miss doping tests. In terms of physical privacy, 43% of the athletes felt that the '1-hour time slot' limits their freedom, but only 26% of the athletes agreed with the statement that the distinction between their sport and private life is disturbed. For 28% of the respondents the whereabouts system has a negative influence on the pleasure they experience in being an elite athlete. 89% of the athletes felt that their whereabouts information was treated confidentially. In terms of possible future changes to the system, 94% of the athletes would accept giving their phone number to doping control officials, but only 47% of the athletes would accept sharing their location on their mobile phone. Just 18% would accept wearing a permanent wrist or ankle bracelet and 20% would accept being implanted with a GPS chip in order to facilitate future anti-doping testing. Discussion The results of this study indicate great dissatisfaction with the whereabouts system. Most respondents support anti-doping testing in general, but many athletes feel that WADA's whereabouts system is unacceptable in several respects. The current whereabouts system needs to be improved in order to increase athletes' satisfaction with the anti-doping rules. The results of this study indicate that a majority of the athletes are not likely to accept a greater violation of their privacy than the current whereabouts regulations already entail. PARALYMPICS AND THE REPRODUCTION OF TRAGEDY: ON ABJECTION, AESTHETICS, AND ATTITUDES

Jönsson, K.

Faculty of Education and Society, Malmö University

Background Paralympics 2012 in London has been vividly described as a complete success. The media coverage was intense before and during the Games, many of the competitions were in front of a full house crowd, and some of the athletes even became celebrities. To this the British TV channel Channel 4 produced an artistically suggestive short film, entitled "Meet the Superhumans", in order to advertise the Games. Afterwards, the legacy of the Paralympics was generally described as a real breakthrough not only for the Paralympics but also for disability sport in general. This was before the "backlash". One year after the Games in London, the British charity organization Scope published a report in which it was claimed that the attitudes towards disabled people had not improved as a result of the attention from the Paralympics. Quite the contrary, many in the disability community said that the situation in fact had worsened due to the attention from the Paralympics. The previous well-established triumph had turned into a failure. How can one philosophically understand this? Discussion By analyzing how the Paralympic Games 2012, and the Paralympians, were portrayed in the media as well as in the film "Meet the Superhumans", we may find some of the reasons why Paralympics turned into somewhat of a failure. Generally speaking, the pattern from how the Paralympians were publicly described, as well as how the Games were advertised, demonstrates a rather dubious attitude towards disability sport. In my presentation I will argue (1) that the general focus on disability as an inherent (and unwanted) tragedy, may contribute to patronizing attitudes towards disabled athletes; (2) In defining disability as an inherent tragedy, the Paralympians are being victimized before the public eye, which in turn means that disabled athletes can never be seen as athletes equal to able-bodied athletes; (3) The patronizing and victimizing attitudes towards disabled athletes are fuelled by how Paralympics, and disability sport in general, are being aesthetically presented. PREDICTING UPTAKE OF CYCLING FOR TRANSPORT IN ADULTS

Titze, S.1, Brown, W.J.2, Oja, P.3, Stronegger, W.4

1.Institute of Sport Science, Uni of Graz, Austria 2. School of Human Movement Studies, Uni of Queensland, Australia 3.UKK, Finland

4.Institute of Social Medicine and Epidemiology, Uni Graz Austria

Cycling for transport represents an opportunity to regularly integrate moderate-intensity physical activity into everyday life. Little is known about the factors that predict uptake of this type of cycling in adults. Purpose To investigate the social-ecological-model's predictors of taking up cycling. Method Telephone interviews were used to ask a representative population sample (N=1000) of adults (16-60 years) about cycling for transport, and about individual incentives and barriers for cycling, as well as distance, social support, and built environmental characteristics along the route. They were also asked to report socio-demographic characteristics and height and weight. Four years later they were contacted again and were asked more or less the same questions. T-tests were used to compare differences in continuous variables, and potential predictors for the adoption of cycling were examined using logistic regression models. Results Out of the 1000 initial participants, 293 (29.3%) (mean age 37.1 years, SD=12.2; mean BMI 23.5, SD=3.8) completed the full interview at both t1 and t2 and were included in this analysis. The majority were stable non-cyclists (n=170, 58.1%), 61 (20.7%) were stable cyclists, 40 (13.7%) adopted and 22 (7.6%) relapsed from cycling as a means of transport. Stable cyclists had a significantly lower BMI (21.6, SD=3.1) than stable non-cyclists (24.2, SD=3.7). After controlling for gender and age, the strongest baseline predictors of adopting cycling in this four year period were the perceptions that cycling is a highly flexible transport mode (OR=4.1, CI=1.5-11.6), and that it causes little physical discomfort (OR=4.3, CI=1.6-11.6). Surprisingly, middle to low perceived health status also predicted the adoption of cycling (OR=3.6, CI=1.2-9.6) compared to perceived good to very good health. Conclusion In this study none of the built environmental or social factors predicted the adoption of cycling. Instead, individual perceptions about comfort and flexibility were strong predictors of taking up cycling. These findings suggest that 'marketing' cycling for transport could focus on the ease and convenience of this mode of transport, especially among those with middle to low health status, who stand to gain most benefits from increased activity. Although no cause and effect

can be confirmed, the fact that cyclists had significantly lower BMI than non-cyclists also suggests that weight control may be a benefit of cycling. This could also be used to encourage greater uptake of this mode of transport

COST-EFFECTIVENESS OF TWO INTENSITIES OF A COMBINED LIFESTYLE INTERVENTION AIMED AT IMPROVING PHYSICAL ACTIVITY AND NUTRITIONAL BEHAVIOR.

Hendriks, M.

Maastricht University

Introduction Overweight and obesity are associated with an increased morbidity risk leading to increased healthcare utilization and related costs. We studied the cost-effectiveness of a combined lifestyle intervention program (BeweegKuur) aimed to improve physical activity and nutritional behavior in adults with overweight and obesity. Subsequently the program aimed to increase quality of life, and reduce healthcare utilization and subsequent costs. **Methods** In a clustered RCT (29 clusters; n=411) participants allocated to the control condition received a start-up program and those allocated to the intervention condition received the supervised Beweegkuur program with more guidance by the physiotherapist. Healthcare utilization and clinical outcomes were assessed from a societal perspective by means of self-administered questionnaires every three months for a period of 24 months. First a cost-effectiveness and cost-utility analysis were done from a healthcare perspective with a time horizon of 12 months. Differences in costs and effects are presented in Incremental Cost-Effectiveness Ratios (ICERs). Uncertainty was assessed by means of 1000-times bootstrap and sensitivity analyses. **Results** Baseline characteristics were comparable between both groups. Program costs of the supervised Beweegkuur program were higher compared to the start-up program. However, other healthcare costs were lower for the supervised Beweegkuur program. Utilities increased in both groups, and one-year QALYs were somewhat higher in the supervised program. The ICER showed that the supervised program was related to additional costs and effects, which was confirmed by bootstrap and sensitivity analyses. **Conclusion** The more expensive supervised Beweegkuur program achieved reduced healthcare utilization, resulting in slightly higher total costs with additional quality of life compared to the start-up program. The supervised program is perceived to be cost-effective from a healthcare perspective after one year follow-up. Additional analyses must reveal whether these results remain on a longer time horizon from a broader perspective.

IMPACT OF AN NHS WORKPLACE HEALTH PROMOTION PROGRAMME ON STAFF HEALTH AND WELLBEING: A FEASIBILITY STUDY

Scaife, R., Carter, A., Kesterton, S., Humphreys, L., Breckon, J., Till, S., Flint, S.W., Maynard, I., Copeland, R.

Sheffield Hallam University

Introduction The importance of employee wellbeing is increasingly being recognised. At present, approximately 40 per cent of NHS staff exercise less than two days a week (The Boorman Report, 2009). In support of this David Nicholson concluded that "the opportunities for the NHS to lead by example on key public health issues such as mental health and physical activity are significant" (NHS Sport and Physical Activity, 2010). The aim of this feasibility study was to measure the impact of an NHS workplace health promotion programme on staff health and wellbeing. **Methods** The study was a cross-sectional feasibility study, with a representative sample of 50 participants randomly selected from volunteers in each of the 8 hospital work groups (male = 10, female = 40). Participants attended a client centred health screen and lifestyle review at baseline and 6-month follow-up. All attendees were given the opportunity of receiving additional support via attendance at educational workshops, follow-up lifestyle sessions, or signposting to existing NHS services, targeted at specific health needs. Outcome measures were assessed at baseline and 6-month follow-up and included a health and lifestyle questionnaire (quality of life, physical activity, nutrition, smoking and work performance) and health indicators (BMI, % body fat, total cholesterol, blood pressure, high density lipoproteins). Service user feedback and staff perceptions were measured via questionnaire at the end of the programme. Return on investment was estimated based on reported absenteeism. **Results** BMI had improved at 6 months with 50% of participants in the normal weight category compared to 38% at baseline. Waist circumference also improved at 6 months with 60% of participants in the ideal category compared to 44% at baseline. Changes in blood pressure approached significance with 50% and 56% of participants with high systolic and diastolic blood pressure at baseline respectively, in the recommended range after 6 months. Evaluation of the study via participant responses demonstrated that the programme led to 87% of participants modifying their health behaviours (e.g., smoking cessation, increased physical activity). Additionally, 88% of participants strongly agreed, or agreed, that the programme had a positive impact on their overall motivation to make healthy lifestyle changes. **Discussion** Improvements were evident for the health indicators measured. In line with previous research (e.g., Pronk & Kotke, 2009), the innovative workplace health promotion programme improves health indicators. This study demonstrated that a multi component onsite health promotion programme had high NHS staff engagement, a significant impact on improving health and has the potential for a return on investment. **References** NHS Sport and Physical Activity (2010): Meeting the NHS Challenge to get more staff active by 2012. REPEATED LIFESTYLE INTERVENTION LEADS TO WEIGHT LOSS MAINTENANCE

Dandanell, S.1,2, Dela, F.1, Helge, J.W.1

University of Copenhagen

Introduction Weight loss (WL) and physical activity are considered first line approaches in the treatment of obesity. One option, which leads to significant WL (1% of body weight/wk) is intensive Lifestyle Intervention (ILI). Unfortunately, the overall success rate after a single ILI is low as most participants gradually regain weight (1). To our knowledge no one has previously investigated the effect of repeated ILIs over a period of years. In this retrospective descriptive study, we report the effect on body weight (BW) and composition (BC). **Methods** Over the last 13 years 2151 obese participants (BMI: 39.0±0.2) attended the ILI with duration of 10-14 weeks. Participants lived at a resort during the week, but had the opportunity to go home for the weekends. On their own accord 513 returned for a 2nd, 128 for a 3rd, 41 for a 4th and 13 for a 5th ILI. The intervention consisted of self-selected daily exercise (1-3 hrs.) of different intensities and a hypocaloric diet. Diet composition followed Nordic Nutritional Recommendations (CHO: 55-60%, Fat: 20-30%, Protein: 15-20%). BW and BC was measured by bio-impedance before, halfway and at the end of each ILI. Mixed model statistical analysis was performed by SAS Enterprise 5.1. **Results** Average WL (11.8±0.1kg), loss of fat (8.5±0.1kg) and lean body mass (3.3±0.1kg) were significant after each consecutive ILI (1-5)(p<0.001), but the size of the WL was dependent on the number of ILI (interaction, p<0.001). Participants returning for ILI 2-5 had on average regained 41±4.7 % of their lost BW, but were able to reduce their BW even further. Average total WL after 1, 2, 3, 4 and 5 ILIs were

-12.0±0.1, -19.8±0.8, -20.8±3.0, -23.7±3.0 and -26.9±5.5 kg, respectively, corresponding to percentage changes in BW of -11.7±0.1, -15.9±0.4, -16.9±0.9, -17.7±1.9, -20.4±2.7 %. This was achieved over average time periods of 0.23±0.1, 1.5±0.1, 2.6±0.2, 3.5±0.3 and 5.2±0.8 yrs. for the 1-5 ILLs, respectively. Discussion Through repeated ILLs it was possible to maintain a WL over several years. WL of clinical relevance and with the potential to reduce cardiovascular risk factors has been defined as ≥5% (2). The WL achieved in this study exceeds, what has been reported after a single ILL (1), but most importantly also lasts for a longer period. The applicability of repeated ILLs for WL maintenance to the general population has not been investigated and future studies should determine the optimal duration, intensity and frequency, especially in relation to cost effectiveness. ADEQUATE WORKING ABILITY AND LOW EXHAUSTION IS CONNECTED WITH GOOD OVERALL FITNESS

Malvela, M., Heiskanen, J., Komulainen, J.

LIKES Foundation for Sport and Health Sciences

Introduction In Finland the Government is focusing on preventing incapacity for work and extension of careers which are necessary to the balance between the dependency ratio and public finances. Health problems pile up in less-educated population and the level of education affects the length of working life. Men's well-being is divided into extremes more than among women. The life expectancy of Finnish working class men is six years shorter than men in higher positions. Fit for Life Program designed a successful, easy-going campaign called the Adventures of Joe Finn. The goal was to awaken and activate working-aged men towards regular physical activity and healthy eating habits and increase the working capacity. **Methods** The campaign includes lorry tours, Joe Finn Fitness tests, communication, materials, a website and local actions. In Spring 2013, the lorry tour stopped in 36 municipalities offering fitness tests especially only for men. Inside the lorry was test laboratory where men were tested: a grip strength, a body composition by inbody 720 analyzer, a waist circumference and a cardiorespiratory fitness with Polar Own Index fitness test. Before tests men filled the background form and assessed their exhaustion (1-5) and ability to work (0-10). The overall test summary, Body Fitness Index (BFI), was calculated from the most essential measurements (endurance fitness, fat%, visceral fat, muscle mass and grip strength) and described the fitness compared with same gender and age population. The BFI had scores and rating: under -3 alarming, -3- -1 worrying, -1 - 1 alright, 1-3 good and over 3 athlete. **Results** The data included the results of working-aged men 20-64 y (n=5903). BFI revealed that 63% of men should improve their physical activity and/or eating habits. Half of the men had excessive fat reserves (visceral fat and fat%). 76% of the tested men had adequate endurance fitness as health aspect (VO₂max>34 ml/kg/min). Men in good or athlete level condition (BFI>1) assessed their working ability higher and exhaustion lower than unfit men: 87% of them rated good (8-9) or excellent (10) working ability and 68% felt themselves quite rarely (4) or almost never (5) exhausted. Similar results were found when working ability and exhaustion were compared with the endurance fitness. **Conclusion and discussion** Adequate working ability and low exhaustion was connected with good overall fitness and endurance fitness. The recommendations of health enhancing PA is sufficient for maintaining work ability. The trade unions, pension insurance companies and employees should pay attention to PA and health promotion to increase the length of working life.

OBJECTIVELY DETERMINED ACTIVITY ENERGY EXPENDITURE DURING PREGNANCY AND CHANGES IN BODY MASS: THE HAPPY-STUDY

Moss, S.J.1, Van Oort, A.1, de Boer, M.R.2, Schutz, Y.3

North-West University

Introduction A decrease in activity energy expenditure (AEE) is related to an increase in body weight. Pregnancy is associated with the development of new life with an increase in body mass during gestation. Weight retention post-partum has been associated with negative birth outcomes. Therefore, the aim of this study was to objectively determine activity energy expenditure in pregnant women and related the changes in weight gain and weight retention post-partum. **Methods** Activity energy expenditure (AEE) was determined objectively (ActiHeart) in 60 pregnant females from first trimester of pregnancy to 3 months post-partum. Data was captured in 60 sec. epochs for seven consecutive days. Body mass was measured (Seca, Italy) at the beginning of each trimester and three months post-partum together with foetal growth parameters by means of sonar. Longitudinal changes in AEE expenditure and changes in body mass were determined by means of GEE analyses. **Results** The average age of the participants were 28 ± 5 years with a third from low, middle and high socioeconomic status respectively. AEE decreased from the first trimesters (802 kCal) to the third trimester (592 kCal) significantly (p=0.04) with a slight increase at three months post-partum (634 kCal). During pregnancy body mass increased between 9 - 12 kg with an average weight retention of 7 kg three months post-partum. **Discussion** The decrease in activity energy expenditure during pregnancy observed in this study by means of objective measurement support the findings of studies reporting on data collected by means of physical activity questionnaire (Brunette et al., 2012) and doubly labelled water Lof (2011). The level of energy expenditure found in the present study can be categorised as low activity level which become sedentary at three months post-partum as was also found by Evenson et al. (2012). The simultaneous low level of activity energy expenditure and weight retention post-partum may predispose the mother to achieve an unhealthy body mass. Should the trend continue in subsequent pregnancies the detrimental effects of overweight and obesity may become a reality in women of childbearing age. The findings from the present study indicate that physical activity during pregnancy should be promoted in order to manage weight gain and weight retention during pregnancy and post-partum. **References** Brunette EL, Kotze J, Wood PS, Du Toit PJ, Grant CC. 15:00 - 16:30**Oral presentations****OP-BN02 Kinematics****SPINAL AND KNEE KINEMATICS IN LOW BACK AND LOWER LIMB INJURY IN CRICKET PACE BOWLERS**

Olivier, B., Stewart, A., Green, A., Mckinon, W.

University of the Witwatersrand

Introduction Cricket fast bowlers are especially prone to sustain lower quarter (low back and lower limb) injuries. The kinematics of the spine and front knee influence the whole kinetic chain and may be associated with lower quarter injuries. The association between low back and knee kinematics and low back injuries has been established, but no studies have been done on its association with lower quarter injuries. The objective of this study was to compare pre-season and post-season spinal and knee kinematics and between injured and non-injured bowlers. **Methods** This was a longitudinal observational study. Kinematic and injury related data of thirty-one injury free, premier league (amateur) pace bowlers were obtained. Injuries were monitored monthly. Pre-and post-season as well as injured and non-injured groups were compared using Student's t-tests. **Results** Sixteen (51.6%) bowlers sustained one or more lower quarter injuries during the course of the eight month cricket season. A difference was found between lumbar spine lateral flexion positioning ($p=0.021$) as well as the range of movement between front foot placement and ball release ($p=0.021$) at the start compared to at the end of the season in injured fast bowlers. No difference was found in non-injured bowlers. The shoulder girdles in relation to the pelvis of the injured bowlers were in a position of extension while the shoulder girdles of the non-injured bowlers were in a position of flexion at the start of the season ($p=0.0093$). The range of flexion between front foot placement and ball release at L1 is much greater in the non-injured group than in the injured group as measured at the end of the season ($p=0.031$). **Conclusions** The association between kinematics and lower quarter injuries may exist as a result of altered sensory-motor control strategies (protective mechanisms), reflect an attempt to increase ball release speeds or may indicate altered trunk load adaptation strategies. This study shows that low back and knee kinematics is associated with and may predict lower quarter injuries in cricket fast bowlers.

AN INTEGRATED MEASUREMENT SYSTEM FOR ANALYSING LOWER LIMB BIOMECHANICS DURING HOCKEY SKATING

LeVangie, M., Buckeridge, E., Stetter, B., Nigg, S., Nigg, B.M.

University of Calgary

Introduction Skating is the most fundamental skill in ice hockey at any level of play. However, due to the inherent difficulties of on ice data collection, little research has been conducted in this area. The complexity of on ice data collection has lead previous research to be conducted on smaller scales (Lafontaine, 2007), skating treadmills (Upjohn et al, 2008), or synthetic ice (Stidwell, 2009). To overcome these limitations, a novel, wireless, and portable measurement approach which integrates multiple data collection systems, was developed in order to compare on ice skating biomechanics between high and low caliber skaters. **Methods** Nine high caliber and nine low caliber hockey players performed fifteen 30 m maximum effort forward skating trials. The 2nd and 6th strides were defined as acceleration (AC) and maximum velocity (MV) strides respectively. Independent measurement systems, housed in a backpack worn by the skater, were synchronized and collected through a remote laptop. A 3D accelerometer was mounted to the chassis of the right skate for the purpose of stride detection. Muscle activity of the vastus medialis (VM) and lateralis (VL), gluteus medius (GM), tibialis anterior (TA) and medial gastrocnemius (MG) was recorded using surface electromyography. Two biaxial goniometers were used to quantify the sagittal and frontal plane hip and knee joint angles. Biomechanical differences across caliber and strides were assessed using a mixed model ANOVA. **Results** High caliber subjects exhibited an earlier onset and a greater peak muscle activity of the VL during MV strides compared to low caliber ($p<0.01$). They also demonstrated greater hip adduction at initial ice contact during AC and MV strides, and greater hip extension at toe-off during AC strides ($p<0.01$). Hip abduction velocity during AC and MV strides, and knee extension velocity during MV strides were also shown to be greater in high compared to low caliber subjects ($p<0.01$). **Discussion** The integration of multiple measurement systems allowed for a successful data collection of lower limb biomechanics on ice. High caliber skaters demonstrated greater hip and knee angular velocities than low caliber skaters, coupled with earlier and higher peak knee extensor muscle activity. These caliber differences indicate that this measurements system is sufficiently sensitive to distinguish between the quality of players. As such, this system may be useful for athlete monitoring, and to provide coaches and athletes with biofeedback and training advice.

THE POWER OF FORWARD FLEXION IN HOCKEY SKATE BOOT DESIGN

Lockwood, K., Tokuno, C., Cadeau, L., Christmas, K., McGurk, M., McKenzie, A.

Brock University

Introduction Evolution of hockey skate boot designs has emphasized the importance of stiffness and support. Because efficient skating mechanics requires significant ankle and knee flexion, players have adopted the practice of compromising the boot lacing systems by not using the top lace holes in order to achieve this. However in doing so, they sacrifice the lateral support inherent to the material properties of the boot. Therefore, the objective of this study was to determine if modifications in boot design permitting forward flexion improved skating mechanics and performance. For the purpose of the study, an innovative device, called a lace extender, was designed to permit flexion without compromising the lateral support of the skate boot. **Methods** Biomechanical analyses were conducted in a laboratory setting using a skating treadmill and 3D motion analysis to develop a theoretical model for comparison. Four elite level ice hockey players skated under two boot conditions; (i) custom fit skates (CS), and (ii) CS with lace extenders (LE). Stride length (SL), stride frequency (SF), and ankle and knee angles were measured and averaged over 10 strides. Mean differences were compared between boot conditions ($p<0.05$). Performance analyses were conducted using eight on-ice skating drills completed under the same two boot conditions. A six gate timing system was used to measure total time (ms) and time per interval (ms) to complete each of the skating drills. Mean differences were compared between boot conditions ($p<0.05$). **Results** Significant differences in SL and ankle and knee angles were revealed in the LE condition ($p<0.05$). An analysis of total time to complete the skating drills by condition revealed varied results; however, an analysis of times per interval revealed significant differences between conditions ($p<0.05$). Specifically, starts and acceleration intervals

were significantly faster in the LE condition, suggesting that high power movements were enhanced with additional forward flexion ($p < 0.05$). Discussion Theoretically, the ability to bend or flex at the ankles and knees has the potential to contribute significantly to players' ability to generate force and enhance on ice skating speed. By increasing the amount of forward flexion allowed by the skate boot, the increased SL resulted in more contact time and consequently, more power per push. High power on ice movements, such as starts and acceleration were also faster with increased flexion. Stability and flexibility are both important qualities of a hockey skate boot design and should be complementary offerings as opposed to one compromising the other. Until hockey skate boot manufacturers can produce a skate that incorporates both, lace extenders seem to be a useful tool to help optimize performance.

PHYSICAL LOAD OF TOP-LEVEL ROAD RACING MOTORCYCLING COMPETITIONS VIA KINEMATICAL ANALYSIS.

D'Artibale, E.

University of Hawaii at Hilo

Introduction Top-level road racing motorcycles are machines of 160 Kg, powered by engines generating about 240 bhp, often reaching a track speed of 350 Km/h. Intense accelerations and fierce braking actions are technical maneuvers influencing individual performance, they could determine the physical load experienced by the rider. Few studies have investigated the physiological responses to racing (D'Artibale et al. 2008) and no studies have analyzed this high-risk sport using dynamics. This study was aimed at analyzing kinematical data from top-level motorcycling road racing competitions to determine the physical load suffered by riders. **Methods** Top-level performance data such as track characteristics, laps, length and speed of competitions were collected from official reports (18 races) during the 2013 FIM Road Racing MotoGP™ World Championship. Kinematical data such as braking duration, deceleration peak, and velocities / displacements of braking actions were obtained from official reports published by a leading company manufacturing braking systems (Brembo, Italy). Descriptive statistics was used to describe model of performance. Results In dry conditions, riders are required to perform for 43 ± 2 minutes, riding at 163 ± 7 Km/h, braking 173 ± 43 times and leaning to curve 373 ± 49 times per race. Riders spend $27 \pm 5\%$ of their time decelerating, performing a braking action lasting 4 ± 1 sec every 12 ± 4 sec of race. With each braking action, riders apply a force on the brake lever of 5 ± 1 Kg, they are subject to 1.3 ± 0.2 G of horizontal deceleration peak, experiencing an average negative acceleration of 9 ± 2.3 m/s². Discussion Road racing motorcycling has been shown to require physiological effort (D'Artibale et al. 2013), and kinematical records quantify the physical stress riders undergo when competing. High intensity horizontal accelerations (increasing and decreasing speed) and high quantity lateral weight shifting (leaning to curve) show the amount of forces riders are required to counteract. Technological advancements and material developments make motorcycles more competitive; riders are required to increase skills as well as to be able to bear higher mechanical stresses to improve racing performances. Frequency and intensity of actions performed by riders during competitions could suggest training patterns that focus on increasing the level of readiness of such athletes. Further data are needed to measure and describe the level of muscular strength needed while competing. Road racing motorcycling is a high risk sport (Lippi et al. 2007) and athletes would benefit from scientifically-based training programs. References D'Artibale E, et al. (2008) JSpSci. LONG-TERM EFFECTS OF A COMPLEX FALL PREVENTION PROGRAM IN IN THE GENERAL PRACTITIONER SETTING [PRE-FALLS]

Geilhof, B., Siegrist, M., Freiburger, E., Salb, J., Hentschke, C., Landendoerfer, P., Blank, W., Halle, M.

Technische Universität München

Background International studies show that every third person aged 65 years and above falls at least once a year and a high percentage of those even more. Falls are often associated with increased morbidity, fear of falling, reduced physical activity and social isolation. The aim of this fall prevention program was to evaluate the effects of a 16-week fall prevention program in the setting of general practices (GP) regarding the numbers of falls, physical function, physical activity, and fear of falling. **Participants and methods** In total 378 patients of 33 general practices (93 men, 77.7 ± 5.8 years; 285 women, 78.2 ± 5.9 years) took part in a cluster-randomized and controlled fall prevention program. Participants were eligible for the study if they were aged 65 years and above, showing an increased risk of falling and living independently. The intervention groups (IG, $n=222$) took part in the 16-week training program (1 hour per week) which consisted of strength and balance training, exercises for improving one's body perception, self-efficacy, activities of daily living as well as a 12-week home training program. The control group received usual care (CG, $n=156$). At the start of the study and after 1 year a fall risk assessment including Timed-up-and-go-Test (TUG), physical activity (PAR) and fear of falling (FES-I), was carried out by the GP. Additionally, all participants were asked to fill in a fall diary to quantify the number of falls, which had to be sent back monthly. **Results** During the 12-month study period 291 falls were reported in the intervention group ($n=222$) compared to 367 falls in the control group ($n=156$) (linear mixed model $p=0.007$). Fear of falling was reduced in the intervention group (23.0 pts. to 21.0 pts.) compared to a further increase in CG (24.0 pts. to 25.0 pts.) (linear mixed model $p < 0.001$). Fear of falling was associated with reduced physical activity in CG ($r=-0.42$; $p \leq 0.001$), whereas in IG no association was found ($r=-0.04$; $p=0.638$). **Conclusions** The result of the [PreFalls] study confirmed that the implementation of a complex exercise intervention in the primary care setting can significantly reduce numbers of falls. The observed improvements in fear of falling are important as this aspect often results in reduced physical activity.

VALIDATION OF WEB-BASED PHYSICAL ACTIVITY MEASUREMENT SYSTEM USING TRIAXIAL ACCELEROMETERS

Namba, H.1, Yamada, Y.2, Kimura, M.3, Ishida, M.4, Takase, H.4, Kurosaka, Y.1, Minato, K.1

Introduction Accelerometers (ACC) are easily available and include memory for long-term data collection. However, because they are expensive, they cannot be used for epidemiological studies that require physical activity or energy expenditure measurements in large populations. Web-based physical activity measurement systems are useful for accurately assessing physical activity at low cost. Thus, we collect the date of behavior and physical activity via the Internet to develop Web-based physical activity systems, and examine their validity against triaxial accelerometers. **Methods** Seventy-five healthy subjects (female, 20–22 years) responded using a Web-based physical activity measurement system (24hWEB"lifestyle24.jp") before bedtime every day for a week. 24hWEB included 91 types of action behaviors to account for different lifestyles. Participants recorded activities every 15 minutes for a screen illustration. A triaxial accelerometer (Omron Healthcare, Kyoto, Japan, HJA-350IT) was attached to an elastic belt and worn at the back of the waist for a week. Criteria of analysis data were over 10 hours of wearing per day; non-wearing time was defined as when no signal was received continuously for 60

min. Validity as a reference, the physical activity level (PAL), and the total energy expenditure (TEE) were calculated per week using ACC methods. BMR predicted Ganpule's estimation equation. Results The Pearson's correlation between PAL24hWEB and PALACC was moderate ($r = 0.715$, $p < .001$), and between TEE24hWEB and TEEACC was high ($r = 0.875$, $p < .001$). The mean PAL24hWEB and PALACC were 1.87 (SD 0.18) and 1.70 (SD 0.11), and the mean TEE24hWEB and TEEACC were 2193 kcal (SD 309) and 1989 (SD 245), respectively. In a comparison of time and intensity, light intensity (1.6–2.9 METs) time of 24hWEB was 125 min (SD 53), significantly less than for ACC (243 min, SD 82). Over moderate intensity (>3 METs), the time of 24hWEB was 159 min (SD 95), significantly longer than for ACC (65 min, SD 24); however, over 4 METs there was no significant intensity time difference between 24hWEB (31 min, SD 62) and ACC (25 min, SD 16). Discussion The correlation between 24hWEB and ACC of PAL and TEE in the present study was similar to that found in previous research using DLW methods (Namba et al. 2012). However, the possibility of overestimation has been suggested compared with ACC. Therefore, we compared the time by intensity, and found that 24hWEB was underestimated at light intensity and overestimated at moderate intensity. Behavior over 3 METs was likely to stay in the memory, but behavior at light intensity might be difficult to retain in memory. Further study should be made in another population. In conclusion, 24hWEB appears to be valid for estimating PAL and TEE, and is effective for collecting physical activity data in large communities. References Namba H, et al. PS-PL01 Women versus men in sport and exercise

SEX DIFFERENCES IN NEUROMUSCULAR FATIGUE AND PERFORMANCE: WHY DOES IT MATTER?

Hunter, S.K.

Marquette University

Each human cell has a sex. The fundamental presence of XX or XY chromosome pairs in human cells leads to sex-related differences in physiology and anatomy that are responsible for some profound differences in fatigability and performance between men and women. While men are stronger and more powerful, women are usually less fatigable than men for similar intensity isometric fatiguing contractions. This sex difference in fatigability, however, will alter depending on the details of the task because different neuromuscular sites will be stressed when the requirements of the task are altered, and the stress on these sites can differ for men and women. Task variables that can alter the sex difference in fatigue include the type, intensity and speed of contraction, the muscle group assessed, and the environmental conditions. Physiological mechanisms that are responsible for sex-based differences in fatigability may include activation of the motor neuron pool from cortical and subcortical regions, synaptic inputs to the motor neuron pool via activation of metabolically-sensitive small afferent fibres in the muscle, muscle perfusion, and skeletal muscle metabolism and fibre type properties. Non-physiological factors such as the sex bias of studying more males than females in human and animal experiments can also mask a true understanding of the magnitude and mechanisms of sex-based differences in physiology and fatigability. Examining the underlying mechanisms of sex-based differences in neuromuscular function and fatigability across different task conditions shed light on the benefits and limitations that muscle fatigue can exert in both men and women during daily tasks, exercise performance, training and rehabilitation.

GENDER DIFFERENCES IN PHYSICAL ACTIVITY AND SEDENTARY TIME: DO THEY TRANSLATE TO GENDER DIFFERENCES IN HEALTH OUTCOMES?

Brown, W.

University of Queensland

Centre for Research on Exercise, Physical Activity and Health, School of Human Movement Studies, The University of Queensland, Australia. Introduction: Most large data sets from around the world suggest that men are more active than women. Yet statistics suggest that this does not transfer to survival or chronic disease benefits for men. Recognising that there are clearly more factors at play in chronic disease aetiology than just physical inactivity, this presentation will consider sex differences in patterns of both activity and sedentary behaviours and in the relationships between these behaviours and chronic disease. Methods: Data will be drawn from large population-based data sets, including surveillance and prospective cohort studies that include common measures of activity, sitting time and health outcomes in women and men. Smaller studies will be used to examine levels of activity and sitting in different domains, and relationships with health outcomes in men and women. Results: Most of the early physical activity studies and many surveillance instruments used physical activity questionnaires that were designed for men. They focused largely on sports and organised recreation activities, and did not (for a range of reasons) include home-based activities. The majority of studies that report relationships between inactivity and chronic disease use different absolute measures of both activity and risk, making it difficult to directly compare relationships in men and women. More recent studies include consideration of a wider range of activity measures; evidence on relationships between 'light' activity and health outcomes appears to be becoming more salient when considering sex-differences in health outcomes. Discussion: As patterns of activity and sitting are changing in many countries, it may be time to re-think the way we conceptualise relationships between activity and health outcomes, with consideration of 'background' levels of lifestyle activity as well as of more structured or planned activities. This is particularly important for countries where demographic shifts mean that there are more older people, for whom it may be salient to measure and promote non-exercise activity for health benefits, especially for men.

OP-PM04 Nutrition & Supplements

DIETARY NITRATE SUPPLEMENTATION: EFFECTS ON PLASMA NITRITE AND PULMONARY O₂ UPTAKE DURING EXERCISE IN HYPOXIA AND NORMOXIA

Kelly, J., Vanhatalo, A., Bailey, S.J., Wylie, L.J., Jones, A.M.

University of Exeter

Introduction Recent investigations have elucidated the physiological effects of dietary nitrate (NO₃⁻) supplementation, in the form of beetroot juice (BR), in humans under normoxic conditions. NO₃⁻ may elevate nitric oxide (NO) bioavailability, reduce the steady-state oxygen uptake (VO₂) and improve exercise tolerance in normoxia. Considering that the NO₃⁻ reduction pathway is augmented by hypoxia, we reasoned that dietary NO₃⁻ may ameliorate the negative effects of hypoxia on exercise tolerance by increasing NO bioavailability. We therefore investigated the effects of NO₃⁻ supplementation on the dynamics of plasma nitrite concentration ([NO₂⁻]), VO₂ and exercise tolerance in normoxia (N) and hypoxia (H). We hypothesized that the dynamics of [NO₂⁻] during exercise would be influenced both by the fraction of inspired O₂ (FIO₂) and by NO₃⁻ supplementation and that NO₃⁻ supplementation would improve tolerance to severe-intensity, constant-work-rate cycle exercise in hypoxia. **Methods** Following ethical approval, twelve healthy subjects completed cycle exercise tests, twice in N (20.9% O₂) and twice in H (13.1% O₂), in a double-blind, crossover design. Subjects supplemented their diet with either 140 ml/d of NO₃⁻-rich BR (8.4 mmol NO₃⁻) or NO₃⁻-depleted beetroot juice (PL; 0.08 mmol NO₃⁻) for 3-days prior to moderate-intensity and severe-intensity exercise tests in N and H. **Results** Resting plasma [NO₂⁻] was elevated in both H-BR and N-BR compared to H-PL and N-PL (P<0.05). The rate of decline in plasma [NO₂⁻] was greater during severe-intensity exercise in H-BR (-29.8 ± 21.7 nM/min compared to H-PL (-7.0 ± 9.5 nM/min, P<0.05) and in N-BR (-26.1 ± 18.9 nM/min) compared to N-PL (-1.3 ± 5.9 nM/min, P<0.05). During moderate-intensity exercise, steady-state pulmonary VO₂ was lower in H-BR (1.91 ± 0.28 L/min) compared to H-PL (2.05 ± 0.25 L/min, P<0.05) and VO₂ kinetics was faster in H-BR (phase II τ: 24 ± 13 s) compared to H-PL (31 ± 11 s, P<0.05). NO₃⁻ supplementation had no significant effect on VO₂ kinetics during severe-intensity exercise in hypoxia, or during moderate- or severe-intensity exercise in normoxia. NO₃⁻ supplementation improved tolerance to severe-intensity exercise in hypoxia (H-PL: 197 ± 28 vs. H-BR: 214 ± 43 s, P<0.05), but not normoxia. **Conclusion** The metabolism of [NO₂⁻] during exercise is influenced both by the FIO₂ and by NO₃⁻ supplementation. In hypoxia, the VO₂ response was positively modulated during moderate-intensity exercise and tolerance to severe-intensity exercise was improved as a result of NO₃⁻ supplementation. These findings may have important implications for individuals exercising at altitude and for disease populations where tissue hypoxia is prevalent. Contact J.A.Kelly@exeter.ac.uk

EFFECTS OF DIETARY NITRATE SUPPLEMENTATION ON BLOOD PRESSURE, THE O₂ COST OF EXERCISE, AND WALKING PERFORMANCE IN INDIVIDUALS WITH TYPE 2 DIABETES

Shepherd, A.I.1,2, Gilchrist, M.2, Winyard, P.G.2, Jones, A.M.1, Benjamin, N.2, Shore, A.C.2, Wilkerson, D.P.1

1: SHS (Exeter, UK), 2: UEMS (Exeter, UK)

1College of Life and Environmental Sciences, Sport and Health Sciences, University of Exeter, Devon, UK, 2University of Exeter Medical School, St. Luke's Campus, University of Exeter, Devon, UK **Introduction** Individuals with Type 2 diabetes (T2D) have a reduced exercise tolerance compared with non-diabetic controls (Regensteiner et al., 2005). Reductions in exercise tolerance may underpin the reluctance of an individual to attain recommended amounts of exercise (NICE 2008). Dietary nitrate (NO₃⁻) supplementation has been shown to reduce blood pressure (BP), reduce the O₂ cost of exercise, and enhance exercise tolerance in healthy volunteers (Bailey et al., 2009). The aim of this study was to determine if similar effects of NO₃⁻ supplementation were observed in individuals with T2D. **Methods** Following familiarisation, forty eight participants with T2D visited the laboratory on two occasions. Prior to each visit, participants consumed 70 mL/day of either NO₃⁻ rich (6.43 mmol NO₃⁻; BR) or NO₃⁻ depleted beetroot juice (identical in taste, colour, and texture to BR; 0.07 mmol NO₃⁻; PL) for 4 days. BP was measured following 10 minutes of supine rest. Participants then completed low intensity treadmill walking (with pulmonary gas exchange measured throughout) and the 6 minute walk test (6MWT). **Results** Plasma NO₃⁻ and plasma NO₂⁻ were both significantly elevated for BR vs. PL (plasma NO₃⁻: 319 ± 110 vs. 57 ± 66 µM, respectively P < 0.001; plasma NO₂⁻: 1065 ± 607 vs. 679 ± 255 nM, respectively P < 0.001). No significant differences were observed between BR vs. PL for systolic BP (133 ± 12 vs. 134 ± 10 mmHg; P=0.27), diastolic BP (76 ± 11 vs. 77 ± 7 mmHg; P=0.27), end exercise O₂ uptake for treadmill walking (946 ± 221 vs. 939 ± 223 mL.min⁻¹; P=0.59), and distance covered in the 6MWT (550 ± 83 vs. 554 ± 90 m; P= 0.17). **Discussion** Despite a statistically significant increase in plasma [NO₂⁻], four days of BR supplementation with 6.43 mmol of NO₃⁻ did not reduce BP, lower the O₂ cost of exercise, or improve walking performance in individuals with T2D. The lack of effect from dietary NO₃⁻ supplementation in this study may be explained by (in isolation or in combination): (i) T2D per se (i.e. NO₃⁻ is ineffective in individuals with metabolic dysfunction); (ii) the age of the participants; and/or (iii) the elevated 'baseline' plasma [NO₂⁻] observed in these participants. **References** Bailey SJ, Winyard P, Vanhatalo A, Blackwell JR, DiMenna FJ, Wilkerson DP, Tarr J, Benjamin N, Jones AM. DIETARY NITRATE IMPROVES COGNITIVE FUNCTION AND EXERCISE PERFORMANCE DURING PROLONGED INTERMITTENT SPRINT CYCLING

Thompson, C.1, Wylie, L.J.1, Fulford, J.2, Jeukendrup, A.E.3, Vanhatalo, A.1, Jones, A.M.1

University of Exeter

1 Sport and Health Sciences and 2 NIHR Exeter Clinical Research Facility (University of Exeter, U.K); 3 GSSI (Barrington IL, USA) Introduction Dietary nitrate (NO₃⁻) supplementation has been shown to improve intermittent exercise performance of short duration (~15-20 min; Wylie et al. 2013, Bond et al. 2013). However, success in team sport is determined not only by the ability to maintain high-intensity intermittent exercise, but also by the speed and accuracy of decision making. Dietary NO₃⁻, which may enhance nitric oxide bioavailability, has the potential to improve both physical and cognitive performance via its influence on blood flow and muscle energetics. Therefore, the aim of this study was to assess the effects of NO₃⁻ on performance and cognitive function during an extended intermittent sprint protocol. Methods Following ethical approval, 16 male amateur team sport players were familiarised to the intermittent sprint test (IST) (two 40-min "halves" of repeated 2-min blocks consisting of a 6-s "all-out" sprint, 100-s active recovery at 35% VO₂max and 20 s of rest), during which cognitive tasks were simultaneously performed. In a double-blind randomised crossover design, subjects were allocated to receive NO₃⁻-rich (BR; 140 mL.d⁻¹; 12.8 mmol of NO₃⁻), and NO₃⁻-depleted (PL; 140 mL.d⁻¹; 0.08 mmol NO₃⁻) beetroot juice for 7 days (Beet It, James White Drinks Ltd., U.K). On day 7 of supplementation, subjects completed the full IST. Results There was a significant interaction effect (supplement by sprint number) on total work done during the 1st (BR: 61.2±19.1 vs. PL: 58.1±17.1 kJ; P<0.05), but not the 2nd, half of the IST. Specifically, subjects completed more work in 5 of 20 1st half 6-s sprints in BR compared to PL (P<0.05). Reaction time of response to the cognitive tasks in the 2nd half of the IST was improved in BR compared to PL (P<0.05) (BR 1st: 826±100 vs. 2nd: 825±96 ms; PL 1st: 824±114 vs. 2nd: 847±118 ms). However, there was no difference in response accuracy (BR 1st: 6.9±6.1 vs. 2nd: 7.1±7.3; PL 1st: 7.3±6.0 vs. 2nd: 7.1±5.8 incorrect responses; P>0.05). Discussion In conclusion, dietary NO₃⁻ supplementation improved total work done and sprint performance during the 1st 40 min of the IST. Moreover, reaction time during the cognitive tasks was improved with NO₃⁻ in the 2nd compared to the 1st half. These findings suggest that dietary NO₃⁻ enhances repeated sprint performance and may attenuate the decline in cognitive function that typically occurs during team sport gameplay. INFLUENCE OF DIETARY NITRATE SUPPLEMENTATION ON INTERMITTENT EXERCISE PERFORMANCE

Wylie, L.J.1, Bailey, S.J.1, Kelly, J.1, Blackwell, J.R.1, Vanhatalo, A.1, Jones, A.M.1

University of Exeter

1: SSHS (Exeter, United Kingdom) Introduction Dietary nitrate (NO₃⁻) supplementation has been shown to improve exercise tolerance during continuous high-intensity exercise in recreationally-active subjects (e.g., Bailey et al., 2009). However, the influence of NO₃⁻ on intermittent exercise performance is controversial. The purpose of this study was to assess the effect of NO₃⁻ on performance in a variety of intermittent exercise protocols commonly used in training and/or competition. Methods Ten male recreational team-sport players were assigned in a double-blind, randomised, crossover design, to consume NO₃⁻-rich beetroot juice (BR; ~ 10.08 mmol NO₃⁻/d) and NO₃⁻-depleted placebo juice (PL; ~ 0.10 mmol NO₃⁻/d) for 5 days. Subjects completed 24 x 6-s all-out sprints interspersed by 24 s of recovery, 7 x 30-s all-out sprints interspersed by 240-s of recovery and 6 x 60-s self-paced maximal efforts interspersed by 60-s of recovery on days 3, 4 and 5 of supplementation, respectively. All sprints were completed on an electronically braked cycle ergometer for assessment of power output and work done. Pulmonary gas exchange was assessed in all tests. Results On days 3-5 of supplementation, plasma [nitrite] was 237 % greater in BR compared to PL (P<0.01). In the 24 x 6-s sprint protocol, mean power was greater in sprints 1-6 (5 %; P<0.05), and tended to be greater in sprints 13-18 (3 %; P=0.08) and 19-24 (3 %; P=0.07) with BR. Across all 24 x 6-s sprints, mean power was 3 % greater (BR: 595 ± 87 vs. PL: 578 ± 79 W; P<0.01) and the respiratory exchange ratio was 4% greater (BR: 1.14 ± 0.04 vs. PL: 1.10 ± 0.02; P<0.05) with BR. Power indices, total work done and pulmonary gas exchange were not impacted by BR in the 7 x 30-s and 6 x 60-s tests (all P>0.05). Discussion This study suggests that the extent to which NO₃⁻ might be ergogenic during intermittent exercise is dependent upon the interval duration, intensity and work:rest ratio. NO₃⁻ supplementation enhanced performance across a series of 6-s all-out sprints with a work:rest ratio of 1:4, but did not improve performance during repeated 30-s all-out sprints or 60-s self-paced maximal efforts with work:rest ratios of 1:8 and 1:1, respectively. These results suggest that NO₃⁻ supplementation has the potential to enhance performance in team sports. References Bailey, S.J, Winyard, P, Vanhatalo, A, Blackwell, J.R, DiMenna, F.J, Wilkerson, D.P, Tarr, J, Benjamin, N, Jones, A.M. (2009). J Appl Physiol, 107, 1144-1155.

INCREASING MUSCLE TOTAL CARNITINE CONTENT MAINTAINS PDC FLUX DURING REPEATED BOUTS OF VERY INTENSE EXERCISE

Shannon, C.E., Ghasemi, R., Greenhaff, P.L., Stephens, F.B.

University of Nottingham

Background Increasing skeletal muscle total carnitine (TC) content increases pyruvate dehydrogenase complex (PDC) activation and flux during exercise at 80% maximal aerobic capacity (VO₂max; [1]). Whether these carnitine-mediated effects on PDC are operative during more intense exercise, when the rate of PDC activation is rapid and flux declines with successive bouts is unknown. We hypothesised that increasing muscle TC content by daily carbohydrate and L-carnitine feeding over 24 wks of exercise training would increase acetyl-group buffering capacity during repeated bouts of exercise at 100% VO₂max and thereby maintain PDC flux compared to control. Methods Ten healthy, untrained male volunteers (Age 23 ± 4 yrs, BMI 24 ± 3 kg/m², VO₂max 42 ± 6 ml/kg/min) performed 2 x 3-minute bouts of exercise at 100% VO₂max, separated by 5 min of rest, before and after 24 wks of exercise training combined with daily ingestion of 2 x 500ml drinks containing 80g carbohydrate (CHO) or 80g carbohydrate + 2g L-carnitine L-tartrate (1.36g L-carnitine; CARN). Muscle carnitine moieties and PDC activation status (PDCa) was measured in quadriceps muscle biopsy samples taken immediately before and after each bout. Training consisted of 4 bouts of supervised cycling exercise at 100% VO₂max, 3/wk. Two-way ANOVA (Bonferroni-corrected) was used to compare absolute and delta muscle values; data are expressed as mean ± SE. The University of Nottingham Ethics Committee approved the study. Results Muscle TC was increased 10% in CARN (20.1 ± 1.8 vs 22.1 ± 2.3; P<0.01) but unchanged in CHO (18.2 ± 1.4 vs 17.2 ± 1.5 mmol/kg dry mass) over 24 wks. There were no differences between CARN and CHO in work output, carnitine acetylation, or PDCa during the first bout of exercise at 24 wks. This resulted in free carnitine availability being 55% greater in CARN vs CHO prior to the second bout of exercise (17.7 ± 2.2 vs 11.3 ± 0.8 mmol/kg dm, respectively; P<0.05). Consequently, carnitine acetyla-

tion during the second bout was greater in CARN vs CHO (3.8 ± 2.4 vs 0.1 ± 1.4 mmol/kg dm; $P < 0.05$), despite similar work output (43.6 ± 6.0 vs 44.5 ± 3.9 kJ) and increases in PDCa (5.9 ± 3.0 vs 3.9 ± 3.7 nmol/min/mg protein, respectively). Conclusions Daily carbohydrate and L-carnitine feeding increased muscle TC content over 24 wks of exercise training. This resulted in PDC flux being maintained during a second bout of very intense exercise compared to control, despite similar PDC activation. Increasing muscle free carnitine content therefore improves muscle acetyl group buffering capacity during repeated bouts of very intense exercise, resulting in enhanced PDC flux. References 1. EFFECTS OF VITAMIN C AND E SUPPLEMENTATION IN HEPcidIN SECRETION AND IRON REGULATION

Barba Moreno, L., Peinado, A.B., Butragueño, J., Díaz, V.

Technical University of Madrid. Madrid, Spain.

Introduction The main regulator of iron metabolism is the hepatic antimicrobial peptide hepcidin. Hepcidin acts by inhibiting cellular iron efflux through binding to and inducing the degradation of ferroportin, the sole known cellular iron exporter (1). Exercise and muscle contraction increase hepcidin response, causing an iron absorption reduction (2). Therefore, this response was proposed to explain iron deficiency among athletes. Thus, the aim of this study is to elucidate the influence of vitamin C and E in the regulation of hepcidin after exercise in healthy humans. **Methods** Ten well-trained male students of Sport Sciences (26.9 ± 6.7 years, 69.3 ± 8.8 kg and 176.6 ± 7.5 cm) participated in this study. Subjects received an oral supplementation with a combination of ascorbic acid (500 mg/day) and RRR- α -tocopherol (400 IU/day). Before and after 28 days of supplementation the participants performed 1.5 h running trial at the speed corresponding to the 75% of the maximum oxygen consumption (VO_{2max}) previously determined. Venous blood samples were obtained pre-trial (BS), immediately post-trial (0 h), and at 3, 6, and 10 h post-trial. **Results** There were not significant differences in hepcidin levels between before and after supplementation at the different measures times pre and post-trials (BS: 11.84 ± 5.18 vs. 12.13 ± 7.47 ng/mL; 0 h: 13.45 ± 6.20 vs. 15.02 ± 10.11 ng/mL; 3 h: 26.90 ± 12.51 vs. 26.69 ± 11.86 ng/mL; 6 h: 23.67 ± 10.24 vs. 23.72 ± 11.71 ng/mL; 10 h: 17.22 ± 7.99 vs. 16.51 ± 8.06 ng/mL, respectively). However, hepcidin response was significantly higher after exercise regarding to baseline levels. **Discussion** Hepcidin levels were greater after exercise regarding to baseline levels. These results are similar to those obtained by Peeling et al. (2). However, supplementation with vitamin C and E did not seem to influence hepcidin response. The peak of hepcidin was reached three hours post-trial as Kemna et al. reported in their study (3). Nevertheless, hepcidin values were maintained over baseline levels until 10 hours post-trial. Thus, these high levels could indicate us when the athletes' supplementation should start. **References** 1. Nemeth E, Ganz T. HUMAN ACHILLES TENDON PLASTICITY IN RESPONSE TO CYCLIC STRAIN: EFFECT OF RATE AND DURATION

Bohm, S.1, Mersmann, F.1, Tettke, M.2, Kraft, M.2, Arampatzis, A.1

1: HU (Berlin, Germany), 2: TU (Berlin, Germany)

Introduction Tendons adapt to cyclic strain by changing either their material and/or morphological properties. From a mechanobiological point of view, the magnitude, frequency, rate and duration of the applied strain affect the adaptive response of tendons. Earlier studies of our group showed that a high strain magnitude and low strain frequency induced pronounced adaptations (Arampatzis et al., 2007, 2010). To our knowledge, the effect of modulating strain rate and duration on tendon adaptation has not been investigated yet and, therefore, was the purpose of the present study. We hypothesized that increasing the strain rate and duration compared to a reference protocol (Arampatzis et al., 2007) would facilitate tendon adaptation. **Methods** Two interventions were conducted featuring a modification of strain rate ($n=14$) and strain duration ($n=12$) of the Achilles tendon (AT). The participants exercised (14 weeks, 4x/week, 5 sets) a reference protocol (4x 3s loading/3s relaxation) that was designed based on our earlier studies on one leg and with either a comparatively higher strain rate (72 one-legged jumps) or longer strain duration (1x 12s loading), yet the same loading volume and high strain magnitude on the other leg. A matched control group ($n=13$) remained inactive. Before and after the interventions we examined the AT stiffness, Young's modulus and cross-sectional area by means of magnet resonance imaging, ultrasound and dynamometry to assess tendon adaptation. **Results** After the training using the reference and long strain duration protocol we found a significant increase ($p < 0.05$) of the AT stiffness of 57% and 25%, of the cross-sectional area of 4.2% and 5.3% and of the Young's modulus of 51% and 17%, respectively. The increase of Young's modulus was more pronounced following the reference compared to the long strain duration protocol ($p < 0.05$). Although a region-specific hypertrophy of the AT was also detected after the high strain rate training, AT stiffness and Young's modulus increased only by tendency ($p=0.08$ and $p=0.09$, respectively). The control group did not show any changes ($p > 0.05$). **Discussion** Our results provide evidence that repetitive (3s loading/3s relaxation) high strain magnitude loading causes the most pronounced adaptive responses of the AT material and morphological properties compared to a higher rate and longer duration of strain. Therefore, we can conclude that a high strain magnitude, an appropriate strain duration and cyclic (repetitive) loading are essential components of an efficient training stimulus for tendons. **References** Arampatzis A, Karamanidis K, Albracht K. PRINCIPAL COMPONENT ANALYSIS OF IN-SKATE PLANTAR FORCE TO DISCRIMINATE HIGH AND LOW CALIBER HOCKEY PLAYERS

Buckeridge, E., Hoerzer, S., Enders, H., Nigg, B.M.

University of Calgary

Introduction Hockey skates act as an important interface between a player and the ice. As such, the plantar force application within a skate could be an important feature which affects hockey skating. In this study, Principal Component Analysis (PCA, Federolf et al., 2012) was used to (1) determine principal patterns of in-skate force application and (2) distinguish between high and low caliber skating. This approach identifies specific components of force application that can be used to characterize player performance in hockey. **Methods** Nine high caliber (25.7 ± 3.7 yrs, 86.2 ± 7.8 kg) and nine low caliber hockey players (35.7 ± 5.7 yrs, 85.7 ± 13.6 kg) performed 15 repetitions of a 30 m sprint whilst plantar pressure was measured in the right skate using pressure sensing insoles. Pressure data from accelerative (ACC) and maximum velocity (MV) strides were extracted and analyzed. Insole pressure was converted to force at the medial and lateral forefoot segments, medial and lateral midfoot segments and heel segment, and subsequently time normalized (0-100%). PCA was applied to all trials of both groups. PCA results in a set of principal components (PC) arranged in descending order according to their explained variance of the original data set. The first component describes the most relevant aspects with respect to in-skate force application. PC scores were obtained by projecting the original data onto the PCs and analyzed for group differences using an independent t-test ($\alpha=0.05$). Scores were then used to calculate the variance of each group for the PCs. **Results** During ACC and MV strides the largest loading on PC1 was the heel segment. PC2 of the ACC stride was represented by medial and lateral forefoot push-off and initial heel contact force. PC2 of the MV stride contained just medial and lateral forefoot push-off. Significantly different PC scores were identified for PC1 and PC2 across calibers during the ACC stride ($p<.01$). However, during the MV stride a caliber difference was seen only at PC2 ($p<.01$). The low caliber group represented 64% of the variance contained in PC1 scores. **Discussion** This study shows that PCA can be used discriminate high and low caliber skating with respect to in-skate force application. Low caliber players exhibited greater variance in PC1 during ACC, thus caliber differences existed in the most fundamental pressure patterns. This suggests that high caliber players can execute the most important pressure patterns with greater precision and consistency. On the other hand, differences in caliber during MV could only be discriminated at PC2. Therefore as players reach MV, differences in plantar force application become more subtle. **References** Federolf P, Tecante K, Nigg B (2012). J Biomech, 45, 1127-32.

FATIGUE NEGATIVELY AFFECTS PURPORTED INJURY PREDICTORS DURING BAREFOOT BUT NOT SHOD RUNNING

Coetzee, D., Tucker, R., Tam, N.

University of Cape Town

Introduction Barefoot running is said to be the most natural form of running and has been associated with a reduced risk of injury. Although fatigue is synonymous with physical activity, very few studies have considered its effect on barefoot running. The purpose of this study was to determine the effects of acute fatigue on the biomechanical and neuromuscular differences that exist between barefoot and shod running. **Methods** Fifteen habitually shod runners were required to perform overground running trials at 3.5m/s in four varying conditions; pre-fatigue barefoot, pre-fatigue shod, post-fatigue barefoot and post-fatigue shod. Three-dimensional analysis was used to measure kinetic and kinematic variables while surface electromyography was used to measure activation levels of seven lower limb muscles. **Results** Initial loading rate increased with fatigue in the barefoot, but not the shod condition. Initial loading rate was associated with sagittal plane ankle angle at foot strike, with increased dorsiflexion being associated with an increased loading rate in the barefoot condition only. Pre-activation of the lateral gastrocnemius decreased when fatigued in both footwear conditions, while a fatigue by condition affect was found in the pre-activation activity of the peroneus longus. **Discussion** Acute fatigue is associated with potentially harmful biomechanical changes which may lead to increased risk of injury when running barefoot, but not when running with shoes. Increased cushioning provided by the sole of modern day running shoes might attenuate impact forces, thus allowing for greater deviations in ankle angle at foot strike without affecting initial loading rate. Neuromuscular variables such as co-activation patterns of the shank are affected by fatigue which may be associated with decreased muscular stability and increased risk of injury. Barefoot running may be associated with an increased risk of injury, with the effects of fatigue accentuating this risk. Contact devoncoe13@gmail.com

THE INCLUSION OF ROTATIONAL ACCELERATION IN ALPINE HELMET TESTING METHODOLOGY

Dawson, L., Post, A., Hoshizaki, T.B.

University of Ottawa

Introduction Alpine skiing is a popular winter sport in which concussion has been found to be a common injury [1]. Concussion has been identified through research to be associated with rotational acceleration, however current impact testing standards such as ASTM F2040 and CE-EN 1077 do not measure this variable [2]. The purpose of this study was then to develop a methodology for alpine helmets to measure rotational acceleration using impact conditions with the highest risk of injury. **Methods** In this study a large alpine helmet tested to ASTM 2045 was fitted on to a Hybrid III headform and impacted using a linear impactor at 5 sites that have been shown to have a high risk of concussion [2]. The impact velocity chosen was 8 m/s with a modular elastic programmer impact cap. **Results** For sites 1-5, the linear acceleration was found to be: 206.3, 206.1, 225.1, 184.9, and 176.6g respectively. Rotational acceleration values were found to be 9753, 19317, 20761, 23661, and 15462 rad/s² for site 1-5. **Discussion** A methodology employing sites associated with high risk of concussion based on linear and rotational values was used to determine the safety of an alpine helmet. Based on Zhang et al (2004), the results of this study found an 80% risk of concussion for all sites for both peak linear and rotational acceleration [3]. The site with the highest risk was site 4, at the rear of the helmet outside of the centre of gravity. This location had the highest risk for concussion as it had the greatest dynamic response for rotational acceleration at 23661 rad/s². These results demonstrate a high risk of concussive injury even while using current helmets in moderately high velocity impacts. A standard employing noncentric impacts and reporting rotational acceleration would be beneficial in decreasing the risk of injury. It is therefore suggested that a helmet test protocol including a rotational component would encourage helmet design to take into account that mechanism of injury to decrease the risk of concussion. **References** 1.Ackery, A., Hagel BE, Prowindenza, C., and Tator, C.H. INCREASED POWER OUTPUT DURING CYCLING IS CHARACTERIZED BY CHANGES IN MUSCLE ACTIVATION STRATEGY AND VARIABILITY.

Enders, H., Nigg, B.M.

University of Calgary

Introduction Variability of muscle activation strategies is an important component of neuromuscular control. We have previously shown that increased power output in cycling is characterized by a decrease in amplitude variability of muscle activation (Enders et al., 2013). However, it was unclear if temporal variability changed and how muscle activation strategies might have shifted. Building upon these findings, the purpose of this study was to investigate changes in (1) muscle activation strategy and (2) their temporal variability at different power outputs during cycling. **Methods** An ergometer was used to collect EMG of seven leg muscles while subjects ($N = 14$) were cycling with 90 RPM at a constant load of 150 W and 300 W. Principal component analysis (PCA) was used to investigate muscle activation strategies for both loads. The results of a PCA describe the correlated activation pattern of the muscles (principle components) as well as a measure of the contribution of each pattern (explained variance) to the entire activation strategy. Temporal variability of the muscle activation was quantified using a novel sample entropy based method (Zandiyeh and von Tscharnner, 2013). **Results** The muscle activation strategy in the 150 W condition was dominated by the correlated activation of ankle plantar flexor and knee flexor muscles. In the 300 W condition the strongest contributor to the muscle activation strategy was the rectus femoris muscle, followed by the biceps femoris and the vastus medialis and lateralis. Temporal variability was significantly decreased in the 300 W condition compared to the 150 W condition ($P < 0.001$). **Discussion** A clear shift in muscle activation strategies was observed when muscular output was increased during cycling. In this study, muscle activation patterns switched to a dominant activation of biarticular knee extensor muscles as power output increases. As the rectus femoris spans the hip and knee joint its function is to transfer energy between these two joints (Ryan et al., 1992). Being the most dominant muscle in the 300 W condition, it may be speculated that energy transfer between hip and knee joint plays a crucial role to maintain a higher power output during cycling. Furthermore, the chosen activation strategy was characterized by a more precise temporal activation pattern solidifying our previous findings that the most relevant activation patterns become more precisely controlled as more muscle force needs to be produced. **References** Enders H, Maurer C, Baltich J, Nigg BM. MOMENT ARM DETERMINATION: SOURCES OF ERROR AND VIOLATIONS OF ASSUMPTIONS

Miller, S.C., Korff, T., Waugh, C., Fath, F., Blazeovich, A.J.

Middlesex University

Introduction Accurate estimates of tibialis anterior muscle force are important in many contexts linked to human movement and injury. Two approaches commonly used to estimate moment arms are the tendon excursion (TE) and geometric (GEO) methods. Previously, poor agreement between the two approaches has been reported. The purposes of this study were to (i) assess the impact of methodological variations in the two methods of moment arm estimation and (ii) determine how these variations affect the agreement between the methods. **Methods** Moment arms were determined using the traditional TE and GEO approaches. Using a novel combination of MRI and ultrasound imaging, a new approach to determining the moment arm was derived. Errors associated with tendon stretch/hysteresis, talus rotation relative to the foot, and location of the line of action were investigated, and accounted for. **Results** For TE, differences between moment arm estimates calculated from plantar- and dorsiflexion rotations were found at -15° (0° =neutral; effect size=0.84; $p=0.045$). Large errors in moment arm estimates across the range of motion ($p=0.001$) were found when inevitable tendon length changes ($p=0.001$) were not corrected for. For GEO, the estimated moment arm was reduced at -15° when discrepancies between talus and foot rotations were accounted for or an alternative tendon line of action was used (located as the tendon inserts onto the foot), either separately (effect size=0.46 and 0.58 respectively; $p>0.05$) or together (effect size=0.89; $p>0.05$). TE-derived moment arms were smaller than GEO-derived moment arms (effect size=0.68 to 4.86, varying by angle) before accounting for sources of error, however were similar after error correction ($p>0.05$). Nonetheless, the shape of the moment arm-joint angle relationship was curvilinear for TE but linear for GEO. **Discussion** The largest error resulted from not incorporating tendon length change within the TE approach, although joint rotation direction also affected the estimates. This effect of rotation direction is thought to be due to a greater hysteresis within the fascicles than the tendon (1). Several sources of error were also found within the GEO method, associated with the estimation of talus rotation and the location of the line of action of the muscle tendon unit. Differences between TE- and GEO-derived moment arm estimates were removed after accounting for these methodological errors. Given that a more realistic pattern of the relationship between joint angle and moment arm was obtained with the new TE method, however, this methodology appears to be more appropriate for use than the GEO method. **References** 1. OP-PM05 Sports Medicine & Exercise Therapy

EFFECT OF LOW VERSUS HIGH INTENSITY PHYSICAL EXERCISE DURING CHEMOTHERAPY ON PHYSICAL FITNESS, FATIGUE AND CHEMOTHERAPY COMPLETION RATES: RESULTS OF THE PACES RANDOMIZED CLINICAL TRIAL

van Waart, H., Stuver, M., Sonke, G., van Harten, W., Aaronson, N.

Netherlands Cancer Institute

Introduction Exercise programs have been demonstrated to have a beneficial effect on patients undergoing chemotherapy. The optimal intensity of such programs is as yet unknown. This study evaluated the efficacy of a low intensity, home-based, self-management physical activity program (Onco-Move), and a high intensity, structured, supervised exercise program (OnTrack) in terms of maintaining or enhancing cardiorespiratory fitness and muscle strength, minimizing fatigue, enhancing health-related quality of life, and maximizing

chemotherapy completion rates of patients undergoing adjuvant chemotherapy for breast and colon cancer. **Methods** In this multicenter, prospective, RCT, 253 patients were randomized to: Onco-Move (n=85), OnTrack (n=83) or a Usual Care control group (n=85). Outcomes were assessed prior to chemotherapy, at the end of chemotherapy, and 6 months later (only first follow-up results will be presented). Between group differences were evaluated using ANCOVA. **Results** Participants in OnTrack had significantly less decline in cardiorespiratory fitness (ES=0.52 and ES=1.17), enhanced muscle strength (ES=0.59) and experienced less physical fatigue (ES=0.64) as compared to the control group. Both exercise groups reported better physical functioning (ES=0.62), less nausea (ES=0.43) and pain (ES=0.33); only participants in OnTrack reported less constipation (ES=0.78) at follow-up than the control group. Significantly more participants in OnTrack completed their prescribed chemotherapy regimen without dose adjustments than those in the control group (84% versus 62%) (OR=3.3). **Discussion** This study showed that high intensity physical exercise during chemotherapy is most effective. It enhances muscle strength, reduces the decline in cardiorespiratory fitness and fatigue, and leads to less dose reductions in chemotherapy regimens. When unable or unwilling to participate in high intensity exercise during chemotherapy, low intensity is a second best. Although less effective, it also has a salutary effect on physical fatigue and other symptoms. Interestingly, this study supports the hypothesis that exercise may enhance tolerability of the toxic effects of chemotherapy (Courneya et al., 2007) and mitigate the cardiotoxic effects of Trastuzumab (Wodners and Reigle, 2009). **References** Courneya K, Segal R, Mackey J, et al. (2007). *J Clin Oncol*, 25, 4396-4404. Wonders K, Reigle B (2009). *Integr Cancer Ther*, 8, 17-21.

A PILOT STUDY OF MODERATE PHYSICAL ACTIVITY IN HIV-INFECTED PERSONS RECEIVING ANTI-HIV DRUGS: BENEFITS ON SOLUBLE AND CELL MARKERS OF INFLAMMATION

Bonato, M.1, Longo, V.2, Bossolasco, S.2, Pavei, G.1, Galli, L.2, Merati, G.1, La Torre, A.1, Cinque, P.2

1: *Università degli Studi di Milano*; 2: *San Raffaele Scientific Institute*

Introduction HIV infection and combined antiretroviral therapy (cART) are associated with chronic immune activation, which can contribute to the development of metabolic problems and chronic diseases, e.g., cardiovascular diseases, type-2 diabetes. In the general population moderate physical activity has shown to reduce both inflammation and burden of chronic diseases. **Aim** of this study was to evaluate the effects of brisk walking, as moderate aerobic exercise, on physical fitness, metabolic measures and soluble and cell inflammatory markers among HIV-infected treated subjects. **Methods** A pilot study was designed including HIV-infected, cART-treated, sedentary subjects with metabolic problems, in a 12-week protocol consisting of 3 outdoor sessions/week of 60 min brisk walking at 65-75% of HRmax with ("walk-strength" group) or without ("walk" group) 30 min circuit training at 65% of 1-repetition maximum (RM). Measures at baseline (BL) and at week 12 (W12) included distance walked at 6 minute walking test (6MWT) and 1-RM Test; morphometric measures; fasting lipid and glucose blood profile; plasma level of d-dimer, high-sensitivity CRP (hsCRP), interleukin-6 (IL-6), interleukin-18 (IL-18), soluble CD14 (sCD14), myostatin, and CD38 and HLA-DR expression on CD4+ and CD8+ cells. Differences between groups were tested by the Mann-Whitney test and W12 changes from BL by the Wilcoxon-signed rank test. Results are expressed as median values. **Results** Forty-nine subjects were enrolled and 35 completed the 12-week program: 14 in the 'walk-strength' group and 21 in the 'walk' group. Median adherence was 67%. At W12, significant improvements from BL were observed of both aerobic and strength performance, with a 14% improvement of distance walked during 6MWT, of BMI, waist and hip circumference, and total and LDL cholesterol, without differences between training groups. Significant reductions were observed of plasma levels of d-dimer (from 272 to 181 ng/mL, $p=0.0002$), hsCRP (from 2.02 to 1.14 $\mu\text{g/mL}$, $p=0.001$), IL-6 (from 4.63 to 4.47 pg/mL, $p=0.021$), IL-18 (from 354 to 304 pg/mL, $p=0.010$) and myostatin (from 20.9 to 13.5 pg/mL, $p=0.006$), and of frequency of CD8+CD38+ (from 10.19 to 10.23%, $p=0.010$), CD8+HLA-DR+ (from 4.34 to 1.79%, $p=0.001$) and CD4+HLA-DR+ cells (from 10.87 to 6.85%, $p=0.024$). **Conclusions** A 12-week protocol of brisk walking was associated with a significant reduction of immune activation in HIV- treated subjects with metabolic disorders. Moderate physical activity can be proposed as a strategy to control long-term consequences of treated HIV infection. Contact matteo.bonato@unimi.it

LOW GI MEALS MINIMISE POST-PRANDIAL HYPERGLYCAEMIA WHILST PROTECTING FROM EARLY ONSET HYPOGLYCAEMIA FOLLOWING EVENING EXERCISE IN T1DM

Campbell, M.

Northumbria University

INTRODUCTION Low glycaemic index (GI) foodstuffs elicit more favourable glycaemic profiles than high GI equivalents in type 1 diabetes (T1DM) patients (Parillo, Annuzzi et al. 2011). However, it is unknown whether low GI foodstuffs consumed following evening exercise aid in the prevention of early or late onset hypoglycaemia, when adopting current recommendations for reducing pre- and post-exercise rapid-acting insulin dose (Campbell, Walker et al. 2013). This study compared a low versus high GI feeding strategy on post-prandial glycaemia following evening exercise in T1DM. **METHODS** Ten male T1DM patients (mean \pm SEM) age 27 \pm 1 years, HbA1c 6.7 \pm 0.2% completed two evening-time trials (beginning at ~17:00 PM). On each occasion patients administered a 25% dose of rapid-acting insulin and ingested a standardised carbohydrate bolus 60-min prior to performing 45-min of intensive treadmill running. 60-min after exercise, patients administered a 50% dose of rapid-acting insulin with one of two isoenergetic meals (1.0g carbohydrate.kg⁻¹BM) matched for macronutrient content but differing in GI (LOW=37; HIGH=92) then rested for 180-min. Patients then consumed one of two isoenergetic bedtime snacks (GI: LOW=38; HIGH=86) before returning home to sleep. Interstitial glucose (IS) responses were captured in-lab and for a further 20-h post-lab using continuous glucose monitoring. **RESULTS** Both conditions provided protection from early onset hypoglycaemia, however all patients under HIGH experienced hyperglycaemia (mean interstitial glucose HIGH 13.8 \pm 1.6 mmol.L⁻¹), whereas glycaemia following LOW was typically euglycaemic (LOW 7.4 \pm 1.0 mmol.L⁻¹; $p<0.001$) and hyperglycaemia limited to 4 patients. Overnight glycaemia was comparable with declines in IS occurring similarly ~8 hours post-exercise inducing late nocturnal hypoglycaemia (HIGH n=4, LOW n=4). **DISCUSSION** Incorporating evening exercise safely into the lives of T1DM patients is hampered by inadequate dietary guidelines for managing post-exercise glycaemia. We demonstrate that foodstuff composition has implications for modulating post-prandial glycaemia after exercise. Compared to the high GI post-exercise meal, the low GI meal reduced hyperglycaemia by 60%, whilst protecting from early hypoglycaemia. This finding is clinically important, as normalizing glycaemia is fundamental to diabetes management (Thomas, Elliott et al. 2007), especially for exercising patients (Chu, Hamilton et al. 2011). However, risk of nocturnal hypoglycaemia following evening exercise remains, thus carbohydrate intake alone may not negate the development of late-onset hypoglycaemia.

THE USE OF LEFT VENTRICULAR STRAIN ANALYSIS AND EXERCISE TO IDENTIFY SUB-CLINICAL CARDIAC DYSFUNCTION IN OTHERWISE ASYMPTOMATIC CANCER SURVIVORS

Kearney, M.

Cardiff Metropolitan University

Introduction Anthracycline (ANT) chemotherapeutic agents are widely used in the treatment of many cancers despite being cardiotoxic (Monsuez et al., 2010). The early detection of sub-clinical left ventricular (LV) dysfunction caused by ANT treatment would permit timely clinical intervention. The measurement of LV strain quantifies multi-directional myocardial deformation and has recently been used during exercise to uncover sub-clinical LV dysfunction in hypertensive patients (Tan et al., 2010). The purpose of this study was to determine whether LV strain is sensitive to subtle cardiac dysfunction at rest and during exercise provocation in asymptomatic cancer survivors previously treated with ANT. **Methods** Thirteen cancer survivors (36 ± 10 yrs) with prior ANT exposure and 15 controls (34 ± 12 yrs) took part in the study. Heart rate (ECG), LV volumes (2-D echocardiography) and strain (Speckle tracking echocardiography, Vividq, GE Healthcare) were measured at rest and during low-intensity exercise (50% of anaerobic threshold) on a supine cycle ergometer. Data were analysed using repeated-measures ANOVA and post hoc tests with Bonferroni correction. Alpha was set at 0.05. **Results** At rest, despite comparable heart rate (HR), ejection fraction (EF) and cardiac output (CO), the ANT group had significantly lower longitudinal systolic strain than controls (-18 ± 2 vs $-20 \pm 2\%$, $p=0.011$). Upon exercise CO remained similar between the two groups but the ANT group showed higher HR (95 ± 9 vs 86 ± 12 bpm, $p=0.038$) and lower EF (60 ± 6 vs $64 \pm 4\%$, $p=0.024$). This was coupled with failure of the ANT group to augment basal (-15 ± 3 vs $-19 \pm 3\%$, $p=0.027$) and apical (-27 ± 5 vs $-34 \pm 8\%$, $p=0.009$) circumferential systolic strain. **Discussion** Using LV strain analysis and exercise provocation we were able to identify differences in LV function between patients previously exposed to ANT and healthy controls. At rest global LV function was similar between groups and there were few differences in LV strain parameters. However, with exercise differences in basal and apical circumferential strain became apparent. Combining strain analysis with exercise may provide a useful tool to identify sub-clinical dysfunction, and therefore prompt early clinical intervention, in this patient population. **References** Monsuez J.J. et al., (2010). *Int J Cardiol*, 144, 3–15. DISSOCIATION IN THE EFFECT OF TERBUTALINE ON HYPERPNOEA-INDUCED RESPIRATORY SYMPTOMS AND BRONCHOCONSTRICTION IN ATHLETES

Simpson, A.J., Romer, L.M., Kippelen, P.

Brunel University

Introduction Exercise-induced bronchoconstriction (EIB) is highly prevalent in athletes (Carlsen et al., 2008). Self-reported respiratory symptoms are neither sensitive nor specific for the diagnosis of EIB in athletes (Rundell et al., 2001; Holzer et al., 2002). Nonetheless, physicians typically rely on self-reported respiratory symptoms for diagnosis and often use a change in the perception of respiratory symptoms following treatment to aid diagnosis (Hull et al., 2009). **Aim** To demonstrate a disconnect between perception scores for respiratory symptoms and bronchoconstriction following hyperpnoea of dry air in athletes with EIB pre-medicated with either inhaled beta2-agonist or placebo. **Method** Thirty five recreational athletes with EIB took part to a randomised, double-blind, placebo-controlled, cross-over study. The athletes completed an 8-min eucapnic voluntary hyperpnoea (EVH) challenge with dry air on two separate days. A single therapeutic dose of 0.5 mg of the inhaled beta2-agonist terbutaline or a placebo was administered by inhalation 15 min before EVH. Lung function was assessed at regular intervals following EVH (up to 60 min recovery) and respiratory symptoms (cough, wheeze, chest tightness and mucus secretion) were recorded on a 10 cm visual analogue scale 15 min post-challenge. Paired t-tests and Pearson correlation tests were conducted. **Results** Terbutaline offered complete bronchoprotection to 80% of athletes [i.e., maximal post-EVH fall in forced expiratory volume in 1 sec (FEV1) $<10\%$]. The maximal fall in FEV1 was reduced from $16 \pm 7\%$ (mean \pm SD) in the placebo condition to $7 \pm 5\%$ with administration of terbutaline ($p < 0.001$). Although terbutaline reduced group mean symptom scores ($p < 0.01$), the degree of bronchoprotection did not correlate with individual changes in symptom scores between terbutaline and placebo ($p > 0.05$). Of the 28 athletes who had complete bronchoprotection, 14 (50%) rated at least one respiratory symptom higher under terbutaline compared to placebo. **Conclusion** Changes in hyperpnoea-induced respiratory symptoms following treatment with terbutaline do not correlate with changes in airway calibre. Therefore, subjective changes in respiratory symptoms after treatment with inhaled beta2-agonists should not be relied upon for the diagnosis of EIB. This reinforces the need for objective evidence of EIB for effective diagnosis and management of EIB in athletes (Rundell et al., 2001; Holzer et al., 2002). **References** Carlsen et al., *Allergy*, 2008 Hull et al., *BMC Pulm Med*, 2009 Holzer et al., *J Allergy Clin Immunol*, 2002 Rundell et al., *Med Sc Sports Exerc*, 2001 Contact Andrew.Simpson@Brunel.ac.uk

ASSOCIATION BETWEEN SELF-REPORTED WALKING PACE AND INDICATORS OF SLEEP-DISORDERED BREATHING: A POPULATION-BASED INVESTIGATION

Suri, S.1, Batterham, A.M.1, Ells, L.1, Danjoux, G.1,2, Atkinson, G.1

Introduction Sleep-disordered breathing refers to a continuum of abnormalities ranging from relatively benign snoring to debilitating obstructive sleep apnoea syndrome (OSAS). A screening tool for OSAS is the "STOP-Bang" questionnaire, consisting of simple yes/no questions relevant to known risk factors (Chung et al., 2012). In this context, we examined the cross-sectional association between a simple question relating to self-reported walking pace (an important indicator of "frailty") and sleep apnoea, loud snoring, and daytime tiredness in the large population-based Multi-Ethnic Study of Atherosclerosis (MESA). **Methods** In the MESA sample, 2912 men and 3213 women, aged 46–87 years, self-reported their walking pace outside the home. A walking pace <0.89 m/s (or no reported walking) was classified as "slow", with ≥ 0.89 m/s classified as "average/ brisk". The prevalence of self-reported loud snoring (heard behind a closed door), excessive daytime tiredness and physician-diagnosed sleep apnoea was also recorded. Data were analysed with multivariable-adjusted binomial regression, providing risk differences and their confidence intervals (95% CI). Because body mass index is likely to be on the causal pathway between the exposure (walking pace) and the outcomes (sleep-disordered breathing), it is not appropriate to adjust for this potential mediator. **Results** The prevalence of sleep-disordered breathing outcomes in the sample was 3.5% for sleep apnoea, 20.5% for loud snoring, and 22.2% for daytime tiredness. The prevalence of slow walking pace was 26.9%. In age- and sex-adjusted models, the risk difference for slow vs. average/ brisk walking pace was 1.4% (95% CI: 0.4 to 2.5%) for sleep apnoea, 5.3% (1.7 to 8.9%) for loud snoring, and 4.7% (2.3 to 7.2%) for daytime tiredness. These risk differences were similar for men and women ($P > 0.5$). **Discussion** In this population-based study, we have found a greater prevalence of sleep-disordered breathing, including physician-diagnosed sleep apnoea, among older people who report walking slower than 0.89 m/s. Importantly, this finding was not restricted to

women, as previously reported in another population-based study (Endeshaw et al., 2009). Prospective observational and experimental studies should follow to confirm these new findings. We propose that a simple question about walking pace might improve the diagnostic utility of the STOP-Bang questionnaire. References Chung F, Subramanyam R, Liao P, Sasaki E, Shapiro C, Sun, Y. OP-PM06 High Intensity Intermittent Training (HIT)

TRAINING INDUCED ALTERATION IN MITOCHONDRIAL ADP SENSITIVITY DEPENDS ON TRAINING INTENSITY

Dohlmann, T., Dela, F., Helge, J.W., Larsen, S.

University of Copenhagen

Introduction In the literature, diseases associated with a sedentary lifestyle have been linked to impaired mitochondrial function. Since physical training improves the mitochondrial function, a training regime could potentially counteract the impairment induced by lifestyle diseases and inactivity. However, since mitochondria serve multiple functions it is necessary to clarify the specific mitochondrial adaptation to training. One of the predominant mitochondrial functions is the production of ATP by oxidative phosphorylation, which is stimulated by an increased ADP:ATP ratio. Here we aimed to investigate how the mitochondrial ADP sensitivity is influenced by high intensity interval training (HIT), and if the adaptation is dependent on training intensity. **Methods** Two matched groups of healthy sedentary adults (age 38 ± 3 yrs, BMI 33 ± 1 kg/m², $\dot{V}O_{2\max}$ 2.7 ± 1.3 l/min) completed 18 sessions of HIT. One group (n=12) followed a protocol consisting of 7x1 min at ~94% of $\dot{V}O_{2\max}$ interspersed with 1 min rest periods (MHI), and the other group (n=9) followed a protocol of 5x1 min at ~132% of $\dot{V}O_{2\max}$ interspersed with 1.5 min rest periods (VHI). Changes in mitochondrial respiration were measured ex vivo in permeabilized muscle fibers from the vastus lateralis, and mitochondrial ADP sensitivity was determined using Michaelis-Menten kinetics. **Results** Following training, MHI decreased the mitochondrial ADP sensitivity as evidenced by 102% increased apparent K_m (0.14 ± 0.02 to 0.29 ± 0.03 , $P=0.002$) with no change in maximal ADP stimulated respiration ($\dot{V}O_{2\max}$, 21 ± 1 to 22 ± 1 pmol O₂/s/mg). In contrast, VHI did not change the apparent K_m (0.19 ± 0.10 to 0.16 ± 0.04), but $\dot{V}O_{2\max}$ increased 93% (11 ± 1 to 21 ± 2 pmol O₂/s/mg, $P=0.001$). The training intensity of VHI was 40% higher than MHI ($P<0.05$), but both groups increased $\dot{V}O_{2\max}$ 7% ($P<0.05$). **Discussion** The decreased ADP sensitivity in MHI may be explained by an increased activity of mitochondrial creatine kinase (miCK) and creatine kinase (CK), which shuttles high energy phosphate between the mitochondrion and the ATP utilizing sites, thus decreasing the ADP flux across the mitochondrial membranes. In rodents, the CK shuttle system is most expressed in slow twitch (ST) muscle fibers. In our study the intensity of VHI was significantly higher than MHI, and therefore the unchanged ADP sensitivity in VHI is probably due to a lack of recruitment and adaptation in the ST fibers. Only VHI increased $\dot{V}O_{2\max}$, and we speculate that this is due to activation of adenylate kinase (AK), which is most expressed in fast twitch fibers. AK uses ATP and AMP to produce 2 ADP which reenters the ATP synthase and stimulates respiration. We are the first to demonstrate that training induced alteration in ADP sensitivity differs with different training intensities.

THE EFFECT OF CONCURRENT RESISTANCE AND HIGH INTENSITY INTERVAL EXERCISE ON ACUTE MRNA RESPONSE IN UNTRAINED SKELETAL MUSCLE

Pugh, J.K., Faulkner, S.H., Jackson, A.P., King, J.A., Nimmo, M.A.

Loughborough University

INTRODUCTION It is recommended that individuals perform a combination of resistance and endurance exercise to improve cardio-metabolic health. Lack of time is often cited as a reason for being unable to do so. Therefore, combining both in one session may be beneficial. However, work continues to elucidate whether signaling interference occurs when endurance and resistance exercise are performed together. PGC-1 α is key to mitochondrial biogenesis, and has been linked to aerobic adaptation. However, preferential expression of PGC-1 α isoforms 1 (PGC-1 α 1) and 4 (PGC-1 α 4) may occur with aerobic and resistance exercise respectively, thus giving rise to a possible increase in total PGC-1 α expression, which may be augmented following concurrent training (Ruas et al. 2012). **METHOD** In a balanced cross-over design with at least 7 days between trials, 10 untrained males performed either resistance exercise only (RE; 4 x 8 leg extensions at 70% 1 RM), or RE followed by high intensity interval cycling (RE-HIIE; 10 x 1 min at 90% HR_{max}). Muscle biopsies were obtained before exercise and at 2 h and 6 h post the RE component. PGC-1 α (total, isoform 1, and isoform 4) and myostatin expression was analysed with RT-qPCR. Two-way repeated-measure ANOVA was used for statistical analysis. **RESULTS** In the RE-HIIE trial, total PGC-1 α expression was increased by 9.1 and 4.7 fold above baseline at 2 and 6 h respectively ($P < 0.01$), whereas no difference occurred with RE. In the RE-HIIE trial, expression of PGC-1 α 1 increased 2.3 fold ($P < 0.01$) at 2 h and PGC-1 α 4 increased expression (11.7 and 6.4 fold above baseline) at 2 and 6 h respectively (both $P < 0.01$). In the RE trial there was no change in either isoform at any time point. Myostatin expression showed a 2.0 fold down-regulation at 6 h in RE ($P < 0.05$) with a greater reduction in RE-HIIE (3.2 fold; $P < 0.01$). **DISCUSSION** We conclude that the combination training yields higher PGC-1 α 4 expression than RE alone and this occurs simultaneous to a decrease in myostatin expression. This may suggest that RE-HIIE results in a parallel regulation of skeletal muscle hypertrophy through an increase in PGC-1 α 4 and the suppression of myostatin pathways. Furthermore, RE-HIIE may augment mitochondrial biogenesis above that of RE alone with an increase in PGC-1 α 1 expression. **REFERENCES** Ruas et al. ORAL CONTRACEPTIVE USE AND ADAPTATIONS TO HIGH INTENSITY INTERVAL TRAINING IN RECREATIONALLY-ACTIVE WOMEN

Schaumburg, M.1, Jenkins, D.1, Frawley, E.1, Stanley, J.1, Emmerton, L.2, Janse de Jonge, X.3, Skinner, T.1

1: UQ (Brisbane, AUS), 2: Curtin (Perth, AUS), 3: UoN (Ourimbah, AUS)

Introduction Initiated oral contraceptive (OC) use reduces peak aerobic capacity (VO₂peak) in both recreationally-active and highly-trained women (1, 2). However, whether VO₂peak and other adaptations to training are influenced by OC use is yet to be explored. This study investigated whether OC use influenced adaptations to high-intensity interval training (HIIT) in recreationally-active women. Methods Women taking an oral contraceptive (OC; n=10; age 22±3 years, VO₂peak 38±6 mL/kg/min; mean±SD) or experiencing natural menstrual cycles (MC; n=8; age 23±4 years, VO₂peak 38±4 mL/kg/min; mean±SD) participated in this study. On two occasions, under stringently controlled hormone, nutrition and hydration conditions, participants completed an incremental exercise test to volitional exhaustion to determine VO₂peak, power output at ventilatory threshold (POVT) and peak power output (PPO) prior to and following a 12-session HIIT program. Further, a square-wave step-transition protocol was used to determine pulmonary oxygen uptake kinetics (τVO₂on) at moderate and heavy exercise intensities and time to fatigue (TTF). Each HIIT session consisted of 10 one minute cycling intervals in a 1:2 work:rest ratio at 100-120% PPO. Results Groups did not differ at baseline in any demographic, physiological, or performance variables (p>0.05). Following training both OC and MC increased PPO (13%, p<0.001; 10%, p<0.001) and TTF (297%, p<0.001; 234%, p<0.001), respectively, with no difference between groups (PPO, p=0.224; TTF, p=0.270). VO₂peak and POVT increased in MC following HIIT (9%, p=0.003; 14%, p=0.005; respectively), but there was no increase in OC (2%, p=0.401; 2%, p=0.710; respectively); differences between groups were significant for POVT (p=0.049) and trended towards significance for VO₂peak (p=0.060). τVO₂on trended towards improvement in moderate (28%; p=0.104) and improved heavy (21%; p=0.022) exercise in MC, however there were no significant changes for OC (moderate=10%, p=0.624; heavy=8%, p=0.543). Discussion HIIT increased performance outcomes (PPO and TTF) in recreationally-active women. However, while MC improved physiological adaptations (VO₂peak, POVT and τVO₂on) following training there were no improvements for OC. These results suggest that OC use may rescind physiological adaptation to HIIT independent of performance outcomes. Further investigation is required to explain the apparent disparity between performance and physiological adaptations to training with OC use. References 1. EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON THE RESTING METABOLIC RATE AND FAT OXIDATION

Scheuer, C., Helge, J., Larsen, S.

University of Copenhagen

Introduction Obesity is associated with comorbidities as metabolic syndrome (MetS), type 2 diabetes and cardiovascular disease (CVD). Regular physical activity is known to increase VO₂max and reduce risk factors of CVD and all-cause mortality, but despite of this many retain a sedentary lifestyle. The most common reason for not engaging in physical activity is lack of time, however high-intensity interval training (HIT) could comply with this difficulty. The aim of this study was to evaluate the effects of HIT on resting metabolic rate (RMR), fat oxidation (Fox) and risk factors of MetS. Methods RMR as well as resting and submaximal Fox were measured by indirect calorimetry and diagnostic criteria of MetS obtained in 13 healthy, sedentary overweight subjects (8 women / 5 men) at baseline and after a 6-week HIT-protocol. The HIT-protocol consisted of 3 supervised training sessions per week of 5 intervals of 1min each at an individually determined load corresponding to approximately 130% (130 ± 8 %) (mean ± SD) of Wattmax on a cycle ergometer. Supplementary to the diagnostic parameters of MetS, body composition (BC) was determined by DXA and glucose tolerance tested by HbA1c and measurement of fasting plasma glucose. Preliminary results RMR was not significantly changed after HIT, although a tendency was observed (PRE 1763 ± 263; POST 1809 ± 257 kcal/d; P = 0.13). The change in RMR was correlated with the change in lean body mass (LBM) (LBM PRE 56.8 ± 9.8; POST 57.3 ± 10.3 kg; P 0.22. PRE R2 0.89; POST R2 0.83; both P < 0.0001). Total body fat (PRE 42.2 ± 7.0; POST 41.3 ± 7.3 %; P < 0.015) and gynoid fat percentage (PRE 42.3 ± 8.4; POST 40.8 ± 8.8 %; P < 0.002) were decreased, and android/gynoid ratio (PRE 1.2 ± 0.2; POST 1.3 ± 0.2; P < 0.002) was increased. Furthermore, Fox at rest (PRE 70 ± 18; POST 83 ± 22 mg/min; P < 0.05) was increased. Discussion Studies of the influence of physical activity on RMR have reported contradictory results with some showing significant increases and others showing no effect (1). RMR accounts for approximately 70% of total daily energy expenditure in sedentary adults but changes with weight loss and increasing muscle mass, all of which makes it a potentially important factor in lifestyle changing health interventions. Though the increase in RMR was not significant in this study resting Fox was significantly higher indicating a change in fuel oxidation at rest after 6 weeks of HIT. Since the increase in RMR was associated with increase in LBM it is possible that a longer intervention could elicit a greater response. INTERVAL EXERCISE, BUT NOT ENDURANCE EXERCISE, PREVENTS ENDOTHELIAL ISCHEMIA-REPERFUSION INJURY IN HEALTHY SUBJECTS

Seeger, J.1, Lenting, C.1, Schreuder, T., Landman, T.1, Cable, N.1, Hopman, M., Thijssen, D.1

Radboud University Nijmegen Medical Centre

Introduction Myocardial ischemic-reperfusion injury (IR-injury) importantly contributes to the poor prognosis during ischemic (myocardial) events. Preconditioning, i.e. repeated exposure to short periods of ischemia, effectively reduces IR-injury. In this study, we examined whether exercise has preconditioning effects on endothelial IR-injury. Therefore, we studied whether an acute bout of endurance or interval exercise is able to protect against endothelial IR-injury. Methods In 17 healthy young subjects, we examined changes in brachial artery endothelial function using flow-mediated dilation (FMD) before- and after a bout of interval exercise, endurance exercise or a control intervention. Subsequently, IR-injury was induced by inflation of a blood pressure cuff around the upper arm to 220 mmHg for 20-min followed by 20-min of reperfusion, followed by another FMD measurement. Near infrared spectrometry was used in order to examine local tissue oxygenation during exercise. Results No differences in brachial artery FMD were found at baseline for the three conditions. IR induced a significant decline in FMD (7.1±2.3 to 4.3±2.3; P<0.001). When preceded by the interval exercise bout, no change in FMD was present after IR (7.7±3.1 to 7.2±3.1; P=0.56), whilst the decrease in FMD after IR could not be prevented by the endurance exercise bout (7.8±3.1 to 3.8±1.7; P<0.001). Our NIRS data revealed no differences in total deoxygenation between interval and endurance exercise. It was however demonstrated that interval exercise induced repeated, short periods of local ischemia, while endurance exercise induced a stable level of (de)oxyxygenation throughout the exercise bout. Discussion Our study showed the ability of interval exercise to prevent endo-

thelial IR-injury in a group of healthy young subjects, whilst this effect of exercise was absent when IR-injury was preceded by endurance exercise. These protective effects of lower limb interval exercise were observed in the upper limb arteries, which suggests that the pre-conditioning effects represent a 'remote', rather than a local effect of interval exercise. Our findings may have potential clinical relevance for the protection of the heart and other tissues against IR-injury by interval exercise. Contact Joost.Seeger@radboudumc.nl

THE EFFECT OF HIGH INTENSITY INTERVAL TRAINING ON THE MITOCHONDRIAL CAPACITY TO OXIDIZE FAT IN HUMAN SKELETAL MUSCLE

Søndergård, S., Larsen, S., Dela, F., Helge, J.W.

Faculty of Health and Medical Science, University of Copenhagen

Aim: High intensity interval training (HIT) is a potent and time efficient training method to induce metabolic adaptations and to improve exercise performance. However, compared to endurance training, the literature regarding HITs potential to induce a shift in substrate utilization towards an increased fat oxidation in skeletal muscle, is limited and inconsistent. The aim of the study was thus to investigate the effect of HIT on the mitochondrial capacity to oxidize fat in skeletal muscle. Due to the short and intense nature of HIT, we hypothesized that the training would not induce any changes in the mitochondrial capacity to oxidize fat. **Method:** 10 healthy, but overweight and sedentary subjects (2 F/8 M) completed 6 weeks of HIT, 3 days/week. Their average (\pm SE) age, body mass index and maximal oxygen uptake (VO_2 max) was 38 ± 3 yr, 33 ± 1 and 2.9 ± 0.2 l/min, respectively. The training consisted of 5 x 60 s cycling at maximal workload (corresponding to $128 \pm 2\%$ of maximal workload elicited during an incremental VO_2 max test), interspersed with 90 s of recovery. High-resolution respirometry was used to measure skeletal muscle mitochondrial lipid oxidation (OXPHOS) capacity and oxidative phosphorylation (OXPHOS) capacity. Furthermore, maximal activity of citrate synthase (CS) and β -hydroxy-acyl-CoA-dehydrogenase (HAD) were measured. **Results:** Mitochondrial lipid OXPHOS capacity (15 ± 2 vs. 14 ± 1 pmol/s/mg) and HAD activity (100 ± 7 vs. 117 ± 5 $\mu\text{mol/g/min}$) in skeletal muscle were not different after training. Skeletal muscle oxidative capacity, reflected by complex I and II linked maximal OXPHOS capacity, was however increased significantly (56 ± 3 vs. 68 ± 5 pmol/s/mg). In line with this, CS activity increased ($P < 0.05$) by 36% (107 ± 8 vs. 145 ± 7 $\mu\text{mol/g/min}$) and VO_2 max increased ($P < 0.05$) by 7% (2.9 ± 0.2 vs. 3.1 ± 0.2 l/min). **Discussion:** This study demonstrates that 6 weeks of HIT increases the skeletal muscle oxidative enzyme activity and increases the mitochondrial oxidative capacity in overweight and sedentary subjects. In contrast, the mitochondrial capacity to oxidize fat did not increase, indicating that not all HIT protocols improve lipid metabolism and hence substrate utilization. It is likely that the intensity of the HIT protocol applied in this study produces a high flux through the glycolytic pathway and consequently a decreased flux through the β -oxidative pathway why stimulation of this pathway did not occur. The apparent discrepancy in the literature concerning HIT and adaptations in the lipid metabolism might therefore be found in the different exercise intensity and duration applied in the HIT protocols. OP-BN04 Motor Control & Learning

CENTRE OF PRESSURE AND MUSCLE DYNAMICS DURING STANDING WITH UNSTABLE FOOTWEAR

Buchecker, M.1, Birkblauer, J.1, Wegenkittl, S.2, Müller, E.1

1: University of Salzburg, 2: Salzburg University of Applied Sciences

Introduction The concept of instability in terms of unstable shoe constructions, such as Masai Barefoot Technology (MBT), is primary based on linear outcome measures of movement variability (Nigg et al., 2012). These standard averaging procedures, however, typically mask the dynamical features of motor behaviour. Therefore, the aim of the current research was to re-analyse the framework of MBT - by employing also nonlinear techniques - to gain novel insights into resultant strategies of postural control while standing with this type of footwear. **Methods** Thirty healthy men conducted three 30 seconds bipedal standing trials using unstable MBT or standard shoes in a counterbalanced within-subject design. Concurrently, the centre of pressure (COP) trajectory and the electromyographic (EMG) activity of the tibialis anterior were collected. To examine time varying characteristics (nonlinear approach) and the amount (linear approach) of COP and EMG fluctuations, the sample entropy (SampEn) and the standard deviation (SD) were calculated, averaged over trials and compared between conditions via paired Student's t-tests. In addition shuffled and phase-randomized surrogate data sets were computed to explore the nature of the underlying dynamics of the captured signals. **Results** SampEn was statistically higher in all surrogates with respect to their original counterparts (all $P < 0.001$, all $d > 0.8$). Unstable MBT shoes increased the amplitude of tibialis anterior and of COP variability in anterior-posterior direction and decreased the irregularity of these time series as evidenced by lower SampEn (all $P < 0.001$, all $d > 0.8$). Regarding the COP in medio-lateral direction, similar findings were obtained for SD ($P < 0.001$, all $d > 0.8$), while no significant difference was observed for SampEn ($P > 0.05$, $d = 0.19$). **Discussion** Results derived from surrogation methods generally suggest a pronounced deterministic component in acquired COP and EMG waveforms and consequently justify the implementation of entropy analyses within this experiment. The noticed increase in predictability coupled with greater linear deviations in the MBT data may be assigned to the amplified demands on postural regularisation. Accordingly these findings point towards the functional role of movement variability in maintaining balance (van Emmerick and van Wegen, 2002) and advocate for a distinct multi-dimensional evaluation of biomechanical signal properties in upcoming related investigations. **References** Nigg B, Federolf PA, von Tscharner V, Nigg S (2012). IMPACT OF MOTOR IMAGERY AT SPINAL LEVEL

Grospretre, S., Lebon, F., Papaxanthis, C., Martin, A.

INSERM U1093

Introduction Motor imagery (MI), the mental representation of actual contraction, was shown to activate same cortical structures as actual contraction without producing movement (Lotze et al. 1999). However, the question of MI effect at a spinal level is not still resolved, since results found with an H-reflex technique vary within the literature. It was previously shown that a sub-threshold cortical output could modulate spinal excitability without activating alpha-motoneurons (Grospretre et al. 2014). Because spinal interneurons have excitability threshold lower than motoneurons (Daniele & McDermott 2009), it could be hypothesized that MI induces a cortical output that is too low to activate motoneuronal pool but sufficient to activate spinal interneurons. Thus, the aim of this study was to evaluate the impact of imagined eccentric, concentric and isometric contraction on presynaptic inhibition. This study could also show if eccentric, concentric or isometric contraction share same cortico-spinal pathways. **Method** 8 healthy young subjects participated in this study. H-reflexes and M-waves of soleus muscle (SOL) were elicited by electrical stimulations of the posterior tibial nerve. SOL H-reflexes were conditioned by stimulation of the common peroneal nerve in order to induce D1 presynaptic inhibition of SOL Ia afferences onto alpha motoneurons. Conditioning-test interval used was 21ms (Achache et al. 2010). Conditioned and unconditioned H-reflexes were elicited during rest and during MI of eccentric, concentric and isometric contractions of the SOL muscle. **Results** Whatever the imagined contraction type, no effect of MI was found on SOL EMG activity as well as on H test reflexes. However, conditioned H-reflexes statistically increased between rest and imagined contraction. At rest, conditioned H-reflexes were 16% lower than unconditioned ($p < 0.05$). During motor imagery, whatever the imagined contraction type, no differences were found between conditioned and unconditioned H-reflexes. **Discussion** The lack of EMG activity or H-reflex modulation showed that alpha-motoneurons were not activated during MI. However, a significant impact on presynaptic inhibition of SOL Ia afferences was found for all imagined conditions. This result demonstrates that MI of muscle contraction induces the activation of corticospinal pathway that is too low to activate motoneuron pool but sufficient to activate primary afferent depolarization interneurons mediating presynaptic inhibition. **References** Achache et al. THE EFFECT OF A FAMILY BASED RCT IN ENHANCING PHYSICAL ACTIVITY AND GROSS MOTOR SKILLS IN CHILDREN IS INFLUENCED BY SEASONAL VARIATION

Laukkanen, A., Pesola, A., Heikkinen, R., Sääkslahti, A., Finni, A.

University of Jyväskylä

Introduction The importance of home environment to physical activity (PA) and development of gross motor skills (GMS) in children is generally accepted. However, only few interventions promoting PA and GMS in children have focused on families themselves, even though it would be a key element for habitual and lifelong development (Riethmuller et al 2009). Therefore, this study examined the effects of a year-long family based randomized controlled trial on PA and GMS in children (Finni et al 2011). **Methods** Parents of families randomized to intervention group ($n=47$) received tailored counseling where individualized goals were set with aims of increasing brisk physical activity of their children and decreasing inactive habits related to commute, work time and leisure time in themselves. Intervention was reinforced by frequent contacts until 6 months after counselling but no structured PA was served. Control group (families $n=43$) did not receive counselling but underwent the same assessments as the intervention group. PA in children ($n=95$; mean age 6.1 ± 1.3 years at baseline) was measured by triaxial accelerometers at baseline and after 3, 6, 9 and 12 months, and the proportion of moderate-to-vigorous PA (MVPA) was analysed (van Cauwenberghe et al. 2010). GMS ($n=94$) were measured at baseline and after 6 and 12 months by KTK-test battery (Kiphard & Schilling 2007) and throwing and catching a ball test (TCB) (Numminen 1995). The effect of intervention was analyzed by linear mixed-effects model fit by REML in R-statistics software. **Results** There were no significant increases in MVPA with age ($p=0.17$) nor differences between groups ($p=0.054$). Mean score of KTK increased with age ($p < 0.001$) but not of TCB ($p > 0.05$). Among girls of the intervention group the TCB significantly improved compared to girls in control group from baseline to 6 months ($U=453$, $p=0.015$). Both MVPA and KTK were affected by seasonal variation and a three-way interaction of group \times time \times season indicated a greater improvement among intervention group in KTK ($L=9.79$, $df=4$, $p=0.04$) which was explained by more steady development when moving from summer to winter at the time of the follow-up ($p=0.014$). **Discussion** Counseling given to parents did not increase MVPA in their children but had a positive effect on development of ball handling skills in girls which may be a key determinant for PA level later in life (Barnett et al 2009). The study also suggests that the timing of intervention is an important element in countries with a great seasonal variation. **References** Barnett et al. 2009. *J Adolesc Health* 44 (3), 252–259. MIRROR ILLUSION REDUCES MOTOR CORTICAL INHIBITION IN THE IPSILATERAL PRIMARY MOTOR CORTEX DURING EFFORTFUL UNILATERAL MUSCLE CONTRACTIONS

Zult, T.1, Goodall, S.2, Thomas, K.2, Hortobágyi, T.1,2, Howatson, G.2,3

University Medical Center Groningen

1: Center for Human Movement Sciences, University of Groningen, University Medical Center Groningen (Groningen, The Netherlands), 2: Department of Sport, Exercise and Rehabilitation, Faculty of Health and Life Sciences, Northumbria University, (Newcastle-upon-Tyne, United Kingdom), 3: Water Research Group, School of Biological Sciences, North West University (Potchefstroom, South Africa) **Introduction** Unilateral strength training is a promising therapeutic strategy to strengthen the contralateral homologous muscles of the resting limb for patients who suffer from unilateral orthopaedic and neurological conditions. It is hypothesized that viewing the exercising hand in a mirror can augment the strength transfer by modulating intracortical, intercortical and corticospinal pathways. Consequently, we examined the corticospinal and cortical responses to transcranial magnetic brain stimulation (TMS) in the left flexor carpi radialis (FCR) with and without viewing a mirror; 1) at rest, and 2) during a forceful shortening contraction of the right wrist flexors. We hypothesized that viewing the mirror would increase corticospinal and motor cortical excitability. **Methods** Corticospinal excitability and short-interval intracortical inhibition (SICI) of the “ipsilateral” (right) primary motor cortex (M1), and interhemispheric inhibition (IHI) from left to right M1 were measured in young healthy right-handed adults ($N = 27$). These responses were recorded in 4 conditions: at rest and during contractions (at 60% maximal voluntary contraction), with and without viewing a mirror. During the no mirror condition, neither hand was visible, whereas in

the mirror condition, a reflection of the right hand was seen thereby giving the illusionary view of the left hand. Results Corticospinal excitability increased almost twofold during contractions but there was no effect of the mirror. However, viewing the mirror image of the contracting wrist attenuated SICI with 8.6% compared with the no-mirror contraction condition ($46.6\% \pm 18.4$ vs. $38.0\% \pm 15.4$; $P = 0.023$). Viewing the mirror at rest did not affect IHI ($P = 0.274$). Discussion Seeing the mirror image of the contracting right wrist modulated a specific inhibitory intracortical pathway, SICI, in the right M1 without modifying IHI. It is suggested that the attenuation of SICI, without changes in corticospinal excitability, is associated with movement initiation. This implies that viewing the mirror during a contraction creates the illusion that the left, non-active hand, is moving and hence attenuates the magnitude of intracortical inhibition. This augmented sensory feedback lends evidence to the hypothesized therapeutic effect of a mirror aiding contralateral strength improvement. Contact f.d.zult@umcg.nl

TASK DEPENDENT CHANGES OF CORTICOSPINAL EXCITABILITY DURING OBSERVATION AND MOTOR IMAGERY OF POSTURAL TASKS

Mouthon, A., Ruffieux, J., Wächli, M., Keller, M., Taube, W.

SMS (Fribourg, Switzerland)

Task dependent changes of corticospinal excitability during observation and motor imagery of postural tasks Introduction: Immobilization decreases postural control and physical balance training is not possible during this period. Non-physical forms of training should therefore be considered. In this context it was previously shown that motor imagery and observation of postural tasks improves static and dynamic postural control (Taube et al.). In order to highlight the underlying mechanisms the current study applied transcranial magnetic stimulation to assess corticospinal excitability during action observation and motor imagery of different postural tasks. Methods: Fifteen participants (age 27 ± 5) were asked to either perform motor imagery (MI), active or passive observation (AO and PO) of two postural tasks: quiet upright stance (STATIC) or compensation of a medio-lateral perturbation (DYNAMIC). These conditions were shown in a video and subjects were asked to imagine being the person in the video (AO) or just watching it without putting any mental effort in it (PO). The third condition was to imagine the announced task from a first-person perspective with eyes closed. In summary, six experimental conditions, three MENTAL STATES (AO, PO, MI) and two POSTURAL TASKS (STATIC, DYNAMIC) were randomly presented. Results: For each experimental condition, twenty MEPs were recorded. The data from the soleus muscle display a significant main effect for MENTAL STATE ($F_{2, 28} = 6.3$; $p < 0.01$) for POSTURAL TASK ($F_{1, 14} = 12.0$; $p < 0.01$) and for the interaction of MENTAL STATE and POSTURAL TASK ($F_{2, 28} = 5.1$; $p = 0.013$). Post hoc tests showed that AO induced significantly greater MEPs than PO ($p = 0.05$) and MI revealed a trend to produce larger MEPs than PO ($p = 0.06$). Discussion: The observation of facilitated MEPs with AO and MI is in line with the general notion that corticospinal excitability is increased during MI and action observation. However, Clark et al. (2004) did not find significant differences between AO and PO. This may be due to the fact that the tasks presented for active and passive observation differed. Most similar to the present approach, Roosink et al. (2010) found larger MEPs during AO than during PO and MI in hand muscles. Furthermore, like in the present study, MEP amplitudes were larger during more complex tasks independent of the mental state. In conclusion, both mental state and postural task difficulty influence corticospinal excitability and propose that AO and MI of demanding postural tasks may be most beneficial to activate the corticospinal system. Thus, these mental states seem appropriate for non-physical balance training. References: Clark S, Tremblay F, Ste-Marie D. (2004). *Neuropsychologia*, 42, 105–112. Roosink M & Zijdwind I. TRAINING AND FATIGUE IN COMPETITIVE SWIMMING: COACHES PERCEPTIONS

Thow, J., Turner, A.P., Nash, C., Sanders, R.

University of Edinburgh

Introduction The performance of swimmers is often limited by fatigue; a complex, multi-factorial phenomenon (Alberty et al., 2009). However, little is known about coaches' understanding of fatigue, nor how they currently manage it during training in swimming. The purpose of this study was to examine coaches' current practices and knowledge about fatigue during training in competitive swimming. Methods A questionnaire was sent to 374 UK based coaches, currently coaching national age-group swimmers, using the Bristol Online Survey website. The questionnaire was separated into 5 sections: demographic information; causes and effects of fatigue (Ament and Verkele, 2009); methods of monitoring fatigue; the management and prevention of fatigue; additional information. Open and closed questions and 7-Point Likert-scales were used throughout the questionnaire (Portney and Watkins, 2000). Results Out of the 100 respondents, 79% monitored the state of fatigue of their athletes during a training session. Coaches were most familiar with a 'psychological decrease in motivation, interest or enthusiasm' as a mechanism (25%) and effect (32%) of fatigue. The main method used to monitor fatigue was the personal visual observation of technique. Significant associations were found from the Chi square test (p value) between the key variables of coaching qualification and years of experience; the equipment used to monitor fatigue during training, including; underwater video ($p = 13.081$, 14.496 respectively), above water video ($p = 16.975$), sleep quantity/quality ($p = 9.512$), body mass ($p = 14.534$) and hydration level ($p = 9.646$); and blood lactate levels ($p = 18.530$). No significant associations were found between the key variables and coaches' knowledge and fatigue mechanisms and effects. 98% of the respondents made changes to their session plan to enable swimmers to cope with the training intensity. Discussion This study identified that coaches place a high importance on the effect and management of fatigue during training in competitive swimmers. Their methods of monitoring fatigue during training are linked to coaching experience and qualifications in swimming. More research is needed to ensure current coaching practices and courses are effective to enable swimmers to cope with the high physical and mental demands of training in swimming. Introduction. Exercise-training is associated with improvement in measures of vascular function such as flow-mediated dilation (FMD), due in part to repeated exposure to increased blood flow and shear stress. Less is known regarding the effects of acute exercise on vascular function, despite some suggestions of a decrease in FMD immediately post-exercise, followed by a secondary increase. This response pattern may be influenced by both the intensity (differential blood flow and shear) of exercise which, to date, has not been investigated. Our aim was to describe the effects of stepwise increases in localised handgrip exercise intensity on the time-course of change in post-exercise FMD. **Methods.** Eleven healthy men attended the laboratory on 3 separate occasions. Subjects completed 30 minutes of acute localised handgrip exercise at 5, 10 or 15% maximal voluntary contraction (MVC), during which brachial artery blood flow and shear rate were continuously assessed. Before, immediately following, and 60 minutes post-exercise, we examined brachial arterial function using the flow mediated dilation (FMD) technique. **Results.** 30 minutes of localised handgrip exercise induced dose-dependent increases (interaction-effect: $P < 0.01$) in both mean blood flow (5%: 139 ± 41 , 10%: 305 ± 130 and 15%: 459 ± 172 ml/min, all $P < 0.01$) and shear rate (5%: 204 ± 72 s⁻¹; 10%: 360 ± 146 s⁻¹; 15%: 503 ± 188 s⁻¹, all $P < 0.01$). In addition, 30 minutes of acute handgripping evoked a time*intensity interaction effect for FMD ($P < 0.01$), whereby elevated FMD was observed at the highest intensity 60 minutes post-exercise (5.9 ± 2.8 to $10.41 \pm 5.8\%$, t-test: $P = 0.01$). **Discussion.** Acute handgrip exercise did not induce immediate changes in post-exercise brachial artery FMD, a finding which contrasts with previous studies of leg exercise. However, FMD was elevated 60 minutes following the cessation of exercise at the highest intensity. This finding has direct implications for our understanding of how different levels of exercise, and accompanying shear stress, have distinct acute effects on artery function in humans.

ALTERED VENTRICULAR MECHANICS AND INCREASED TROPONIN AFTER A 60-MIN COMPETITIVE CYCLE RACE.

Introduction Transient reductions in myocardial strain, coupled with cardiac-specific biomarker release, have been reported following prolonged (>180 min) exercise (La Gerche et al., 2012). However, it is unknown if: a) shorter duration exercise can perturb cardiac function, and b) if exercise-induced reductions in strain are masked by altered hemodynamic conditions during supine post-exercise recovery (Vitello et al., 2013). **Methods** Fifteen cyclists (age: 28 ± 3 yr; $\text{VO}_{2\text{peak}}$: 5.1 ± 0.7 L/min; training volume: 13 ± 5 h/wk) who regularly participate in a local 60-min high-intensity cycling race (CRIT60) completed the study. Echocardiograph-derived left (LV) and right (RV) ventricular global longitudinal strain (GLS), and LV torsion (LVT); heart rate and blood pressure; and high-sensitivity cardiac troponin (hs-cTnT) were examined before and after a CRIT60. Echocardiography and blood pressure measurements were performed in a semi-recumbent position at rest and during low-intensity cycling exercise (power output: 85 ± 8 W; heart rate: 99 ± 3 beats/min). **Results** Average heart rate during the CRIT60 was 169 ± 4 beats/min (~88% of maximum heart rate). Following the CRIT60, arterial blood pressure and systemic vascular resistance (SVR) decreased at rest (SVR: 18.2 ± 1.0 vs. 13.3 ± 0.9 , $p < 0.01$) but not during low-intensity exercise (SVR: 8.2 ± 0.4 vs. 7.6 ± 0.4 , ns). During rest, there were no significant changes in strain and torsion after the CRIT60. During low-intensity exercise, LV GLS ($-20.0 \pm 0.5\%$ vs. $-18.2 \pm 0.4\%$, $p < 0.01$) and RV GLS ($-29.6 \pm 1.6\%$ vs. $-24.7 \pm 1.5\%$, $p < 0.05$) decreased after the CRIT60; LVT decreased in the least-trained individuals only, with the magnitude of change (pre-post CRIT60) correlated with training history ($r = 0.95$, $p < 0.01$). Serum hs-cTnT (5.7 ± 0.6 vs. 20.8 ± 6.9 ng/L, $p < 0.05$) increased after the CRIT60. **Conclusions** During passive recovery, post-exercise vasodilatation may confound measurements of ventricular strain. In contrast, a low-intensity exercise stimulus provides comparable loading conditions for the assessment of ventricular strain. Altered ventricular mechanics after the cycling race were evident when assessed during low-intensity exercise and may indicate functional cardiac limitations following 60-min of high-intensity exercise. Individuals with the least training history were most likely to experience exercise-induced functional and biochemical perturbations. **References** 1. La Gerche, A. et al., (2012). INTRINSIC VENTRICULAR FUNCTION DOES NOT EXPLAIN REDUCED STROKE VOLUME AT REST AND DURING EXERCISE AT HIGH ALTITUDE.

Stembridge, M., Ainslie, P.N., Stöhr, E.J., Tymko, M., Day, T.A., Bakker, A., Hughes, M.G., Smith, K.J., Willie, C.K., Lewis, N.C.S., Shave, R.

Cardiff Metropolitan University

Introduction Both impaired systolic dysfunction and myocardial relaxation have previously been advanced as possible mechanisms contributing to decreased stroke volume (SV) at high altitude (HA). To determine whether myocardial performance is a limiting factor in the generation of SV at HA, we assessed left ventricular (LV) mechanics due to their close relationship with filling and ejection. **Methods** Left ventricular volumes and mechanics were assessed using echocardiography in 10 healthy participants (aged 32 ± 2 ; mean \pm SEM) at rest and during incremental exercise up to 50% peak power at sea level (SL; 344 m) and after ascent to 5050 m. Arterial oxygen saturation (SaO_2) was assessed using pulse oximetry. Data were analysed using a repeated measures analysis of variance and post-hoc tests with Bonferroni correction. Alpha was set at 0.05. **Results** Ascent to altitude was associated with a significant reduction in resting ($\text{SaO}_2 = 81\%$) and exercise ($\text{SaO}_2 = 72\%$) arterial oxygen saturation. In contrast to SL, LV end-diastolic volume (EDV) was lower at rest (104 ± 6 vs. 128 ± 6 ml, $p = 0.004$) and did not increase from rest to exercise despite a greater untwisting velocity and preserved coupling of systolic-diastolic twist velocities ($r_2 = 0.99$ and $r_2 = 0.98$ at SL and HA, respectively). Furthermore, whilst an increase in resting ejection fraction (EF; 6%), LV

twist (43%), and apical circumferential strain (17%) was observed at HA, resting SV was significantly lower (60 ± 3 vs. 70 ± 3 ml, all $p < 0.05$). With exercise at HA, the increase in SV was limited (12 ml vs. 22 ml), and LV twist failed to augment. Discussion In conclusion, in vivo diastolic relaxation, as assessed by LV untwist velocity, was not impaired despite moderate-severe hypoxemia at HA. The increase in EF observed previously and in the current study alongside greater LV twist may represent a mechanism by which SV is protected in the presence of a reduced EDV. However, higher resting LV twist and apical circumferential strain reduce the functional mechanical reserve normally available at SL. Consequently, whilst hypoxia does not suppress systolic function per se, the ability of the LV to respond to an exercise challenge at HA is limited.

EFFECTS OF CO₂ ON VENTILATORY AND CEREBROVASCULAR RESPONSES DURING PASSIVE HEATING IN HUMANS

Tsuji, B.1, Davide, F.2, Fujii, N.3, Hayashi, K.4, Eguchi, T.1, Kondo, N.5, Honda, Y.1, Nishiyasu, T.1

1: University of Tsukuba, 2: Loughborough University, 3: University of Ottawa, 4: University of Shizuoka, 5: Kobe University

Introduction During passive heating of resting humans, minute ventilation (VE) changes little as esophageal temperature (Tes, an index of core temperature) rises until the temperature reaches about 38°C. Above this threshold, VE increases by ~30 L/min with respect to 1°C rise in Tes and results in a decrease in arterial CO₂ pressure (PaCO₂) (Tsuji et al. 2012). In normothermic condition, generally, change in PaCO₂ can affect both ventilatory and cerebrovascular responses such that the decrease in PaCO₂ suppresses VE via central chemoreceptors, and also reduces cerebral blood flow by cerebral vasoconstriction. However, the effect of reduced PaCO₂ on ventilatory and cerebrovascular responses during hyperthermia at rest is not well understood. We previously found that, during prolonged moderate exercise in the heat, restoration of PaCO₂ to the eucapnic level augmented the ventilatory sensitivity to rising Tes (slope of the Tes-VE relation) by threefold (Hayashi et al. 2011). The present study thus examined the effect of PaCO₂ on the ventilatory sensitivity and cerebrovascular response to rising Tes at rest. **Methods** Fourteen healthy male were passively heated using hot-water immersion (41°C) and a water-perfused suit until Tes reached 39°C or the subjects could no longer tolerate the heating. During the heating on two separate occasions, subjects breathed room air (Control trial) or CO₂-enriched air (a mixture of room air and 100% CO₂) to prevent a reduction in PETCO₂ (an index of PaCO₂) (CO₂ trial). **Results and Discussion** Tes threshold for increase in VE was seen at both trials (Control vs. CO₂: 38.4 ± 0.4 vs. 38.1 ± 0.6 °C, $P = 0.13$), and above the thresholds VE increased linearly with rising Tes. In Control trial PETCO₂ declined gradually with rising Tes above the threshold, whereas it in CO₂ trial remained at eucapnic level. Ventilatory sensitivity to increasing Tes did not differ between Control and CO₂ trials (38.1 ± 43.1 vs. 16.5 ± 11.1 L/min/°C, $P = 0.15$). These suggest that ventilatory response with rising core temperature at rest is unaffected by a decrease in PaCO₂. Middle cerebral artery mean blood velocity (MCAVmean) decreased gradually with rising Tes in Control trial (59.9 ± 8.4 and 49.9 ± 9.7 cm/s at Tes 36.8 and 38.8°C, respectively), and the reduced MCAVmean was restored by about 40% in CO₂ trial (53.8 ± 5.6 cm/s at Tes 38.8°C), but inhaling CO₂ had no significant effect on MCAVmean. Furthermore, the restoration of MCAVmean by CO₂ inhalation was similar among each Tes level of 37.2, 37.6, 38.0, 38.4 and 38.8°C. These suggest that the decrease in PaCO₂ accounts for the reduction in MCAVmean by 40% at Tes range of 37–39°C during passive heating at rest. **References** Tsuji B, Honda Y, Fujii N, Kondo N, Nishiyasu T (2012). THE IMPACT OF WATER IMMERSION DURING EXERCISE ON CEREBRAL PERFUSION

Pugh, C.J.A.1, Sprung, V.S.1,2, Ono, K.3, Spence, A.L.1, Thijssen, D.H.2,4, Carter, H.H.1, Green, D.J.1,2

University of Western Australia

1.School of Sports Science, Exercise and Health, UWA, AUS, 2.Research Institute for Sport and Exercise Sciences, LJMU, UK, 3.Graduate School of Health Science, Kobe University, Japan, 4.Radboud University Medical Center, NED. **Introduction** Regular exercise induces recurrent increases in cerebrovascular perfusion. In peripheral arteries, such episodic increases in perfusion are responsible for improvement in arterial function and health. Recent studies from our laboratory have reported that water immersion induces an increase in cerebrovascular perfusion at rest, however, no previous research has examined the impact of water immersion during exercise on cerebrovascular perfusion. We hypothesized that exercise during euthermic water immersion would augment cerebrovascular perfusion compared to intensity-matched land-based exercise. **Methods** Fifteen normotensive participants were recruited (26 ± 4 yrs, 24.3 ± 1.9 kg/m²). We continuously assessed mean arterial blood pressure (MAP), heart rate (HR), stroke volume, oxygen consumption and blood flow velocities through the middle and posterior cerebral arteries before, during and after 20-min bouts of water- and land-based stepping exercise of matched intensity. The order in which the exercise conditions were performed was randomized between subjects. Water-based exercise was performed in euthermic water to the level of the right atrium. **Results** Water- and land-based exercise were closely matched for oxygen consumption [13.3 ml.kg⁻¹.min⁻¹ (95% CI=12.2, 14.6) vs. 13.5 ml.kg⁻¹.min⁻¹ (95% CI=12.1, 14.8); $P=0.89$] and HR [95bpm (95% CI=90, 101) vs. 96bpm (95% CI=91, 102); $P=0.65$]. Compared with land-based exercise, water-based exercise induced an exaggerated increase in MAP [106mmHg (95% CI=100, 111) vs. 101mmHg (95% CI=95, 106) $P<0.001$], middle cerebral artery velocity [74cm/s (95% CI=66, 81) vs. 67cm/s (95% CI=60, 74) $P<0.001$], posterior cerebral artery velocity [47cm/s (95% CI=40, 53) vs. 43cm/s (95% CI=37, 49) $P<0.001$] and expired CO₂ [44.5mmHg (95% CI=42.8, 45.9) vs. 42.8mmHg (95% CI=40.6) $P<0.001$]. **Discussion** This is the first study to demonstrate that water-based exercise augments cerebrovascular perfusion, relative to land-based exercise of a similar intensity in healthy humans. This observation provides a rationale to investigate the therapeutic impact of water-based exercise training on cerebrovascular function and health in humans. chris.pugh@uwa.edu.au

08:30 - 10:00**Oral presentations****OP-SH02 Sports Sociology****DETERMINING THE USE AND INTEREST IN HEALTH-RELATED SERVICES AND PRODUCTS BY EVENT RUNNERS**

Janssen, M.A.1, Vos, S.1,2, Brombacher, A.C.3, Scheerder, J.2

1: Fontys University of Applied Sciences, 2: University of Leuven, 3: Eindhoven University of Technology

Introduction Running events have a mass appeal, attracting a diversity of people of which a considerable number are 'less experienced' runners (Bottenburg, Scheerder & Hover, 2010; Vos & Brombacher, 2013). Health-related services (i.e. coaching, guidance, counselling) in combination with health-related products (e.g. heart rate monitors) contribute to a thorough preparation for running events. This raises the question: do event runners use these services and products and what are the needs and interests. The purpose of this study is (1) to map usage of these services and products and (2) to identify which determinants (i.e. socio-demographics, running-related characteristics and attitudes) influence the needs and interests in these services and products among event runners. **Methods** Data are used from an online survey among participants (N=2172) of the half marathon in the city of Eindhoven. First the use of health-related services/products and needs/interests were related to characteristics of runners. Then running-related attitudes were derived from principal component analyses on opinions and views about running. Finally binary logistic regression analyses were carried out to investigate the contribution of determinants to predict usage of health-related services and products. **Results** Results show that 88,8% of the runners uses one or more health-related services or products, while 55,4% uses two or more of these services/products. Running shoes, being measured by gait analysis are most popular (66,9%). Over 50% of the runners are interested in sports medical assessments, training schemes or health-related information. The outcomes of the regression analyses indicate that, besides the runners characteristics, attitudes towards running have a considerable contribution to both the use and needs of health-related services and products. Attitudes towards running are an important factor in determining the use and interests of health-related services and products. It is suggested that substantial efforts, in terms of coaching, guidance, counseling and the targeted provision of a more differentiated package of services, need to be done. Possibly, running events become drivers for sensible and sustainable running, and subsequently contribute considerably to public health. **References** van Bottenburg, M., Scheerder, J. & Hover, P. MALMÖ YOUTH SPORT STUDIE

Petersson, T.

Dep. of Sport Sciences

Introduction This is a presentation of a longitudinal observational study in children attending the "Malmö idrottsgrundskola" combined with a cross-sectional study comparing the children with their peers at other schools. In recent years, many upper secondary schools in Sweden have specialized in physical activity. This trend has attracted considerable support from both youngsters and policymakers. The aim is often twofold – to foster elite athletes and to promote an active lifestyle. However, the impact of these schools is unclear. We don't know whether these pupils become elite athletes in adulthood. Further, it is not known whether the pupils at those schools even take part in competitive or recreational sports in adulthood to a greater extent than their peers at ordinary schools. In the multidisciplinary research project "Malmö Youth Sports Study" (MUSSE), both these aspects are being studied: are sport profiles in upper secondary schools an effective means to promote elite sport development? And does it generate public health in adulthood? The overall aim is to investigate which selection factors (gender-related, physiological, social, or psychological) influence continuous and successful participation in sports. **Methods** In the longitudinal part of the study, we will investigate factors influencing continuation in sports. We will compare background factors in groups of subjects taking part in competitive sport, recreational sport and sedentary subjects. The background factors will be gender, social background, psychological and physiological factors. All children starting grade 7 at "Malmö idrottsgrundskola" are asked to participate. Baseline data will be collected during the autumn of 2013 and 2014, and follow-up measurement are planned in grade 9 and 12. Control groups will be recruited from other schools at Malmö. Gender-related aspects, social factors and psychological factors will all be evaluated by questionnaires. The questionnaires concerning gender and social factors will be similar to the ones used previously in Swedish studies of children in sport. Psychological factors will be evaluated with internationally used questionnaires. A range of physiological measurements will be made in the children. We will measure physical activity over one week with accelerometers, maximum oxygen uptake on a treadmill, strength tests with a Biodex instrument, cardiac function by ECG and echocardiography as well as lung function. Body composition will be measured by dual-energy X-ray absorptiometry. This part of the study builds on the experience from the "Bunkeflo project" about increased physical activity in a primary school and uses much of the same methods. The research group involves members from the University of Lund, the University of Malmö and Halmstad University.

A DECLINE OF YOUTH SPORT IN SWEDEN?

Norberg, J.

Idrottsvetenskap

Introduction International comparisons show that children and young people in the Scandinavian countries engage in sport and physical activity more than the European average. These high levels of participation are often explained with reference to specific aspects of the Nordic welfare systems and the organisation of voluntary sports in large popular movements. However, new data indicate a decline in voluntary organised youth sports in Sweden. The Swedish National Centre for Research in Sports (CIF) conducted the study as part of its on-going assignment to monitor government support to sport. **Methods** The survey is based on analyses of public subsidies to local clubs for youth sport activities. These subsidies are contingent on the number of participants and training sessions for young people (ages 7-20). The statistics are collected annually and cover all eligible sports clubs. The quantitative study was supplemented by a qualitative analysis of factors that play into whether young people continue to practise or quit practising organised sports. This part was de-

signed as a special report in which prominent researchers from different disciplines discussed the problem of dropout in sports based on their expertise. Results The study shows that the declining level of activity in organised children and youth sport in Sweden since 2008 cannot be explained with reference to demographic fluctuations. Analyses of gender and age indicate that the decline is greater among older adolescents (ages 15-20). Furthermore, girls drop out of club sports to a greater extent than boys. Discussion Several questions remain to be answered. Is the decline temporary, or an indication that organised sport is becoming less popular among Swedish adolescents? To what extent can the decline be explained by structural changes in Swedish society and the leisure habits of young people – and to what extent is it a result of the clubs' own actions? Current Swedish research shows that clubs are often good at supporting and developing their most talented athletes, but are less adept at supporting youngsters with lower athletic ambitions. This indicates that the Swedish sports movement must develop adequate strategies to engage and encourage its young members. 'WILLFUL BLINDNESS' AS A CONTRIBUTOR TO ATHLETE MALTREATMENT

Cook, E., Kerr, G.A., Stirling, A.E., Dorsch, K.

University of Toronto

The purpose of this presentation is to examine the concept of 'willful blindness' in the context of safeguarding athletes from maltreatment. There now exists a substantial body of research highlighting the occurrence of sexual and emotional abuse of male and female athletes in sport. Further, there is emerging evidence that suggests that various stakeholders in sport may be engaging in 'willful blindness' with respect to occurrences of athlete abuse. 'Willful blindness' refers to turning a blind eye to what is known to be unethical, harmful, illegal or inappropriate behaviours (Heffernan, 2011). For example, research by Cook and Dorsch (2014) suggest that 77% of all harmful coaching behaviours are indirect in nature, that is to say, witnessed by athletes and adult stakeholders. Similar results from a survey of sport psychology consultants revealed that 70% had witnessed harmful coaching behaviours that could be classified as emotionally abusive and yet they did not intervene (Stirling & Kerr, 2010). Parents of elite athletes have also been shown to have observed emotionally abusive coaching practices and remained silent - behaviours they regret once the athlete retires from sport (Kerr & Stirling, 2012). Brackenridge (2001) cites numerous cases in which the sexual abuse of athletes by coaches was known to others in the sport context. Taken together, these findings suggest that to advance safeguarding initiatives for athletes, the apparent willful blindness of stakeholders must be addressed. Recommendations for such proactive measures as well as further research will be proposed. References: Brackenridge, C. H. PRESSURE TO PLAY: A SOCIOLOGICAL ANALYSIS OF PROFESSIONAL FOOTBALL MANAGERS' BEHAVIOURS TOWARDS INJURED PLAYERS

Bloyce, D., Law, G.

University of Chester

Introduction The focus of this paper is to examine the ways in which professional football managers behave towards injured players and to what extent they might contribute to a 'pressure to play' in football. Methods Semi-structured interviews were completed with ten current professional football managers from all levels of the professional game in England from the Premier League to the Conference. The interviews focused centrally on the managers' experiences of dealing with injured players and if at certain stages of the season or in certain games their behaviour towards an injured player was influenced. Discussion The findings indicate that managers knew that they were unlikely to ever field eleven fully fit players and that players were deliberately inconvenienced when they were injured to encourage a quicker return to playing. This was an especially important tactic for some in light of a perception that there was increasing 'player power' within the game. This was further underlined by the importance managers placed on having the right 'backroom staff', many of whom were chosen on the basis of how loyal and trustworthy they would be to the manager in supporting his decisions about playing players that might otherwise have declared themselves 'injured'. It was also evident that managers from all levels were prepared to take greater risks with players they regarded as "key" especially in matches of high importance. Finally, although some managers were increasingly prepared to use sport science support specialists in order to enable the best possible training conditions and rehabilitation and recovery options, most expressed that irrespective of this while they did not want to risk the long term health of the players they were constrained to do so largely due to the perceived insecurity of the typical professional football manager's job. 08:30 - 10:00**Oral presentations****OP-SH03 Sports Psychology****PERCEIVED MOTIVATIONAL CLIMATE, GOAL ORIENTATIONS AND ACCEPTANCE OF CHEATING AND GAMESMANSHIP IN YOUNG FOOTBALLERS**

González, L.I., Castillo, I.I., Fabra, P.I., Duda, J.L.2, Balaguer, I.I

1: Research Unit of Sport Psychology, Universitat de València (Valencia, Spain); 2: School of Sport, Exercise and Rehabilitation Sciences, University of Birmingham (Birmingham, U.K.)

Introduction Grounded in Achievement Goal Theory (e.g., Nicholls, 1989), this research focused on the contextual and dispositional motivational antecedents of attitudes to moral decision making in youth sport. Specifically, the purpose of this study was to examine the relationship of perceptions of the motivational climate (task and ego involving features) and dispositional goals (task and ego orientation) to young footballers' attitudes toward cheating and gamesmanship and to test the theoretically-assumed mediational effect of goals orientation between perceptions of the motivational climate and cheating and gamesmanship. Method 809 young Spanish male footballers between 9 and 13 years old ($M=11.5 \pm .116$ years) completed the Spanish versions of the Perceived Motivational Climate in Sport Questionnaire (PMCSQ-2; Newton, Duda, & Chi, 2000; Balaguer, Castillo, & Duda, 2003), the Task and Ego Orientation in Sport Questionnaire (TEOSQ; Duda, 1989; Balaguer, Castillo, & Tomás, 1996) and the Attitudes to Moral Decision-making in Youth Sport Questionnaire (AMDYSQ; Lee, Whitehead, & Ntoumanis, 2007). Results Structural equation modeling analysis revealed perceptions of the task-involving and ego-involving features of the climate, respectively, to positively predict the footballers' degree of task and ego orientation ($\beta=0.59$ and $\beta=0.42$, respectively). Task orientation negatively predicted cheating and gamesmanship ($\beta=-0.30$ and $\beta=-0.12$, respectively), whereas ego orientation positively predicted cheating and gamesmanship ($\beta=0.44$ and $\beta=0.41$, respectively). Following Holmbeck (1997) recommendations, the mediational analysis indicated that task orientation acted as a partial mediator between a perceived task-involving climate and positive attitudes toward cheating, whereas ego orientation acted as a total mediator between a perceived ego-involving climate and acceptance of cheating and gamesmanship behaviours. Discussion The results point to the importance of promoting more task-involving and less ego-involving atmospheres and encouraging stronger task goal orientations in order to reduce anti-social attitudes in youth football. Findings also suggest that player ego orientations need to be tempered if we want to decrease cheating and gamesmanship. PACING IN A BROADER SENSE: TACTICS IN SHORT TRACK SPEED SKATING

Konings, M.J.1,2, Noorbergen, O.S.2, Elferink Gemser, M.T.2,3, Hettinga, F.J.1

University of Essex

1: University of Essex, SBS, CSES, UK, 2: University of Groningen, UMCG, The Netherlands, 3: HAN University of Applied Sciences Introduction Pacing has been studied in time trial sports extensively. However, research is limited in sports with a direct form of competition, such as short track speed skating, where the main goal is to be the first instead of the fastest. Intermediate positions (i.e. the ranking of each athlete per lap) may provide a way to analyze pacing strategies in sports where direct opponents play a large role. Further, we want to examine if these strategies are affected by gender or distance (500,1000,1500m). We hypothesize high positive correlations of the intermediate position with the final position during the laps in the final stages of the race in all short track competitions. A positive correlation would indicate that a high intermediate position is related with a high final position, and thus skating in first intermediate position is favourable compared to lower intermediate positions. Method Short Track World Cup season 2012/13 lap times were used to access final and intermediate positions in 500m (N=1764, 415 races), 1000m (N=1564, 365 races), and 1500m (N=1201, 213 races) competitions. Spearman Rho correlations were used to assess relationships between intermediate and finishing positions. Correlations >0.70 were perceived as strong. Finally, the winning% of the first ranked in each lap (i.e. percentage of all first ranked in a certain lap who won their race) were determined. Results In the 500m (4.5 laps of 111,12m), strong correlations were found with the final position during all laps for women. The winning% were high for the first ranked in each intermediate lap (4 laps to go: $r=0.72$, with increasing correlations towards the finish line; 75% of current leaders won the race). For men this was the case in all laps except the first (3 laps to go: $r=0.71$ with increasing correlations towards the finish line; 58%). In the 1000m (9 laps) the last three laps for women (3 laps to go: $r=0.71$; 66%) and last two laps for men (2 laps to go: $r=0.82$; 71%) showed strong correlations with the final position. In the 1500m (13.5 laps), the last two laps for women (2 laps to go: $r=0.80$; 62%) and last three laps for men (3 laps to go: $r=0.72$; 64%) showed strong correlations with the final position. Conclusion The strong positive correlations of intermediate ranking and end placement at the final stages of the race during all events indicate that tactical positioning at the latter phase of the race is a strong determinant of the final position. During the 500m, tactical positing seemed already important in the beginning of the race. In all events, being first ranked in the final stages of the race was related with high (>58-92%) final winning%. Contact mkonings@essex.ac.uk; fjheft@essex.ac.uk

INTUITION: A DECISIVE ADVANTAGE WHEN PERFORMING UNDER PRESSURE?

Laborde, S.

German Sport University

Intuitive people usually make their decisions based on effortless and heuristic processes, while deliberative people tend to do so based on effortful and rational processes. Preliminary lab evidence suggested that intuitive players (IP) make better and faster decisions than deliberative players (DP). However whether this is true in ecological settings and under pressure is still unknown. This research project aimed to address these issues in two studies, combining the field and the lab. Study 1 aimed to investigate stress, coping, and performance appraisals of IP and DP. Method(1): First, 651 handball players filled out the Preference for Intuition and Deliberation (PID) inventory. Second, they filled out after three games the coping inventory for competitive sports, as well as stress, coping, and performance apprais-

als items. According to their PID score, participants were classified in three groups: IP (N=214), DP (N=199) or situation-specific players (N=238). For group comparisons, only IP and DP were retained. Results(1): IP and DP were found to perceive a similar stress intensity and to use similar coping strategies, however IP were found to have a higher perceived stress controllability, coping effectiveness, and performance satisfaction than DP. Discussion(1): When competing in ecological settings, intuition seem to give a subjective advantage to handball players. However, the underlying mechanisms of such advantage are still unclear, which prompted the realisation of study 2 in the lab. Study 2 aimed to investigate the underlying cognitive and physiological mechanisms that could explain the subjective advantage of IP under pressure. Method(2): Handball players (N=99) performed a decision-making task, in a within-subject design, with a low-pressure (LP) and a high-pressure (HP) conditions. Classification based on the PID inventory resulted in the following groups: IP (N=34), DP (N=30), and situation-specific players (N=35). Heart rate variability was measured as a physiological evidence of pressure. Results(2): In the LP condition, IP performed better than DP, such as they generated fewer options, they had a shorter decision time, a shorter generation time, a lower dynamic inconsistency, and a higher first option quality. In addition, the performance of DP significantly decreased from the LP to the HP condition, while this was not the case for IP. Finally, the decrease of the parasympathetic system activity under pressure was higher for DP in comparison to IP. Discussion(3): Study 2 showed a higher use of the Take-the-First heuristic under pressure for IP. General discussion: Taken together, these findings indicate that IP perform better under pressure than DP. A challenging step for future research would be to investigate whether intuition can be trained.

REAPPRAISING AROUSAL FACILITATES MOTOR PERFORMANCE UNDER PRESSURE

Moore, L.J., Vine, S.J., Wilson, M.R., Freeman, P.

University of Exeter

Introduction Given the negative effect of threat states on motor performance (Moore et al., 2013), it is vital to identify strategies that help athletes successfully evaluate and respond to pressurized tasks. One strategy that has received recent attention but has yet to be examined in a pressurized sporting context is arousal reappraisal (Jamieson et al., 2010). The present study examined the influence of a reappraisal manipulation on individuals' psychological and cardiovascular responses and performance during a pressurized golf putting task. **Methods** Fifty participants (mean age = 20.24, SD = 4.27) were assigned to a reappraisal or control group. After performing six baseline putts, participants received instructions regarding the pressurized task. Next, the reappraisal group were given the reappraisal manipulation. All participants then performed one pressurized putt. Participants' psychological (somatic anxiety direction, demand resource evaluation score) and cardiovascular (challenge and threat index) responses were recorded prior to the pressurized putt and performance (performance error) was measured after the putt. **Results** Results revealed that the groups performed similarly at baseline ($p = .678$). However, prior to the pressurized task, the reappraisal group reported their somatic anxiety as more facilitative for their performance than the control group ($M = 0.44$, $SD = 1.33$ vs. $M = -0.44$, $SD = 1.39$, $p = .026$), supporting the effectiveness of the reappraisal manipulation. The reappraisal group also reported a higher evaluation score than the control group ($M = 1.32$, $SD = 1.57$ vs. $M = 0.46$, $SD = 1.25$, $p = .040$), reflecting a challenge psychological response. The reappraisal group exhibited a larger index value than the control group ($M = 0.33$, $SD = 2.20$ vs. $M = -0.48$, $SD = 1.54$), signifying a challenge cardiovascular response. However, this was not statistically significant ($p = .185$). Finally, the reappraisal group achieved a lower error during the pressurized task than the control group ($M = 8.63$, $SD = 10.01$ vs. $M = 24.92$, $SD = 31.29$, $p = .019$), indicating superior performance. **Discussion** These results demonstrate that a reappraisal manipulation can help athletes evaluate and respond to pressurized tasks more adaptively, as a challenge rather than a threat. Further, these results imply that reappraising arousal can lead to better motor performance under pressure. Thus, applied practitioners should encourage athletes to interpret heightened arousal as a tool that can help maximize performance rather than an unwanted negative experience. **References** Jamieson, J.P., Mendes, W.B., Blackstock, E., & Schmader, T. MONITORING PERCEIVED STRESS, RECOVERY AND SUBMAXIMAL PERFORMANCE DURING PREPARATION AND COMPETITION IN ELITE FEMALE ATHLETES

Otter, R.T.A., Brink, M.S., Lemmink, K.A.P.M.

Hanze University of Applied Sciences Groningen; University of Groningen, University Medical Center Groningen

Introduction Elite athletes enhance their performance by physical training. However, it is suggested that performance is also affected by perceived stress and recovery (Kentta and Hassmen, 1998). The purpose of this study was to analyze the relationship between changes in perceived stress, recovery and submaximal performance during the preparation and competition phase. **Methods** Fourteen competitive female athletes (9 ice skaters, 3 tri-athletes and 2 cyclists; age, 27 ± 9 years; height, 171 ± 5 cm; weight, 62 ± 5 kg and VO2max, 50 ± 5 mL/min/kg), completed 4 questionnaires (Dutch RESTQ-sport) in which perceived stress and recovery were measured (Nederhof et al., 2008) followed by 4 HR-based submaximal cycling tests (LSCT, Lamberts et al., 2011) before the preparation phase (T1), during the preparation phase (T2), at the beginning of the competition phase (T3) and during the competition phase (T4). The LSCT protocol involves athletes to perform 6 minutes at 60% of maximal heart rate (HRmax) followed by 6 minutes at 80%HRmax and 3 minutes at 90%HRmax. Performance was measured as the mean power output over the last 2 minutes at 90%HRmax (PO90). **Results** PO90 (i.e. performance) changed by -3 ± 19 W (T2-T1), -2 ± 14 W (T3-T2) and 3 ± 17 W (T4-T3), respectively. Changes in general stress, general recovery, sport-specific stress and sport-specific recovery ranged from -0.8 ± 3 to 0.1 ± 2.0 for T2-T1 (i.e. preparation phase), -1.3 ± 1.7 to 1.3 ± 2.2 for T3-T2 (i.e. preparation to competition phase) and -0.3 ± 1.3 to 0.9 ± 2.4 for T4-T3 (i.e. within the competition phase). No relationships were found between PO90 and perceived stress and recovery within the period of the preparation to the start of the competition phase (T1, T2 and T3). However, increased sport-specific recovery was related to increased PO90 during the competition phase (T4-T3) ($r=0.59$, $p=0.04$). **Discussion** It is shown that a higher perceived sport-specific recovery is related to better submaximal performance during the competition phase of elite female athletes. This implicates that the lack of recovery may result in decreased performance. Monitoring perceived recovery during the competition phase can provide insights that can help to optimise training programs of female athletes by means of appropriate recovery strategies/interventions. **References** Lamberts, R. A GROUNDED THEORY OF CONTINUED PARTICIPATION IN YOUTH RUGBY UNION

Sellars, P.A., Mellalieu, S.D., Knight, C.J.

Swansea University

Introduction Despite the rise in participation in sport and physical activity at primary school level there has been a marked decline post 15 years of age across all sports in Wales over the last 15 years (Sport Wales, 2013). Rugby union has experienced this decline. This project seeks to examine and develop a grounded theory of continued participation in youth rugby union. **Method** Straussian grounded theory methodology was used (Corbin & Strauss, 2008). Participants were key stakeholders involved in rugby union provision for 15 year olds and upwards, including development and participation officers, performance and community management staff, and current and ex-rugby union players. Data was collected via individual semi-structured interviews. Questions used in the initial interviews focused on participants' perceptions of the decrease in retention rates from junior (U16) to youth grade (U19) rugby in South Wales, UK. As data collection progressed the questions became more specific to gain detailed verification or falsification of the emerging theory (Corbin & Strauss). **Post transcription**, analysis occurred through a process of open and axial coding, and theoretical integration. **Results and Discussion** A substantive grounded theory of continued participation in youth rugby union in was formed. The core category was termed the ongoing evaluation for future rugby union participation at key transition points and was underpinned by four categories. Firstly, identifying as a rugby union player encompassed the level to which an individual identified as a rugby union player, the strength of their ties to the clubs and teams they have played for, and the rugby traditions they hold. Secondly, opportunities to participate in rugby union and the clarity of the performance pathway incorporated training times, the season structure, facilities, availability to a local club, and successful transition following de or non-selection. Next, perceived quality of coaching experience entailed the level, experience and style of coaching and the player coach relationship. Finally, competing demands focused upon external responsibilities which may conflict with participation in rugby union such as work, education, social life and family. **Conclusion** Overall, it may be suggested that to enhance continued engagement in rugby union post 15 years of age individuals must view continued participation as more favourable than the competing demands they experience at key transition points in their development. **References** Corbin, J., & Strauss, A. (2008). *Basics of qualitative research* (3rd ed.). London: Sage. Sport Wales (2013). *Sport Wales Corporate Plan 2013-2015*. 08:30 - 10:00**Oral presentations****OP-PM08 Physical activity in children****DIFFERENCES IN ACCELEROMETER ASSESSED PHYSICAL ACTIVITY LEVELS AND ACTIVITY-HEALTH RELATIONSHIPS IN CHILDREN USING INDIVIDUALLY CALIBRATED AND EMPIRICAL INTENSITY CLASSIFICATION CUT POINTS**

Boddy, L.M.1, Graves, L.E.F.1, Fowweather, L.1, Gobbi, R.2, Hopkins, N.D.1, Stratton, G.3

1. Liverpool John Moores University 2. Liverpool Hope University 3. Swansea University

Introduction The way in which accelerometer data are processed substantially influences reported physical activity (PA) levels and PA-health relationships. Empirical cut points vary in their classification of PA intensities, and individual differences between participants are not routinely accounted for. The aim of this study was to investigate the number of children reaching 60 minutes/day of moderate to vigorous PA (MVPA), differences in moderate (MPA) and vigorous (VPA) PA levels and PA-health associations using three sets of PA intensity cut points. **Methods** Cardiometabolic risk, cardiorespiratory fitness (CRF), anthropometric and 7 day accelerometer data generated by the Liverpool arm of the REACH Y6 study were used for this analysis. The cut point sets used were: individually calibrated (IC), Evenson et al., 2008 (Ev) and Mackintosh et al., 2012 (Mc). The number of 10-12 year old children (n = 45) meeting 60 minutes/day of MVPA was examined by PA intensity cut point set. Differences in minutes of MPA and VPA between cut point sets were investigated using MANCOVA. The associations between MPA and VPA with CRF, clustered cardiometabolic risk, waist circumference and BMI Z-score were assessed by cut point sets using multiple regression. **Results** The proportion of the cohort meeting ≥ 60 mins/day MVPA ranged from 62%-78% depending on the cut point used. MANCOVA revealed a significant difference in MPA between the Ev (MPA = 47.6 mins/day) and Mc (MPA = 63.23 mins/day, $p < 0.01$) cut points. Differences in IC MPA (60.02 mins/day) vs Mc MPA approached statistical significance ($p = 0.051$). VPA mins/day were significantly lower for IC (10.62 mins/day) in comparison to Ev (31.12 mins/day, $p < 0.01$) and Mc (21.46 mins/day, $p = 0.04$). Results of multiple regression found that IC MPA was a significant predictor for BMI Z-score (standardised beta = -.32, $t = -2.06$, $p = 0.048$). No other significant PA-health associations were observed irrespective of cut point set used. **Discussion** The number of children meeting PA guidelines and reported MPA and VPA levels differed substantially by cut point and a standardized approach is urged. The choice of cut point appears less important when examining PA-health associations, but further research is needed with larger cohorts to fully examine the potential of using individually calibrated cut points to classify children's PA. **References** Evenson KR, Catellier DJ, Gill K, Ondrak KS, McMurry RG. AN INTEGRATED CURRICULUM APPROACH TO INCREASING HABITUAL PHYSICAL ACTIVITY IN PRIMARY SCHOOL CHILDREN, UK: A FOCUS ON SOUTH ASIAN CHILDREN FROM DEPRIVED BACKGROUNDS

Eyre, E.L.J., Duncan, M.J., Birch, S.L., Cox, V.

coventry university

Introduction South Asian children have low physical activity levels and increased metabolic risk factors (Owens et al., 2009; Whincup et al., 2002). The purpose of this study was to ascertain whether an integrated school based curriculum and pedometer intervention could increase physical activity in children from deprived and ethnic backgrounds. **Method** Following ethical approval and informed consent, 134 children (63 boys, 71 girls) from a primary school in central England, a control (n=40 with mean age \pm SD= 11.12 \pm 0.32 years) and intervention group (n= 94 with mean age \pm SD= 9.48 \pm 0.62 years) completed a 6 week integrated physical activity intervention based on

virtually walking from their school to the coast of England, UK (252 miles). Habitual physical activity was assessed using a pedometer (New Lifestyles, NL2000, Montana, USA) at baseline and 6 weeks post intervention for both groups, and measured weekly during the intervention for the intervention group. Results The results from ANCOVA indicated that average daily steps were significantly higher at 6 weeks post intervention compared to baseline for the intervention group but not the control group ($P = 0.001$, change from control to 6 weeks post = -984 steps/day control and +8672 steps/day intervention). In addition, significant decreases in BF% and waist circumference were observed in the intervention group post 6 weeks ($P = 0.001$, -2.8%, -7.2 cm respectively) but not the control group. Discussion Integrating PA within a curriculum using pedometer based open loop feedback is effective in enhancing habitual physical activity in children (Duncan et al., 2012; Oliver et al., 2006) and is feasible for use within schools. The findings from this study support these prior studies and provide evidence for its effectiveness and sustainability over 6 weeks, against a matched control group and for use in South Asian children from deprived backgrounds. EXECUTIVE FUNCTIONING MEDIATES THE RELATIONSHIP BETWEEN PHYSICAL FITNESS AND ACADEMIC ACHIEVEMENT IN PRIMARY SCHOOL CHILDREN

van der Niet, A.G., Smith, J., Hartman, E., Visscher, C.

University of Groningen, University Medical Center Groningen

Introduction Recently, studies in children have shown that there is a positive relation between physical fitness and executive functioning (Buck et al., 2008) as well as between physical fitness and academic achievement (Castelli et al., 2007). How these three factors are related when examining them together is unclear. The aim of this study therefore was to investigate the relationships between physical fitness, executive functioning and academic achievement simultaneously, more specifically to test whether the relationship between physical fitness and academic achievement is direct or indirect, via executive functioning. **Methods** This study examined 263 children (145 boys, 118 girls), aged 7 to 12 years old, who performed tests on physical fitness (PF), executive functioning (EF) and academic achievement (AA). PF was measured with the Eurofit, and included both strength and aerobic components. EF included planning (Tower of London) and cognitive flexibility (Trailmaking test), and AA included scores on math, reading and spelling tests. The constructs PF, EF and AA were included as three separate latent variables in the models. Models were designed using structural equation modeling. All models were controlled for age and gender. **Results** In a structural equation model linking PF to EF and AA there was a significant relationship between PF and EF ($r = .43$, $R^2 = .19$), and between PF and AA ($r = .33$, $R^2 = .11$). Adding a mediating relationship from EF to AA resulted in a non-significant direct link between PF and AA ($r = -.08$, $R^2 = .01$). However, a significant indirect relation through EF persisted. This indirect relation between PF and AA ($r = .41$, $R^2 = .17$) was stronger than both the direct and total relation ($r = .33$, $R^2 = .11$ for both). **Discussion** Our study showed that PF was more strongly related to EF than AA. The significant relationship between PF and EF confirms findings from neurophysiological studies, which show that EF can be improved by gains in aerobic fitness by means of increased blood flow and brain neurotransmitters (Best, 2010). EF served as a mediator in the relation between PF and AA, highlighting the importance of including EF when studying the relationship between PF and AA in children. More research is needed to study the specific role of different components of PF in relation to cognition in children. **References** Best JR (2010). *Dev Rev*, 30, 331-351. PHYSICALLY ACTIVE TEENAGERS MORE SATISFIED WITH BODY FUNCTIONS AND MORE PRONOUNCED EGO- AND TASK-ORIENTED THAN INACTIVE PEERS

Sollerhed, A.C., Apitzsch, E.

Kristianstad University, Lund University

Introduction Experiences of physical activity (PA) during adolescence have been shown to affect adult body-image. Some studies have shown associations between body image and PA in adolescence, while other studies have shown no associations. Successes and failures can be explained by a variety of attributions, which affect not only expectations of success or failure but also affect emotional reactions (Biddle et al., 2001). **Methods** A questionnaire including questions about self-reported PA, attribution style, attitudes, perceived body functions and appearance was used among 1011 teenagers, 15-16 years old, in Sweden, Germany, New Zealand and the US. The TEOSQ form was used (Duda & Whitehead, 1998). Chi squared test and Student's t-test in the statistical analyses. **Results** Teenagers who reported high levels of PA were more satisfied with body functions (73% vs 58%; $p = 0.022$), more satisfied with appearance (46% vs 31%; $p = 0.016$) than more inactive peers. They had higher scores in ego-orientation (20.5 vs 18.1; $p = 0.001$), in task-orientation (29.4 vs 26.8; $p < 0.000$). Teenagers with positive attitudes towards PE had higher scores in both ego- (19.3 vs 17.7; $p < 0.000$) and task-orientation (28.3 vs 26.2; $p < 0.000$). **Discussion** Active teenagers were more satisfied with body functions and appearance. Physical aesthetics and bodily attributes, including somatic self-perceptions, affect people's lives in many ways. Positive perceptions of bodily attributes and PA is favorable for the self-esteem. Students with high PA were more pronounced in both ego- and task-orientation. Being ego-oriented, when combined with high task-orientation, has been shown to be associated with high motivation (Wang & Biddle, 2001). The inactive teenagers were not high in ego-, nor in task-orientation. Students with the combination low-task low-ego have low motivation for PE and for PA in general. Those students are not task-oriented enough to put any effort to do PA, and the ego-orientation is too low to be a driving factor. Together with low satisfaction or dissatisfaction with bodily attributes and low self-esteem, it will be difficult to motivate activity. **References** Biddle, S.H.J., Hanrahan, S.J., & Sellars, C.N. EFFECT OF PHYSICALLY ACTIVE ACADEMIC LESSONS ON PHYSICAL FITNESS OF PREADOLESCENT CHILDREN

De Greeff, J.W., Hartman, E., Mullender Wijnsma, M.J., Visscher, C.

University of Groningen, University Medical Center Groningen

Introduction There is an increasing prevalence of overweight and unfit preadolescent children, especially in children with a low socioeconomic status (socially disadvantaged children; SDC) (Poulton, 2002). Overweight and low physical fitness (PF) have been related to increased cardiovascular risks (Ruiz, 2006). Combining physical activity at moderate to vigorous intensity with academic lessons can contribute to reducing overweight and improving physical fitness and academic performance (Donnelly, 2009). The aim of this study was therefore to examine the effects of physical active academic lessons on PF of SDC and children without a social disadvantage (non-SDC).

Methods The study is part of the 'Fit and academically Skilled at school' program (F&S). Children in the second and third grade, from six schools in the Northern Netherlands were classified as either experimental (n = 92) or control group (n = 91). Both groups included SDC as well as non-SDC children. SDC was based on the education of the parents. The experimental group followed the in-class F&S program for 22 weeks, three times a week, with a duration of 30 minutes each session. The control group followed the regular academic program. PF was evaluated before (T0) and after (T1) the F&S program, measuring muscular fitness (standing broad jump, sit-ups and handgrip strength) and cardiovascular fitness (10x5m shuttle run and 20m endurance shuttle run). Results At T0, no differences between SDC and non-SDC were found for PF. An ANCOVA, with scores at T0 as covariates, showed that the experimental group scored significantly higher on the 20m endurance shuttle run at T1, compared with the control group ($F(1,185) = 3.8$, $p = .027$). No significant differences were found for standing broad jump, sit-ups, handgrip strength and the 10x5m shuttle run. Interaction effects showed a significant improvement for sit-ups within SDC ($p = .038$) and for the 10x5m shuttle run within the second grade ($p = .015$). Discussion SDC did not appear to have a lower physical fitness compared to non-SDC. It can however be concluded that, for both SDC and non-SDC, F&S improves the cardiovascular fitness after 22 weeks. Effects on academic performance will be discussed during the presentation. References Poulton R, Caspi A, Milne BJ, Thomson M, Taylor A, Sears MR, et al. (2002). *Lancet*, 360(9346), 1640-1645. PERCEPTION OF RECREATION FACILITIES, URBAN GREEN SPACES AND FOOD RETAILER: RELATIONSHIP WITH PHYSICAL ACTIVITY AND JUNK FOOD INTAKE.

Autran, R., Abreu, S., Pina, M.F., Mota, J., Santos, M.P.

Research Centre in Physical Activity, Health and Leisure

Introduction: Nowadays, many researchers have been focused on complex relationship between urban environment attributes and healthy behaviors as physical activity (PA) and dietary intake. However, there are major gaps in our understanding of the way shifts in the physical and social environments affect changes in dietary intake, physical activity patterns and weight change. The aim of this study is verify the relationship among proximity perception to recreation facilities (RF), urban spaces (US) and food retailer's (FR) with physical activity and food intake, respectively.

Methods: Data were obtained from 237 adolescents (58.4% girls) aged 14 to 18 years-old attending public schools in Porto municipality. PA was measured with accelerometers (Actigraph GT1M) during 7 consecutive days, considering 8 hours per day. Minutes of Moderate Vigorous Physical Activity (MVPA) were calculated with Evenson (2008) cut-points. The RF and FR proximity perception were accessed by NEWS-Y questionnaire. The recreation facilities and food retailers were categorized in 3 classes, considering until 10 minutes of distance walking from home: 0 (none RF), 1 (1 to 2 RF) and 2 (≥ 3 RF) the same procedure was used to food retailers. The amount of US was categorized in 2 classes 0 (none) and 1 (1 to 2) us near home until 10 minutes. The food intake was assessed using a food frequency questionnaire adapted for Portuguese adolescents. Linear regression was calculated. Results: The median and std deviation of MVPA in adolescents was 53.05 ± 23.25 minutes per day. Considering the proximity perception within 10 minutes walking from home, 66.7% of boys perceived more than 3 recreation facilities and 58.1% of girls perceived more than 3 retailers. No relationship was found between the amount of recreation facilities perceived considering the class 2 ($\beta = 0.78$, $p < 0.232$) and amount of US ($\beta = 0.29$, $p < 0.654$) considering the class 1 with MVPA. The proximity perception of retailers food considering the class 2 with consuming sweets and pastry ($\beta = -0.64$, $p < 0.318$), fast food ($\beta = 0.35$, $p < 0.585$) and sugar-sweetened beverages ($\beta = 0.08$, $p < 0.182$) were not related. Conclusion: The majority of adolescents perceived more than 3 sports facilities and food retailers up to 10 minutes walking from home. However, that was not related with MVPA and with consumption of junk food. Project grant FCT/FCOMP-01-0124--FEDER 014697/PTDC/DES/11807/2009

08:30 - 10:00**Oral presentations****OP-PM09 Chronobiology & Exercise****TIME-OF-DAY EFFECT ON PHYSIOLOGICAL AND IMMUNOLOGICAL RESPONSES TO A TIME TRIAL IN A HOT AND HUMID ENVIRONMENT.**

Boukelia, B.I., Gomes, C.G.I., Malone, E.I., Florida James, G.I.

Napier Edinburgh University

Purpose: To investigate the physiological and immunological response to an intense bout of exercise performed by highly trained individuals at 09:00hs and 18:00hs. **Methods:** Using a crossover randomized design, 13 well trained runners (range VO_{2max} 61-79 ml.kg⁻¹.min⁻¹) performed a 10 km time trial run, at 2 different times of day (09:00hs and 18:00hs), in an environmental chamber (28°C and 70% relative humidity). Lung function tests and blood samples were taken immediately pre, post and 1h-post trial to determine, total WBC counts, WBC variables, total RBC counts, RBC variables, IL-6, CC16 and HSP70 levels. Nasal lavage procedure for the analysis of upper respiratory airway was conducted pre-, post-trial and 1h-post trial. Core body temperature, heart rate, power, strength and flexibility were measured pre-, post-trial and 1h-post trial. Results: The time taken to complete the trial was not significantly different. During the time trial,

heart rate and core body temperature was significantly higher at 18:00hs ($P < 0.05$). A significant diurnal difference ($P < 0.05$) was found for total WBC, neutrophil and lymphocyte counts with higher values at 18:00hour (pre-trial: total WBC counts 22%, neutrophil 40% and lymphocyte 9%. Post-trial: total WBC counts 27%, neutrophil 38% and lymphocyte 20%. 1h post-trial: total WBC counts 36%, neutrophil 43% and lymphocytes 20%). Resting plasma CC16 and IL-6 was higher at 09:00hs compared to 18:00hs (23% and 87%, respectively), whereas, HSP70, total RBC and RBC variables counts were not affected by the time of the day. No significant differences were observed in power, strength or flexibility. Conclusion: a 10 km time trial run, in a hot and humid environment, can cause different physiological and immunological responses dependent on the time-of-day in which it is performed. Despite no statistically significant difference in diurnal running performance a 19 second mean difference in completion time would decide the race winner or even new records.

DOES RAISING MORNING RECTAL TEMPERATURE TO EVENING LEVELS OR AN 'OPTIMAL' LEVEL $<38.5^{\circ}\text{C}>$ OFFSET THE DIURNAL VARIATION IN QUADRICEPS MAXIMAL VOLUNTARY CONTRACTION FORCE?

Edwards, B.J.1, Gibbins, K.P.1, Morgan, C.J.1, Pullinger, S.A.1, Robertson, C.M.2, Burniston, J.G.1, Waterhouse, J.M.1

1 Liverpool John Moores University, 2 University of Bolton, UK

Muscle force production in active males is higher in the evening than the morning. This diurnal variation is attributed to motivational, peripheral and central factors, and higher core and muscle temperatures in the evening. We investigated whether increasing morning rectal temperatures to evening resting values by an active warm-up, or raising them passively in the morning or evening to a proposed optimal level (38.5°C), leads to muscle force production in the quadriceps becoming equal to evening values. Eight active males (mean \pm SD: age, 25.5 ± 1.9 yrs; body mass, 71.0 ± 6.7 kg; height, $1.79 \pm .06$ m) volunteered and completed five sessions (separated by >48 h): control morning (M, 07:30 h) and evening (E, 17:30 h) sessions (both with an active 5-min warm-up) and three further trials - an active warm-up 07:30 h trial (ME, until resting evening temperatures were reached), a morning (M38.5) and an evening (E38.5) passive warm-up trial which continued until rectal temperature reached 38.5°C (subjects being immersed in a water-bath @ $\sim 40^{\circ}\text{C}$, 45-50% Relative humidity). During each trial, 5 measures of maximal voluntary contraction (MVC) of the quadriceps on an isometric dynamometer (utilizing the twitch-interpolation technique) were performed with force and percentage activation recorded. Trec, rating of perceived exertion (RPE) and thermal comfort (TC) were measured. Measurements were made after the subjects had reclined for 30 min at the start of the protocol and after the warm-ups and prior to the measures for isometric dynamometry. Muscle temperatures and Tm (at 3, 2 and 1 cm depths) were taken at rest, after the warm-up and immediately before the isometric MVC measurements. Warm-ups were either active (cycle ergometer at 150 W) or passive (resting in a water bath at 40°C), ambient relative humidity = 45% in both cases. Data were analysed by GLM with repeated measures. Isometric peak force for knee extension showed higher values in the evening (mean difference of 83.2 N; $P = 0.006$). Trec and Tm (at 3 cm depth) values were higher at rest in the evening than the morning (0.47 and 0.85°C respectively; $P < 0.05$), and increased from rest by 0.54 and 2.2°C , 1.78 and 2.2°C , and 1.31 and 1.8°C , in the ME, M38.5 and E38.5 conditions, respectively, the subjects' ratings of thermal comfort reflecting this ($P < 0.0005$). There was no significant effect of active or passive warm-ups on peak torque, and subjects reported maximal values for effort for each MVC measure ($P > 0.05$). Results indicate that the diurnal variation in Trec and Tm cannot fully explain time-of-day oscillations in isometric MVC performance. Although central temperature may provide some endogenous rhythm to muscle strength performance, the causal link that has been proposed does not seem to be simple but rather due to multiple components and mechanisms.

CLINIC AND AMBULATORY BLOOD PRESSURE RESPONSES AFTER A SESSION OF AEROBIC EXERCISE ARE DIFFERENT IN THE MORNING AND EVENING

Brito, L.1, Rezende, R.1, Silva Jr, N.D.1, Tinucci, T.1, Cipolla Neto, J.2, Forjaz, C.L.M.1

1: EEFUSP (São Paulo, Brazil), 2: ICBUSP (São Paulo, Brazil)

Introduction: An aerobic exercise session promotes post-exercise hypotension. Previous studies observed lower clinic blood pressure (BP) reduction after exercise performed in the morning than in the evening. However, these studies did not consider the circadian variations of BP, which limits data interpretation. Moreover, they did not investigate ambulatory BP responses. Thus, the aim of this study was to compare clinic and ambulatory BP after an exercise session performed in the morning and evening corrected by the responses obtained in control sessions performed at the same times of day. Methods: 16 young pre-hypertensive men underwent four experiments conducted on a randomized order: two at 9 am and two at 6:30 pm. At each time of day, a control and an exercise session (cycle ergometer 45 min, 50% VO_2peak) were performed. Before and after the sessions, clinic BP and heart rate (HR) were evaluated in the laboratory, and an ambulatory BP was evaluated for 24 hs. The rate pressure product (RPP) was calculated for clinic and ambulatory measurements. The net effects of exercise [(post-pre exercise) - (post-pre control)] were calculated for each time of day and were compared by a paired T-test, $P \leq 0.05$. Results: Clinic systolic BP decreased significantly more after exercise performed in the morning than in the evening (-7 ± 3 vs -3 ± 4 mmHg, $P \leq 0.05$), while diastolic and mean BP decreased similarly at both times of day. Clinic HR and RPP increased less after exercise in the morning ($+5 \pm 1$ vs $+9 \pm 1$ bpm, and $+424 \pm 786$ vs $+1003 \pm 683$ U, $P \leq 0.05$ respectively). Asleep systolic BP decreased significantly only after exercise performed in the evening ($+1 \pm 11$ vs -4 ± 7 mmHg, $P \leq 0.05$) while 24h and asleep HR increased only after exercise performed in the morning ($+4 \pm 6$ vs $+2 \pm 8$ bpm and $+6 \pm 7$ vs 0 ± 8 bpm, $P \leq 0.05$ respectively). Discussion: BP reduction occurred after exercise performed at both times of day. However, the net systolic hypotensive effect was greater after exercise performed in the morning, while this effect was more prolonged after exercise performed in the evening. On the other hand, HR and RPP increased after exercise performed at both times of day, but the increase was lower after exercise performed in the morning, nevertheless, it persisted elevated for a longer period when exercise was performed at this time of the day. In conclusion, aerobic exercise promotes a greater hypotensive effect with a lower cardiac work increases when performed in the morning. However, it promotes a longer time hypotensive effect when performed in the evening. Financial support: CNPq: 472288/2011-3, FAPESP: 2011/03584-8.

POST-EXERCISE PARASYMPATHETIC REACTIVATION IS BLUNTED IN THE EVENING IN PRE-HYPERTENSIVE SUBJECTS

Peçanha, T., Brito, L.C., Silva Junior, N., Costa, L.R., Tinucci, T., Forjaz, C.L.M.

University of Sao Paulo

Introduction: Heart rate (HR) recovery (HRR) and post-exercise HR variability (HRV) are non-invasive tools to assess cardiac autonomic recovery after exercise. Strong evidence indicates that slower cardiac vagal restoration and sympathetic withdrawal after exercise are independently associated with cardiovascular morbidity and mortality. In healthy subjects, cardiac autonomic recovery after exercise presents circadian variations, but it is unknown whether HRR and post-exercise HRV also differ in the morning and evening in subjects

with cardiovascular risk factors. This study was designed to verify the influence of the circadian rhythm on post-exercise HRR and HRV in prehypertensive men. Methods: Eleven prehypertensive men (age = 33 ± 6 ys, body mass index = 28.4 ± 2.9 kg/m², systolic blood pressure = 124 ± 7 mmHg and diastolic blood pressure = 94 ± 5 mmHg) performed, on separate days, two maximal exercise tests followed by 5 min of active recovery. One test was conducted in the morning (8–10 am) and the other in the evening (6–8 pm). HR was continuously registered during the tests. The following indices of HRR were calculated: T30 (the negative reciprocal of the slope of the regression line between the natural logarithm of HR and the first 30 s after exercise - indicative of vagal reactivation) and HRR_t (the time constant of the first order exponential fitting of the HRR curve evaluated at 5 min after exercise - indicative of vagal reactivation and sympathetic withdrawal). HRR indexes were compared between sessions by a paired T-test ($p \leq 0.05$). Post-exercise HRV was assessed through the calculation of the rMSSD30s index (square root of the mean of the sum of the squares of differences between adjacent normal R-R intervals on subsequent 30-s non-overlapped segments during the whole recovery period). For this analysis, it was determined the recovery moment at which the rMSSD30s index begins to rise above its value at the first 30s of recovery (indicative of vagal reactivation). A one-way ANOVA for repeated measures was used to compare rMSSD30s throughout recovery in each session. Results: T30 index was greater in the evening compared to the morning (344 ± 52 vs. 296 ± 77 s, $P < 0.05$). There was no difference in HRR_t between the sessions (96 ± 29 vs. 81 ± 16 s, $P > 0.05$). The time required for the rMSSD30s index to rise in relation to its value at the first 30s of recovery was 90 s in the evening and 30 s in the morning. Conclusion: The results indicate that parasympathetic reactivation after exercise is blunted in the evening in comparison to the morning in prehypertensive men. DOES RAISING MORNING RECTAL TEMPERATURE TO EVENING LEVELS OR AN 'OPTIMAL' LEVEL $<38.5^{\circ}\text{C}>$ OFFSET THE DIURNAL VARIATION IN REPEATED SPRINT ABILITY ON A NON-MOTORISED TREADMILL?

Samuel Pullinger, A., Liam Clark, F., Joe Guyatt, W.F., Jatin Burniston, G., Dominic Doran, A., James Waterhouse, A., Ben Edwards, J.

Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, UK.

Muscle force production and short-term (<6 s) repeated-sprint ability (RSA) cycling and team-sport specific RSA treadmill tests values are significantly greater in the evening compared to the morning. This is attributed to motivational, peripheral and central factors, and possibly the higher core and muscle temperatures observed in the evening. The aim of this study was to investigate whether modulating (increasing through passive warm-up) morning rectal temperatures (T_{rec}) to previously observed resting evening levels or morning or evening T_{rec} to a proposed optimal level (38.5°C), would influence RSA performance in a causal manner. Twelve active male athletes (mean \pm SD: age, 21.0 ± 2.4 yrs, maximal oxygen uptake, 59.4 ± 3.8 mL.kg.min⁻¹, height, 1.78 ± 0.06 m, body mass, 79.6 ± 11.5 kg) volunteered and completed the study. The subjects were familiarized with the techniques and protocol and completed five sessions counterbalanced in order of administration: control morning (07:30 h) and evening (17:30h) sessions (with a 5-min active warm-up at 10km.h⁻¹ on a motorised treadmill followed by 3 task-specific warm-up sprints at 50, 70 and 80%, on a non-motorised treadmill), and then three further sessions - a morning passive warm-up trial (until evening resting T_{rec} were met), a morning and an evening passive warm-up trial (until T_{rec} levels reached 38.5°C). During each trial, 10 x 3s repeated sprints with 30s recoveries were performed. T_{rec} and muscle temperature measurements were taken after subjects had reclined for 30-min at the start of the protocol and following the warm-up. Values of heart rate, thermal comfort, rating of perceived exertion and effort were measured throughout. Blood samples were taken at rest, after the sprints and 5-min post sprints. Data were analysed using GLM with repeated measures. There was a significant diurnal variation present for T_{rec} and T_m (0.48°C and 0.69°C respectively; $P < 0.0005$). Distance covered per sprint, average velocity and average power values were all significantly higher in the evening than the morning (a range of 7.8–8.3%, $P < 0.05$). There was no significant effect of passive warm-ups on RSA performance and subjects reported maximal values for 'effort' for each sprint ($P > 0.05$). There were significant positive correlations between T_{rec} and T_m, both T_{rec} and T_m for RPE and TC, a trend for a negative correlation between T_{rec} and some measures of RSA performance (AV and DC); and T_m and PP. Results indicate that in this population of motivated subjects, time-of-day effects were seen in resting T_{rec} and T_m values and most performance measures of RSA, in partial agreement with past research. The diurnal variation in T_{rec} and T_m cannot fully explain time-of-day oscillations in RSA on a non-motorised treadmill, further there was evidence that our proposed 'optimal' level of T_{rec} had a negative effect on RSA performance such that values reduced to M condition irrespective if this warm-up was done in the morning or evening.

IS-PM06 Handcycling: from rehabilitation to elite sports performance *

HANDCYCLING TO PROMOTE HEALTH AND FITNESS DURING AND AFTER REHABILITATION

Janssen, T.W.J.

VU University Amsterdam

Introduction Individuals with lower-limb impairments predominantly depend on upper-body exercise for locomotion, therapy or sports activities. Wheelchair exercise, the more traditional form of upper-body exercise, is related to a high incidence of upper-limb injuries, probably as a result of frequent high loads. During the last decades, a relatively new form of upper-body exercise, handcycling, has evolved from a combination of wheelchair and arm cranking exercise. Handcycling is less straining and more efficient than wheelchair propulsion, making this exercise an ideal training for upper-body exercise in the context of rehabilitation and an active life style, but also an attractive and exciting sport to perform for people with lower-limb disabilities. Several types of handbikes are now available and handcycling exercise is performed by a very diverse group of individuals, from the rather inactive person during rehabilitation to the elite athlete. Methods This presentation will focus on studies investigating exercise and shoulder loading responses during handcycling in different populations, especially individuals with spinal cord injury (SCI), and potential mechanisms for health and fitness promotion will be discussed. Subsequently, handcycling interventions during and after the clinical rehabilitation phase will be discussed, including

effects on variables such as wheelchair performance capacity, muscle strength, and cardiorespiratory function. In addition, handcycling combined with electrical-stimulation induced leg cycling as a means to increase active muscle mass and potential health and fitness benefits will be discussed. Results From several studies it has become clear that handcycling is a more mechanically efficient exercise mode than wheelchair exercise. In addition, higher metabolic rates and power output levels can be achieved with handcycling than with wheelchair exercise, and strain on the shoulder joint and muscles prone to overuse injuries is lower (Arnet et al. 2012), suggesting that handcycling is more suitable for improving health and fitness, especially for those with impaired arm function. Intervention studies during rehabilitation show that additional hand cycle training leads to favourable results on physical capacity compared with regular care (Valent et al. 2010). After rehabilitation, handcycling can effectively promote health and fitness, even in the inactive ageing population with SCI. The addition of lower-limb muscle activation using electrical stimulation can provide additional health and fitness benefits. No studies have found adverse effects of handcycling. Conclusion Despite the limited evidence base, the current literature suggests an important role for handcycling during and after rehabilitation as a safe and effective exercise mode to promote health and fitness in persons with lower-limb disabilities. References Arnet U, et al. (2012) J Rehabil Med 44(3):222-8. Valent L, et al. (2010). Disabil Rehabil 32(26): 2191-2200.

THE INS AND OUTS OF HANDCYCLING EXERCISE TESTS

Abel, T.

German Sport University Cologne

Handcycling exercise tests, evolved from wheelchair and arm cranking exercise test, are currently highly specific tests that can be used during rehabilitation or in the field of competitive sports. Similar to tests for able-bodied individuals using leg exercise, handcycling tests are very diverse and can serve several purposes. Aim of the presentation is to present the current status of knowledge on the use of handcycling tests, describe various protocols for different purposes and populations, and discuss how these tests can be used to help improving the sports performance of elite handcycling athletes.

INNOVATIVE HANDCYCLING TRAINING INTERVENTIONS: OPTIMIZING PERFORMANCE

Perret, C.

Swiss Paraplegic Centre

Introduction Handcycling performance has considerably improved in the last decades and winning or losing a time trial race of about 25min duration is nowadays a question of only few seconds. Whereas the difference between first and third place at the Athens Paralympic Games 2004 (first time that handcycling was a Paralympic discipline) was 4.9%, it dropped below 0.6% in the same race category at the London Paralympic Games 2012. Such examples underline the necessity of optimizing training interventions and equipment for athletes in order to achieve top class performance. Methods Beside conventional training strategies, the following presentation will focus on various interventions in order to improve handcycling performance based on study results but also on personal single case experiences working with elite handcyclists with a spinal cord injury. Such interventions include respiratory muscle training, nutritional interventions (e.g. supplementation) as well as individual equipment adaptations based on wind tunnel experiments. Results In general, handcyclists seem to benefit from respiratory muscle endurance training and some supplementation strategies (e.g. caffeine, basic salts) as well as from adaptations of the personal equipment. However, benefits seem to differ from athlete to athlete and vary widely depending on individual factors such as completeness and level of lesion. As a consequence one has to take into account the special physiological constraints of persons with a spinal cord injury concerning e.g. energy expenditure and thermoregulation. Conclusions There seem to exist several intervention strategies in handcycling to further optimize exercise performance. However, personal circumstances such as level and severity of impairment have to be taken into account and individual solutions have to be found for elite athletes with a spinal cord injury.

IS-BN02 The Power-Duration Relationship: Physiological Determinants and Implications for Performance Assessment and Exercise Prescription sponsored by adidas *

THE POWER-DURATION RELATIONSHIP: MECHANISMS OF VASCULAR CONTROL

Poole, D.

Kansas State University

For high-intensity muscular exercise, the time-to-fatigue (t) increases as a predictable and hyperbolic function of decreasing power (P) or velocity (V). This relationship is highly conserved across diverse species and different exercise modes, is well-described by two parameters: the 'Critical Power' (CP or CV) which is the asymptote for power or velocity and the curvature constant (W') of the relationship such that $t = W'/(P-CP)$. CP represents the highest rate of energy transduction (oxidative ATP production, oxygen consumption) that can be sustained without drawing continuously upon the energy store W' (comprised, in part, of anaerobic energy sources and expressed in kJ). The limit of tolerance (time t) occurs when W' is exhausted (Poole et al. 1988). The CP concept provides a practical framework within which to explore mechanisms of fatigue and help resolve crucial questions regarding the plasticity of exercise performance (Jones et al. 2010). For cycle ergometry CP represents a finite metabolic rate that can be achieved by different combinations of power and contraction frequency (Barker et al. 2006). Intriguing recent evidence, however, demonstrates that, at a given power, manipulation of the muscle(s) duty cycle can impact CP and the metabolic rate at which CP occurs (Broxterman et al. 2013). Above CP specific populations of fast twitch fibres (Type IID/X) are recruited and their blood flow is substantially dependent upon nitric oxide bioavailability derived from neuronal nitric oxide synthase (Copp et al. 2010, 2013). This contrasts markedly with the role of endothelial nitric oxide synthase which preferentially increases blood flow to highly oxidative fibres (Type I and IIA) (Hirai et al. 1994). These observations provide a putative mechanistic link

between nitrate supplementation (via beetroot juice (Ferguson et al. 2013) or other means) and its ability to enhance exercise performance in some, but not all, athletic events and individuals (Wilkerson et al. 2012; Wylie et al. 2013). METABOLIC DETERMINANTS OF THE CRITICAL POWER

Vanhatalo, A.

University of Exeter

The power-duration relationship characterises exercise tolerance within the severe exercise intensity domain. The power-asymptote of the relationship (CP) indicates the boundary between the heavy intensity domain, within which a physiological steady-state is attainable, and the severe domain, within which exercise is non-steady state and the pulmonary oxygen uptake (VO₂) continues to rise until the VO₂max is attained. Whether steady-state is attainable or not has important implications for exercise tolerance and therefore the establishment of CP is of paramount importance for diagnostic and research purposes. Non-invasive assessment of skeletal muscle bioenergetics during small muscle mass exercise has indicated that the CP represents a critical threshold for intramuscular metabolic control (Jones et al. 2008). This interpretation has recently been corroborated, and extended to whole body exercise, by novel investigations utilising muscle biopsy technique. Collectively, the non-invasive and invasive assessments of muscle bioenergetics concur in showing that exhaustive exercise above the CP (i.e., in the severe domain) results in the attainment of a consistent, perhaps limiting, muscle metabolic milieu (as indicated by markers such as pH and concentrations of phosphocreatine and inorganic phosphate) irrespective of the work rate chosen. The limited exercise tolerance above the CP is quantified as the curvature constant of the power-duration relationship (W'). As severe-intensity exercise proceeds, the progressive loss of muscle homeostasis signals a stimulation of 'excess' VO₂ (i.e., the so-called VO₂ slow component), and thereby a loss of efficiency, which propels the VO₂ on a trajectory towards VO₂max. Recent evidence suggests that the power-duration relationship is inherently linked with the VO₂ kinetics (Murgatroyd et al. 2011; Vanhatalo et al. 2011). Specifically, interventions which accelerate the rate of increase in VO₂ at exercise onset and reduce the size of the slow component tend to increase the CP and reduce the size of the W'. These changes are reflected as a rightward shift in the power-duration curve and improved exercise tolerance. The power-duration relationship may therefore be considered a manifestation of the predictable progression of muscle metabolic perturbations during severe intensity exercise which ultimately drives VO₂ to its maximum and limits exercise tolerance. EXERCISE INTENSITY DOMAINS: IMPORTANCE FOR EXERCISE PRESCRIPTION IN CLINICAL POPULATIONS

Mezzani, A.

Salvatore Maugeri Foundation - Scientific Institute of Verona

The critical power (CP) demarcates the boundary between the moderate to high and high to severe exercise intensity domains, representing the highest work rate sustainable in conditions of both VO₂ and lactate steady-state, i.e. the upper limit of sustainable prolonged aerobic exercise. Accordingly, CP can be considered the maximal 'dosage' of continuous aerobic training intensity prescription for an individual subject/patient, whereas exercise intensities higher than CP are used for prescription of a very different aerobic training modality, i.e. interval training. The CP corresponds to around 65-80%peak work rate/peak VO₂ and 75-90%peak heart rate as assessed by incremental exercise testing, but with higher steady-state %peak VO₂ and %peak heart rate values during constant-work-rate exercise. This is due to the appearance of a 'slow component' of the VO₂ kinetics after approximately 2 to 3 minutes of the start of constant-work-rate exercise in the moderate to high- and high to severe-intensity domains, which is not detectable during incremental exercise. The VO₂ slow component elevates the VO₂ and heart rate steady-states at a level higher than expected according to the below-1st ventilatory threshold VO₂ vs. work rate relationship, making VO₂ change not only as a function of work rate, but also as a function of time in these domains. Consequently, irrespective of the subject's/patient's peak exercise capacity, without precise stipulation of the exercise conditions and timing of measurements, it is misleading to define a given intensity as a percentage of peak VO₂ in the moderate to high- and high to severe-intensity domains. Notwithstanding these important physiological tenets, the concept of CP still remains almost unknown in the clinical setting, which may be due to both the cultural inertia of clinicians and the demanding experimental procedures needed to determine CP. A means of routine CP determination in the clinical setting is strongly needed to match the unique physiological responses of different exercise intensity domains to the individual patient pathophysiological and clinical status, maximizing the benefits obtainable from aerobic exercise training in different patient populations.

IS-PM03 The beneficial effects of exercise training on muscle microvascular endothelial function in health and disease ***NORMAL MUSCLE MICROVASCULAR ENDOTHELIAL FUNCTION AND OBESITY INDUCED IMPAIRMENTS**

van Hinsbergh, V.W.M., Eringa, E.C.

Institute for Cardiovascular Research, VU University medical center

The muscle microcirculation regulates delivery of nutrients and oxygen to myocytes, acutely and chronically matching supply and demand. Consequently, microvascular characteristics such as resistance, surface area and flow regulate myocellular glucose uptake and exercise tolerance. Microvascular endothelium plays a critical role in these functions through control over vascular resistance, angio- and arteriogenesis, distribution of blood flow and transendothelial transport (TET) of proteins such as insulin to myocytes. Moreover, microvascular endothelium controls local inflammation and infiltration of adipocytes. The functional properties of the muscle microcirculation are determined by "fitness" and "fatness", or muscle activity and adipose tissue. Bioactive products of adipose tissue (adipokines) such as cytokines, fatty acids and adiponectin have all been shown to regulate flow and endothelial surface area in muscles. The balance between secretion of NO and endothelin-1 by endothelial cells is an important mediator of these effects. Recent data have demonstrated that perivascular adipose tissue (PVAT) within muscles determines vasomotor responses to insulin, thus contributing to regulation of nutrient delivery to myocytes. PVAT is an important location of inflammation in muscle, and increased inflammatory activity in PVAT alters vascular functioning and impairs insulin-induced vasodilatation in muscle of obese people. Insight in the complex relationships between local adipose tissue, microvascular endothelium and muscle cells is growing and provides new avenues for improvement of perfusion and nutrient delivery in 'obese' muscle.

ALTERED PERFUSION DISTRIBUTION AND TEMPORAL ACTIVITY AT BIFURCATIONS IMPAIRS MICROVASCULAR BLOOD FLOW DISTRIBUTION IN METABOLIC SYNDROME: DOES A SHIFTED ATTRACTOR DEFINE PERIPHERAL VASCULAR DISEASE?

Frisbee, J.

West Virginia University

A key clinical outcome for non-atherosclerotic peripheral vascular disease (PVD) in patients is a progressive decay in skeletal muscle performance and its ability to resist fatigue with elevated metabolic demand. This study builds on previous work to evaluate in situ arteriolar hemodynamics in skeletal muscle of the obese Zucker rat (OZR) model of the metabolic syndrome to integrate existing knowledge into a greater understanding of impaired muscle perfusion and performance. In OZR cremaster muscle, perfusion distribution at microvascular bifurcations (γ) was consistently more heterogeneous than in controls. However, the underlying mechanistic contributors were spatially divergent as altered adrenergic constriction was the major contributor to altered γ at proximal microvascular bifurcations, with a steady decay with distance, while endothelial dysfunction was a stronger contributor in distal bifurcations with no discernible role proximally. Using measured values of γ , simulations predict that successive alterations to γ in OZR caused more heterogeneous perfusion distribution in distal arterioles than in controls; an effect that could only be rectified by combined adrenoceptor blockade and improvements to endothelial dysfunction. To minimize this negative outcome in spatial perfusion heterogeneity, a likely compensatory mechanism against an increased γ could be an increased temporal switching at arteriolar bifurcations to minimize downstream perfusion deficits. Using the in situ cremaster muscle, we determined that temporal activity (the cumulative sum of absolute differences between successive values of γ , taken every 20 seconds) was lower in OZR than in control animals, and this difference was present in both proximal (1A-2A) and distal (3A-4A) arteriolar bifurcations. While adrenoceptor blockade (phentolamine) improved temporal activity in 1A-2A arteriolar bifurcations in OZR, this was without impact in the distal microcirculation, where only interventions against oxidant stress (TEMPOL) and thromboxane A₂ activity (SQ-29548) were effective. Analysis of the attractor for γ indicated that it was not only elevated in OZR as compared to LZR, but also exhibited severe reductions in range. Taken together, these results suggesting that the ability of the microcirculation to respond to any imposed physiological or pathological challenge becomes highly restricted with metabolic syndrome, and may represent the major contributors to the manifestation of poor muscle performance at this age in OZR.

EFFECT OF DIFFERENT TRAINING MODES ON SKELETAL MUSCLE MICROVASCULAR DENSITY AND ENDOTHELIAL ENZYMES CONTROLLING NO PRODUCTION

Cocks, M.

Liverpool John Moores University

Impairments in microvascular perfusion that occur as a result of capillary rarefaction or reduced insulin mediated dilation of terminal arterioles have been proposed to limit nutrient and insulin delivery to skeletal muscle in sedentary individuals, obesity, metabolic syndrome and ageing, via a mechanism involving reductions in endothelial NO production. As such the mechanisms that underlie these impairments, and how lifestyle interventions influence them, are of great scientific and clinical significance. Current knowledge on the enzymes that determine NO bioavailability is primarily based on measurements in isolated blood vessels from animal models. A lack of suitable techniques has meant there is a paucity of data regarding the mechanisms that lead to impaired microvascular perfusion in human skeletal muscle. As such our lab has recently developed immunofluorescence microscopy methods which allow quantitation of the protein content and phosphorylation state of enzymes within the endothelium of the microvasculature of human muscle (1). Using these techniques our lab has demonstrated that the microcirculation in human muscle is highly responsive to increases in physical activity with substantial changes in capillary density and content and activity of endothelial enzymes that control muscle perfusion occurring. In support of this, endurance training (ET) in lean healthy individual results in increased capillarization and elevated eNOS protein

content (2). Interestingly, ET in obese individuals causes similar increases in capillarization and eNOS content, but also results in decreased NADPH oxidase content, which, is not apparent in lean individuals. Such adaptations are not restricted to endurance-type activities. High intensity interval training (HIT) induces comparable improvements in capillarization and endothelial enzymes to ET in both lean (1) and obese individuals (unpublished data). However, 6wks of HIT in lean individuals increased eNOS protein content of the muscle microvascular endothelium more than ET (2; $P < 0.05$). These findings add to the growing support that HIT is an effective time-saving training method. Furthermore, unpublished data suggest that resistance training induces smaller improvements in endothelial enzymes than ET and HIT. It is becoming increasingly apparent that precise regulation of skeletal muscle perfusion by the microvasculature is crucial for maintaining healthy skeletal muscle function. As such interventions aimed at improving microvascular perfusion are crucial, with the above data suggesting that exercise training is an essential lifestyle modification capable of maintaining or improving skeletal muscle endothelial function. IS-PM12 Efficiency in endurance sports

EFFICIENCY IN ENDURANCE EXERCISE: EFFICIENCY OF WHAT?

Ettema, G.

Norwegian University of Science and Technology

The debate on how to determine the efficiency of doing work in endurance sports and exercise is ancient but still ongoing. It is often argued that some of the energy consumed is not related to doing work and therefore the total energy consumption should be corrected for this, which is referred to as base-line subtraction. Often this is the metabolism at rest, but also metabolism when doing zero "external" work is used for this purpose. In delta efficiency the energy cost at some level of doing work is used as base-line. One problem with these subtractions regards the consistency of this baseline metabolism during exercise (Cavanagh and Kram, 1985). A more important one is if the paradigm is correct at all (Cavanagh and Kram, 1985; Ettema and Lorås, 2009). This issue is directly linked to the definition of the energy transforming system, i.e., the whole body (no base-line subtraction, gross efficiency) or the working muscles (which muscles? base-line subtraction, but which one?). The ongoing discussion on the estimation and role of "internal" work (energy used to move body segments) is exemplifying. We argue that estimation of internal work cost i.e. making movements without external resistance (e.g. cycling at 0 Watts) is flawed and that total internal work in cyclic movements is zero. Energy that is linked to motion of body segments may be utilised for propulsion, but obviously this is impossible when one is not allowed to propel (zero external load). Even more, the term "internal" is misleading; once the energy transforming system is well defined, the only form of work of interest is "external" and therefore does not need this specification. We propose to regard the entire relationship between metabolic - and work rate, and consider efficiency an incomplete description of the relationship (thereby only providing partial understanding). The use of efficiency as a comprehensive variable for relative energy cost of doing work should be abandoned. We studied this relationship for cross-country skiing and cycling. Cross-country skiing, irrespective of technique, requires considerably more energy than cycling for all work rates investigated. This difference is not explained by weight-bearing. The small but significant relationship between performance level and energy cost in ski-skating is most likely explained by perfection of technique (Sandbakk et al 2010). On the other hand, in bicycling the differences between groups (from top athlete to patients) is extremely small (if existing at all), indicating the low number of degrees of freedom in movement execution. This makes cycling and excellent exercise model for investigation of physiological aspects of energy conversion. Cavanagh PR, Kram R (1985). *Med Sci Sports Exerc* 17, 304-308. THE ROLE OF GROSS MECHANICAL EFFICIENCY IN ENDURANCE SPORTS

Sandbakk, Ø., Holmberg, H.C., Ettema, G.

Norwegian University of Science and Technology

Gross efficiency (GE) reflects the efficiency of the entire human body in action and provides insight into how the external work rate affects the metabolic cost of the movement. To increase the understanding of the role of GE in endurance sports, our research group has performed a series of experiments investigating the effects of performance level, technique and gender in various sports involving the upper, lower and whole body to various extents. More specifically, work rate and metabolic responses have been measured in ergometer cycling, treadmill roller-skiing with different skiing techniques and terrains and during arm, upper-body and whole body double poling. When comparing different types of locomotion, the magnitude of work rate produced and the way force is generated (i.e., continuous vs discontinuous movement, movement frequency etc.) are the most influential factors affecting GE and not the involvement of the upper and/or lower limbs per se. When correcting for differences in work rate, a higher performance level is associated with better technique and higher GE in technically complex sports. A particular focus has been placed on cross-country skiing where the inter-dependence of power produced by upper and lower extremities leads to large effects of external conditions and technique on GE. In less complex types of locomotion, participants over a large range of fitness levels follow the same work rate-metabolic cost regression lines. Due to differences in physical capacities, men and women at a comparable performance level differ significantly in the technical execution in technically complex movements. However, the two genders show close to identical metabolic costs for a given work rate. In conclusion, work rate, force generation and technique are the major determinants of GE in endurance sports, and men and women demonstrate similar efficiencies.

GROSS EFFICIENCY DURING HIGH INTENSITY EXERCISE

Noordhof, D.A.1, Foster, C.2,1, de Koning, J.J.1,2

(1) VU University; (2) University of Wisconsin-La Crosse

Gross efficiency (GE), the ratio between mechanical power output and metabolic power input, can be determined reliably during steady-state exercise performed below the ventilatory threshold. However, athletic performances are mostly completed at an intensity above the ventilatory threshold, what excites our interest in GE during high intensity exercise. To gain insight in GE during and after high intensity exercise de Koning et al. (2013) proposed a new methodology. Using this methodology, GE is determined during submaximal exercise performed before and after high intensity exercise, which allows GE to be estimated, using back-extrapolation, at the end of high intensity exercise (GE_{end}). In a follow-up study this methodology was applied to cycling time trials. It was shown that GE decreased significantly during time trials with a length varying between 500 and 40,000 m and that the decrement in GE differed between distances ($F = 5.49$, $P = 0.001$). GE at the end of time trial exercise differed significantly between the 1,000 and 15,000 m and 1,000 and 40,000 m ($P < 0.05$; 19.8 ± 1.4 vs. $21.2 \pm 1.0\%$; 19.8 ± 1.4 vs. $21.4 \pm 1.4\%$). Thus, although GE declined during all time trials, the magnitude of the decrement was smaller for the longer trials (15,000 and 40,000 m). It is assumed that a decrement in efficiency will be even more pronounced during technically more demanding sports, like speed skating. As it is more difficult to determine power output during speed skating and thus to obtain GE, insight in GE during skating was addressed by studying changes in push-off effectiveness. Push-off effectiveness deteriorated significantly in elite athletes during World Cup races, with a greater decline in push-off effectiveness during the 1,500 m ($P < 0.05$). In addition, for the 5,000 m the change in effectiveness was significantly associated with the change in skating velocity ($\beta = -0.069$, $[-0.11, -0.030]$; Noordhof et al., 2014). Although the cause and effect relationship has not been investigated, it seems most likely from a biomechanical view that the deterioration in effectiveness (i.e. larger push-off angle) will result in a decrement in skating velocity. In conclusion, GE and push-off effectiveness deteriorate during high intensity exercise. Pacing strategy influences the magnitude of the decline, and, at least in skating, the decline is associated with a performance decrement. References De Koning, J. J., Noordhof, D. A., Uitslag, T. 10:20 - 11:50**Invited symposia****IS-BN03 Muscle contractile mechanics of human multi-joint movements****FORCE-VELOCITY RELATIONS OF HUMAN MULTI-JOINT MOVEMENTS**

Yamauchi, J.

Tokyo Metropolitan University

To evaluate physical fitness in humans, it is very important to understand the physiological and mechanical properties underlying not only cardiovascular but also locomotor system. For any type of human movements, activity of skeletal muscle is required. Under the conditions of muscular contraction, the length-tension and force-velocity relations have been determined and regarded as important factors to determine the ability of muscle to generate a variety of movements. The mechanical properties of muscle have been extensively studied from molecular to organism levels. Gordon et al. (1966) found that isometric force from a single fiber of frog semitendinosus muscle changed with sarcomere length, and a maximum tension was developed at a sarcomere length of about $2.0\mu\text{m}$ (the length-tension relation). On the other hand, for the dynamic properties of muscle, it is well known that velocity of shortening depends on generated muscle force (the force-velocity relation). In the sartorius muscle of frog, the relationship between force and velocity has been described as an exponential function shown by Fenn and Marsh (1935). Hill (1938) further characterized it based on heat measurements and showed that this relation was more adequately fitted to a hyperbola (Hill's characteristic equation): $(P+a)/(V+b) = (P_0+a)/b$ where, P_0 is the maximum isometric force, and a and b are constants (Hill constants). The hyperbolic force-velocity relation shown by Hill appears to be preserved in muscles of all living creatures. Since studies with human single-joint movements such as elbow flexion have shown that the relations between joint torque and angular velocity are also described well with this classical, hyperbolic function (Wilkie, 1950), this nature is kept essentially unchanged up to the level of single-joint movements around a small joint. In human movement, because skeletal muscle is attached to bones via tendons at both proximal and distal end of muscle, force produced by muscle fibers is transmitted through tendons to bones. It is interesting to understand the whole organism basis of human movement and force generation. The mechanical characteristics of muscles that control the movement are important in determining the human locomotor system and can be modified with aging and exercise training. In this symposium, we will address the mechanical characteristics (dynamic property) of muscles that control in human multi-joint movements. Some insights into the mechanisms underlying the force-velocity characteristics of the multi-joint movements are discussed.

WHY IS THE FORCE-VELOCITY RELATIONSHIP OF MULTI-JOINT MOVEMENTS QUASI-LINEAR RATHER THAN HYPERBOLIC?

Bobbert, M.F., Casius, L.J.R., van Soest, A.J.

MOVE Research Institute Amsterdam

In 1938, Hill showed that the force-velocity relationship of muscle during isotonic contractions is hyperbolic [1]. For multi-joint movements of subjects, however, relationships have been found that are not curved. For example, the relationship between external force and velocity on a leg extension dynamometer is quasi-linear [2]. To explain this, it has been proposed that force drops more as extension velocity increases because subjects have more difficulty coordinating their muscles [2]. However, using a forward dynamic musculoskeletal model with maximal muscle stimulation as only independent input, we also found a quasi-linear relationship between leg extension velocity and external force, even though the relationship between leg extension velocity and muscle force was hyperbolic [3]. The dis-

crepancy was explained by segmental dynamics cancelling more and more of muscle force as the leg extension velocity increased. Hence, there is no need to appeal to neural mechanisms to explain why in linear leg extension tasks the force-velocity relationship is quasi-linear rather than hyperbolic. In sprint cycling, the relationship between peak tangential pedal force and crank angular velocity is quasi-linear as well [4]. Is this also explained by segmental dynamics? We investigated this using a forward dynamic musculoskeletal model of the human leg [5]. Muscle stimulation over time was optimized to maximize average power output at different isokinetic crank angular velocities. Just as in subjects, the relationship between peak tangential pedal force and crank velocity was found to be quasi-linear. As it turned out, this was not due to segmental dynamics but rather to excitation dynamics: as the crank angular velocity was increased, muscle forces not only decreased because of the intrinsic force-velocity relationship, but also because muscle active state during the power stroke dropped. At 60 rpm, active state of the vasti was nearly maximal when peak tangential pedal force occurred, but at 140 rpm it was below 60% of maximal. The latter was due to deactivation of the vasti, which in turn was necessary to prevent them from having a high force when lengthening started and hence prevent them from dissipating power during the upstroke. In conclusion, in sprint cycling the relationship between peak tangential pedal force and crank angular velocity is quasi-linear as an indirect consequence of the purpose to maximize average power output. FORCE-VELOCITY PROPERTIES CONTRIBUTION DURING BALLISTIC MOVEMENTS

Samozino, P., Morin, J.B.

Universities of Savoie and Lyon-Saint-Etienne

The overall dynamic mechanical capabilities of the lower limb neuromuscular system have been well described by inverse linear force-velocity (FV) and maximal power output (Pmax) during various types of multi-joint movements (Yamauchi et al 2007, Bobbert et al 2012). Ballistic performances (e.g. jump, running sprint) have been shown to directly depend on Pmax (e.g. Yamauchi et al. 2007). However, two athletes with similar Pmax could present different FV mechanical profiles (i.e. slope of the F-v relationship), which represent different combinations of maximal theoretical force (F0) and velocity (V0). The issue is therefore to determine whether the FV profile may influence ballistic performances independently of Pmax. A recently validated biomechanical macroscopic model of jumping showed that ballistic performance is also influenced by the FV profile, independently from Pmax (Samozino et al 2012). The relationship between performance and FV profile is curvilinear with an apex corresponding to an optimal FV profile maximizing performance. For each individual, the optimal FV profile can then be accurately determined and represents the best balance between its force and velocity capabilities. For a given Pmax, an unfavourable balance between force and velocity qualities can lead to an ~30% lower performance. This theoretical influence of the FV profile has then been supported by experimental data during jumping (Samozino et al 2013). From two different protocols using squat or countermovement jumps on ~100 high level sportsmen, multiple regression analyses ($r^2=0.931$ and 0.952 , $P<0.001$, $SEE=0.015$ and 0.011 m) showed significant contributions of Pmax and FV imbalance (FVimb, difference between actual and optimal FVprofile) to explain interindividual differences in jumping performance. For a given Pmax, the greater FVimb, the lower the jumping performance. Thus, considering both Pmax and the individual FV profile compared to the optimal one might be of great interest for exploring ballistic performances and optimizing athletic training. Moreover, a simple validated method was proposed to allow scientists and sports practitioners to easily and accurately determine in field conditions the individual Pmax, FV profile and FVimb of athletes using loaded jump heights (Samozino et al 2008). Furthermore, these influences of Pmax and FV profile on sprint running performance are also currently tested using a recently validated simple field method (Samozino et al 2013). OP-PM10 Exercise Metabolism

MUSCLE METABOLIC RESPONSES AND FATIGUE MECHANISMS DURING MODERATE-, HEAVY- AND SEVERE-INTENSITY CYCLING EXERCISE

Black, M.

University of Exeter

Introduction The sub-maximal exercise intensity continuum comprises three domains – moderate, heavy and severe. The upper limit of the moderate domain is indicated by the lactate threshold (LT) and the boundary between the heavy and severe domains is given by the critical power (CP). The neuromuscular and the muscle metabolic responses that characterise these domains have largely been investigated during small muscle mass exercise, and have not been measured in synchrony. The purpose of this study was to characterise the neuromuscular and muscle metabolic responses during cycling exercise in all three sub-maximal exercise intensity domains. We tested the hypothesis that the muscle metabolic perturbation and fatigue mechanisms would differ between moderate, heavy and severe exercise intensity domain. **Methods** Following ethical approval, 10 recreationally active males completed a minimum of four constant-work rate (CWR) severe intensity trials, a heavy intensity CWR trial, and a moderate intensity CWR trial in a randomised design. All trials were performed until task failure or a maximum of 6 h. Venous blood samples were obtained before and during the exercise. Femoral nerve electrical stimulation was used to quantify peripheral evoked responses (M-wave amplitude) in m. vastus lateralis during exercise. Pre- and post-exercise muscle tissue samples (m. vastus lateralis) were collected from 7 subjects. **Results** Similar muscle metabolic milieu (i.e., [PCr], [ATP], [lactate] and pH) was attained at exhaustion in all severe intensity trials. Muscle metabolic perturbation was greater (i.e., lower pH and [ATP], and higher [lactate]) at exhaustion following severe compared to heavy intensity exercise (all $P<0.05$), and also following severe and heavy compared to moderate intensity exercise (all $P<0.05$). Muscle [lactate] and pH were not different from rest following moderate intensity exercise. Normalised M-wave amplitude was correlated with the changes from baseline to end-exercise in muscle [ATP] ($r=-0.41$), [lactate] ($r=0.54$), and pH ($r=-0.52$), and plasma [K⁺] ($r=-0.34$) and blood [lactate] ($r=-0.34$) across all exercise

intensities (all $P < 0.05$). Discussion These findings provide novel insight into the in-vivo relationship between metabolic perturbation, neuromuscular function and exercise performance. The results support the notion that the LT and CP separate exercise intensity domains within which exercise tolerance is limited by discrete fatigue mechanisms.

ROS PRODUCTION BY NADPH OXIDASE PLAYS AN IMPORTANT ROLE IN GENE EXPRESSION INDUCED BY EXERCISE IN SKELETAL MUSCLE CELLS.

Henríquez Olgún, C., Díaz-Vegas, A., Valladares, D., Jaimovich, E.

Universidad de Chile

Reactive oxygen species (ROS) have long been implicated in cellular pathology, but more recently have emerged as important physiologic signaling agents especially in skeletal muscle. During exercise, ROS are produced by several subcellular sources, however, it has been reported that skeletal NADPH oxidase complex is a major contributor to ROS production during contractile activity. The aim of this study was to explore NOX2-dependent intracellular signaling during electrical stimulation (ES) and endurance exercise in skeletal muscle of mouse. Myoblast and flexor digitorum brevis (FDB) muscle fibers were isolated from Balb/c mice. ROS production during ES was evaluated by CM-DCF probe and for fluorescent hyper protein. NF- κ B gene activity was measured using luciferase reporter and immunofluorescence. In addition, 6-week-old mice were treated with daily intraperitoneal injections of apocynin 3 mg/kg for 3 days. Exercise-induced gene expression was determined in mice after two hours of swimming exercise. Gene expression was studied by RT-qPCR. ES induced ROS production in myotubes and FDB muscle fibers and was significantly blocked by NOX2 inhibitors apocynin and gp91ds-tat. In myotubes, NF- κ B activation was partially blocked by apocynin, moreover, IL-6 gene expression after ES was dependent of NOX2 activation. Finally, mice treated with apocynin shown a significant reduction in gene expression related with exercise adaptation such as Catalase, IL-6 and Citrate Synthase. In conclusion, NADPH oxidase may play a relevant role in ROS production and gene expression induced by acute exercise.

HEMOGLOBIN MASS, BLOOD VOLUME AND VO₂MAX IN PREPUBERTAL CROSS-COUNTRY SKIERS

Aaeng, A., Landgraff, H.W., Hallén, J.

Norwegian School of Sport Sciences

Introduction In adults, a high aerobic power (VO₂max) is associated with a high hemoglobin mass (Hbmass) (Eastwood et al. 2011) and males has higher values than females for both variables. This study aims to identify if gender differences in Hbmass, blood volume (BV), and VO₂max also exist in a group of prepubertal Norwegian cross-country skiers and if Hbmass and VO₂max are associated. Methods Subjects were 72 Norwegian children (boys n= 46, age 11.9 \pm 0.3 and girls n=26, age 11.8 \pm 0.2) recruited from cross-country ski clubs. Hbmass and BV were measured by the optimized CO-rebreathing method. Venous blood was sampled from an antecubital vein. VO₂max was determined by incremental treadmill running to exhaustion. Height, body mass and percentage of body fat (bioimpedance) were measured. Results Heights were 151 \pm 7 and 154 \pm 7 cm, weights were 39.2 \pm 4.9 and 41.0 \pm 6.0 kg and body fat were 12% \pm 6% and 13% \pm 4% for boys and girls, respectively, with no significant differences between genders. Hemoglobin concentrations were 132 \pm 69 and 132 \pm 57 g/l, Hbmass were 406 \pm 57 and 400 \pm 56 g and BV were 3370 \pm 490 and 3340 \pm 490 ml in boys and girls, with no differences between genders. Relative to body mass, both Hbmass (10.3 \pm 0.8 vs. 9.8 \pm 0.8 g/kg, $p = 0.02$) and BV (86 \pm 2.7 vs. 82 \pm 6.1 ml/kg, $p = 0.01$) were higher in boys than girls. Also VO₂max was higher (65 \pm 6.3 vs. 59 \pm 5.1 ml/kg/min, $p < 0.001$) and time to exhaustion was longer (6.13 \pm 1.15 vs. 5.31 \pm 0.94 min, $p = 0.003$) in boys. There was a significant correlation between absolute VO₂max (L/min) and Hbmass (g) ($r = 0.70$) (boys and girls combined) and the correlations were similar for both genders. The correlation for relative values between VO₂max (ml/kg/min) and Hbmass (g/kg) was weaker ($r = 0.52$). Discussion In prepubertal cross-country skiers (11,9 years), height, weight and body fat were similar in boys and girls. However, Hbmass, BV and VO₂max relative to body mass were 5%, 5% and 10% higher in boys, respectively. There were significant correlations between Hbmass and VO₂max both for absolute and relative values, but these correlations were lower than correlations normally found in adults. This is probably, at least partly, due to larger coefficient of variation for these measurements in children compared to for adults. Hence, it is likely that VO₂max are influenced by Hbmass also in prepubertal children. References Eastwood, A., Bourdon P. C., Norton, K.I., Lewis, N. MONITORING TRAINING STATUS IN CYCLISTS USING MAXIMAL RATE OF HEART RATE INCREASE

Bellenger, C., Thomson, R., Howe, P., Karavirta, L., Buckley, J.

University of South Australia

Introduction: Changes in maximal rate of HR increase (rHRI) have recently been found to correlate with fatigue-induced changes in exercise performance (1). The purpose of this study was to evaluate whether within-individual changes in rHRI can track changes in exercise performance resulting not just from fatigue, but across a range of training states. Methods: rHRI was assessed during 5 mins of cycling at 100 W and 5 mins of running at 8 km/h in male cyclists/tri-athletes following 2 weeks of light-training (LT), 2 weeks of heavy-training (HT) and a 2 day recovery period (RP). rHRI was the first derivative maximum of a sigmoidal curve fit to the HR data recorded. Exercise performance and peak oxygen consumption (VO₂peak) were measured during a 5 min cycling time-trial. Results: 13 participants completed the study. Exercise performance decreased by 2.5% ($P = 0.016$) following HT, and then increased by 4% ($P = 0.006$) following RP. Cycling rHRI decreased by 17% ($P = 0.01$) following HT, and remained unchanged following RP. Running rHRI remained unchanged following HT and RP. Pre-exercise HR and steady-state HR were 5 bpm ($P = 0.019$) and 10 bpm ($P = 0.003$) lower during cycling than running. Changes in exercise performance between LT and HT were correlated with changes in running rHRI ($r = 0.66$, $P = 0.03$), but not with changes in cycling rHRI. Cycling and running rHRI were not correlated with exercise performance when analysed within-subjects, however the strength of the within-subject relationship between running rHRI and exercise performance was inversely associated with VO₂peak measured after LT ($r = -0.58$, $P = 0.05$), such that rHRI tended to track changes in exercise performance more strongly within individuals who had a lower VO₂peak. Discussion: Running rHRI, but not cycling rHRI, was able to track fatigue-induced changes in exercise performance following HT. This may be due to running rHRI being assessed at a higher exercise intensity than cycling rHRI, which is supported by the finding of a stronger within-subject relationship between rHRI and exercise performance in individuals with a lower VO₂peak, as rHRI assessment in these individuals would represent a higher relative exercise intensity. ECCENTRIC STRAIN DETERMINES EXERCISE INDUCED MUSCLE DAMAGE

Hicks, K.M., Onambele Pearson, G.L., Winwood, K., Morse, C.I.

Manchester Metropolitan University Cheshire

Introduction Fascicle strain, eccentric torque, muscle and tendon properties, have all been suggested to be determinants of exercise-induced muscle damage (EIMD) yet these remain to be assessed in vivo (Butterfield, 2010). Therefore, the aim of the present study was to establish the in vivo muscle and tendon determinants of EIMD. **Method** Vastus Lateralis (VL) structural properties (anatomical cross-sectional area (ACSA), architecture), and Patella Tendon (PT) properties (CSA, length) were recorded using B-mode ultrasonography in 16 recreationally active males (22±2 years). PT displacement during Isometric knee extensions was used to determine PT stiffness, and Young's modulus. Six sets of 12 isokinetic maximal eccentric knee extension contractions (knee angle 20-90deg, 30deg/s) were performed. During the first 3 reps, VL fascicle length (strain) was recorded using ultrasonography. During the eccentric phase, torque and strain were recorded at every 10deg knee angle. Markers of EIMD (creatine kinase (CK) [from 6mL venous blood sample] and isometric MVC torque [to calculate torque loss]) were taken pre, 0, 48, 96 and 168 hours post EIMD. Pearson's correlations were used to establish any associations between markers of EIMD and muscle-tendon properties. **Results** Tendon stiffness, normalised for tendon force, did not correlate with change in CK ($r=0.131$, $p=0.314$) or isometric torque loss ($r=-0.221$, $p=0.205$). There was a significant correlation between change in CK and strain ($r=0.534$, $p=0.017$). Eccentric torque, made relative to VL ACSA (stress), did not correlate with markers of EIMD. **Discussion** The current study can report that the tendon does not directly attenuate markers of EIMD. However, tendon may reduce markers of EIMD indirectly through attenuating strain (Hicks, Onambele-Pearson, Winwood, & Morse, 2013). Our data showed change in CK to be associated with VL muscle strain in vivo, thus supporting the in vitro findings of Lieber and Friden (1993). Despite eccentric contractions generating high torques, when made relative to muscle size, tendon stress was not associated MVC torque loss. In conclusion, in vivo, strain is a determinant of EIMD, whereas eccentric stress and the viscoelastic tendon properties are not. **References** Butterfield, T A. (2010). MAINTAINED CEREBRAL OXYGENATION IN ELITE KENYAN RUNNERS DURING A 5KM TIME-TRIAL

Santos Concejero, J., Billaut, F., Grobler, L., Oliván, J., Noakes, T.D., Tucker, R.

UCT/MRC Research Unit for Exercise Science and Sports Medicine

Introduction: It has been hypothesised that the ability to avoid a decline in cerebral oxygenation (Cox) during maximal endurance exercise is a critical determinant of performance, and may distinguish between elite and near-elite performers (1). To date, no study has ever tested this hypothesis in elite Kenyan runners, whose success in endurance running remains unelucidated. Therefore, the aim of this study was to investigate Cox responses during maximal self-selected and imposed pace running trials in elite Kenyan runners. **Methods:** Nine elite Kalenjin Kenyan runners (24.6 ± 3.2 years and 28.9 ± 0.4 min 10-km race time) performed a maximal incremental peak treadmill speed test (PTS) and a 5km time-trial (TT) on a treadmill. Changes in Cox were monitored via near-infrared spectroscopy every minute during the PTS test and every 0.5 km during the 5kmTT through concentration changes in oxy- and deoxyhaemoglobin ($\Delta[O_2Hb]$ and $\Delta[Hb]$). Tissue oxygenation index ($TOI = \Delta[O_2Hb] / (\Delta[O_2Hb] + \Delta[Hb])$) was calculated and the normalised tissue haemoglobin index was used as an index of change in regional blood volume. **Results:** During the 5kmTT, $\Delta[O_2Hb]$ rose over the first 2.5 km, and then remained constant until completion. TOI declined during the first 1.5 km, before remaining stable for the remainder of the 5kmTT. In contrast, during the PTS test there was a significant progressive decline in both $\Delta[O_2Hb]$ and TOI during the last half of the test ($p=0.001$). Despite the significant decline during the PTS test, TOI was maintained at lower levels during the 5kmTT than at exhaustion in the PTS test ($61.6 \pm 7.3\%$ vs. $69.2 \pm 4.1\%$, $p<0.05$; $ES=1.28$). **Discussion:** Elite Kenyan runners are able to maintain Cox during self-paced 5kmTT, which is in contrast with previous studies investigating well-trained runners (2). Interestingly, elite Kenyan runners also appear to tolerate lower TOI values during a self-paced 5kmTT than during imposed maximal incremental exercise, suggesting a limitation to exercise other than cerebral oxygenation per se. The ability to maintain cerebral oxygenation within a stable range during self-paced strenuous exercise may partially explain the Kenyan running phenomenon. **References** 1. Nielsen HB, Seifert T. 10:20 - 11:50**Invited symposia****IS-SH02 Sport organizations in Europe – opportunities and challenges****VOLUNTEERING IN SPORT CLUBS**

Nagel, S., Schlesinger, T.

University of Bern

Volunteers are the most important resource for non-profit sport clubs seeking to bolster their viability (e.g. sporting programs). Although many people do voluntary work in sport clubs, stable voluntary engagement can no longer be granted. This difficulty is confirmed by existing research across various European countries. From a club management point of view, a detailed understanding of how to attract volunteers and retain them in the long term is becoming a high priority. The purpose of this study is (1) to analyse the influence of individual characteristics and corresponding organisational conditions on volunteering in sports clubs as well as (2) to examine the decision-making processes in relation to implement effective strategies for recruiting volunteers. For the first perspective a multi-level framework for the investigation of the factors of voluntary engagement in sports clubs is developed. The individual and context factors are estimated in different multi-level models based on a sample of $n = 1,434$ sport club members from 36 sport clubs in Switzerland. Results indicate

that volunteering is not just an outcome of individual characteristics such as lower workloads, higher income, children belonging to the sport club, longer club memberships, or a strong commitment to the club. It is also influenced by club-specific structural conditions; volunteering is more probable in rural sports clubs whereas growth-oriented goals in clubs have a destabilising effect. Concerning decision-making processes an in-depth analysis of recruitment practices for volunteers was conducted in nine selected sport clubs (case study design) based on the garbage can model. Results show that the decision-making processes are generally characterised by a reactive approach in which dominant actors try to handle personnel problems of recruitment in the administration and sport domains through routine formal committee work and informal networks. In addition, it proved possible to develop a typology that deliver an overview of different decision-making practices in terms of the specific interplay of the relevant components of process control (top-down vs. bottom-up) and problem processing (situational vs. systematic). Based on the findings some recommendations for volunteer management in sport clubs are worked out.

SPORTS CLUBS IN EUROPE - SIMILARITIES, PECULIARITIES AND PROBLEMS OF MEASUREMENT

Breuer, C.

German Sport University Cologne

Sports clubs in Europe share same structural features. At the same time country-specific peculiarities can be identified. In order to strengthen an European understanding of sports' clubs role in society and sports systems, functioning as well as determinants of viability there is a need for more systematic intercultural and panel research. However, there are serious challenges in terms of comparability and reliability.

ORGANISING FOR "NEW" DEMANDS: THE ORGANISATION OF SPONTANEOUS SPORTS

Fahlén, J.

Umeå University

Introduction Commonly voiced critique against organised club sport concerns the shutting out of underprivileged groups and the sorting out of less talented participants. In response, governments and sport organisations launch interventions to develop sport to meet new preferences and demands. In Sweden, the Swedish Sports Confederation has launched "Drive-in-sport" in an effort to engage with some of the assumed mechanisms behind skewed social recruitment and early drop-outs. In the study this paper reports on, one Drive-in-sport project was investigated with an ambition to provide an answer to the over-arching question: What happens when spontaneous sport activities are organised, and why? Methods The project under study was launched within the latest government sport policy programme in Sweden with the aim of recruiting non-members from underrepresented groups. In the project, local sports clubs organise spontaneous sport activities where children and youth previously not involved in club sports can take part under the device "come as you are, do what you please, at no cost". Aiming at an understanding of the organisation of spontaneous sport and its implications for clubs and participants, the results of this case study is based on an analysis of project documentation, qualitative interviews with activity leaders, structured observations of the activities and questionnaires to participants in one Drive-in-sport project. Results Results show how organisation, marketing, financing, leader's competence, facilities, participants' wishes, and the nature of the activities combine into activities very similar to club sport activities. More specifically, they show how already club affiliated participants and activity leaders doubling as coaches in regular club sport activities define the content and nature of the activities, making participation difficult and unattractive for beginners and less experienced participants. They also show how the organising principles in club sport are emulated in project activities in terms of rewarding continuity in attendance, which lend more ambitious participants the interpretative prerogative over what Drive-in-sport should be. Discussion These results can be understood by drawing on the theoretical concepts of embedded expectations and embodied knowledge. Since few beginners can match their embodied knowledge with the expectations embedded in the activities defined by club affiliated participants and leaders, the intended group of participants shrinks. The increasing majority of participants with embodied club sport experiences, on the other hand, become increasingly likely to enjoy the activities which they are given mandate to define, which in turn increases the likelihood of their continued participation. These two processes together work in homogenising the participant group and by that narrowing the scope of the activities further.

IS-SH04 Tactical performance analyses in soccer: what approach matches?

TACTICAL PERFORMANCE ANALYSIS IN SOCCER BY MEASURING INTER-TEAM COORDINATION

Lemmink, K.A.P.M., Frencken, W.G.P.

University Medical Center Groningen, University of Groningen

Tactical match performance addresses the quality of actions of individual players or teams in space and time during match-play in order to be successful. In recent years, several approaches have been used to analyze tactical behaviour of players. Technological innovations have led to new possibilities to capture accurate spatio-temporal information of all players and unravel the dynamics and complexity of a soccer match. This lecture will focus on interactive behaviour of soccer teams or clusters of soccer players, f.e. midfielders, in full-sized matches (11 vs 11). It appears that small-sided games and full-sized matches adhere to and exhibit traits of dynamical systems. Based on positional match data interactive behaviour of teams or clusters of 'active' players will be evaluated by calculating geometrical configurations, like centroids, surface areas, stretch indices and length per width ratios of both teams and relate them to each other. Variability in these inter-team measures obtained for different time windows will be mapped to match events using qualitative video analysis. Besides, critical events during the soccer match, like goal-scoring opportunities and goals, will be analyzed from this perspective. TACTICAL PERFORMANCE ANALYSIS IN SOCCER BY MEASURING INTER-PLAYER COORDINATION

Sampaio, J., Folgado, H., Gonçalves, B., Therón, R.

University of Trás-os-Montes and Alto Douro (1,3), University of Évora (2), Research Center for Sport Sciences, Health and Human Development (1,2,3), University of Salamanca (4)

We will describe how soccer players' dynamic positional match data can be used to assess tactical performance by measuring inter-player synchronization and coordination. The data will be used to calculate overall, sectorial and position-specific centroids and, afterwards, the players' and dyads distances, angles and coupling to these collective attractors will be presented in covariation with several situational variables. Data analysis will be processed with non-linear statistical procedures, such as approximate entropy, to identify the amount of randomness in each time series; and relative phase, to identify different modes of coordination (in-phase, anti-phase and transitions) during the matches dynamics'. The results will be complemented with visual analysis tools to improve the understanding of emergent self-organization behaviours and the dynamic functional constraints at the scale of the environment.

TACTICAL PATTERN RECOGNITION IN SOCCER BY MEANS OF A SPECIAL NEURONAL NETWORK APPROACH

Memmert, D.

German Sport University Cologne

State of the art of research as well as public interest are calling for a detailed and objective scientific analysis of soccer matches. The main aim of this research is the quick and valid identification of tactical performance patterns in men's soccer. Here, some novel objective analysis tools come into play, e.g., neural networks (for an overview, Perl & Memmert, 2012), which can identify tactical pattern based on position data. In the last couple of years, we developed a hierarchy of several artificial neural networks that allow for a rapid identification and classification of complex tactical patterns in soccer (Memmert & Perl, 2009a,b). This project was funded over four years by the German Research Foundation (DFG). Based on the position data of 22 players and the ball, we can find the characteristic movement and interaction patterns of each team and characteristic interaction patterns between both teams (Grunz et al., 2012). Characteristic means that several slightly distinct realizations of movements on the soccer field are summarized in only one movement pattern. If a team attacks always in a similar fashion, the algorithm will reduce these attacks to a pattern. For example, if a team attacks always on the left side, we obtain movement patterns describing the movements on the left wing. That means, the frequency of attacks on the wings / via the center, or the number of attacks that were conducted by means of short / long passes (always including the respective probabilities of success). Such statistics could lead to more elaborate findings than the average information that are usually discussed (e.g., percentage of ball possession) but still collected manually. Our complex characteristic patterns can be calculated automatically in a very short time (less than three seconds). In an additional step this pattern can be visualized on a drawn soccer field and be presented to coaches (Perl, et al., 2013). References Grunz, A., Memmert, D. & Perl, J. (2012). OP-PM11 Ageing and Exercise Training

THE COMBINATION OF PROGRESSIVE RESISTANCE TRAINING AND DIETARY CHANGES IMPROVES ANTI-INFLAMMATORY STATUS AND MUSCLE MASS IN HEALTHY, PHYSICALLY ACTIVE ELDERLY WOMEN

Strandberg, E.1, Hosford Donovan, A.1, Ponsot, E.1, Wählin Larsson, B.1, Risérus, U.2, Kadi, F.1

Örebro University

1: Örebro University (Örebro, Sweden) 2: Uppsala University (Uppsala, Sweden) Introduction It is common knowledge that resistance training can be used as a non-pharmacological approach to counteract sarcopenia. An age-related increase in systemic inflammation has been suggested to contribute to sarcopenia and systemic inflammation has been shown to blunt post-prandial muscle protein synthesis in aged rats (Balage M et al., 2010). Resistance training and dietary interventions can influence systemic inflammation. Studies reporting significant decreases in systemic inflammatory markers commonly included inactive elderly with elevated systemic inflammation level whereas such investigations are rarely performed in healthy and physically active elderly women. Moreover, only few studies include in their design an approach combining exercise- and dietary-based interventions. The present study aims to determine the effects of six-month progressive resistance training with or without diet with anti-inflammatory properties on systemic inflammatory levels and muscle fiber characteristics in healthy, physically active elderly women. Methods 63 healthy elderly women (65-70yrs) were randomized into a control group (CON), a resistance training group (RT) and a resistance training group eating a diet with anti-inflammatory properties and based on Nordic nutritional recommendations (RT-D). A 24-week resistance training program for lower- and upper body was performed. Muscle biopsy samples were obtained from the mid-portion of m. vastus lateralis. Blood samples were collected to assess levels of CRP, IL-6, TNF- α , docosahexaenoic acid and arachidonic acid before and after the intervention. Results Muscle mass

increased only in RT-D. Interestingly, a significant decrease in the pro-inflammatory precursor arachidonic acid ($-5.4\pm 9.4\%$) occurred only in RT-D. Moreover an increase in the ratio docosahexaenoic acid($\omega 3$)/arachidonic acid($\omega 6$) occurred only in RT-D ($+16.1\pm 21.1\%$). No changes in CRP, IL-6 and TNF- α were observed in any of the groups. Moreover, preliminary results indicate no changes in the distribution of type I and type II fibers in any of the groups. Analysis of muscle fiber cross-sectional area is undergoing. This would allow us to determine if RT-D has a fiber type specific effect. Discussion This is the first study to show that in healthy and physically active elderly women combined resistance training and anti-inflammatory diet but not resistance training alone can further improve skeletal muscle mass and systemic inflammatory status. EFFECT OF AEROBIC AND STRENGTH TRAINING COMPARED TO AEROBIC TRAINING ALONE ON AEROBIC CAPACITY IN ELDERLY: A 12-WEEK RANDOMIZED CONTROLLED TRIAL

Teljigovic, S.1,2, Burich, R.1,2, Boyle, E.1, Sjøgaard, G.1

1: SDU (Odense, Denmark), 2: Fysium ApS (Næstved, Denmark)

Introduction Adaptations to aerobic training and strength training are different and may counteract each other when performed concurrently. Several studies have examined the effect of combining these training modalities, but results remain ambiguous. Discrepancies may be caused by differences in initial physical fitness levels, frequency and volume of exercise, methods of measuring aerobic capacity and strength, and sequencing of aerobic and strength training (Wilson et al., 2012). It was recently found that strength training performed immediately after aerobic training doubled the increases in early markers of mitochondrial biogenesis and substrate regulation compared to aerobic training alone (Wang et al., 2011). Thus, the aim was to investigate if combined training can enhance aerobic capacity in elderly to a similar extent as aerobic training alone, when the training program is matched for time and strength training is performed in extension of aerobic training. **Methods** Elderly subjects (age 63.2 ± 4.7 years, weight 74.8 ± 16.5 kg) were randomized to two intervention groups; an aerobic group (AG, $n=17$) and a combined group (CG, $n=16$). Subjects trained 40 min three times a week for 12 weeks. Both groups trained 20 min at 65% of heart rate reserve on ergometer cycles followed by another 20 min on the ergometer cycles for AG and 20 min strength training of the lower body for CG. **Results** At baseline $\dot{V}O_{2\max}$ was 1.9 ± 0.6 l/min and MVC was 283 ± 83 N with no difference between groups, and these values increased significantly in both groups ($p < 0.01$). $\dot{V}O_{2\max}$ increased 17% in CG and 26% in AG, respectively, with no significant difference between groups. MVC increased 22% in CG and 9% in AG, respectively, and CG improved significantly more than AG. **Discussion** The main finding was that $\dot{V}O_{2\max}$ increased in both groups with no significant difference between the groups in spite of replacing half of the aerobic training by strength training in CG. This finding shows that elderly can use combined training to improve both cardiovascular function and strength without increasing training duration. It also supports results of several other studies conducted in the elderly population, where strength training has not been found to negatively interfere with improvements in aerobic capacity (Wood et al., 2001). CAPILLARY MUSCLE SUPPLY IS MORE AFFECTED BY IMMOBILIZATION IN ELDERLY COMPARED TO YOUNG

Wiuff, C., Vigelsoe, A., Gram, M., Dela, F., Helge, J.W.

University of Copenhagen

With ageing a decline in capillary muscle supply and an impaired angiogenic response to physiological stress and injury has been observed. This may leave elderly individuals at a higher risk for adverse physiological consequences during periods of inactivity. The aim of the present study was to evaluate the effect of short-term inactivity and subsequent aerobic retraining on the capillary muscle supply in young (Y) and elderly (E) healthy, active men. It was hypothesized that E would be more susceptible to the negative effects of immobilization (IM) and have a reduced recovery compared to Y. **Methods** 17 Y (aged 23 ± 1 yrs. (mean \pm SEM); 48 ± 1 ml $\dot{V}O_2$ /min/kg) and 15 E (aged 68 ± 1 yrs.; 33 ± 1 ml $\dot{V}O_2$ /min/kg) male subjects were recruited to two weeks of IM of one leg using a Donjoy brace. This was followed by six weeks (20 sessions of 50-60 min) of aerobic training on an ergometer bicycle at 84-89% of HRmax. Daily physical activity level was monitored with a three-axial accelerometer before, during and after the IM period. Anthropometric characteristics were measured by a DXA. Muscle biopsy samples at rest were obtained from the v. lateralis at baseline, after IM and after training. These were stained for fibre type, fibre area and capillaries by myofibrillar ATPase histochemical and immunohistochemical (using UEA-I and collagen IV antibodies) techniques. **Results** During IM the physical activity level decreased ($P < 0.001$) similarly in both Y and E, after which it returned to baseline during the training period. Neither group demonstrated a decline in mean fibre cross-sectional area (FCSA) of the test leg after IM, while training led to an increased FCSA of type I (18%) in Y, and of type IIa (48%) and IIx (53%) in E. E experienced a decline ($P < 0.05$) in the capillary to fibre ratio (C:F, 19%) and in capillaries around fibre (CAF) of type IIa (31%) after IM. A tendency ($P = 0.08$) to increase was observed in C:F and CAF type IIa after retraining in E. IM did not affect Y on any of the capillary supply parameters, but retraining increased CAF of type I (14%). Capillary density was unchanged in Y, while E experienced a decrease after six weeks of training. **Discussion** A marked decrease in capillary muscle supply, after IM, was observed in E. As fibre size was unaffected, the metabolic consequence is an increased diffusion distance and a decreased surface area for $\dot{V}O_2$ exchange, which together increase transport time of $\dot{V}O_2$ to the mitochondria. E did not fully regain the loss of capillaries after retraining, however a tendency to an increase was apparent. In contrast, Y experienced capillary proliferation after retraining. Thus, in line with the hypothesis, E demonstrated an overall reduced capability to recover from short-term inactivity in regards to the capillary supply.

THE EFFECTS OF 2 WEEKS ARM IMMOBILISATION ON MUSCLE FUNCTION MODULATORS

Bostock, E.

Manchester Metropolitan University

Introduction Prolonged reduction in muscle activity and mechanical loading, as seen with limb immobilisation, results in skeletal muscle structural and functional maladaptation including atrophy and asthenia (see review by Bostock et al., 2013). Previous research suggests that immobilisation results in a greater decrease in muscle strength than muscle size which may be a result of neuromuscular adaptations (Miles et al., 1994). The aim of this study was, thus, to investigate the principal physiological contributors to asthenia induced through upper limb immobilisation. **Methods** The non-dominant arm of 6 healthy, habitually active females (aged 29 ± 6 years) was immobilised

in a sling for nine waking hours a day for two continuous weeks. Measures of tissue thickness (B-mode ultrasonography), arm girth (anthropometry), body composition (DEXA), isometric (60-110° elbow angle) and isokinetic (30-240°/s) torque (dynamometry), vascular kinetics (Doppler ultrasonography), fatigue index (slope of electromyography trace) and Creatine Kinase Activity (Colorimetry at 340nm) were taken before immobilisation (PRE), on removal of the sling (POST), and two weeks after re-mobilisation (POST2). Results No differences existed between the immobilised and non-immobilised limbs at baseline for any measures ($P>0.05$). PRE to POST changes in the immobilised limb in arm girth (upper = -1.2%, lower = -1.0%), muscle thickness (biceps = -3.5 to -6.5%, triceps = -7.1 to -10.2%), lean mass (-4.7%), sub-cutaneous adipose thickness (7.7 to 12.7%) and bone mineral content (-2.7%) were significantly different from those in the non-immobilised limb ($p<0.05$). These changes reverted to PRE values at POST2 (except for adipose thickness and bone mineral content). Torque significantly decreased with immobilisation (-5.2 to -17.5% changes, $p<0.05$), with only one torque test not reverting to PRE values at POST2. There was a trend towards an increase in Creatine Kinase activity at POST ($P>0.05$). Immobilisation did not affect muscle fatigability or vascular kinetics. Discussion Our data demonstrate that a relatively modest degree of limb immobilisation is sufficient to impact on muscle, adipose, and bone parameters. Whilst our results support the previously observed dissociation between degree of atrophy and asthenia (Miles et al., 1994), the physiological modulator of this effect remains unclear. Indeed, neither blood flow, vascular dimensions nor compliance, nor muscle fatigability, changed in this cohort. We propose that endocrine profile changes may be key to the early response to immobilisation. References Bostock EL, Morse CI, Winwood K, McEwan I, Onambélé-Pearson GL. A NIRS STUDY ASSESSING CHANGES IN PREFRONTAL CORTEX ACTIVATION DURING WALKING IN ELDERLY FOLLOWING TRAINING

Eggenberger, P.1, Schumann, M.1, Wolf, M.2, de Bruin, E.D.1

1: *Institute of Human Movement Sciences and Sport, Department of Health Sciences and Technology, ETH Zurich,*

Introduction Prefrontal cortex (PFC) activation has been associated with the acceleration phase of walking in younger adults (Suzuki et al., 2004). Reuter-Lorenz and Cappell (2008) demonstrated PFC over-activation in elderly in attention demanding tasks. This study aimed to investigate training effects on PFC activation in older adults during challenging walking. We hypothesized that levels of oxygenated hemoglobin (HbO2) in the PFC were reduced after eight weeks of training. Methods 39 elderly (74.9±6.9 years) were randomly assigned to combined physical and cognitive training (video-game dancing, DAN), or an active control group training balance (BAL). Both groups performed three 30-minutes training sessions per week for eight weeks. Activation of the left and right PFC was assessed during normal and fast treadmill walking with near-infrared spectroscopy (NIRS) of HbO2. This test was performed pre- and post-training. Pre-post test differences and interactions were analysed with repeated-measures ANOVA. Results 33 elderly finished the study with data resulting in 15% drop-out rate. PFC activation was significantly greater during walking, compared to rest in both groups (paired t-test: $p<0.001$). Levels of HbO2 were reduced post-intervention in both training groups in the left and right hemisphere at both walking speeds during the first seven seconds of walking (left: $p=.031$, one-tailed, $r=.33$; right: $p=.052$, one-tailed, $r=.30$). Group differences in PFC activation were found at the end of the fast walking condition in the left hemisphere. Levels of HbO2 were significantly lower post training in DAN and elevated in BAL from four seconds before the end of walking until four seconds into rest (time*group $p=.035$, one-tailed, $r=.32$). Discussion This study demonstrated a reduction of PFC activation at the initiation of walking after both DAN and BAL training. Particularly DAN training reduced the duration of PFC activation at the end of the 30-second fast walking task. Similarly, Ohsugi et al. (2013) reported shorter PFC activation in younger adults when performing dual-task stepping. We conclude that combined physical-cognitive training might be a promising approach to influence PFC function in older adults during walking and, thereby, enhancing cognitive resources availability for other attention demanding tasks. NEUREGULIN1 INJECTION ALTERS BLOOD GLUCOSE RESPONSES IN AN AGE DEPENDENT MANNER IN RATS EXPOSED TO ORAL GLUCOSE CHALLENGE.

Caillaud, K.1, Boisseau, N.1, Ennequin, G.1, Chavanelle, V.1, Etienne, M.1, Denis, P.2, Sirvent, P.1

Université Blaise Pascal

Introduction The acute fixation of NRG1 on its receptors (ErbBs) induces glucose consumption in skeletal muscle cells from Glut4 translocation activation. Furthermore, chronic NRG1 exposure in muscle cells increases insulin sensitivity, potentially by inducing greater oxidative capacity and mitochondrial biogenesis. The ageing process appears to have deleterious effect on tissue sensitivity to insulin and favors glucose intolerance. Although the longevity of several mammal species are correlated to blood NRG1 concentrations, the link between ageing, NRG1/ErbBs signaling pathway and glucose metabolism have never been studied. The aim of our study was to investigate the impact of NRG1 injection on blood glucose responses after a glucose charge (OGTT) performed in 6 and 22 month-old wistar rats. We hypothesized that i) NRG1 may alter blood glucose responses following an oral glucose charge and that ii) this adaption would be age dependent. Protocol Ten old (22 months) and six adult (6 months) wistar male rats received saline or NRG1 injection 15 min before an OGTT. Glycaemia were measured 15 min before OGTT (-15), at the moment of the glucose charge (0) and then 15, 30, 60, 90 and 120 min later. Values were expressed as absolute blood glucose values and area under the curves (AUC). NRG1 signaling pathway has also been investigated in skeletal muscle and liver 30min after injection of NRG1. PKB expression and phosphorylation were assessed by Western-Blot in gastrocnemius and hepatic tissues. Results As expected, old rats showed lower glucose tolerance (group effect; $p<0.05$). NRG1 injection decreased glycaemia in both groups (time effect; $p<0.05$) whereas a tendency for a stronger effect was noticed in the younger rats (NRG1 x time effect; $p=0.08$). By separating the kinetics in two phases (-15 until 30 and 30-120 min), we observed a delayed effect of NRG1 in the older rats ($p<0.05$). During the first phase, NRG1 was showed to have an effect only in the younger rats ($p<0.05$) whereas its effects were similar in both groups during the second phase ($p<0.05$). PKB activation was increased after NRG1 injection in the liver ($p<0.05$) but not in the gastrocnemius. No age difference was observed concerning PKB activation. Conclusion Taken together, these results confirm the potential role of NRG1 in glucose homeostasis with a NRG1 delayed effect due to ageing. PKB protein activation results indicate a predominant role of hepatic tissue over skeletal muscle in the NRG1-induced glucose consumption.

LEFT VENTRICULAR STRUCTURE AND FUNCTION IN HIGHLY-TRAINED PRE-PUBERTAL SOCCER PLAYERS

Unnithan, V.1, Rowland, T.2, George, K.3, Oxborough, D.3

1Staffordshire University (UK), 2Baylor Medical Center (USA), 3Liverpool John Moores University (UK)

Introduction Equivocal evidence exists in the literature with regard to the prevalence of the athlete's heart (bradycardia, left ventricular (LV) adaptations) in highly-trained, pre-pubertal endurance athletes. With the high training loads that now exist in youth soccer, there is limited evidence with regard to the cardiac structural and functional consequences of this intensive training. The aim of this study was to evaluate LV structure and function of highly-trained, pre-pubertal soccer players. **Methods** Fifteen, highly-trained (years training: 4 ± 2 years), male soccer players (SP) from an English Premier League soccer club (age: 11.4 ± 0.2 years) volunteered for the study. Fifteen recreationally active boys (CON), of similar age (age: 11.7 ± 0.2 years) were also recruited for the study. LV volume (LVEDV and LVESV) was determined by Simpson's rule and allometrically scaled to body surface area. Tissue Doppler imaging was employed to determine peak longitudinal mitral annular septal tissue velocities. Myocardial speckle tracking was used to assess global, longitudinal, basal, mid and apical circumferential and radial myocardial strain and strain rate (CSR and RSR). Global LV diastolic function was represented by peak blood flow velocities across the mitral valve during early (E) and late (A) diastole determined using pulsed-wave Doppler interrogation of trans-mitral blood flow and global LV systolic function was derived from the ejection fraction (EF). **Results** Resting heart rate was significantly ($P < 0.05$) lower in the SP compared to the CON (SP: 64 ± 12 vs. CON: 72 ± 9 bpm). LVEDV (SP: 51.0 ± 3.9 vs. CON: 44.5 ± 5.8 (mL/m²) $\cdot 1.5$) and LVESV (SP: 18.7 ± 3.4 vs. CON: 16.1 ± 2.7 (mL/m²) $\cdot 1.5$) were also significantly ($P < 0.05$) higher in the SP compared to the CON. Peak, trans-mitral flow velocities during (E) were significantly ($P < 0.05$) higher in the SP compared to CON (SP: 1.08 ± 0.14 vs. CON: 0.96 ± 0.10 cm/s), even after adjusting for resting HR. There were no inter-group differences in EF. Speckle tracking strain analyses demonstrated a significantly ($P < 0.05$) lower mid CSR response during late diastole in the SP compared to CON (SP: 0.33 ± 0.15 vs. CON: 0.44 ± 0.13 1/s). A similar, blunted ($P < 0.05$) response, was noted for the SP for RSR during late diastole (SP: -0.55 ± 0.30 vs. CON: -0.89 ± 0.38 1/s). **Discussion** The structural data suggests that there is some evidence of cardiac-remodeling in the SP. The trans-mitral flow velocity data supports the contention that early diastolic filling is superior in the SP and this is also supported by the blunted strain rate responses during late diastole in the SP. These changes are mediated, either through training or genetic pre-disposition. Contact V.Unnithan@staffs.ac.uk

IS THE MAXIMAL SHORTENING VELOCITY OF HEART TISSUE RELATED TO HEART RATE DURING RESISTANCE EXERCISE?

Stöhr, E., Stenbridge, M., Newcombe, D., Assassie, E., Esformes, J.I.

Cardiff Metropolitan University

Introduction It is commonly believed that the maximal shortening velocity of in vivo heart tissue (=strain rate, SR) is strongly related to heart rate (HR). However, in healthy individuals, the true interdependence between HR and SR remains poorly understood. Existing data from dynamic endurance exercise is not conclusive because most physiological parameters, including blood pressure (BP), increase in this condition and a concomitant increase in SR and HR may not be causal. Thus, measuring SR and HR during resistance exercise may provide new insight. **Methods** We measured SR (GE Medical, Horten, Norway), HR (ECG) and beat-by-beat mean arterial BP (Finapres, FMS, Arnhem, Netherlands) in nine active men (Age = 20 ± 1 years; 1 repetition maximum, (1RM) = 313 ± 81 kg) immediately before, during and 7-12 seconds following double-leg press exercise at 30% and 60% of 1RM, respectively. SR was analysed (EchoPAC, GE Medical) in three principal directions of cardiac deformation: radial, circumferential and longitudinal. Linear regression was performed for SR vs. HR and SR vs. BP for the 30% and 60% conditions separately and also combined. Non-linear regression was used to determine whether exponential relationships revealed better associations. The change in HR and mean BP during 30% and 60% 1RM was evaluated using two-way repeated-measures ANOVA. **Results** HR rose significantly during leg pressing and remained elevated immediately following 30% and 60% 1RM, respectively, while mean BP increased significantly during leg pressing but returned to baseline levels thereafter. Throughout the experiment, HR ranged from 49 to 98 (bpm) and SR ranged from 0.49 to 4.22 (1/s). Linear relationships between HR vs. SR and HR vs. BP in the radial and circumferential direction were mostly poor (r^2 from .0004 to .11, all $P > 0.05$) except for radial SR vs. HR during the 30% condition ($r^2 = .24$, $p = 0.01$). The best correlation was detected between HR and longitudinal SR during the 30% condition ($r^2 = .42$, $p = 0.001$). Non-linear analysis did not increase the strength of any of the associations. **Discussion and conclusion** During resistance exercise, HR and SR were not strongly associated. This was caused by extensive variability in peak SR across different cardiac regions (HR explained between <1% and 42% of the variance of SR). Furthermore, BP also did not explain the change in SR. Therefore, we conclude that SR is not necessarily determined by HR or BP and may reflect a more intrinsic cardiac contractile state. Contact estohr@cardiffmet.ac.uk

MYOCARDIAL BLOOD FLOW AND OXYGEN UTILIZATION IN DIFFERENT WALLS OF THE HUMAN HEART AT REST AND DURING EXERCISE

Heinonen, I.1,2, Kalliokoski, K.K.1, Sipila, H.T.1, Duncker, D.J.2, Knuuti, J.1, Kudomi, N.1,3

1: University of Turku and Turku University Hospital (Turku, Finland), 2: Erasmus Medical Center Rotterdam (Rotterdam, the Netherlands), 3: Kagawa University (Kagawa, Japan)

Introduction Myocardial blood flow (MBF), oxygen extraction fraction (OE), and oxygen consumption (MVO₂) in human right ventricle has been measured in pulmonary hypertensive patients, but to the best of our knowledge never in healthy human subjects and simultaneously also compared against left ventricle and septum of the heart. **Methods** In the present study MBF, OE, and MVO₂ were measured in the septum and left and right ventricles with positron emission tomography in 15 healthy untrained young men (30 ± 5 years, 75 ± 7 kg and VO_{2max} 40 ± 5 ml/kg/min) not only at rest but also during supine bicycle exercise. **Results** Resting MBF was lower ($p < 0.03$) in the right ventricle (0.76 ± 0.24 ml/g/min) as compared to the septum (0.99 ± 0.28 ml/g/min) and the left ventricle (0.95 ± 0.34 ml/g/min). Exercise increased blood flow similarly in all regions, but MBF was maintained lower in the right ventricle (1.33 ± 0.70 ml/g/min) as compared

to the septum (1.77 ± 0.72 ml/g/min) and left ventricle (2.00 ± 0.79 ml/g/min). In contrast, resting OE was similar between the right ventricle (79 ± 12 %) and septum (82 ± 7 %), but significantly lower in the left ventricle (61 ± 10 %). OE increased in response to exercise and as MBF, similarly in all walls (85 ± 9 % in the right ventricle, 88 ± 16 % in the septum, and 73 ± 12 % in the left ventricle), being the lowest in the left ventricle also during exercise. MVO2 increased about twofold from rest to exercise, but similarly in all ventricular regions and did not differ significantly between the three walls either at rest or during exercise (0.13 ± 0.04 and 0.28 ± 0.13 ml/g/min in the right ventricle, 0.16 ± 0.04 and 0.28 ± 0.12 ml/g/min in the septum, and 0.15 ± 0.05 and 0.33 ± 0.10 ml/g/min in the left ventricle at rest and during exercise, respectively). Discussion In conclusion, as reported for the first time in the present study, there are marked differences in MBF and OE between the different walls of the resting and exercising human heart, but MVO2 per gram of myocardium appears to be similar. A COMPREHENSIVE TECHNICAL ASSESSMENT OF THE ATHLETE'S HEART: THE "MORGANROTH HYPOTHESIS" RE-VISITED.

Utomi, V., Oxborough, D., Whyte, G., Somauroo, J., Sharma, S., George, K.

Liverpool johnmoore's university

Aims: The current study evaluated; A) global left ventricular (LV) adaption to endurance vs. resistance training in highly trained male athletes; B) the additional insight into the athlete's heart phenotype provided by modern imaging technologies, and C) the impact of scaling for body size on LV structural data. Methods: A prospective cross-sectional design was employed to comprehensively assess the athlete's heart in 18 elite endurance-trained (ET), 19 elite resistance-trained (RT) and 17 sedentary control (CT) participants. Standard 2D, tissue-Doppler imaging (TDI) and speckle tracking echocardiography (STE) were employed to assess LV structure as well as global and regional LV function including myocardial strain. The indexing of LV structural parameters to body surface area (BSA) was undertaken using simple linear ratio scaling as well as a nonlinear allometric model. Results: Absolute, ratio and allometrically scaled LV mass was significantly higher in ET (200 ± 34 g; 98 ± 15 mm/m², 42 ± 7 mm/m^{2.7}) than both RT (187 ± 31 g; 78 ± 15 mm/m² and 36 ± 6 mm/m^{2.7}) and CT (165 ± 32 g; 74 ± 11 mm/m² and 33 ± 6 mm/m^{2.7}) ($p < 0.05$). The predominant LV geometry in the ET was normal (65%) and eccentric hypertrophy (30%). There was no significant difference in LV mass between the RT and CT groups. Apart from a higher stroke volume in ET, compared to RT and CT, there were no significant group differences in global function during systole or diastole. Whilst regional TDI data were not different between groups, longitudinal, basal circumferential and mid radial strain was reduced in RT compared to ET. Conclusion: In this comprehensive, technical evaluation of the athlete's heart, a larger LV was present in ET even after appropriate body size scaling. Evidence for hypertrophy was lacking in RT. Differences in body size and discrimination of AH from disease pathology can be enhanced by appropriate scaling of data. Further work should evaluate cardiac strain and strain rate in RT athletes.

PEAK OXYGEN UPTAKE 12 MONTHS AFTER CARDIAC REHABILITATION: A RANDOMIZED CONTROLLED TRIAL OF LOW-EFFORT INTERVENTION VERSUS USUAL CARE

Moholdt, T.1,2, Arbo, I.1, Granoien, L.3, Walderhaug, L.3, Madssen, E.1,4

Norwegian University of Science and Technology (Trondheim, Norway)

1: K.G. Jebsen Center of Exercise in Medicine, Department of Circulation and Medical Imaging, Faculty of Medicine, Norwegian University of Science and Technology (Trondheim, Norway), 2: Women's Clinic, St.Olavs Hospital (Trondheim, Norway), 3: Aalesund Hospital (Aalesund, Norway), 3: Department of Pulmonary Medicine, St.Olavs Hospital (Trondheim, Norway) Background Exercise capacity is a strong predictor of survival in patients with coronary artery disease (CAD) (1, 2), but there is a lack of studies that follow patients after discharge from cardiac rehabilitation with respect to the adherence to physical exercise, and to counter deconditioning. Methods Two-centre, open, parallel randomized controlled trial with 12 months follow-up comparing usual care to a low-effort intervention program consisting of a written training program, one monthly supervised session with aerobic interval training, and a maximum exercise test every three months. Forty-nine patients (15 women) on optimal medical treatment were included after ending a 12-week rehabilitation program. The primary endpoint was change in peak oxygen uptake (VO2peak) at follow-up; secondary endpoints were physical activity level, quality of life and biomarkers. Results No change in VO2peak from baseline to follow-up was observed in neither group (intervention group 27.9 ml*kg⁻¹*min⁻¹ versus 28.8 , control group 32.0 versus 32.8 , no between-group difference). In the intervention group, VO2peak was at its highest at the third maximum exercise test and declined slightly towards end of follow-up. Quality of life and blood biomarkers remained essentially unchanged at follow-up. Self-reported and measured physical activity level was equal between groups. Discussion A low-effort intervention program did not improve exercise capacity in CAD patients 12 months after discharge from cardiac rehabilitation compared to usual care. We therefore conclude that the intervention given was not sufficient to improve VO2peak above usual care. There may be several explanations to our findings. Participants enrolled in clinical exercise studies may be highly motivated for exercise, also when allocated to a control group. Further, patients being aware of future follow-ups by cardiac rehabilitation units may act motivating for the adherence to physical activity. Also, an exercise test at baseline can act as an intervention itself to influence self-efficacy and physical activity after a cardiac event (3). References 1. Myers J et al (2002). WALKING TRAINING DECREASES AMBULATORY BLOOD PRESSURE VARIABILITY IN INTERMITTENT CLAUDICATION: A RANDOMIZED CONTROLLED TRIAL

Chehuen, M.1, Cucato, G.G.1, Costa, L.A.R.1, Ritti Dias, R.M.2, Leicht, A.S.3, Carvalho, C.R.F.1, Wolosker, N.1, Forjaz, C.1

1:USP (São Paulo, Brazil), 2:UPE (Pernambuco, Brazil), 3:JCU (Townsville, Australia).

Introduction Low walking capacity and high ambulatory blood pressure (BP) have been reported as prognostic markers of cardiovascular mortality in patients with intermittent claudication (IC). Walking training (WT) has been recommended for the treatment of IC as it improves walking capacity. Additionally, WT decreases resting BP, but its effects on ambulatory BP levels and variability are unknown with these indices reported to be better cardiovascular prognostic markers than resting BP (Mena et al. 2005). This study assessed the effect of WT on ambulatory BP levels and variability in IC patients. Methods Thirty-five IC patients were randomly assigned to two groups: Control (C, n=16) and WT (n=19). Patients performed 30-min classes of stretching (C) or WT (15 sets of 2:2-min walk:rest at the heart rate at claudication pain) (Cucato et al., 2012) twice a week. Walking capacity (claudication onset distance, COD and total walking distance, TWD), and resting and 24-h BP were assessed prior to and following the 12 week of study. Ambulatory BP was assessed as the mean of the entire 24-hour recording and the average BP during the awake and sleep periods. BP variability was assessed as standard deviation of the 24-

h recording corrected for number of hours in day and night (SDdn) and the average real variability (ARV). A 2-way ANOVA for repeated measures was used ($P < 0.05$). Results WT significantly increased COD (WT: $+87 \pm 50$ vs. C: -38 ± 10 m) and TWD (WT: $+303 \pm 71$ vs. C: -59 ± 11 m), and decreased resting systolic BP (WT: -10 ± 2 vs. C: -1 ± 3 mmHg). Ambulatory BP levels were not changed by WT (24-h mean BP, WT: -1 ± 0 vs. C: 2 ± 0 mmHg) but ambulatory BP variability indices decreased (SDdn mean BP, WT: -1.0 ± 0.1 vs C: 0.7 ± 0.0 mmHg; ARV mean BP, WT: -0.8 ± 0.2 vs. C: 0.5 ± 0.3 mmHg). Discussion As expected, WT improved walking capacity and reduced resting BP for IC patients. Importantly, WT decreased ambulatory BP variability as assessed by different indices, which indicates that WT may reduce cardiovascular risk for IC patients (Mena et al. 2005). Interestingly, WT did not change mean ambulatory BP values. This lack of change for ambulatory BP may have resulted from pain-induced increases in BP that occurred during routine daily activities. In conclusion: WT did not change ambulatory BP levels but decreased ambulatory BP variability which may represent another exercise-induced cardiovascular benefit in IC. PS-PL04 Who has the future in public health – young or old?

BEND THE TWIG AND BEND THE TREE

Chin, A., Paw, M.

EMGO Institute for Health and Care Research and VU University Medical Center

Childhood overweight and obesity is a rising global problem caused by lack of physical activity, excessive sedentary time and unhealthy diets. About 22 million children aged under 5 years are overweight. As a result type 2 diabetes in children and adolescents – previously unheard of – has increased worldwide. Above-mentioned unhealthy risk behaviors are often established in youth. If these risk behaviours were eliminated, at least 80% of all heart disease, stroke and type 2 diabetes would be prevented, and over 40% of cancer would be prevented. Governments have a crucial role in improving the health and well-being of populations. This is especially true for children, who cannot choose the environment in which they live, their diet and their family support in sports participation. Children also have a limited ability to influence their environment as child participation is rare in health promotion. What do children think of their school environment? And what do they believe influences their dietary and physical activity behaviour? This lecture will focus on the child perspective and what we can learn from it. Healthier, informed kids, will have a better chance of growing into a healthy and happy old age as well as raising a new generation of healthy, informed children. Since future generations are affected by the decisions that we make today, we need to invest in today's youth. We cannot always build the future for our youth, but we can build our youth for the future. Franklin D. Roosevelt 32nd president of US (1882 - 1945)

THE CASE FOR EXERCISE PROMOTION IN THE ELDERLY

Boreham, C.

University College Dublin

From the pioneering studies of Jerry Morris in the 1950's, a small mountain of evidence has accumulated showing the health benefits of exercise irrespective of age. However, in an era of rising healthcare costs, the question of value for money arises as to which section of society might benefit most from exercise promotion; the young or the elderly? The case for promoting exercise in children is usually based on a model of preventing later chronic disease in adulthood. This assumes two things; that childhood risk factors and behaviours track into adulthood, and that exposure to risk in childhood has to be dealt with at that time, otherwise it will do long term harm. In fact, there is little convincing evidence for either premise. Tracking of all risk factors for chronic disease from childhood to adulthood is moderate at best, and there is little evidence for childhood programming of adult mortality. Rather, many population studies have shown that taking up exercise in adulthood reduces risk to that of the already active, begging the question, why bother in childhood? The second problem with promoting childhood exercise for health is that it is relatively inefficient, compared with adulthood and older age. Children are generally active and fit, and the law of diminishing returns dictates that at the population level, a large volume of intense activity (typically in the order of one hour of vigorous activity per day) is required before changes in fitness, fatness etc. emerge. Finally, the lack of hard evidence linking childhood exercise levels with adult morbidity and mortality undermines the case. Even for bone health, where there is some evidence of an exercise carry-over from childhood to adulthood, there is no evidence that if exercise ceases, the "bone bank" will be maintained into old age when it is needed most to prevent fractures. It is unlikely that the cohort studies lasting 60 years or more needed to provide such hard end points will ever be completed, leaving us in the hands of speculation and extrapolation. Unlike the case for children, the elderly do suffer from chronic disease and frailty, they are generally responsive to even low training loads, and the benefits of exercise are demonstrably important and immediate. Indeed, the effects of carrying out simple exercise regimes (such as strength training) span multiple dimensions (physical, mental and social) and the elderly are often highly motivated to exercise and get fitter. Changing demographic and social landscapes also make the maintenance of functional capacity in the elderly a priority. Worldwide, the number of people over 60 will double by 2040, and rising social and health expenditure is forcing the elderly to work longer and stay healthy as long as possible. Indeed, next to climate change, the aging population has been described as the second biggest problem facing developed nations. Compared with these challenges, the promotion of exercise in children seems a luxury that must take second place to the elderly.

NON-INVASIVE ESTIMATION OF MUSCLE FIBER TYPE COMPOSITION IN SWIMMERS

Bex, T.I., Baguet, A.I., Derave, W.I

University Ghent

(I) Department of Movement and Sports Sciences, GHENT University (Ghent, Belgium) Aim Excellence in sports with short and long exercise duration requires a high proportion of fast (FT) and slow twitch (ST) muscle fibers, respectively. Based on the positive correlation between the carnitine concentration and the percentage area of FT fibers in skeletal muscle, proton magnetic resonance spectroscopy (1H-MRS) has been proposed as a non-invasive method to estimate muscle fiber type composition (MFTC) (Baguet et al, 2011). In athletics, there is a strong relationship between estimated MFTC and optimal running distance (Baguet et al., 2011), but it is unclear whether this also applies to swimming. The aim of this study is to explore estimated MFTC in swimmers, excelling at various distances. Methods Eleven Belgian elite swimmers and 10 control subjects were recruited to measure muscle carnitine content in soleus, gastrocnemius and deltoid muscles by 1H-MRS. They were divided in 3 groups (short, middle and long distance) based on their best swimming distance. Results The long distance swimmers had the lowest relative carnitine concentration in the leg (soleus + gastrocnemius) muscle compared with middle ($p = 0.011$) and short ($p = 0.001$) distance swimmers (0.126, 0.180 and 0.213, respectively). In the deltoid muscle, the long distance swimmers had a significant lower carnitine concentration and the middle distance swimmers had a tendency to lower carnitine concentration than the short distance group (0.071 and 0.095 vs. 0.133). The total group of swimmers had a lower relative carnitine concentration in the deltoid muscle compared to the control group ($p = 0.004$), but for the gastrocnemius muscle no significant differences were found ($p = 0.442$). Conclusions In all measured muscles, differences were found between the three distance groups of swimmers, which indicates that the relationship between MFTC and optimal distance and exercise duration also applies to swimming. The lower baseline carnitine concentration in deltoid muscle from swimmers could suggest a long-term transition from type II to type I muscle fibers, which is probably caused by chronic aerobic training of the upper body, which does not occur in the controls. So this new method may have useful applications in talent identification and discipline (re)orientation in all MFTC-dependent sports. CAN TOTAL HAEMOGLOBIN MASS BE USED IN THE PERFORMANCE PREDICTION IN ELITE ATHLETES?

Zelenkova, I., Zotkin, S., Korneev, P., Koprov, S., Grushin, A.

Innovation center of Russian Olympic Committee

Introduction The total haemoglobin mass (tHb-mass) is one of the key factors for elite endurance athletes [1]. There is a strong correlation between tHb-mass and maximal oxygen consumption (VO_{2max}) [2]. Nevertheless the relationship between the tHb-mass and performance in real-life competition environment has not been described clearly. The aim of the present study was to define the relationship between tHb-mass in elite endurance athletes and their performance under competition environment. Methods Forty-one athletes members of Russian Olympic biathlon and speed skating team participated in the study: 16 male biathletes (BM: 176 ± 2.2 cm, 73 ± 1.9 kg, 27 ± 1.3 years), 7 females biathletes (BW: 165 ± 1.7 cm, 62 ± 1.1 kg, 28 ± 1.6 years) and 12 male speed skaters (SM: 182 ± 2.0 cm, 79 ± 2.3 kg, 26 ± 1.3 years), 6 female speed skaters (SW: 168 ± 2.4 cm, 60 ± 2.4 kg, 28 ± 2.0 years). The total hemoglobin mass (tHb-mass) was measured using optimized CO-rebreathing method (ABL80 FLEX CO-OX analyzer), hemoglobin concentration (Hb) and hematocrit (Hct) were measured in capillary blood. Measurements were taken during the pre Olympic year. tHb-mass values closest to the following competition were taken in the analysis: IBU World Cup 8 Biathlon 2012/2013 (C1), IBU World Cup 9 Biathlon 2012/2013 (C2), Summer Biathlon Russian Championships and Cup 2012/2013 (C3), IBU World Cup 1 Biathlon 2013/2014 (C4), Speed Skating Russia Cup 2012/2013 (C5) and Russian Speed Skating Championships 2012/2013 (C6). t-Student tests were used to examine correlations between tHb-mass and competition results, with statistical significance set at $p < 0.05$. Results The mean reliable tHb-mass in BM group after C1 and before C2 was 15.5 ± 0.4 g/kg. There was found a relationship between the competition result and reliable tHb-mass $r = -0.88$, $p < 0.05$ and $r = -0.96$, $p < 0.05$. The reliable tHb-mass in BM group before C3 was 13.9 ± 0.4 with a correlation to performance was $r = -0.88$, $p < 0.05$. The reliable tHb-mass in BW before C4 was 11.3 ± 1.8 with a correlation to performance $r = -0.81$, $p < 0.05$. In speed skaters the mean reliable tHb-mass before C5 in SM was 13.1 ± 1.7 , with a correlation to performance $r = -0.61$, $p < 0.05$. The mean reliable tHb-mass before C6 in SW was 12.9 ± 0.3 and in SW 10.5 ± 1.6 with the relationship to performance $r = -0.80$, $p < 0.05$ and $r = -0.77$, $p < 0.05$ respectively. For Hb and Hct such correlation wasn't found. Discussion When analyzing elite endurance athletes performance, tHb-mass can be used as one of the values that can help in performance prediction. These values can be used by coaches in making right decision on athletes allocation to relay or team race. References 1. Kanstrup IL, Ekblom B. (1984) Med Sci Sports Exerc. 16: 256-262. 2. RESISTANCE TRAINING INCREASES SKELETAL MUSCLE OXIDATIVE CAPACITY AND NET INTRAMUSCULAR TRIGLYCERIDE BREAKDOWN IN TYPE I AND II FIBRES OF SEDENTARY MALES

Shepherd, S.I, Cocks, M.I, Tipton, K.D.2, Witard, O.C.2, Ranasinghe, A.M.3, Barker, T.A.3, Wagenmakers A.J.M.1, Shaw, C.S.4

[1] Liverpool John Moores University, [2] University of Stirling, [3] University of Birmingham, [4] Victoria University

Introduction: Recent in vitro and in vivo experimental observations suggest that improvements in insulin sensitivity following endurance training are mechanistically linked to increases in muscle oxidative capacity, intramuscular triglyceride (IMTG) utilization during endurance exercise and increases in the content of the lipid droplet-associated perilipin-2 (PLIN2) and PLIN5. However, the muscle adaptations to resistance training (RT) contributing to improved insulin sensitivity are less well-understood. Aim: This study investigated the hypothesis that increased muscle oxidative capacity, PLIN protein expression and IMTG breakdown during exercise may also contribute to the well-

known RT-induced improvements in insulin sensitivity. Methods: Thirteen sedentary males (20 ± 1 years, 24.8 ± 0.8 kg.m⁻²) performed 6-weeks of whole-body RT (3 times per week) and changes in VO₂peak and insulin sensitivity were assessed. Muscle biopsies were obtained (n=8) before and after 60-min steady-state cycling at ~65% VO₂peak pre and post-training. Immunofluorescence and brightfield microscopy was used to assess changes in oxidative capacity (measured as COX protein content and SDH activity), IMTG, and PLIN2 and PLIN5 protein content. Results: RT increased VO₂peak ($8 \pm 3\%$), COX protein content ($46 \pm 13\%$, $61 \pm 13\%$ in type I and II fibres, respectively), SDH activity ($17 \pm 5\%$, $23 \pm 5\%$ in type I and II fibres, respectively) and the Matsuda insulin sensitivity index ($47 \pm 6\%$) (all $P < 0.05$). In type I fibres IMTG ($52 \pm 11\%$; $P < 0.05$) and PLIN2 content ($107 \pm 19\%$; $P < 0.05$) was increased and PLIN5 content tended to increase ($54 \pm 22\%$; $P = 0.054$) post-training. In type II fibres PLIN2 content increased ($57 \pm 20\%$; $P < 0.05$), and IMTG ($46 \pm 17\%$; $P = 0.1$) and PLIN5 ($44 \pm 24\%$; $P = 0.054$) content tended to increase post-training. IMTG breakdown during moderate intensity exercise was greater in both type I and II fibres ($43 \pm 5\%$, $37 \pm 5\%$, respectively; $P < 0.05$) post-RT. Conclusions: The results confirm the hypothesis that RT enhances muscle oxidative capacity, and increases IMTG breakdown during endurance-type exercise and the content of PLIN2 and PLIN5 in both type I and type II fibres. The adaptations in IMTG metabolism likely contribute to the improvement in insulin sensitivity following RT.

INHIBITION OF BRAIN GLYCOGENOLYSIS SUPPRESSES ENDURANCE PERFORMANCE: A PHYSIOLOGICAL ROLE OF BRAIN GLYCOGEN

Omuro, H.1, Matsui, T.1,2, Shima, T.1, Soya, H.1

1University of Tsukuba, 2JSPS Research Fellow

Introduction The brain is fuelled by blood glucose and brain glycogen, which is a glucose storage molecule in astrocytes. Brain glycogenolysis produces lactate as a neuronal energy source particularly during hypoglycemia (Bélanger et al., 2011). Since we recently revealed that brain glycogen decreases during prolonged exhaustive exercise with hypoglycemia, suggesting the importance of brain glycogen for brain energy supply during exercise (Matsui et al., 2011), we hypothesized that utilization of brain glycogen during exercise contributes to endurance performance. To test this, we examined the effects of inhibition of brain glycogenolysis on endurance performance in exercising rats with an intracerebroventricular (ICV) injection of a glycogen phosphorylase inhibitor (1, 4-dideoxy-1, 4-imino-D-arabinitol: DAB). **Methods** Adult male Wistar rats had cannulae inserted into the lateral ventricle and external jugular veins, were injected with either saline or DAB (150 mM, 10 µl) into the ICV and then exercised by treadmill running to exhaustion (20 m/min). We measured running time, and sacrificed using a high-power (10 kW) microwave irradiation method immediately after exhaustion. Five brain loci (cortex, hippocampus, hypothalamus, cerebellum and brainstem), in which glycogen decreases with prolonged exercise, were collected to quantify brain glycogen and lactate concentrations. We also measured blood glucose and lactate concentrations every 30 min during exercise, and determined glycogen levels in muscle and liver. **Results** With ICV injection of DAB, exercise-induced brain glycogen decrease and lactate increase were suppressed, and running time to exhaustion was shortened by 20.6% ($p < 0.05$). DAB injection had no effects on blood glucose and lactate levels or glycogen levels in muscle and liver, but accelerated hypoglycemia, blood lactate increase, and glycogen depletion in muscle and liver during exercise. **Discussion** Here, we provide the first evidence that inhibition of brain glycogenolysis during exhaustive exercise decreases lactate production and suppresses endurance performance. Inhibition of brain glycogenolysis accelerates the occurrence of glycogen depletion in muscles and liver and of hypoglycemia, which are limiting factors for endurance performance, supporting a current study showing the role of hypothalamic lactate in regulation of glucose metabolism in the whole body (Chan et al., 2013). Collectively, our findings suggest that brain glycogen plays a crucial role in endurance performance by sparing carbohydrates in peripheral tissues. **References** Bélanger M, Allaman I and Magistretti P. CORRELATION BETWEEN SKELETAL MUSCLE LIPID CONTENT AND INSULIN SENSITIVITY IN HUMAN MALES

Kristensen, M., Gomez Cabello, A., Larsen, S., Dela, F., Prats, C.

University of Copenhagen

The prevalence of obesity has increased markedly the last years and this is mirrored by a similar increase in the prevalence insulin resistance (IR) and type 2 diabetes mellitus (T2DM). Energy overload leads to obesity, where ectopic lipid depositions and glycogen storage impairment are seen, this is thought to be involved in development of IR. The aim of the present project was to use a recently developed method to measure skeletal muscle lipid and glycogen content to investigate the association between whole body insulin sensitivity (IS) and skeletal muscle lipid and glycogen content. T2DM, age- and BMI-matched obese male controls and age-matched lean controls were recruited. Subjects were examined after an overnight fast. A muscle biopsy from vastus lateralis was obtained. Lipid and glycogen content were determined with an improved histochemical technique using Bodipy-493/503 (lipid) and a glycogen specific antibody, respectively (1). Confocal images were acquired with a Zeiss LSM710 and quantification was performed using Image J software. The clamp M-value was correlated with both total and fiber type specific lipid and glycogen content in all three groups together using a Pearson correlation test in SigmaPlot 12.0. A negative correlation between total skeletal muscle lipid content and the clamp M-value in the whole group were detected ($R = -0.750$, $P = 0.000091$). This correlation also applied to the different fiber types (type I: $R = -0.637$, $P = 0.002$; type II: $R = -0.745$, $P = 0.0001$). No significant correlation between glycogen content and clamp M-value was detected. With an improved histochemical technique we show that the intramyocellular lipid content highly correlates with IS and is likely to be involved in IR development, however, the exact mechanisms are still a matter of debate. The correlation between increased intramyocellular lipid content and IR has been observed by other authors (reviewed by (2)) and a current belief is that toxic intermediates of lipid metabolism are key players in this pathology. The glycogen content per se was not associated with IR development. This does not exclude impairments in glycogen storage as a player in IR development and more research is warranted in investigating the spatial organization and quality of both lipid and glycogen stores. 1) Prats, C.; Gomez-Cabello, A.; Nordby, P.; Andersen, J.L.; Helge, J.W.; Dela, F.; Baba, O.; Ploug, T. EFFECTS OF HABITUAL EXERCISE AND DIET RESTRICTION ON THE EXPRESSION OF HEPATIC CARNITINE PALMITOYL-CoA TRANSFERASE-1 IN ZUCKER FATTY RATS

Kurosaka, Y.1, Kitamura, H.2, Yamauchi, H.3, Shiroya, Y.1, Nanba, H.1, Minato, K.1

Introduction: The function of mitochondria is to convert fatty acid to energy by beta-oxidation. Carnitine palmitoyl-CoA transferase-1 (CPT1) is a rate-controlling enzyme in mitochondrial fatty acid oxidation. Dietary restriction and exercise are commonly recommended to prevent and ameliorate obesity and lifestyle-related diseases, including fatty liver. However, the effect of habitual exercise and diet restriction on hepatic lipid oxidation is poorly understood. The purpose of this study was to characterize hepatic fat metabolism in relation to diet restriction and habitual exercise in genetically obese Zucker fatty rats with missense mutation of the leptin receptor. **Methods:** Male Zucker lean rats were used as the control group (L, n = 8). Male Zucker fatty rats were divided into obese (Ob, n = 8), diet restriction (DR, n = 8), and diet restriction+exercise (DR+Ex, n = 8) groups. The rats in the L and Ob groups had free access to food. Food intake in the DR and DR+Ex groups was restricted to 67% and 70% of the Ob group level, respectively. The rats in the DR+Ex group voluntarily exercised on a wheel ergometer with a load of 30% of their body weight. After 6 weeks, all rats were prepared for the experiment. Blood was collected to measure serum leptin and free fatty acid (FFA) levels. Liver tissue samples were excised to measure the hepatic triglyceride (TG) content. Additionally the expression levels for CPT1 were also determined using a western blotting method. **Results:** Body weight was significantly lower in the DR + Ex groups than that in the Ob group. There were no significant differences between the DR and DR + Ex groups in body weight and total food intake. The rat of ob group developed fatty liver and hyperlipidemia caused by excessive food intake. The hepatic TG content, serum FFA, and serum leptin levels in the DR group were significantly higher than those in the Ob group, whereas those in the DR+Ex group were significantly lower than those in the Ob group. CPT1 protein expression in the DR group was the similar as that in the Ob group, whereas that in the DR+Ex group was significantly higher than that in the Ob group. **Conclusion:** CPT1 protein, the rate-controlling enzyme in mitochondria fatty acid oxidation, was significantly elevated in DR + Ex group compared with the Ob and DR groups. These results suggest that habitual exercise may offer additional benefits on hepatic lipid oxidation by means of overexpression of hepatic CPT1 which increase fatty acid oxidation and reduces hepatic fat accumulation. Hepatic fat accumulation prevention through daily exercise may be associated with upregulation of hepatic mitochondrial fatty acid oxidation. **Contact:** y-kurosaka@wayo.ac.jp

PHYSIOLOGICAL AND PERFORMANCE RESPONSES TO 120-MINUTES OF SOCCER-SPECIFIC EXERCISE

Harper, L.D.1, Watson, A.1, West, D.J.1, Stevenson, E.1, Russell, M.1

1: Northumbria University (Newcastle upon Tyne, United Kingdom)

Introduction The physiological and performance responses to 90-min of soccer-specific activity have been extensively researched. An additional 30-min period of extra-time (ET) is played in specific tournament matches where scores are level at the end of 90-min. There is currently no data profiling the responses observed when ET is played. Therefore, we assessed the physiological and performance response to 120-min of simulated soccer match-play. **Methods** Nine university soccer players (age: 20±2 years, VO₂max: 54.6±0.9 ml.kg.min⁻¹) performed a modified version of the Soccer Match Simulation (SMS; Russell et al., 2010) adapted to include ET. During exercise, 15-m sprint velocity, heart rate (HR) and rate of perceived exertion (RPE; Borg, 1982) were measured. Peak lower body power output (PPO) measured using countermovement jumps (CMJ) was assessed before and after each half of normal time (pre-exercise, post 1st half, pre 2nd half, post 2nd half) and post-exercise (post-ET). **Results** Sprint velocities reduced by 6.1±4.7% in the last 15-min of ET compared to the same time in the second half (5.2±0.7 ms⁻¹ vs. 5.5±0.5 ms⁻¹, P<0.05), and were significantly reduced compared to all other 15-min blocks (P<0.05). Similarly, decrements of 15-m sprint performance were greater in the final 15-min of ET compared to the last 15-min of normal time (17.2±9.5% vs. 8.6±3.5%, P<0.05). RPE was significantly higher during ET (18±1 units) compared to both the first (15±1 units) and second (16±2 units) halves (both P<0.01), whereas peak and mean HR responses during ET (189±12 beats.min⁻¹, 166±10 beats.min⁻¹, respectively) were similar to the first (191±10 beats.min⁻¹, 169±12 beats.min⁻¹, respectively) and second (191±12 beats.min⁻¹, 166±11 beats.min⁻¹, respectively) halves. PPO was reduced post-ET compared to post 2nd half (3382±321W v 3465±292W, -2.3%, P<0.05). **Discussion** This study is the first to investigate the physiological and performance responses to 120-min of soccer-specific exercise. Sprint velocities and PPO were lower in the final stages of ET when compared to the end of normal time. Therefore, it is plausible that soccer-specific fatigue manifests its effects more so during ET, causing further decrement to markers that are crucial to success in soccer. The subjective responses commonly associated with exercise intensity support a greater physiological challenge towards the end of ET. Therefore, the efficacy of interventions that attenuate reductions in performance throughout the ET period remain to be investigated and thus provide future research opportunities. **References** Russell M., Benton D., Kingsley M (2010). RELATIVE FUNCTIONAL BUFFER CAPACITY INDICATES FATIGUE RESISTANCE DURING REPEATED SPRINTS

Mahler, H.1, Heyde, C.1, Röcker, K.2, Gollhofer, A.1

1: IFSS, Albert-Ludwigs-Universität Freiburg (Germany), 2: HFU (Furtwangen, Germany)

Introduction Resistance to fatigue during repeated sprints is considered to be crucial for soccer match performance (Girard et al. 2011). It is supposed that a performance decrease during repeated sprints may rely on self-induced metabolic acidosis (Gaitanos et al. 1993). In compensation, total in vivo buffering systems are described as limiting factors (Bishop et al. 2004). The concept of the relative functional buffering capacity (relFB) was introduced to discriminate between anaerobic and aerobic trained athletes (Röcker et al. 1994). However, yet is has not been investigated whether relFB, is useful to indicate fatigue resistance during repeated sprints. **Methods** 46 trained athletes performed a standardized incremental test on treadmill to determine workloads at lactate threshold (P_{LT}) and respiratory compensation point (P_{RCP}). relFB was calculated by the workload difference within P_{LT} and P_{RCP} in relation to P_{RCP} (Röcker et al. 1994). Within 7 days subjects also underwent a repeated sprint protocol of 6*40 m sprints separated by 20 sec of rest (Rampinini et al. 2007). Through percentage decrement score (Sdec%) resistance to fatigue was examined (Glaister et al. 2008). Bivariate correlation as well as partial correlation between relFB and Sdec% were calculated when P_{LT} was controlled. **Results** Individual sprint times decreased significantly in all athletes. relFB was significantly correlated to Sdec% (r=-.401 P<0.05). The correlation increased up to r=-.729 (P<0.05) when P_{LT} was controlled. **Discussion** On the basis of more than 50% of variance declaration, our results support the concept of relFB as an applicable indicator of resistance to fatigue during repeated sprints within established lactate and spiroergometry test settings. Among oxidative capacity (Bishop et al. 2004), resistance to fatigue during repeated sprints might also depend on buffering capacity. Though current

discussion about the causal relation between declined pH and muscle fatigue, link between buffer capacity and Sdec% (Bishop et al. 2004) is further strengthened with these results. SKELETAL MUSCLE FAST MYOSIN INCREASES IN SERUM AFTER MAXIMAL CONCENTRIC-ECCENTRIC INERTIAL EXERCISE

Carmona, G.1, Guerrero, M.2, Cussó, R.2, Padullés, J.M.1, Moras, G.1, Lloret, M.1, Bedini, J.L.3, Cadeñau, J.A.1,2

1: INEFC (Spain, Barcelona), 2: UB (Spain, Barcelona), 3: Hospital Clínic (Spain, Barcelona)

Introduction We hypothesized that a model of muscle damage could be made by measuring the time course of the serum concentration of muscle enzymes and proteins following inertial exercise, according to their molecular weight and their fibre compartmentalization. Moreover, by measuring fibre-type specific sarcomere proteins, fast myosin (FM) and slow myosin (SM), the type of fibres that are affected could be assessed (Guerrero et al., 2008). **Methods** Ten recreationally active men were required to perform 7 sets of 10 maximum intensity concentric-eccentric (C-E) repetitions of a half-squat exercise in a flywheel inertial resistance device (Portable VersaPulley™, Heart Rate Inc., Costa Mesa, CA). The exercise dynamic muscle work was characterized using the time course of force, displacement and velocity data, sampled at a frequency of 100 Hz from the force sensor and linear encoder of MuscleLab 4020e (MuscleLab, Ergotest Technology, Langesund, Norway) (Tesch et al., 2004). The muscle damage effect of this exercise was assessed through the evolution of serum muscle enzymes and fibre-type specific myosin isoforms. Serum profiles of creatine kinase (CK), creatine kinase MB isoenzyme (CK-MB), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and myosin isoforms (FM and SM), were measured before and 24, 48 and 144 h post-exercise. **Results** Muscle enzymes, CK, CK-MB and, to a lesser extent, AST, were early increased in serum (24 h), and returned to baseline values at 48 h post-exercise. FM was late increased in serum (48 h) and remained elevated until 144 h post-exercise. SM serum concentration showed no significant changes. **Discussion** The maximal C-E inertial exercise of the knee extensors, involving a highly specific movement similar to several sports actions, induces a different level of damage in fast and slow fibres. Interestingly, while an increase in muscle damage biomarkers like CK, CK-MB, and to a lesser extent AST, indicated increased membrane permeability, FM serum increases revealed sarcomere disruption as well as increased membrane permeability of fast fibres. Consequently, FM could be adapted as a fast-fibre biomarker of muscle damage. The results support a model of muscle damage based on the serum time course of muscle proteins according to their molecular weight and their fibre compartmentalization, depending on exercise and fibre-type. **References** Guerrero M, Guiu M, Cadeñau JA, Parra J, Balas R, Estruch A, Rodas G, Bedini JL, Cussó R. IRISIN SECRETION IN RELATION TO OVARIAN HORMONE STATUS AND METABOLIC FUNCTION

Velders, M., Qiu, S., Weigt, C., Diel, P., Steinacker, J.M., Schumann, U.

Department of Internal Medicine

Introduction Irisin, a muscle derived messenger, increases energy expenditure and heat generation by activation of thermogenic programs. Acute exercise transiently elevates irisin production, with a return to baseline levels observed shortly after cessation of exercise. Injection of recombinant irisin in mice leads to significant reductions in body weight and improved glucose homeostasis. In contrast, loss of ovarian hormones has been shown to promote the development of obesity and insulin resistance. The aim of this study was to determine irisin levels in ovariectomized vs. ovary intact rats and in a rat model of the metabolic syndrome (Zucker diabetic fatty, ZDF rats). **Methods** Female Wistar and ZDF rats were either ovariectomized (OVX) or sham operated (Sham). OVX rats were trained on a treadmill (OVX-Ex, 2 times per day, 15 minutes, 10% incline, 15 m/min) or kept sedentary (OVX-Sed). **Results** Serum irisin concentrations were significantly higher in OVX (81.34 ± 3.05 ng/ml) vs. Sham rats (64.63 ± 3.18 ng/ml) and OVX ZDF rats (53.59 ± 5.40). Visceral fat content was highest for OVX ZDF rats (75.58 ± 16.3 g) and significantly different from OVX (17.3 ± 2.5 g) and Sham rats (10.89 ± 3.4 g). 3 weeks of treadmill running did not alter irisin levels in OVX rats at rest (OVX-Ex: 81.34 ± 3.05 , OVX-Sed: 80.60 ± 5.28). **Discussion** Our data show that the high irisin levels detected in OVX rats are associated with lower visceral body fat, whereas the lower irisin levels detected in OVX ZDF rats are associated with significantly higher visceral body fat content. Similar to increases in insulin levels observed in pre-diabetic OVX rats, we propose that irisin secretion is upregulated as part of a compensatory mechanism in the absence of ovarian hormones to reduce visceral fat content and to improve metabolic function. Based on its role in weight loss and glucose homeostasis, the exercise induced myokine irisin offers an immense therapeutic potential for treating human metabolic diseases, such as diabetes and obesity. Future studies should investigate the physiological mechanisms regulating irisin secretion and the effects of irisin treatment on physical capacity.

14:00 - 15:00**Mini-Orals****MO-BN07 Biomechanics****LIGHTWEIGHT RACING SHOES IMPROVE 5-KM RUNNING PERFORMANCE, RUNNING ECONOMY AND ALTER RUNNING BIOMECHANICS IN TRAINED RUNNERS**

Fuller, J.I., Thewlis, D.I., Margarita, T.I., Brown, N.2, Buckley, J.I

1: University of South Australia, 2: Australian Institute of Sport

Introduction Lightweight footwear is advocated as a means for improving running economy (Moore et al., 2014) but the effect of lightweight footwear on running performance has not been investigated. The purpose of this study was to determine if trained distance runners, unaccustomed to running in lightweight/minimalist footwear and who normally run with a hindfoot strike gait pattern, perform better over a 5-km running distance when wearing a lightweight racing shoe or a standard running shoe. Running economy, vertical oscillation of the centre of mass (COM) and the impulse of the braking shear force were also compared between shoes. **Methods** A cross-over study design was used with order of shoes randomized and balanced across participants. Twenty-six trained runners performed a 5-km treadmill time-trial and three 6-min sub-maximal treadmill-running bouts at 11, 13 and 15 km/h in both shoe conditions. Running economy was determined from energy expenditure at each running speed assessed by indirect calorimetry. Vertical oscillation of the COM and the impulse of the braking shear force were calculated from motion capture data and ground reaction forces, which were measured during five overground running trials using a 12 camera VICON MX F20 system and four force platforms aligned in series. **Results** In the lightweight racing shoe, runners completed the 5-km time trial faster (Mean difference [MD]=21-s; $P<0.01$), were more economical running at 11, 13 and 15 km/h (MD=0.92, 1.66 and 2.59 kJ/min, respectively; $P<0.01$) and ran with less vertical oscillation of the COM (MD=3-mm; $P<0.01$). Improvements in running economy increased with increasing running speed ($P=0.02$). The impulse of the braking shear force did not differ between shoe conditions (MD=0.78 Ns; $P=0.11$). **Discussion** Distance runners can improve 5-km running performance through the use of lightweight racing shoes without any prior experience running in lightweight/minimalist footwear. Similar to previous research (Moore et al., 2014), runners ran with improved running economy when using lightweight shoes. Interestingly, improvements in running economy increased with increasing running speed suggesting that lightweight shoes may be most beneficial to runners capable of running at faster race paces. Additionally, a lower vertical oscillation of the COM suggests that runners performed less mechanical work against gravity running in the racing shoe, which could have contributed to the lower metabolic cost. **References** Moore IS, Jones A, Dixon S. EFFECTS OF DIFFERENT SURGICAL METHODS OF ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION ON KNEE JOINT FUNCTION

MA, Y.B., Deie, M., Iwaki, D., Asaeda, M., Adachi, N., Ochi, M.

Hiroshima University

Introduction The incidence rate of anterior cruciate ligament (ACL) injuries among the general population is calculated to be 1 in 3000. ACL injuries induce the anterior rotatory instability, lead to various functional deficits of the knee, and reduced quality of life. To our knowledge, ACL reconstruction is one important method to treat ACL injuries. In generally, the surgical methods of ACL reconstruction include single bundle (SB), single bundle augmentation (SBA) and double bundle (DB) techniques. However, it remains unclear which surgical method is the best to the knee joint function restore after ACL reconstruction. In addition, it has been reported that balance stability and proprioception are effective to value the knee joint function. The purpose of this study was to investigate effect of SB, SBA and DB on balance stability and proprioception after ACL reconstruction 1-year follow up. **Methods** 54 patients (25 male and 29 female) who underwent ACL reconstruction participated in this study. Equilibrium function meter G-620 (Anima, Tokyo, Japan) was used to measure body sway, which is an index of balance stability. Subjects took 20 seconds of single-leg standing with eyes closed. Kinesthesia, which is an index of proprioception was measured through using a self-designed proprioception testing apparatus (Sensor Ouyou, Hiroshima, Japan). We measured these measurements preoperative, postoperative 6 and 12 months. **Results** The balance stability and proprioception significantly decreased with DB technique compared to SB technique after reconstruction 6 and 12 months, no significantly difference to SBA technique. In addition, DB technique recovery rate faster than SB technique with balance stability and proprioception. **Discussion** The goal of ACL reconstruction is to restore the native ACL anatomy as closely as possible and consequently to approximate normal knee biomechanics. The DB is founded on the distinct anatomical and functional difference between the AM and PL bundle that comprise the ACL. Aglietti et al. found a statistically significant difference in favour of the DB technique in the results of visual analogue scale and subjective International Knee Documentation Committee (IKDC) and Knee Injury and Osteoarthritis Outcome Score evaluations and objective IKDC. Sastre et al. found a statistically significant difference in favour of the DB technique in the results of objective IKDC. Consequently, we believe that DB techniques superior to SB techniques with knee function. **References** Aglietti P, Giron F, Losco M, Cuomo P, Ciardullo A, Mondanelli N (2010). EARLY IDENTIFICATION OF THE FALLING RISK IN PARKINSON'S DISEASE

Moreno Catalá, M., Arampatzis, A.

Humboldt Universität zu Berlin

Introduction Postural instability is one of the greatest problems of Parkinson's disease patients (PDs). The falling rate of PDs is five times higher than in age-matched controls and cannot be reduced significantly by medication. Identifying the reasons for the deficits in postural stability in PDs at a young age would contribute to the development of adequate training interventions aiming to reduce falls. Our aim was to investigate the contribution of muscle strength, balance ability, dynamic stability control and adaptive potential to gait disturbances to the falling risk in PDs. **Methods** Twenty-four young PDs (12 fallers, PDF, 12 non-fallers, PDnF, 48±5 yrs) and 15 matched healthy controls (C) participated in the study. Dynamic stability was examined during simulated forward falls and during 15 gait trials (expected

and unexpected disturbances) to investigate predictive as well as reactive adaptive responses using the "extrapolated center of mass" concept [Hof, 2005]. Muscle strength was assessed by isometric maximal plantar flexion and knee extension contractions on a dynamometer. Balance ability was evaluated by measuring the anterior and posterior limits of stability (LoS) using a force plate. Results PDF showed a lower stability performance in the forward falls compared to C, mainly due to their lower ability to increase the base of support. They also showed lower muscle strength compared to C and a significant relationship was found between stability performance and muscle strength (i.e. knee extension and plantar flexion moments, $r=0.57$ and $r=0.54$ resp.). No significant differences were found in the anterior or posterior LoS, indicating similar balance ability. During baseline, PDs' walking was less stable than C's and this persisted in the disturbed trials. All groups showed direct after the first disturbance "after effects" and thus predictive adaptive responses. However, PDs after the experience in the disturbed walking did not improve their reactive behavior while C showed clear locomotor adaptation. Discussion We could confirm that recovery performance after simulated forward falls is reduced in young PDF and one of the responsible mechanisms is an insufficient increase of the BoS. This deficit may contribute to the higher frequency of falls in this group. Strength of the lower extremities partly explained recovery performance in PDs. Thus, we can argue that young PDs with an increased risk of falls may benefit from leg-extensors strengthening and dynamic stability training. Further, PDs use more unstable gait patterns which may affect their risk of falls. They also present a less effective reactive adaptation to disturbed walking. Therefore exercise interventions aiming to improve reactive behavior would be a suitable strategy for fall prevention in PDs. NEUROMUSCULAR AND KINEMATIC ANALYSIS OF JUMPS AND LANDINGS ON STABLE AND UNSTABLE SURFACES

Prieske, O., Muehlbauer, T., Krueger, T., Kibele, A., Behm, D.G., Granacher, U.

University of Potsdam

Introduction In many sport disciplines, vertical jumps are essential components of athletic performance. Given that unstable surfaces can alter lower limb kinematics (Kerdok et al., 2002) and activation levels of limb and trunk muscles (McBride et al., 2010), instability may influence muscle activity and kinematics during jumping and landing tasks. Thus, the purpose of this study was to investigate sex-specific effects of surface instability on neuromuscular and kinematic parameters during drop jumps (DJ) and landings (LA). **Methods** Physically active young adults (N=28, age: 23 ± 3 yrs; 14 male, 14 female) performed DJ and LA on a force plate (Novotec Medical) under stable and unstable (i.e., AIREX balance pad on top of the force plate) conditions in a randomized order (dropping height: 40 cm). Ground reaction forces (GRF) as well as knee flexion and knee valgus angles during DJ and LA were determined. Further, electromyographic (EMG) activity of trunk (m. rectus abdominis, m. erector spinae) and lower limb muscles (m. vastus medialis, m. biceps femoris, m. gastrocnemius medialis, m. tibialis anterior) were assessed (Noraxon). Additionally, effect sizes (f) were calculated. **Results** Jump height was lower (9%, $p < .001$, $f = 0.92$) and peak GRF was higher (5%, $p = .022$, $f = 0.72$) in DJ on unstable compared to stable surfaces. During DJ and LA, knee valgus angles were higher (19-32%, $p < .05$, $0.43 \leq f \leq 0.54$) whereas knee flexion angles were smaller (6-35%, $p < .05$, $0.43 \leq f \leq 0.90$) under unstable compared to stable conditions. Additionally, higher knee valgus angle (222%, $p = .027$, $f = 0.47$) and smaller knee flexion angles (6-35%, $p < .05$, $0.44 \leq f \leq 0.50$) were found for females compared to males. In terms of EMG data, no changes occurred in trunk muscles between surface conditions (DJ and LA). Muscle activity of the lower limbs was reduced with instability during preactivation in DJ and LA (7-60%, $p < .05$, $0.50 \leq f \leq 3.62$) and during braking and push-off phase in DJ (11-25%, $p < .05$, $0.48 \leq f \leq 1.23$). EMG data were unaffected by sex. **Discussion** The present findings imply that knee motion strategies were modified by surface instability and sex during DJ and LA. This may indicate a higher injury risk in females when jumping and landing on unstable surfaces. However, compared to stable conditions, lower limb muscle activity appears to be reduced during DJ and LA on an unstable surface irrespective of the factor sex. The reduced preactivation level in muscle activity may indicate a modified feedforward activation pattern of the lower limbs to prepare the neuromuscular system for the unstable condition. **References** Kerdok AE et al. MECHANICAL AND MORPHOLOGICAL PROPERTIES OF THE GASTROCNEMIUS MEDIALIS MUSCLE TENDON UNIT AFTER ACHILLES TENDON RUPTURE

Städle, B.1, Laps, G.2, Karamanidis, K.1, Brueggemann, G.P.1, Albracht, K.1

German Sport University Cologne

Introduction Long term deficits in force generation of the triceps surae muscle-tendon unit (MTU) and functional limitations have been described after complete Achilles tendon (AT) ruptures (Mullaney et al., 2006). AT repair can also lead to a lengthening of the tendon (Kangas et al., 2007) and most likely places the calf muscle in a shortened position. We hypothesize a reorganization of the entire triceps surae MTU. To clarify the described deficits, this study investigates the mechanical and morphological properties of the MTU post rupture and their effect on force generation. **Methods** Eleven male subjects (age 44 ± 11 years) who underwent acute surgical repair of a complete AT rupture were analyzed 4.6 \pm 2 years after rupture. Gastrocnemius medialis (GM) tendon length, AT cross-sectional area (CSA), AT moment arm and tendon mechanical properties were determined using ultrasonography (US). Torque-angle relationship was assessed in five different ankle angles (20° dorsiflexion to 20° plantar flexion) capturing GM muscle architecture by US simultaneously. The healthy leg served as control. For all statistical analysis, $\alpha = 0.05$ was accepted as the level of statistical significance. **Results** GM tendon is significantly longer (13 \pm 10%) in the repaired leg (R) compared to the healthy control leg (C). Significant differences between R and C were observed in AT CSA (52 \pm 11%) and GM fascicle length at rest (31 \pm 9%). Tendon mechanical properties changed significantly between sites. While tendon stiffness increased in R compared to C (39 \pm 14%), modulus of elasticity decreased (38 \pm 104%). The deficit in maximum plantar flexor torque of R was 13 \pm 12%. Normalized torque-angle relationship showed no significant differences in dorsiflexed positions. Significant differences occurred in neutral and plantar flexed positions. **Discussion** Repaired ruptures of AT have been discussed to be more compliant 6 months after repair (McNair et al., 2013). The increased tendon stiffness in this study shows, that there must be reorganization in tendon during later stages. Force deficits in plantar flexion angles in R could be explained by a higher tendon-to-fascicle length ratio forcing fascicles to work in a disadvantageous region of their length-tension curve. Stiffer tendons are not able to compensate that effect. **References** Kangas J, Pajala A, Ohtonen P, Leppilahti J, (2007). Am J Sports Med 35, 59-64. PERTURBATION TRAINING ALTERS CORE STABILITY AND KNEE JOINT LOADING IN FEMALE ATHLETES DURING LATERAL MOVEMENTS

Weltin, E., Gollhofer, A., Mornieux, G.

Albert-Ludwigs University Freiburg

Introduction Insufficient core stability and different lower limb biomechanics are presented as factors for the higher anterior cruciate ligament (ACL) injury incidence in female athletes. Among different neuromuscular training forms proposed in the literature to effectively reduce ACL injury rates, perturbation-enhanced training (PT) has been proven to alter hamstrings and gastrocnemius muscle activity and therefore reduce the risk of ACL injury (Hurd et al. 2006). However, the biomechanical consequence of such training during functional movements such as lateral jumps and cuttings is not yet reported. Thus the aim of the present study was to investigate the influence of perturbation training on pelvic and trunk control as well as lower limb biomechanics in female athletes during lateral reactive jumps (LRJ) and cuttings. **Methods** 3D full body kinematics (Vicon) was recorded for 24 women (12 perturbation (PT) and 12 control (CON)) performing LRJ with their left leg and unanticipated cuttings on a force plate (AMTI). All subjects participated in 12 training sessions. CON performed standard plyometric training while PT did LRJ on a plate, which could translate in the medial or lateral directions to induce unpredictable perturbations upon landing. Pre- and posttraining trunk, pelvis and knee kinematics and kinetics at initial contact (IC) and at the time of the maximal knee abduction moment (Max) were compared between and within groups. **Results** After training PT displayed lower thorax rotation ($13.7 \pm 6.2^\circ$ vs. $1.4 \pm 6.8^\circ$, $p=0.001$), and greater pelvic rotation in the new jumping direction ($3.5 \pm 3.4^\circ$ vs. $-2.4 \pm 4.4^\circ$, $p=0.001$) at IC. Thorax rotation was also significantly different from CON ($p=0.003$). The same effect was true at Max. Additionally the knee-loading pattern was altered from an internal to an external rotation moment (0.06 ± 0.11 Nm/kg vs. -0.05 ± 0.11 Nm/kg, $p=0.04$) at Max for both groups and a decreased knee extension moment (0.13 ± 0.12 Nm/kg vs. -0.01 ± 0.2 Nm/kg) after training for PT only. PT influenced movement execution during cuttings in the same way as in LRJ but not significantly. **Discussion** Results suggested that PT alters core control during LRJ. The altered thorax and pelvis rotation at IC as well as Max should ensure proper force distribution during weight acceptance over the whole kinetic chain (Kibler et al. 2006). The alterations of the knee loading pattern after the PT with a knee external rotation and lower knee extension moment possibly results in lesser ACL loads (Markolf et al. 1995) and therefore a lower risk for injury. **References** Hurd WJ, Chmielewski TL, Snyder-Mackler L (2006). *Knee Surg Sport Tr A*, 14, 60-69 Kibler B, Press J, Sciascia A (2006). *Sports Med*, 36, 189-198 Markolf KL et al. PACING STRATEGIES DURING REPEATED MAXIMAL VOLUNTARY CONTRACTIONS

Halperin, I., Aboodarda, S.J., Basset, F.A., Byrne, J.M., Behm, D.G.

Memorial University of Newfoundland

Purpose: Pacing strategies have been reported to occur during continuous cyclical exercises. However, currently no studies have examined if pacing takes place during repeated maximal voluntary isometric muscle contractions (MVICs). Accordingly, the purpose of this study was to examine if informing subjects on the number of MVICs they would perform would affect force, root mean squared electromyography (EMG), rating of perceived exertion (RPE) and evoked twitch properties during similar fatiguing protocols. **Methods:** Thirty well trained male subjects completed 3 fatiguing protocols in a randomized order. In the Control condition participants were informed they would perform twelve MVICs, and then completed all twelve. In the Unknown condition they were not told how many MVICs they would perform but were stopped after twelve. Lastly, In the Deception condition they were initially told they would perform only 6 MVICs, but after the 6th contraction they were asked to perform a few more repetitions and were stopped after twelve. **Results:** Compared to the Unknown condition, subjects demonstrated greater forces ($p<0.05$, $ES=0.35-1.14$, 2-7.5%) and biceps EMG ($p<0.05$, $ES=0.6$, 6%) in the Deception condition during the first 6 MVICs. Additionally, under all conditions subjects applied greater forces in the last repetition (#12) relative to the previous one (#11) ($p<0.05$, $ES=0.36-0.5$, 2.8-3.8%). No significant differences were found in evoked twitch properties and RPE between conditions. **Conclusions:** The anticipation of performing fewer MVICs led to increased force, whereas force decreased when no end point was provided. The results also question the assumption that subjects followed the instruction to exert maximal effort during repeated MVICs.

CONSISTENCY OF MUSCLE SHAPE AND VALIDITY OF SHAPE-BASED VOLUME PREDICTION IN LEG MUSCLES

Mersmann, F., Bohm, S., Schroll, A., Arampatzis, A.

Humboldt-Universität zu Berlin

Introduction Whole-muscle reconstruction of magnetic resonance images (MRI) for muscle volume assessment is a time-consuming procedure. A promising approach of volume prediction using only the muscle length (L), the maximal anatomical cross-sectional area (ACSAmax) and a muscle specific shape factor was presented by Albracht et al. (2008) for the triceps surae muscles (TS). The present study aims to validate the assumed consistency of muscle shape across populations featuring different muscle dimensions, the applicability of the method on other leg muscles and the effect of sex on muscle shape. **Methods** L, ACSAmax, muscle volume and the shape factor (S) were calculated from MRI-based muscle reconstructions for the soleus (SO), gastrocnemius medialis (GM) and lateralis (GL) of untrained individuals ($n = 13$), endurance ($n = 9$) and strength trained ($n = 10$) athletes and for the vastus intermedius (VI), lateralis (VL) and medialis of female ($n = 20$) and male ($n = 17$) volleyball athletes. The average shape factors were used to predict muscle volumes (Vp) for the TS on an independent recreationally active group, $n = 21$) using the equation $V_p = S * ACSA_{max} * L$. **Results** Though there were significant differences in the muscle dimensions of the TS muscles between the untrained, endurance and strength trained group as well as between male and female athletes regarding the quadriceps femoris vastii (QFv), S was similar across groups and in average 0.497, 0.596, 0.556 for the SO, GM and GL, respectively, and 0.582, 0.658, 0.543 for the VI, VL and VM, respectively. The position of ACSAmax showed low variability and was located at 67, 81 and 84 % of the shank length for SO, GM and GL and at 57, 60 and 81% of the thigh length for VI, VL and VM, respectively. Further, there were no significant differences between the measured and predicted TS or QFv with root mean square differences (RMS) of 5 to 8%. **Discussion** Our results suggest that the muscle shape of the investigated leg muscles is independent of muscle dimensions and sex. Predicting the muscle volumes using only the easily measurable parameters L, ACSAmax and the reported shape factors is sensitive enough to detect changes in muscle volume due to degeneration (Morse et al., 2005), atrophy (Alkner and Tesh, 2004) or hypertrophy (Aagaard et al., 2001). **References** Aagaard P, Andersen JL, Dyhre-Poulsen P, Leffers AM, Wagner A, Magnusson SP, Halkjaer-Kristensen J, Simonsen EB. ANKLE STRENGTH INFLUENCE ON EMG STRATEGIES DURING DYNAMIC AND STATIC ANKLE TRAINING MODALITIES

Lucas Cuevas, A.G.1,2, Baltich, J.2, Enders, H.2, Nigg, S.2, Nigg, B.2

1. *Department of Physical Education and Sports, University of Valencia, Spain;* 2. *University of Calgary, Canada.*

Introduction Muscle weakness is considered a risk factor for ankle injury. Numerous training modalities have been used in an attempt to strengthen the muscles crossing the ankle such as balance training or barefoot running. It is expected that training modalities that successfully strengthen the ankle would elicit increased muscular activity. However, it is unknown how an individual's ankle strength will influence the muscle activity used during a given task. Therefore this study aimed to analyse the role that ankle strength may play in EMG strategies of the lower leg muscles during static and dynamic training modalities. **Methods** 26 participants performed dynamic (shod and barefoot running) and static tasks (squat on ground, squat on a bosu ball) believed to strengthen the muscles surrounding the ankle[1]. Muscle activity of the tibialis anterior, peroneus longus, gastrocnemius lateralis and medialis were measured registering surface EMG and analysed using a non-linearly scaled wavelet analysis. Total muscle activity for each task was obtained by adding up all four muscles EMG. Subjects were divided into a strong and a weak group defined as the 9 individuals with the highest (strong) and 9 individuals with the lowest (weak) normalized, isometric plantar flexion torque. **Results** Group differences The strong group used 74% and 76% relatively less muscle activity compared to the weak group during shod and barefoot running, respectively. Stronger participants needed 61% less muscle activity to perform the squats on the ground, whereas no difference was observed between groups during the squat on the bosu ball. **Task differences** During the running tasks, no difference in EMG was observed between shod and barefoot running. Regarding the unipedal squats, participants needed 71% more muscle activity when performing a squat on the bosu ball compared to a squat on the ground. **Discussion** People with stronger ankles need less relative muscle activity to carry out different tasks which have been previously speculated to strengthen the ankle-foot complex structures. Also, dynamic actions (running) elicited higher muscle activity than static actions (squats) and there was a significant effect of training modality on muscle activation level for the weak group, whereas the strong group used similar muscle activity across tasks. We speculate that, for any given task, people with weaker ankles seem to be closer to their physiological limit and, consequently, at greater injury risk when performing any of these situations over time. **References** 1. THE RELATIONSHIP BETWEEN INTERPHALANGEAL JOINT POSITION AND THE MEDIAL LONGITUDINAL ARCH OF THE FOOT

Shiroshita, T.1, Fukubayashi, T.2

1:*Gumma Paz College,* 2:*Waseda University*

Introduction At ECSS Barcelona 2013, we presented on the morphologic relationship between toe exercises and the medial longitudinal arch (MLA). That study compared three toe exercise groups, which were a great-toe-flexor exercise group, a lesser-toe-flexors exercise group and a towel-gathering exercise group. In that study, we showed the relationship between the lesser toe exercise (LTE) and MLA. For the LTE, the toe joint position was set with the distal interphalangeal joint (DIP) extended and the proximal interphalangeal joint (PIP) flexed. Jam, B. (2006) reported that the foot's intrinsic muscles were affected by DIP joint extension and PIP joint flexion positions because of their origin and insertion. Therefore, it was suggested that performance of LTE was affected by the foot's intrinsic muscles. However, our study last year did not compare other toe joint positions. Hence, the purpose of this study was to examine the relationship between interphalangeal joint position and MLA. **Methods** This study included 14 participants (eight men, six women) with a mean age of 20.9 (0.3) years. The participants performed two exercises: a lesser toe flexor exercise with the metatarsophalangeal joint of the foot (MP) extended and PIP and DIP joints mid-position (MPE); and a lesser toe flexor exercise with the MP joint mid-position, PIP flexed and DIP extended (DIPE). In other words DIPE is completely similar to LTE of the last year. Each toe exercise consisted of 10 isotonic contractions. MPE and DIPE were performed with the participants seated and raised their heel with their toes to perform the lesser toe flexor exercises. For measurement of MLA, a modified Navicular Drop Test (NDT) was employed. The modified NDT was set at 20% of foot weight bearing while seated. Its high reliability was confirmed previously. For the statistical analysis, we performed Wilcoxon signed-rank tests using SPSS Statistics 20 (IBM). The results are presented as mean (SD) and were considered significant at values of $p < 0.05$. This study received approval from the ethics committees for Human Research of Waseda University and Gumma Paz College. **Results** The NDT of MPE was only slightly from 4.81 (1.46) mm to 4.63 (1.61) mm ($p = 0.21$). In contrast, the NDT of DIPE significantly changed from 3.95 (1.59) mm to 4.60 (1.61) mm ($p = 0.002$). **Discussion** MPE did not show a morphologic relationship with MLA. In contrast, DIPE increased the rigidity of MLA. Hicks reported that windlass occurred with dorsiflexion of the hallux from approximately 10° and with dorsiflexion of the lesser toes from approximately 5° . The rigidity of MLA increased when the MP joint was in extension; however, the shape of the MLA was not maintained when the MP joint returned to the mid position. Therefore, MPE did not show a morphologic relationship with MLA. In contrast, it was suggested that the foot's intrinsic muscles affected DIPE. We believe that the foot's intrinsic muscles of the lesser toes had a greater relationship with MLA than the windlass mechanism.

Mini-Orals**MO-PM23 Vascular Biology****DISTINCT IMPACTS OF BLOOD FLOW AND TEMPERATURE ON CUTANEOUS MICROVASCULAR ADAPTATION**

Carter, H., Spence, A., Atkinson, C., Pugh, C., Cable, T., Thijssen, D., Naylor, N., Green, D.

University of Western Australia

Introduction Recent studies indicate that local cutaneous microvascular adaptations are apparent after exercise training/acclimation, consistent with changes observed in conduit and resistance vessels. This raises the important issue of microvascular health benefit from repeated exposure to passive heating in humans, given that enhanced microvascular function should be associated with decreased

progression or risk of microvascular disease. However, the relative impact of episodic increases in skin blood flow (SkBF), versus skin temperature, in cutaneous adaptation to repeated body heating has not previously been addressed. We performed two experiments to determine whether cutaneous microvascular adaptations in response to repeated core temperature elevation are mediated by increases in SkBF, and/or, skin temperature. Methods Healthy subjects participated for 8-weeks, 3x weekly bouts of 30mins lower limb heating (40°C). In Study 1, both forearms were "clamped" at basal skin temperature throughout each heating bout (n=9). Study 2 involved identical lower limb heating, with the forearms under ambient conditions (unclamped, n=10). In both studies, a cuff was inflated around one forearm during the heating bouts to assess the contribution of SkBF and temperature responses. We assessed forearm SkBF responses to both lower limb (systemic reflex) heating, and to local heating of the forearm skin, pre and post intervention. Results Acutely, lower limb heating increased core temperature (Study 1: $+0.63 \pm 0.15^\circ\text{C}$, Study 2: $+0.69 \pm 0.19^\circ\text{C}$, $P < 0.001$) and forearm SkBF (Study 1: 0.13 ± 0.03 vs 1.52 ± 0.51 , Study 2: 0.14 ± 0.01 vs 1.17 ± 0.38 CVC, $P < 0.001$), with skin responses significantly attenuated in the cuffed forearm ($P < 0.01$). SkBF responses to local heating decreased in Study 1 (clamped forearms, week 0 vs 8: 1.46 ± 0.52 vs 0.99 ± 0.44 CVC, $P < 0.05$), whereas increases occurred in Study 2 (unclamped; 1.89 ± 0.57 vs 2.27 ± 0.52 CVC, $P < 0.05$). Cuff placement abolished local adaptations in both studies. Discussion Our results suggest that repetitive increases in skin hyperaemia, when associated with increased skin temperature, induces distinct adaptations to those associated with repeated increases in SkBF per se. Whilst episodic increases in SkBF induce microvascular changes consistent with prolonged red blood cell transit time, repeated increases in skin temperature induce functional adaptation and enhanced red cell flux. Interventions that repeatedly increase core temperature and, consequently, both SkBF and skin temperature, likely induce central adaptations in blood volume as well as local microvascular changes which ultimately combine to enhance thermoregulatory capacity. LOCAL TEMPERATURE-SENSITIVE MECHANISMS, INDEPENDENT OF SYSTEMIC RESPONSES, MEDIATE INCREASES IN LIMB TISSUE PERFUSION IN THE RESTING AND EXERCISING HEAT-STRESSED HUMAN

Chiesa, S.T.1, Trangmar, S.J.1, Kalsi, K.K.1, Rakobowchuk, M.1, Banker, D.2, Lotlikar, M.D.2, Ali, L.2, González Alonso, J.1

1. Brunel University London, UK. 2 Dept. of Anaesthetics, Ealing Hospital, UK

Introduction Limb and systemic blood flow increases with heat stress in the resting and exercising human, but the contribution of local vs. systemic mechanisms remains equivocal. This study tested the hypothesis that heat stress-mediated increases in limb tissue blood flow, including that to skeletal muscle, are regulated by local temperature-sensitive mechanisms. Methods 15 male subjects (age 23 ± 4 years; mean \pm SEM) were exposed to 1 h of either 1) full-body passive heat stress (water-perfused suit; n=8) with simultaneous isolated single leg cooling (ice packs), or 2) isolated leg heating or cooling during core normothermia (n=7). Core, skin, and deep femoral venous blood temperatures, limb (common and profunda femoral arteries) and systemic haemodynamics were measured at rest and during incremental single-legged knee extensor exercise. Results Full-body passive heat stress led to significant increases in whole-body core, mean skin and heated leg blood temperatures ($0.5 \pm 0.1^\circ\text{C}$, $6.6 \pm 0.3^\circ\text{C}$, and $1.1 \pm 0.1^\circ\text{C}$), heart rate (24 ± 3 bpm), and cardiac output (2.0 ± 0.3 l.min⁻¹; $P < 0.05$ for all). Heated leg blood flow (common femoral artery) increased 0.6 ± 0.1 l.min⁻¹, partly due to downstream increases in profunda femoral arterial flow (main arterial supply of thigh skeletal muscle; 0.20 ± 0.03 l.min⁻¹ increase; $P < 0.05$). In contrast, leg tissue blood flow in both arteries of the cooled leg remained unchanged throughout ($P > 0.05$). During incremental exercise (up to 50 W), heated leg blood flow was consistently maintained ~ 0.6 l.min⁻¹ higher than that in the cooled leg ($P < 0.01$), with vascular conductance and blood flow in both legs showing a strong correlation with their respective local venous blood temperature ($R^2 = 0.98$ and 0.96 , $P < 0.05$). During isolated limb heating and cooling, leg blood flows were equivalent to those found during full-body heating ($P > 0.05$), despite unchanged systemic temperatures and haemodynamics. Similarly, during incremental exercise, leg blood flow responses were essentially identical to their heated and cooled counterparts during full-body heating, despite a difference in core temperature of almost 1°C between studies. Discussion Local temperature-sensitive mechanisms, independent of systemic temperature and haemodynamic responses, directly influence limb tissue blood flow regulation both at rest and during small-muscle mass exercise. These findings support the use of local heating for the promotion of limb tissue blood flow and oxygen and substrate supply in both athletic and clinical populations, without the increased cardiovascular strain associated with full-body hyperthermia.

EFFECTS OF INTRAMYOCELLULAR AND EXTRAMYOCELLULAR LIPID CONTENTS ON ARTERIAL STIFFNESS

Hasegawa, N., Kurihara, T., Sato, K., Fujita, S., Sanada, K., Otsuka, M., Hamaoka, T., Iemitsu, M.

Ritsumeikan University

BACKGROUND: Obese and overweight patients increased the risk of arterial stiffness. Visceral fat accumulation may relate to the development of arterial stiffness with enhancing inflammatory cytokine secretion (Meyer LK et al, 2013). Additionally, epicardial fat and hepatic fat accumulations are associated with increase in cardiovascular disease risk. Lipids are generally stored in either interstitial adipose tissue (extramyocellular lipid: EMCL) or lipid droplets within muscle cells (intramyocellular lipid: IMCL). Although it is well known that fat accumulation is localized in the whole body and it leads to arterial stiffness, the relationship between IMCL or EMCL contents and arterial stiffness remains unclear. PURPOSE: This study aimed to clarify whether IMCL and EMCL contents affect arterial stiffness in each gender or cardiorespiratory fitness level with a cross-sectional study. METHODS: One-hundred fifty healthy young, middle-aged and older subjects (18-81 years) were enrolled in this study. The study subjects were divided into 2 groups according to fitness level (high-fitness: HF and low-fitness: LF groups). These groups were divided based on the median value of VO_2max in each sex and decade. IMCL and EMCL contents of the right vastus lateralis muscle were evaluated by ^1H -magnetic resonance spectroscopy. Arterial stiffness was estimated by using brachial-ankle pulse wave velocity (baPWV). RESULTS: There were significant correlations between the baPWV and IMCL content ($r = -0.219$, $p = 0.007$) and EMCL content ($r = 0.548$, $p < 0.0001$) in all subjects. In female, the baPWV negatively correlated with the IMCL content ($r = -0.364$, $p = 0.002$), but there was no significant correlation in male. Additionally, significant positive correlation was observed between the baPWV and EMCL in male ($r = 0.427$, $p < 0.0001$) and female ($r = 0.575$, $p < 0.0001$). As a comparison between fitness levels, significant positive correlation was observed between the baPWV and EMCL in the both groups (HF: $r = 0.517$, $p < 0.0001$, LF: $r = 0.57$, $p < 0.0001$). IMCL content negatively correlated with the baPWV in the LF group ($r = -0.223$, $p = 0.05$), but, there was no significant correlation in HF group. CONCLUSION: These results suggest that EMCL content may be associated with arterial stiffness without concerning gender and fitness levels, while the IMCL content may not be a risk factor of arterial stiffness. ANTIBACTERIAL MOUTHWASH ATTENUATES THE PHYSIOLOGICAL EFFECTS OF CHRONIC NITRATE SUPPLEMENTATION IN HUMANS

McDonagh, S., Wylie, L.J., Vanhatalo, A., Jones, A.M.

University of Exeter

Introduction Ingestion of inorganic nitrate (NO_3^-) in beetroot juice (BR) increases plasma nitrite concentration ($[\text{NO}_2^-]$), via NO_3^- -reductases in the mouth, and lowers blood pressure (BP) (Bailey et al., 2009). The use of chlorhexidine-containing mouthwash can disturb the oral microflora and eliminate the beneficial effects of acute NO_3^- ingestion on resting BP (Petersson et al., 2009). The aim of this study was to determine whether chlorhexidine or weaker antiseptic agents can attenuate the effects of chronic BR supplementation on plasma and salivary $[\text{NO}_3^-]$ and $[\text{NO}_2^-]$ and resting and ambulatory BP. **Methods** In a double-blind, randomised, crossover design, 12 volunteers mouth rinsed with non-chlorhexidine (MW1), chlorhexidine (MW2) and control mouthwash (deionised water; CON), 15 min prior to ingesting 70 mL of BR (containing 6.2 mmol NO_3^-), twice a day, for 6 days. Prior to supplementation and on day 6 of supplementation, 4 h post final BR ingestion, BP (during seated and supine rest and during and post 10 min of treadmill walking), arterial stiffness, and plasma and salivary $[\text{NO}_3^-]$ and $[\text{NO}_2^-]$ were determined. **Results** The rise in salivary $[\text{NO}_3^-]$ 4 h post BR on day 6 was greater in MW2 (8.70 ± 2.95 mM) compared to CON (6.30 ± 0.87 mM; $P < 0.05$) and MW1 (5.99 ± 3.02 mM; $P < 0.05$). At the same time point, the increase in plasma $[\text{NO}_2^-]$ was less in MW2 (114 ± 112 nM) compared with CON (322 ± 219 nM; $P < 0.05$) and MW1 (278 ± 250 nM; $P < 0.05$). No effects on arterial stiffness or BP during seated or supine rest, or recovery from exercise were noted between MW1, MW2 and CON ($P > 0.05$). However, 4–6 min into the walking bout, systolic BP was elevated in MW2 (by 6.2 ± 9.5 mmHg) compared to CON (-0.7 ± 8.0 mmHg; $P < 0.05$), and the mean arterial pressure was also higher in MW2 compared to CON ($P < 0.05$). **Discussion** The primary novel finding of this study was that using chlorhexidine mouthwash in association with BR consumption was associated with a higher BP response to low-intensity exercise. It was also shown that mouth rinsing with strong and weak antiseptic agents, prior to BR ingestion, disrupted the oral conversion of NO_3^- to NO_2^- . These results have important implications for dietary advice which aims to lower BP. Regular use of mouthwash may markedly reduce the beneficial effects of dietary NO_3^- ingestion on cardiovascular health. **References** Bailey SJ, Winyard P, Vanhatalo A, Blackwell JR, DiMenna FJ, Wilkerson DP, Tarr J, Benjamin N, Jones AM. TAURINE SUPPLEMENTATION ATTENUATES INCREASE IN ARTERIAL STIFFNESS FOLLOWING HIGH INTENSE ECCENTRIC EXERCISE

Ra, S.G.1,2, Choi, Y.1,2, Akazawa, N.1,2, Ohmori, H.1, Maeda, S.1

1: University of Tsukuba, Japan; 2: Research Fellow of JSPS, Japan

Introduction Is acute increasing arterial stiffness participated in progressing chronic arterial stiffen? This question is still debated but it is generally known that increased arterial stiffness is an independent risk factor for future cardiovascular disease (Safar and London 2000). Recently, high intense eccentric exercise (ECC) has been shown to increase arterial stiffness acutely (Barnes et al. 2010), and it is generally known that oxidative stress positively associated with increased arterial stiffness (Toikka et al. 1999). Taurine is most abundant free amino acid in humans and it has cytoprotective properties through its action on anti-oxidation (Silva et al. 2011). **Purpose** We investigated that whether taurine supplementation attenuates increase in arterial stiffness after high intense ECC in human. **Methods** A total of 29 healthy sedentary or recreationally active men (age, 25.3 ± 0.1 years; weight, 66.2 ± 0.9 kg; height, 174.6 ± 0.1 cm) were recruited and randomly assigned to following two groups in a double-blind manner: placebo supplement group ($n = 14$) and taurine supplement group ($n = 15$). Subjects were ingested 2.0 g placebo or taurine supplement, thrice a day, for two weeks prior to and three days after high intense ECC. Fourteen days after starting supplementation, subjects performed 2 sets of 20 repetition unilateral maximal-effort ECC of the elbow flexors on a Biodex isokinetic dynamometer, with each contraction lasting 3 sec with one repetition performed 9 sec and 4 min of rest in between sets as described previously (Barnes et al. 2010) with slightly modifications. Blood pressure (SBP, MBP, and DBP), heart rate (HR), and indices of arterial stiffness (carotid arterial compliance [CAC] and carotid-femoral pulse wave velocity [cfPWV]) were assessed before exercise and following 4 days. **Results** There were no differences in blood pressure (SBP, MBP, and DBP) and HR between two groups during experiment. As expected, acute high intense ECC resulted in increased arterial stiffness (decreased CAC and increased cfPWV). However, compared with placebo group, the taurine group had attenuated increase in arterial stiffness at 3 and 4 days after ECC. **Discussion** In the previous human study, it has been reported that ECC results in a delayed increase in oxidative stress production (Close et al. 2004). In the present study, increased arterial stiffness after 3 and 4 days following ECC was significantly attenuated by taurine supplementation. Therefore, taurine supplementation may attenuate increase in arterial stiffness due to the anti-oxidative effect. **Conclusion** These results suggest that taurine supplementation is effective as a nutraceutical prescription for inhibiting increased arterial stiffness after high intense ECC. **References** Barnes et al. THE COMBINED EFFECTS OF ACUTE LOW-VOLUME INTERVAL TRAINING WITH POST-EXERCISE BLOOD FLOW RESTRICTION ON ANGIOGENIC GENE EXPRESSION IN TRAINED SKELETAL MUSCLE

Taylor, C.W., Ingham, S.A., Martin, N.R., Ferguson, R.A.

Loughborough University

Introduction We have demonstrated (Taylor et al. unpublished data) that low-volume interval and continuous 'all-out' cycling induce similar increases in the expression of angiogenic compounds that regulate capillary growth. The increased expression of these compounds in response to exercise is stimulated by mechanical signals (i.e. shear stress) as well as changes in metabolism and reduced oxygen delivery. Blood flow restriction (BFR) to the muscles using rapidly inflatable pressure cuffs has previously been utilised to induce all of the above. We therefore tested the hypothesis that low-volume 'all-out' cycling combined with post-exercise blood flow restriction would promote greater angiogenic gene expression compared to that induced by this type of exercise alone. **Methods** In a repeated measures cross-over design, 8 trained males (age, 29 ± 6 yr; height, 180 ± 10 cm; body mass, 76 ± 10 kg; VO_2max , 58 ± 4 mL·kg⁻¹·min⁻¹) performed 4×30 s 'all out' efforts on an isokinetic cycle ergometer, each effort interspersed by 4 min of passive recovery with (BFR) or without (CON) 2 min post-exercise leg BFR using a rapid cuff inflator set to ~ 130 mmHg. Muscle biopsies were obtained from the vastus lateralis before, immediately post- and 3 hours post-exercise. PGC-1 α , VEGF, VEGF-R2, HIF-1 α , eNOS, MMP-9 and Ang-2 mRNA expres-

sion were determined using real-time RT-PCR and expressed relative to RP-11 β . Data were analysed using a two way repeated measures ANOVA and are presented as fold-change from rest (mean \pm SD). Results Total work done was similar ($P > 0.05$) between protocols (CON; 68.3 ± 10.4 vs. BFR; 67.1 ± 9.8 kJ). The mRNA expression of PGC-1 α (5- vs. 6.8-fold, $P < 0.05$), VEGF (2.4- vs. 3.2-fold, $P < 0.05$) and VEGF-R2 (1.4- vs. 2.2-fold, $P < 0.05$) increased at 3 h after CON and BFR, respectively, although the magnitude of fold change for either of these genes was not different between protocols. There was a significantly greater ($P < 0.05$) increase in HIF-1 α mRNA expression at 3 h after BFR compared to CON (1.5- vs. 1-fold, respectively). There was no difference in eNOS, MMP-9 or Ang2 mRNA expression in response to either protocol. Discussion The greater HIF-1 α mRNA expression after BFR suggests this protocol likely induced greater oxygen consumption and/or lowered oxygen tension within the sampled tissue. However, despite the greater HIF-1 α mRNA expression after BFR, both protocols induced similar increases in the expression of PGC-1 α , VEGF and VEGF-R2, suggesting a possible ceiling effect in the magnitude of fold-change for these specific genes.

PHYSIOLOGICAL MECHANISMS IMPAIRING CARDIOVASCULAR FUNCTION AND EXERCISE CAPACITY IN THE HEAT STRESSED HUMAN: ROLE OF SKIN VERSUS BODY TEMPERATURE

Trangmar, S.J.1, Chiesa, S.T.1, Kalsi, K.K.1, Rakobowchuk, M.1, Secher, N.H.1,2, González Alonso, J.1

1 CSMHP (UK); 2 CMRC (Denmark)

Introduction: Cardiovascular strain and hyperthermia are thought to be important factors limiting exercise capacity in heat-stressed humans, but the contribution of elevations in skin (Tsk) versus body temperature remains unknown. Here we tested the hypothesis that an increased body temperature would accelerate the attenuation in leg, brain and systemic perfusion leading to impaired exercise performance, but the sole increase in Tsk would not. Methods: Nine cyclists completed 3 incremental cycling tests after (a) ~30 min whole-body heating (H30), (b) ~10 min whole-body heating (H10), and (c) in control conditions. Tsk and core temperature (Tc), heart rate (HR) and VO₂ were measured continuously; whereas leg, brain and systemic haemodynamics and haematological parameters were assessed at the end of each exercise stage. To eliminate the effects of repeated exercise, the incremental tests were repeated, on a separate day, with each test performed in control conditions. Results: Prior to exercise in H30, Tsk, Tc and cardiac output were elevated by 6.2 ± 0.2 °C, 0.9 ± 0.1 °C and 4.8 L/min ($P < 0.05$) compared to control, whereas only Tsk was elevated prior to exercise in H10 (6.0 ± 0.2 °C). During incremental exercise, Tsk was maintained, yet Tc rose gradually to a similar peak value in the 3 conditions (39.2 ± 0.1 °C). Exercise capacity and VO₂max were reduced in H30 by $13 \pm 1\%$ and $6 \pm 2\%$ ($P < 0.05$), but remained unchanged in H10. On the transition from rest to sub-maximal exercise, VO₂, cardiac output and leg blood flow increased at a similar rate across conditions. In contrast, mean arterial pressure and brain blood velocity increased but were lower, whereas HR and leg a-vO₂ difference were higher in H30 vs. H10 and control. At exhaustion, HRmax ($\sim 186 \pm 3$ beats/min) and leg a-vO₂ difference ($\sim 182 \pm 5$ ml/L) were similar in the 3 conditions, whereas mean arterial pressure ($-14 \pm 1\%$), brain blood velocity ($-16 \pm 6\%$), leg blood flow ($-11 \pm 3\%$) and cardiac output ($-9 \pm 3\%$; all $P < 0.05$) were lower in H30 compared to H10 and control. In the 3 control incremental tests, exercise capacity, VO₂max, HRmax and Tc were similar. Discussion: These findings demonstrate that skin hyperthermia per se does not compromise cardiovascular capacity or incremental exercise performance. Rather, combined skin and internal body hyperthermia reduces VO₂max and exercise capacity through the early attenuation of leg, brain and systemic blood flow. Our findings have important implications for understanding why athletic performance in warm environments is not universally impaired across all sports and exercise modalities. ANGIOGENESIS IN ANIMAL MODELS OF EXERCISE TRAINING

Egginton, S.

University of Leeds

Introduction Exercise intolerance, whether due to lifestyle choices, genetic propensity, or central limitations to aerobic activity is clearly a major issue of increasing prevalence. Physical activity increases capillary growth (angiogenesis) in active skeletal muscle over 4-6 weeks in animals and humans. This elicits a parallel increase in O₂ extraction capacity, so optimising the angiogenic response in other ways may have major benefits. Electrical stimulation of rodent hindlimb extensor muscles is one of the most potent signals for angiogenesis, effective within days, improving fatigue resistance in the absence of central limitations (Egginton and Hudlická, 1999). This may be due to improved peripheral O₂ delivery (Egginton and Gaffney, 2010), which we now explore. Methods Stimulation (10Hz, 0.3ms pulse width) was carried out for up to 28 days. Capillary to fibre ratio (C:F) was calculated from cryosections of extensor digitorum longus (EDL) stained for alkaline phosphatase activity (Sigma) or with lectin (Griffonia simplicifolia, Vector Labs). In order to accommodate the spatial heterogeneity of local capillary supply, an area-based analysis of capillary distribution is used as a basis for modelling tissue PO₂ (capillary domains). Results New capillary growth preferentially occurs around oxidative fibres following endurance training, while after stimulation new capillaries are located adjacent to glycolytic fibre types within mixed muscles (Badr et al., 2003). In both rats and mice an increase in C:F is seen within days of stimulation, with important changes in spatial distribution. Discussion Electrical stimulation is reportedly effective in reducing skeletal muscle dysfunction following immobilisation, myopathies and peripheral vascular disease; possibly due to an improved microcirculation. Intraspecific differences may reflect muscle blood flow, fibre size, and/or oxidative capacity. The consequences for tissue oxygenation are being explored by means of a mathematical model for PO₂ distribution, and functional consequences by fatigue resistance. References Badr I et al. MO-PM24 TT High Intensity Interval Training

EFFECTS OF HIGH INTENSITY TRAINING ON SPECIFIC PERFORMANCE RELATED PARAMETERS IN YOUNG FEMALE BASKETBALL PLAYERS

Sperlich, P.F.1,2, Zinner, C.1,2, Mester, J.1,2

1 Institute of Training Science and Sport Informatics; German Sport University Cologne, Germany, 2 German Research Centre of Elite Sport; German Sport University Cologne, Germany

Introduction Basketball is an intermittent high- intensity team sport, which emphasizes the anaerobic and aerobic energy system. The ability to recover from high intensity activities is limited by the individual's aerobic capacity. Different high intensity training (HIT) protocols have been shown to improve aerobic capacity in male soccer and basketball players (Delextrat and Martinez, 2013; Sperlich et al., 2011; Helgerud et al., 2001). The purpose of this study was to investigate the effect of a 5- week in- season, HIT on aerobic fitness, sprinting and jumping ability, in female elite Basketball players. **Methods** 25 female 1st national youth division basketball players (age: 15.1 ± 1.1 yrs, height: 170 ± 5.1 cm, body mass: 60.8 ± 5.9 kg, mean \pm SD) took part in the study. 11 subjects integrated a 5-week HIT in their team training while 14 served as controls and continued their common team- training routine. Two different basketball specific HIT- sessions were conducted twice a week on nonconsecutive days. A long interval session (4 x 4-min, 3 min rest) was conducted 7 times and every third session consisted of short intervals (2 sets of 15 x 30s with 15s rest, 3 min rest in between sets). Before and after the 5-week training intervention, players' fitness was tested through sprint (with and without ball), vertical jump (CMJ, CMJ with arm swing, SJ) and the Yo-Yo intermittent recovery test Level 1 (Yo-Yo IR 1). **Results** No significant changes were observed for either group in the vertical jump tests or both sprint tests. However the Yo-Yo IR 1 performance increased significantly in the HIT group, with no changes in the control group (pre: 1498.2 ± 266.2 m; post: 1894.6 ± 421.2 m; $p = 0.0042$). **Discussion** The HIT sessions did not involve special power related tasks, therefore the sprint and vertical jump performance remained unchanged. However the HIT did not show any negative effect on these values. Previously published studies suggested, either a 4x4 min protocol (Helgerud et al. 2001), a mix of various types of HIT sessions (Sperlich et al. 2013) or a protocol of shorter intervals would improve the aerobic fitness of male elite basketball players (Delextrat and Martinez, 2013). Based on our findings, an in- season HIT program, with short and long intervals, can be conducted to improve aerobic capacity in elite female players. **References** Delextrat A, Martinez A (2013). *Int J Sports Me* (Epub ahead of print) Helgerud J, Engen LC, Wisloff U, Hoff J (2001). *Med Sci Sports Exerc*, 33(11), 1925-31. EFFECT OF HIGH-INTENSITY INTERVAL TRAINING ON 3-MIN ALL-OUT ROWING EXERCISE AND PERFORMANCE IN TRAINED ROWERS

Cheng, C.F.1, Hsu, W.C.2, Kuo, Y.H.1, Lin, P.Y.1, Lee, C.L.3

1: National Taiwan Normal University (Taipei, Taiwan), 2: University of Taipei (Taipei, Taiwan), 3: National Sun Yat-sen University (Kaohsiung, Taiwan)

Introduction: High-intensity interval training (HIT), often performed with an "all-out" effort or at intensity close to maximal oxygen uptake ($\text{VO}_{2\text{max}}$), has been reported to enhance aerobic capacity in untrained [4] and trained [5] individuals. However, few studies examined the benefits of HIT with all-out effort on aerobic capacity and performance in athletes. Our study [1] reported that the end-test power (EP) derived from 3-min all-out rowing test (3-min RT) could appropriately estimate critical power. Thus, this study examines whether such a regimen of HIT could improve $\text{VO}_{2\text{max}}$, EP and performance in rowers. **Methods:** Sixteen male rowers were assigned to either a HIT or an ET (endurance training) group according to their 2000-m time-trial rowing test (2000TT) performance. The HIT group performed 8–12 sets of 30-s Wingate-based rowing sprint with 4-min rest interval, and the ET group performed 60-min rowing at 60% $\text{VO}_{2\text{max}}$. Before and after a 4-wks (3 times/week) HIT or ET, participants performed the incremental rowing test (IRT), 3-min all-out rowing test (3-min RT), and 2000TT to determine the effects of HIT on aerobic capacity and performance. The blood lactate levels were measured before and after these exercise tests. **Results:** The $\text{VO}_{2\text{max}}$ (from 62.4 ± 3.8 to 65.2 ± 3.6 ml/kg/min, $P < 0.05$) and performance in 1000–1500-m (from 112.0 ± 5.6 to 110.0 ± 5.3 sec, $P < 0.05$) were significantly improved after HIT training, however, no significant changes were found in the ET group. Although there were no significant changes in peak (PO_{peak}) and mean (PO_{mean}) power during 3-min RT in HIT group, the PO_{peak} (from 581 ± 80 to 535 ± 70 W, $P < 0.05$) and PO_{mean} (from 319 ± 35 to 301 ± 32 W, $P < 0.05$) were significantly decreased after ET training. No significant changes were found in EP, 2000TT performance, and blood lactate levels after intervention in both groups. **Discussion:** This study showed that HIT might increase $\text{VO}_{2\text{max}}$ (+4.6%) and reduce the third 500-m time (–2.1 sec) during 2000TT, but could not improve the EP, which is in line with previous study for cyclists [2]. However, Driller et al. [3] found that the lactate threshold in rowers could be improved by 4 wks of HIT (8 sets of 2.5-min intervals at 90% $\text{VO}_{2\text{max}}$). The sprint time (30-s) in HIT might insufficiently induce improvements in EP, especially for the rowers, although the HIT could maintain the power output (i.e., PO_{peak} and PO_{mean}) during 3-min RT. Overall, the low-volume HIT is a time-efficient strategy to improve aerobic capacity and performance in trained rowers. Supported by grants from National Science Council, Taiwan (NSC 102-2410-H-003 -142), and "Aim for the Top University Plan" of the Ministry of Education, Taiwan. **References:** 1.Cheng CF, et al. RELIABILITY OF A NEW REPEATED SPRINT ABILITY TEST FOR YOUNG TENNIS PLAYERS

Hernández Davó, J.L., Sarabia, J.M., Fernández Fernández, J., Moya, M.

Miguel Hernandez University

Introduction The ability to repeat short maximal efforts (<10 s) with incomplete resting periods (<90 sec) is widely accepted as a key factor in intermittent sports (as tennis). Therefore, this ability is commonly tested to evaluate players' performance (Fernández-Fernández et al.

2012; Gabbet, 2010). The aim of this study was to evaluate the reliability of a new repeated sprint ability (RSA) test for young tennis players. Methods To evaluate the reliability of the test, five participants performed 3 testing sessions with 48 hours between them. The RSA test consisted on six repetitions of 20m including three changes of directions (two of 180 degrees and one of 90 degrees), in a 20s cycle. The best time, total time and fatigue index were recorded. Samples of lactate pre and post-test (1, 3 and 5 minutes after concluding the test) were collected, and the intraclass coefficient correlation (ICC) and the coefficient of variation (CV) were calculated. Furthermore, participants performed a 20m linear speed test to establish relationships with the RSA test. Results Analysis of ICC showed a very high reliability for the RSA total time (0.99) and RSA best time (0.94) but not for the fatigue index (0.72). The CV was very small for the RSA total time (1.01%) but bigger for the fatigue index (8.75%). Furthermore Pearson's correlation showed high relationships between linear speed (20m) and RSA total time (0.914) and between RSA best time and all the variables measured. Nevertheless the fatigue index only showed medium correlation (0.64) with the measure of lactate 5' post. Discussion Results of ICC agree other studies which have shown the reliability of a specific test of repeated sprint ability (Gabbet, 2010; Wilkinson et al. 2010). The high ICC and low CV of the RSA total obtained with the data of the three sessions performing the RSA test indicate that this is a very reliable test, and therefore it could be a good tool to check improvements in the ability of tennis players to repeat short maximal efforts with brief resting periods. INFLUENCE OF OPPOSITION STANDARD ON WORK-RATE DURING ELITE GAELIC FOOTBALL MATCH-PLAY

Collins, D.K.1, McRobert, A.P.2, Solan, B.1, Doran, D.A.2

1: ITTD (Dublin, Ireland), 2: LJMU (Liverpool, England).

Introduction An appreciation of the physical demands of elite Gaelic football is required so that preparatory practices can be constructed to respond to the demands of match-play. The aim of the present study was to examine the influence of opposition team standard on the work-rate during elite Gaelic football match-play. Methods The opposition standard was classed according to their league division in descending order (division 1 and division 2, 3 and 4). Twenty-six, male elite Gaelic football players competing in division 1 of the national league wore 4 Hz GPS (VXsports, New Zealand) units in 14 (70 min) competitive games (7 Vs. division 1: n=66; 7 Vs. division 2,3, and 4: n=61). Activity was categorized into total distance covered, high-intensity (HI) distance (>17 km-h⁻¹), and HI distance according to halves (35 min). A repeated measures analysis of variance was used; a paired t-test was used to identify variance between each half and statistical significance set at p<0.05. The means and standard deviation are reported. Results When competing against Division 1 teams the total distance (8495 ± 1369 m Vs. 7684 ± 1589 m), HI distance (1642 ± 512 m Vs. 1355 ± 509 m), first half HI distance (861 ± 285 m Vs. 711 ± 255 m) and second half HI distance (781 ± 269 Vs. 644 ± 299 m) was significantly higher (p<.01) than when competing against teams competing in divisions 2, 3 and 4. Regardless of level of competition a significant (p=.001) decrement in performance (9.7 Vs. 9.8 % decline) was observed between the first and second halves. Discussion Increased work-rates are observed when competing against division 1 teams. These findings may suggest higher defensive and offensive demands when competing against a higher standard of opposition. It is unclear if the difference when competing against lower standard teams is due to the opposition's lower physical capacity or inferior technical proficiency. EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON PERFORMANCE AND NEURAL ADAPTATIONS DURING A 2000-M RACE STIMULATION IN ROWERS

Hsu, W.C.1, Cheng, C.F.2, Kuo, Y.H.2, Li, M.X.2, Kuo, Y.C.3

1: University of Taipei (Taipei, Taiwan), 2: National Taiwan Normal University (Taipei, Taiwan), 3: National Taipei University of Nursing and Health Sciences (Taipei, Taiwan)

Introduction: In rowing, the energy of 2000-m race was provided 67-86% aerobically and 14-33% anaerobically [4]. However, endurance and sprint training are not appropriate to develop in the same training session. Driller et al. [2] found that high-intensity interval training (HIT) performed at an intensity of 90% maximal oxygen uptake (VO₂max) could improve VO₂max and 2000-m time-trial (2000TT) rowing performance. Previous studies indicated that HIT with 30-s Wingate-based sprint increased muscle metabolic adaptations in untrained subjects [3], however, there are no studies to examine whether this training strategy could affect the electromyography (EMG) activity during 2000-m rowing race. Methods: Sixteen male rowers were matched for 2000TT performance and assigned to HIT (n = 8) or ET (endurance training, n = 8) group. The HIT group performed 8-12 sets of 30-s Wingate-based rowing sprint with 4-min rest interval, and the ET group performed 60-min rowing at 60%VO₂max. The incremental rowing test and 2000TT were conducted before and after 4 weeks intervention. During the 2000TT, surface EMG signals were collected unilaterally on the muscles of right leg, i.e., vastus medialis, biceps femoris, medial gastrocnemius and tibialis anterior. Results: After training, the VO₂max in HIT group (from 62.4 ± 3.8 to 65.2 ± 3.6 ml/kg/min, P < 0.05) was significantly enhanced, but not in ET group (from 61.9 ± 3.1 to 61.7 ± 2.2 ml/kg/min, P > 0.05). Although the 2000TT performance in both groups were not significantly different before and after training, the split time at 1000-1500-m in HIT group was significantly increased (pre- vs. post-training, 112.0 ± 5.6 vs. 110.0 ± 5.3 sec, P < 0.05). Significant main effects were found between pre- and post-training on the median frequency (MF) of gastrocnemius at the first 500-m (pre- vs. post-training, 66.9 ± 13.8 vs. 61.4 ± 12.0 Hz, P < 0.05), and the MF of biceps femoris at the second 500-m (pre- vs. post-training, 51.7 ± 7.4 vs. 46.0 ± 13.1 Hz, P < 0.05). Discussion: This study showed that HIT might improve VO₂max (+4.6%) and the third 500-m time (-2.1 sec) during 2000TT in rowers, which is in agreement with previous study [2]. Our results are consistent with the study of Creer et al. [1], who found that the HIT could decrease the MF during the 4 sets of 30-s cycling sprints in cyclists. The decrease in MF may induce synchronization of motor units, thus increasing efficiency and coordination [5], and then to improve the rowing performance at the third 500-m. In conclusion, the HIT might be an effective alternative for traditional ET to ameliorate aerobic capacity and performance in rowers. References: 1.Creer AR, et al. (2004). CROSS-COUNTRY SKIING: SPECIAL POWER+ENDURANCE HIIT-TESTING

Shishkina, A., Tarbeeva, N., Tarbeeva, A.

Ural Federal University

Introduction In cross-country skiing huge variety of skiing landscape and snow surface temperature and the lack of standard testing conditions cause the difficulties for objective diagnostics of special skiing physical workability, strength and endurance. Therefore, the aim of this study was to evaluate the diagnostic possibilities of high-intensity interval training (HIIT) for the assessment of skiers special readiness. **Methods** For testing under training conditions Ercolina Upper Body Power Cross-Country Ski Poling Simulator with power meter option that provides digital power readings (distance in meters, speed in km/h, power for each push in watts, etc) was used. After warming-up trained athletes performed diagonal (single) poling using HIIT training named Tabata Protocol consisting of eight sets of 20-second maximal intensity work interval with 10 seconds of passive recovery between each bout. Heart rate monitoring and blood lactate responses at rest, after last work interval and in recovery were under consideration. **Results** The authors of Tabata Protocol Dr. Izumi Tabata and the researchers from the National Institute of Fitness and Sports, Japan suggested to monitor Tabata account, that is the lowest result of 8 intervals. We suggest to analyze the best result among 8 distance intervals, the lowest one, their delta, amount of 8 results (total distance) as well as the speed of results decreasing. For example, the following distance results were obtained: 149-139-138-123-120-118-113-114. **Discussion** The longest distance (149) corresponds to the anaerobic capacity and serves a measure of speed and power abilities. Distance difference (delta between the longest and shortest distances, $\Delta=36$) accepts as a criterion of the development of speed endurance. Total distance (1014) characterizes the special endurance and anaerobic glycolytic potential of performance muscle groups of skiers. The value of the total distance are affected by speed and power abilities levels, long anaerobic endurance and the rate of results decreasing determined from which cycle and how dramatically the results decreasing occurs. It mainly depends on an athlete ability to rapid recovery during 10 seconds of rest. Thus, Tabata interval training can be used to control the level of readiness of skiers, allow to determine the athletes' weaknesses and to design the training program for them. Regular including HIIT test in training process provides necessary information for managing an athlete preparation and also acts as effective exhaustive intermittent workout. Test may be fulfilled with a variety of training facilities as well as be informative in other sport. **References** Tabata I, Nishimura K, Kouzaki M, Hirai Y, Ogita F, Miyachi M, Yamamoto K. CAN A 2-WEEK BLOCK OF HIGH INTENSITY INTERVAL ENDURANCE TRAINING BOOST REGENERATION?

Bubeck, D., Gerdes-Roeben, H., Alt, W.

University of Stuttgart

It is well known that endurance training realised in long slow distance mode has a positive effect on the regenerative capacity. Additionally it can be seen that high intensity interval training is very useful to enhance the capability in endurance, especially when it is organized in a block training structure. This leads to the question of this study: Has a 2-week block of high intensity endurance training an influence on the vegetative nervous system and enhances therefore the ability to regenerate better? In order to analyse this, a trained athlete (24 years, male) performed a two-week high intensity interval program (HIT) with 14 training sessions. Before and after this HIT block one normal week without any additional training programs was analysed. Training program consisted of a 4x4x3 scheme at an intensity level of 90% of VO₂max executed on a cycle ergometer. In order to get information about the effect on the regenerative system (vegetative nerve system – n. parasympathicus) heart rate variability (HRV) was measured during every night with a 12 hours EKG analysis (Schiller Medilog AR4/AR12). The training and the total daily amount of load was measured by analysing the heart rate 12 hours a day using a Polar electro heart rate monitor and a Polar actigraph for the daily load in MET's. In order to look at the training effect on the vegetative nervous system the EKG was frequency analysed and the frequencies were allocated to the bandwidths committed by the Task Force of the European Society of Cardiology and the North American Society of Pacing and Electrophysiology in 1996. The results show that the impact of the training stimulus can be seen as slightly higher values of the heart rate or the MET's during the both high intensity training weeks. But both values were reduced in the week after the training intervention. The training stimulus led to clear reductions of the heart rate at day and in the night in week four. Analysing the parasympathetic dominated high frequency values of the heart rate variability it can be seen that the values were reduced during the high intensive training phase. After finishing the training process a clear rise in the high frequency values can be seen. Analysing the log of the high frequency/low frequency values of the heart rate shows the same. Additionally using the HRV to predict phases of deep sleeping shows that after the two training weeks the athlete has clear longer deep sleeping phases. These results show that a high intensity training in block training organisation can enhance the ability to regenerate analysed by the higher activity of the nervous parasympathicus.

PERSONAL MOBILE TRACKING OF RESTING AND POST-EXERCISE ENERGY EXPENDITURE REFLECTS EPOC EFFECTS FOR ENHANCED PHYSICAL TRAINING

Jackemeyer, D., Xian, X.J., Tsow, F., Anderson, T., Terrera, M., Tao, N.J., Forzani, E.

Biodesign Institute

INTRODUCTION AND OBJECTIVES: Energy Expenditure (EE) is energy, sustaining life at resting conditions, physical activities, and recovery from physical activities. Estimation of EE during physical activities can be tracked with technologies such as accelerometers. However, EE at sleep, resting conditions, and post-exercise can be strictly assessed at clinical or sport facilities via indirect calorimetry. New emerging technologies are bringing cost-effective mobile indirect calorimetry, making resting energy expenditure (REE) and Excess Post-Exercise Oxygen Consumption (EPOC) parameters easily assessed under free-living conditions. Our study objectives were to explore: 1- the feasibility of study participants to independently use a mobile EE tracker, 2- the capability of the tracker to detect personal REE and EPOC, and 3- the relationship of the EPOC with muscle growth. **SUBJECTS AND METHODS:** Thirty subjects (16 male and 13 female), BMI (17.3 - 31.8), aged (20 - 42 years) divided into a control group (CG, n=11) and a High Intensity Interval Training (HIIT) intervention group (IG, n=19) self-monitored their REE and EE with a personal mobile indirect calorimeter tracker (www.breezing.co). at pre- and post-exercise during high intensity interval training (HIIT). The exercise protocol of HIIT consisted of 8 sets of 20-seconds kettle bell thrusters or sandbag front squats with 10 seconds of seated resting between sets, totaling 4 minutes per session. The HIIT was repeated 3 sessions per week for 6 weeks. The Breezing tracker measurements were performed by CG and IG at the beginning, middle, and end of the study, and each measurement day included REE and EE values. IG measurements were conducted throughout HIIT days at pre- and post-exercise (enabling quantification of EPOC); as well as on non-HIIT days at HIIT-day equivalent timing periods. CG measurements were assessed similarly to non-HIIT day conditions. Body composition was estimated via skinfold and perimeter analysis. **RESULTS:** The Breezing tool enabled each

subject self-measurements of EE. In total, over 640 measurements were conducted. Clear EPOC was measured on HIIT days. We detected significant differences in EPOC from IG HIIT days vs. IG non-HIIT days as well vs. CG non-HIIT days ($p < 0.0001$) ($\alpha = 0.05$). The capability to grow muscle mass after 6-weeks emerged in IG vs. CG ($p < 0.0001$). Lastly, we found that IG subjects with $> 6\%$ muscle growth also demonstrated higher EPOC effect (average 247 kCal/day) vs IG subjects with $< 1\%$ muscle growth (average 47 kCal/day). CONCLUSION: Personalized indirect calorimetry tracking to assess EE and EPOC was shown to be easily feasible with the mobile Breezing tracker. The tracker detected personal EPOC as expected for IG in a HIIT day. An EPOC effect was shown with confidence and a low-precision condition ($\alpha = 0.20$) to be correlated with higher muscle growth within IG. The personal EPOC may inform about exercise recovery and long-term muscle mass growth.

PSYCHOLOGICAL RESPONSES TO AN ACUTE BOUT OF HIGH-INTENSITY INTERVAL AND MODERATE-INTENSITY CONTINUOUS TRAINING IN SEDENTARY WOMEN

Lin, Y.J.1, Yu, H.C.2, Chu, I.H.3

KMU(Kaohsiung, Taiwan)

Introduction While the physiological adaptations that occur following exercise training are more extensively studied, the psychological responses to some types of exercise training remain unclear. Differences in psychological responses between high intensity interval training (HIIT)(Laursen & Jenkins, 2002) and moderate intensity continuous training (MICT) are still unknown. Different training programs may result in different emotional responses. Thus, the purpose of this study was to compare the effects of an acute bout of HIIT and MICT on psychological responses in sedentary women. **Methods** Ten sedentary women (mean age 20.9 ± 1 yr) participated in the study. All participants completed a graded exercise test on a cycle ergometer to determine their peak oxygen uptake (VO_2) and maximal workload. Next, participants performed two exercise sessions (HIIT and MICT) in random order. The two sessions were scheduled at least 48 hours apart. The HIIT consisted of 3 minutes of warm-up and 18 minutes of main exercise, in which participants cycled 60 seconds at maximum intensity followed by 75 seconds of recovery at 50 watts repeated for 8 intervals. The MICT consisted of 3 minutes of warm-up and 17-23 minutes of main exercise at 50% VO_2 reserve. Psychological responses were assessed at baseline, midpoint, the end of exercise session, and 5, 15, and 30 minutes post exercise, using the rating of perceived exertion (RPE) and Self-Assessment-Manikin (SAM). SAM is a non-verbal pictorial assessment technique that measures three dimension of person's affective reaction: pleasure, arousal, and dominance.(Bradley & Lang, 1994) **Results** The results showed significant differences between HIIT and MICT in pleasure scores of SAM at midpoint (4.90 ± 1.4 vs. 6.40 ± 1.3 , $p = 0.005$), end (5.20 ± 1.4 vs. 6.70 ± 1.6 , $p = 0.015$) of the exercise. Arousal scores of SAM showed significant differences at end (5.90 ± 1.6 vs. 3.80 ± 1.8 , $p = 0.023$) of the exercise, and 5 min (3.80 ± 1.5 vs. 2.20 ± 1.3 , $p = 0.011$), 15 min (3.30 ± 1.3 vs. 1.70 ± 0.9 , $p = 0.002$) post exercise session. Dominance scores of SAM showed significant differences at midpoint (4.20 ± 1.4 vs. 3.10 ± 0.9 , $p = 0.007$), end (4.60 ± 2.0 vs. 2.70 ± 1.3 , $p = 0.003$) of the exercise. The RPE score also showed significant difference between two test sessions at midpoint (13.90 ± 1.7 vs. 12.10 ± 1.9 , $p = 0.008$) of the exercise. **Discussion** The results of this study showed that different exercise program may have different influences on emotional responses. Sedentary women appeared to have better psychological responses in MICT than in HIIT. It is suggested that MICT may be a more suitable and acceptable exercise program for this population. **References** Bradley, M. M., & Lang, P. J. (1994). J Behav Ther Exp Psychiatry, 25(1), 49-59. THE TRANSFER FROM PERCEPTUAL-COGNITIVE SKILLS TRAINING OF ANTICIPATORY JUDGMENTS TO FIELD AND ANXIETY CONDITIONS IN ELITE ATHLETES

Alder, D.B.1, Ford, P.R.1, Causer, J.1, Williams, A.M.2

1: Liverpool John Moores University (UK), 2: Brunel (UK)

Introduction Anticipatory judgments and the visual search strategies used to make them are a key part of expert sports performance. Researchers have shown these judgements can be improved through laboratory-based training (Hagemann et al., 2006). However, they are yet to examine whether these laboratory-based improvements transfer to the field or to anxious conditions. The aim of this study was to examine the transfer from perceptual-cognitive skills training of anticipatory judgements in the laboratory to the field and to anxious conditions for elite badminton players. **Method** Participants were 16 international badminton players assigned to either a training group or a control group in a pre-acquisition-post-test design. In pre- and post-tests, both groups completed a laboratory and field-based temporal occlusion test in which they anticipated serve direction under high and low anxiety conditions. In acquisition between tests, the training group received a perceptual-cognitive training intervention detailing the "gold standard" visual search used by Olympic players with trial-by-trial video feedback on their performance, whereas the control group did not. A mobile eye tracker was worn throughout to collect visual search behaviour. Anticipation judgment accuracy and visual fixations were analysed in ANOVA. **Results** In the laboratory pre-test, there were no between-group differences in judgement accuracy (66 %) or final visual fixation duration (1829 ms), but accuracy was lower and final fixation shorter in the high compared to low anxiety condition. In the laboratory post-test, the training group made more accurate judgements (79 %) and had a longer final fixation (2293 ms) compared to both their pre-test (68 %; 1848 ms) and the control group (63 %; 1877 ms) under both high and low anxiety conditions, albeit judgements were less accurate and final fixations were shorter in the high anxiety conditions. In the field pre-test, there were no between-group differences in judgement accuracy (82 %); whereas in the post-test the training group made more accurate judgments (87 %) compared to the control group (78 %). **Discussion** Perceptual-cognitive skills training increased the accuracy of anticipatory judgements compared to control, supporting previous research (Hagemann et al., 2006). The improvements in anticipatory judgments from the training in the laboratory transferred to improved judgments in the field, when compared to control, but did not transfer to anxious conditions. Findings show how training programmes can be

created to improve anticipatory judgments in the field and for anxiety-inducing conditions. References Hagemann, N. et al. (2006). *J Spo & Ex Sci*, 28, 143-158 Contact D.Alder@2008.ljmu.ac.uk

CONTEXTUAL INTERFERENCE AND COGNITIVE EFFORT IN PERCEPTUAL-COGNITIVE SKILLS TRAINING

Broadbent, D.P.1, Causer, J.1, Ford, P.R.1, Williams, A.M.2

1. *Liverpool John Moores University (UK)*, 2. *Brunel University (UK)*

Introduction The contextual interference (CI) effect shows that motor skills practiced in a random order lead to superior learning compared to a blocked order. Greater cognitive effort has been hypothesised during random compared to blocked practice, either through reconstructive processes prior to skill execution or elaborative comparisons directly after (Li & Wright, 2000). The CI effect has recently been extended to perceptual-cognitive skills training of anticipatory judgments in sport. Cognitive effort and its timing around a judgment are yet to be investigated. The aim of this study was to examine the acquisition of anticipatory judgments in tennis under random or blocked practice conditions and the timing of cognitive effort associated with optimal acquisition. **Methods** In the primary task, novice participants in either random ($n=12$) or blocked ($n=12$) practice groups anticipated shot direction from video of opponent tennis shots that occluded at ball-racket contact. Response accuracy (RA) and decision time (DT) were recorded during a pre-test, three practice sessions, post-test, and transfer test to a novel practice condition. During practice, two versions of the same video were shown per trial. The first video occluded and participants responded, whereas the second video directly after the response did not occlude providing feedback. A secondary choice reaction time task involving responses (RT) to high but not low tones was used to assess cognitive effort across each video independently. Greater cognitive effort in the primary task should lead to slower RT in the secondary task. RA and DT in the primary task and RT in the secondary task were analysed using ANOVA. **Results** In the primary task, the blocked group (21 ± 2 trials) had higher RA scores across practice compared to the random group (18 ± 2 trials) ($P<.05$). In the transfer test, the random group (22 ± 3 trials) had greater RA compared to the blocked group (19 ± 2 trials) ($P<.05$). In the secondary task, the random group (496 ± 127 ms) had slower RT compared to the blocked group (394 ± 101 ms) in both the video prior to the response and after it during the feedback video ($P<.05$). **Discussion** Random practice led to better transfer of learning compared to blocked practice, verifying that the CI effect extends to perceptual-cognitive skills training. The data suggests random practice increases cognitive effort invested on the task across acquisition, contradicting previous hypotheses that state it occurs either prior to, or directly after, skill execution (Li & Wright, 2000). Findings demonstrate the importance of high cognitive effort during practice for the learning of perceptual-cognitive skills. References Li Y, Wright DL (2000). *Q J Exp Psychol*, 53A, 591-606. EFFECTIVENESS OF SPORTS VISION TRAINING

Cordes, J., Jendrusch, G., Platen, P.

Ruhr-Universität Bochum, Faculty of Sports Science

Introduction Users of sports vision trainings (SVT) are promised an increase in visual performance (related to sports). So far there is, however, no evidence for SVT's efficiency, which on the one hand is due to the lack of scientifically adequate studies. On the other hand in the remaining studies no significant positive effects on visual or sports related performance are reported. The aim of the present study was a comparison between a SVT, currently (also) used in high performance sports, including a series of coordinative, visual-dynamic, eye moving and stereoscopic exercises and a placebo type exercise that only worked with exercises on a screen. **Methods** The participants were randomly split up into one experimental ($n=18$; mean age 22.6 ± 3.0 years) and one placebo group ($n=16$; mean age 22.9 ± 3.6 years) after collecting pre-training data which next to visual acuity examined peripheral vision, stereoscopic vision and depth perception, the afferent and efferent dynamic visual acuity, anticipation performance as well as the reaction time. Three times a week all subjects participated in a 60-minutes training under the instruction and supervision of sports vision trainers, either at five different training stations from sports vision (experimental group) or at the screen and with the "Augen-Training TM" by Nintendo® (placebo group). After training the above-mentioned visual performance diagnostics were carried out again (by a "blinded" test supervisor). **Results** In the visual performance diagnostics none of the eight visual parameters examined showed group specific significant differences attributable to the SVT. This holds for the two mostly focussed training goals/variables, stereoscopic vision/depth perception (three test series with the help of the three-rod-test according to Helmholtz: $p=0.645$, $p=0.208$, $p=0.837$) and movement perception (afferent: $p=0.207$) or oculomotor performance (efferent: $p=0.949$). Therefore no effects on visual performance followed from the SVT. **Discussion** The results from the present RCT-study confirm previous findings by Abernethy and Wood (2001) and van Velden (2010), assessing SVT as an ineffective method for improving the performance of perception and vision. The fundamental ability to train individual components of visual performance (e.g. oculomotor performance) was often discussed and is scientifically established. However, generalized (nonspecific) SVT under the presently investigated conditions lacks effect-focused specificity. References Abernethy B, Wood J M (2001). Do generalized visual training programmes for sport really work? An experimental investigation. *Journal of Sports Sciences*, 19(3), 203-222. Velden D van (2010). The effect of a perceptual-motor training programme on the coincident anticipation timing and batting performance of club cricket players. Stellenbosch University. Contact jessica.cordes@rub.de

CO-ACTIVATION DURING MAXIMAL AND SUBMAXIMAL STRENGTH TESTS IN ADOLESCENTS WITH SPASTIC CEREBRAL PALSY

Eken, M.M., Dallmeijer, A.J., Doorenbosch, C.A.M., Dekkers, H., Becher, J.G., Houdijk, H.

VU University Medical Center

Introduction Muscle weakness is a common motor impairment in individuals with cerebral palsy (CP). Dynamometry is widely used among individuals with CP to quantify this impairment. However, increased muscle co-activation (CA) in individuals with CP might reduce the validity of these measurements. Therefore, the aim of this study is to investigate the degree of muscle co-activation during maximal and submaximal dynamometer tests in adolescents with CP in comparison to TD adolescents. **Methods** Electromyography (EMG) recordings were made of the quadriceps (m.rectus femoris (RF), m.vastus medialis (VM), m.vastus lateralis (VL) and hamstrings (m.biceps femoris (BF), m.semitendinosus (ST)) in 16 adolescents with CP (GMFCS level I/II) and 15 typically developing (TD) adolescents of 12-19 years old. Subjects performed maximal voluntary isometric knee extension and flexion contractions (MVCs) and series of submaximal isotonic knee extension contractions at three different loads (50-90% of the maximal torque) on a dynamometer. The EMG amplitude (amp) was normalized to the amplitude during MVCs. Co-activation index (CAI) was calculated for each extension contraction using the formula: $CAI = 1 - (\text{amp agonist} - \text{amp antagonist}) / (\text{amp agonist} + \text{amp antagonist})$ (1). CAI was averaged over three MVCs and the first three repetitions

of series of isotonic contractions. Differences in CAI between CP and TD during MVCs were assessed, as well as differences in CAI over different submaximal loads. Results Adolescents with CP showed in the RF and BF a significantly higher CAI during MVCs than TD adolescents, showing a mean CAI [confidence interval] for CP: .542 [.290-1.346] and for TD: .344 [.097-.765] ($p=.03$). Similar results were obtained for the other agonist-antagonist pairs. No differences in CAI were observed between the two groups for all submaximal isotonic conditions. Discussion During isometric MVCs, adolescents with CP showed higher CAI levels than TD adolescents, while there were no differences in CAI during submaximal isotonic contractions. The results suggest that dynamometer measurements with maximal contractions are more influenced by co-activation than submaximal contractions in adolescents with CP. Although there is not a one-to-one relationship between muscle activation and muscle strength, results suggest that with a higher CAI, the strength of the agonists may be underestimated in individuals with CP. Submaximal muscle testing may therefore be preferred when assessing muscle strength in children with CP. Reference (1) Doorenbosch, CAM & Harlaar, J (2003) Clin Biom, 18, 142-9. MENTAL IMAGERY AND MOVEMENT OBSERVATION OF BALANCE TASKS: ACUTE EFFECTS ON BRAIN ACTIVITY AND BEHAVIORAL LONG-TERM ADAPTATIONS

Keller, M., Mouthon, M., Annoni, J.M., Taube, W.

University of Fribourg

Introduction Immobilization is often related to impaired postural control and increased risk of falling (Visschedijk et al. 2010). Therefore, alternative training regimes are needed as countermeasures during long periods of immobilization when no physical training is possible. Mental imagery and movement observation may constitute such countermeasures. Therefore, the present study evaluated its effects twofold: In Protocol 1, brain activity was assessed by means of fMRI during mental imagery as well as active and passive observation of different postural tasks. In Protocol 2, long-term behavioral effects on postural control of non-physical balance training were analyzed before and after 4 weeks of training. Methods Protocol 1: fMRI data were recorded in 16 healthy subjects (27 ± 4.8 years). The protocol contained three different parts: active observation, passive observation, and mental imagery. In contrast to passive observation, subjects were instructed to imagine that they were actually the person shown in the video during active observation. In each of the three conditions, two tasks were evaluated: i) static standing on solid ground and ii) medio-lateral perturbation on an instable surface. Protocol 2: Dynamic and static balance performance were measured before and after a training program of 4 weeks. Subjects ($n=35$) were assigned either to a mental (MBT) or an active observational balance training (OBT) group or served as controls (CON). Results Protocol 1: Our results indicate that i) motor imagery and active motor observation activate brain regions important for balance control (Putamen, Cerebellum, Supplementary and pre-motor Area), ii) subjects displayed higher brain activation in the more challenging (dynamic) postural task, iii) passive observation was not able to induce significant activity in brain areas responsible for balance control. Protocol 2: After training, we observed a significant interaction of TIME * GROUP. Post-hoc tests revealed significant reductions in sway path for OBT and MBT groups in both perturbed and static conditions, whereas CON showed unaltered performance. Discussion Protocol 1 suggests that motor imagery and active but not passive movement observation represent suitable tools to activate brain regions, which are associated with postural control. Protocol 2 shows improved postural control after MBT and OBT. Noteworthy, this is the first study indicating that non-physical training does not only promote motor learning of 'rigid', pre-programmed tasks but also improves performance of highly variable and non-predictable motor actions such as regaining balance after perturbation. This finding might be relevant for the prevention of falls. References Visschedijk J, Achterberg W, Van Balen R & Hertogh C (2010). J Am Geriatr Soc 58, 1739-48 martin.keller@unifr.ch

GAIT PARAMETERS ARE SENSITIVE TO COGNITIVE DECLINE IN OLDER ADULTS

Marusic, U.1, Kavcic, V.2, Gerzevic, M.1, Dolenc, P.1, Piacentini, M.F.3,4, Meeusen, R.4, Simunic, B.1, Pisot, R.1

1:Institute for Kinesiology Research, SRC, UP, (Koper, Slovenia); 2:Institute of Gerontology, WSU (Detroit, USA); 3:IUSM (Rome, Italy); 4:VUB (Brussels, Belgium)

Introduction Cognition and mobility are interrelated in older adults and both decline with aging. Even though walking is mostly controlled by sub-cortical brain regions and generally performed automatically by healthy adults it has been shown that walking involves complex cognitive and sensory processes (Hausdorff et al., 2005). However, in older adults, more attention is required while walking, indicating the involvement of attentional resources in gait (Beauchet & Berrut, 2006). Therefore, we tested if gait parameters could serve as screening approach in clinical practice for early detection of cognitive decline. Methods A sample of 118 older adults (66.6 ± 5.3 years; 39% men) participated in the study. Gait speed (GS) and width (GW) were obtained with OptoGait system (Microgate, Bolzano, Italy) in single-task (ST) and dual-task (DT) conditions (loud counting backwards by 3 from a random number between 400 and 500). Counting accuracy coefficient (CAC) was calculated from total amount of subtracted numbers and errors (Err) made during DT walking. Additionally, dual-task cost (DTC) was calculated for GS and GW parameters as $DTC = (DT-ST)/DT \times 100$. The Montreal Cognitive Assessment (MoCA) test was used to assess global cognitive function of the participants. A multiple linear regression analysis was used to determine which gait variables are the best predictors of performance on MoCA. Furthermore, a discriminant function analysis was used to evaluate the percent of correct subject classification. Results Multiple regression analysis showed that CAC ($\beta=.263$, $p=.004$) and GW_ST ($\beta=-.194$, $p=.032$) are significant predictors of MoCA score, explaining 12.3% of variance. However, separate multiple regression for the lower cognitive performance group ($MoCA \leq 25$) identified significant predictors in Err ($\beta=-.557$, $p=.001$) and GW_DTC ($\beta=.391$, $p=.010$), explaining 48.7% of variance. Furthermore, discriminant function analysis using gait parameters correctly classified 77.6% of subjects in terms of normal/impaired on the MoCA performance. Discussion Results showed that specific gait parameters can predict MoCA scores, with GW_DTC and CAC as the best predictors of cognitive impairments. The outcomes of our study validate that gait could assist for early detection of mild cognitive impairments, potential precursor to dementia. Furthermore, gait parameters could also be used as outcome measures in the development of new prevention and rehabilitation interventions for older adults. References Beauchet O, Berrut G (2006). ON-LINE VISUAL FEEDBACK PROMOTES MORE IMPLICIT ADAPTATION TO A VISUOMOTOR ROTATION THAN POST-TRIAL FEEDBACK

Schween, R.1, Taube, W.2, Gollhofer, A.1, Leukel, C.2

1:Univ. Freiburg, Germany, 2:Univ. Fribourg, Switzerland

Introduction Visuomotor rotation experiments are frequently used to separate underlying processes of motor learning. Recent concepts (Haith & Krakauer 2013) propose four such processes: Explicit learning uses aiming strategies. Implicit adaptation updates an internal model based on prediction errors. Model-free reinforcement strengthens behavior that is successful, and use-dependent learning creates a bias towards repetition of earlier movements. Previous studies found that on-line (OL) feedback causes larger aftereffects than post-trial (PT) feedback and concluded that a greater amount of implicit adaptation was responsible for these effects (Hinder et al. 2008, 2010, Shabott & Sainburg 2010). However, aftereffects in these designs may be caused by implicit adaptation, use-dependent learning and/or model-free reinforcement. We therefore used a design introduced by Mazzoni and Krakauer (2006), which is selectively sensitive to implicit adaptation. **Methods** Subjects performed center-out drawing movements on a touchpad. They received cursor feedback on a screen, where targets were to be hit. Subjects in the OL group (N=10) saw a cursor on a screen representing the position of their hand throughout the movement, while subjects in the PT group (N=10) only saw the final position. After 72 baseline trials, visual feedback was rotated by 45° counterclockwise around the start. Subjects were instructed to aim at clockwise adjacent targets to counter the rotation for 80 trials. Group differences from end of baseline to end of the rotation were tested by ANOVA with post-hoc T-tests between groups. **Results** Both groups were accurate in baseline (OL: mean direction error: $-1.4^{\circ} \pm 2.0^{\circ}$, PT: $-0.9^{\circ} \pm 2.9^{\circ}$, $P=0.68$) and immediately countered the rotation using the strategy. In the subsequent trials, the PT group continued accurate performance, while the OL group drifted clockwise and thus overcompensated for the rotation (cf. Mazzoni & Krakauer 2006). The ANOVA revealed a significant TIME x GROUP interaction ($F = 16.485$, $P < 0.001$). Post-hoc tests indicated a significant difference between groups at the end of rotation (OL: $15.1^{\circ} \pm 11.2^{\circ}$, PT: $0.7^{\circ} \pm 2.0^{\circ}$, $P=0.002$). **Discussion** Overcompensation cannot be driven by task success (model-free reinforcement) or repetition (use-dependent learning), but rather reflects implicit adaptation driven by prediction error. On-line feedback in our experiment therefore promoted more implicit adaptation than post-trial feedback. **References** Haith & Krakauer 2013. *Adv Exp Med Biol* 782:1-21. CONTOUR ANALYSIS, A NOVEL APPROACH TO PERFORMANCE MONITORING IN MOVEMENT SCIENCE

Van der Eb, J., Coolen, B.

VU University Amsterdam

Introduction In elite sports feedback is used more and more to evaluate performance and optimize training programs to the individual needs of the elite athlete (Sands & Stone, 2005). Contour Analysis (CtA) is a novel way for analyzing movements on a daily basis in high performance sports; it is part of an automatic video capture and playback system, the CoachCockPit. Parameters like position, velocity and average body angle are obtained and also less straightforward parameters as step length or step frequency or 3D discus trajectory and speed can be investigated with CtA. The system is designed to operate fully automatic with a minimum of user input. Performance parameters obtained with CtA can be used for direct feedback and to monitor progress over longer periods of time. To illustrate this several examples in different sports are discussed. The CoachCockPit is developed with primarily the coach perspective in mind: it does not interfere with daily training or impede the athlete. **Methods** The process of analyzing a movement with the CoachCockPit generally consists of 5 steps: automatic capture of the movement, displaying for visual feedback, analysis of the footage producing raw data and the specific movement depended analysis and presentation of the results. In a basic setup one camera (up to 3) is positioned perpendicular to the plane of motion. Calibration of the video data is necessary if results of different setups are to be compared. For instance when measurements taken at competitions are to be compared with a daily training situation. With a fixed setup all the video footage can be collected at every training session producing a very detailed database for monitoring purposes. The automatic analysis produces raw data like center of mass, general direction of body, elongation (over 15 basic parameters) and the contour of the body. The parameters are all taken from the footage and therefore represent an optical representation of a biomechanical quantity. For the use in 'direct' feedback and monitoring performance they can be used as similar quantities, with sufficient accuracy. In a Hurdle experiment the standard deviation is ~5 cm, the comparison with laser gun data is good (Tillaar & Eb, 2014). Standard procedures used for marker kinematic data like filtering or fitting can be applied. The raw data is used to calculate performance parameters, e.g. jump height from the center of mass trajectory (Eb et al., 2010). **References** Eb, J.W.v.d., Filius, M., Rougoor, G., Niel, C.V., Water, J.d., Coolen, B., & Koning, H.d. THE INFLUENCE OF FAMILIARISATION ON VARIATION IN PERFORMANCE DURING JUMPING

Pollitt, L., Bissas, A.

Leeds Metropolitan University

Introduction Jumping tasks are often used to assess the level of development of the lower extremities, and the reliability of the counter-movement jump (CMJ) in this regard has been extensively established (Moir et al., 2004). The reliability of the more complex drop-jump (DJ) is however less established as the goal of minimising ground contact time (GCT) while maximising subsequent jump height, especially at greater drop heights, requires a high degree of athletic competence in the test subjects. Therefore, without extensive familiarisation of less-trained subjects with the DJ, the influence of performance variability likely results in low credibility of test results used to evaluate the effectiveness of training interventions. **Methods** 44 males undertook a 2-week progressive DJ familiarisation, in preparation for a 6-week training study, onto surfaces with varying levels of stability. Within 6 sessions, participants completed a total of 120 DJ (0.5-1m), and also a further 48 jumps (CMJ, DJ0.2, 0.6 and 1m) to replicate the testing component, onto a force platform (1000Hz). At the initial stage, the best CMJ were determined from jump height (JH), and DJ from GCT and reactive strength index (RSI), calculated from the resultant JH/GCT. The within-subject variability for a large number of mechanical and performance variables was assessed by a range of relative and absolute reliability statistics including limits of agreement (LOA) and coefficient of variation (CV%). **Results** Variability (CV%) across CMJ performance (3.1-4.7%) was much lower than for all DJ variables (7.5-16.2%), however a trend of a reduction in variation was observed across each variable over the 6 sessions. The greatest reduction in variation was observed during DJ from 1m for RSI from 16.2-11.6% (LOA: -19.1 & 54.4 to -8.2 & 34). Similar changes in variation also occurred at DJ0.6m for both: CGT 12.3-8.4% (LOA: -0.027 & 0.140 to -

0.018 & 0.085) and RSI 13.4-9.1% (LOA: -10.3 & 45 to -7 & 35.8). The mean improvement in GCT at DJ0.6m was 311ms - 262ms (15.7%). Discussion These findings highlight the importance of familiarisation to establish variability and systematic errors within tasks requiring a greater degree of competence. As indicated, CMJ variability was relatively small and stable however the measures of absolute and relative reliability for DJ variables showed that the combined error reached high levels. Therefore, due to the greater variation in DJ performance variables across increasing drop heights, test results should be interpreted with caution especially if used to assess training adaptations. ANAEROBIC POWER IN PUBERTAL FOOTBALL PLAYERS: THE DIFFERENCE BETWEEN TRAINED AND UNTRAINED SUBJECTS

Mendes, J., Vences Brito, A., Rodrigues Ferreira, M.A., Fernandes, R., Prudente, J.

University of Madeira

Introduction The anaerobic metabolism plays a key role during acyclic sports activities like football, making from this a relevant study subject, either in adults or children. About children, there are some authors that had study the anaerobic issue (Andreacchi, Haile & Dixon, 2007; Rowland, 2005) and how it develops among the childhood. This study aims to compare the anaerobic performance from 42 pubescent teenagers on an anaerobic test where 21 subjects play federated football (T) and 21 individuals were sedentary (without formal sport) (NT). **Methods** The T group had a mean age of 13.9 ± 0.7 years old and the NT group had 13.9 ± 0.8 years old. A Wingate Anaerobic Test was applied on both groups in order to access to the subjects Peak Power (PP), Average Power (AP), Relative Peak Power (PPrel), Relative Average Power (APrel), Drop Power (DP), % DP and Heart Rate (HR). All data was processed with SPSS 20.0 software. **Results** The results obtained shown us differences between the groups on relative variables like PPrel (T: $9.4 \pm 1.0 \text{ W} \cdot \text{kg}^{-1}$; NT: $8.7 \pm 0.9 \text{ W} \cdot \text{kg}^{-1}$) and APrel (T: $6.2 \pm 0.6 \text{ W} \cdot \text{kg}^{-1}$; NT: $5.5 \pm 1.1 \text{ W} \cdot \text{kg}^{-1}$) with very strong performance on absolute variables like PP (T: $511.3 \pm 88.6 \text{ W}$; NT: $511.1 \pm 118.6 \text{ W}$) and AP (T: $336.6 \pm 47.7 \text{ W}$; NT: $320.0 \pm 79.9 \text{ W}$). No differences were found between the groups anthropometrically and that fact makes the comparison possible. **Discussion** The obtained values were in agreement with what was found in the literature (Arslan, 2005; Rowland, 2005) and the differences founded on the relative variables (PPrel and APrel) indicates that practicing football, in a regular basis, during the puberty process, seems to lead in to an increase of the anaerobic metabolism. This idea is supported by the results once that absolute variables are profoundly related to the body weight while relative variables exclude that factor giving to the investigators a better notion about the real metabolic capacity and power.

EFFECTS OF DETRAINING ON METABOLIC DEMANDS AFTER 12 WEEKS OF VIGOROUS TRAINING PROGRAM IN A RANDOMIZED GROUP OF OVER 65 YRS

Migliaccio, G.M.1, Roberto, S.2, Padulo, J.1, Mulliri, G.2, Marcelli, M.2, Loi, A.2, Omeri, M.3, Collu, G.1, Milia, R.2

1) CONI Italian Olympic Committee, Sardegna - 2) University of Cagliari - 3) HKSI Hong Kong Sports Institute

Exercise training for subjects over 65 should be applied to improve quality of life. However, physiological adaptations are transitory and disappear after training reduction or cessation (Bousquet et al, 2013 - Mujika & Bousquet, 2010). Beside detraining exerts well known effects in young athletes, while limited information is available for elderly individuals. **PURPOSE:** The aim of this study was to investigate the effects of 8 weeks of detraining in elderly subjects (age > 65 yrs), after 12 weeks of exercise prescription at vigorous intensity. **METHODS:** 17 healthy participants (69.3 ± 4.3 yrs) performed a randomized controlled trial on training program about 12 weeks at vigorous intensity (range 64-85% of Heart Rate Reserve) followed by 8 weeks of detraining. Before and after the training cessation period, subjects underwent an exercise test on a cycle Ergometer test until exhaustion to assess VO_2max . Heart Rate Recovery HRR, Waist-Hip ratio (WHR) and Body Mass Index (BMI) were also assessed. All the activities were monitored in real time by HR in Telemetry (Hosand) to maintain the %HRR and verified after training bout with an HRV test (Minicardio Hosand). Paired t-test were used to compare the detraining effects on all variables before and after 8 detraining weeks. **RESULTS:** VO_2max decreased by 6,65% during the training cessation period (24.2 ± 4.7 to $22.6 \pm 4.5 \text{ ml/kg/min}$ $p=0.32$). However, BMI decreased by 5,3% (26.5 ± 3.5 to $25.1 \pm 3.9 \text{ kg/m}^2$ $p=0.24$). Conversely HRR increased by 7% (62.1 ± 8.8 to $67.1 \pm 9.2 \text{ bpm}$ $p=0.15$) these decrement were not significant. WHR increased significantly by 9% (0.92 ± 0.06 to 1.01 ± 0.09 $p<0.05$). **CONCLUSIONS:** In the present investigation, after the training stoppage period following a vigorous training program, subjects were able to maintain a level of VO_2max without a negative effect. Training exercise at vigorous intensity, instead of moderate intensity which is more commonly applied, was more positive also for BMI and HRR, otherwise The WHR were significantly different. Previous studies, employing moderate intensity (64% Heart Rate Reserve) showed higher tendencies to return back to the pre-training level during detraining. The Medical Doctors could consider also vigorous intensity exercise on the prescription of physical exercise for elderly.

SOLE PARAMETERS OF 5TH GRADE CHILDREN IN NEPAL

Ueda, K., Kokudo, S.

Kobe University

Introduction The foot status of children are influenced many factors such as heredity and environment. It is assumed that the Nepal geographical condition such as hill or mountain environment affect the growth status, especially the foot condition of children are very influenced their walking habit in hill / mountain area. This pilot study was aimed to investigate sole parameters in Nepal hill area. **Methods** The samples were 61 healthy children (38 boys and 23 girls) aged 10-13 years, 5th grade of higher secondary school in Pokhara, Nepal. We measured height and weight of children. Sole photos of the children were taken using a Pedoscope on December 2013. Foot length,

foot width, toes form, planter arch condition and thumb angle were measured from the sole photos. Results and discussion There were significant sexual difference between the height ($t=0.08$, $p<0.01$) and weight ($t=0.2$, $p<0.05$). The height and weight of girls (height= 143.8 ± 8.4 cm, weight= 36.8 ± 9.0 kg) were larger than those of boys (height= 138.3 ± 7.2 cm, weight= 32.1 ± 6.0 kg). There was no significant sexual difference on the sole parameter (foot length (R)= 22.1 ± 2.6 cm, (L)= 22.1 ± 1.18 cm, foot width (R)= 8.8 ± 5.1 cm and (L)= 8.9 ± 5.1 cm for boys, foot length (R)= 22.1 ± 2.6 cm, (L)= 22.1 ± 1.18 cm, foot width (R)= 8.8 ± 5.3 cm and (L)= 8.9 ± 5.1 cm for girls). The width/length ratio (boys=40.1%, girls=40.0%) was similar to the Japanese (boys=39.7%, girls=39.5%). Although Nepal children showed low rate of flat arch (R=4.9%, L=4.9%), they showed very high rate of high arch (R=36.1%, L=27.9%) and very high arch (R=16.4%, L=23.0%). The high arch rate (high + very high, R=52.5%, L=50.9%) of Nepal children were much higher than Japanese children (25%). Prevalence of light hallux valgus were (R)=6.6% and (L)=1.6%, medium hallux valgus were (R)=1.6% and (L)=0%. The shape of the foot is classified into three categories; Egyptian type was 86.9%, Greek type was 13.1% and Square type was 0%. The results suggest that Nepal children have a high incidence of high arch and very high arch. Nepal children usually wear school-shoes in their daily life. However, we observed that they play physical activity such as football, running without shoes even if they are high school students. Additionally, many of them need to walk more than 30 minute on a lot of steep uphill and downhill road of Nepal hill area for going to school. It is assumed that unshod activity and long hill walk may explain the lower prevalence of flat arch and hallux valgus. Conclusion Nepal children have a high incidence of high arch and very high arch instead of the low prevalence of flat arch and hallux valgus. The width/length ratio was similar to Japanese. References UB Rao, B Joseph, The influence of footwear on the prevalence of flat foot, Journal of Bone & Joint Surgery British, 74-B(4): 525-527, 1992.

EFFECTS OF COMBINED EXERCISE TRAINING ON SOLUBLE INFLAMMATORY MARKERS IN ELDERLY WOMEN

Jung, H.H., Miyashita, M., Kwon, Y.C., Kim, E.H., Lim, S.T., Park, J.H., Park, S.K.

Tokyo Gakugei University

Introduction Pathophysiological studies have shown that elevated circulating concentrations of soluble inflammatory markers, including monocyte chemoattractant protein-1 (MCP-1), soluble E-selectin and soluble vascular cell adhesion molecule-1 (sVCAM-1) may be independent risk factors for atherosclerosis and cardiovascular disease (Kressel et al., 2009). However, limited data suggest that improvements in these markers after combined (i.e., aerobic and resistance) exercise training are similar to those achieved with aerobic exercise or resistance exercise training alone in elderly women. The purpose of this study was to investigate the effects of combined exercise training on soluble inflammatory markers in elderly women. Methods The participants were 21 older women (aged 69.6 ± 2.1 years, mean \pm SD). They were randomly assigned to one of two groups: combined exercise or control groups. The combined exercise consisted of walking and resistance (i.e., thera-band and dumbbell) exercise 60 minutes/session, 4 days each week for 12 weeks. In the control group, participants were advised to maintain their normal lifestyle during the study. Fasting venous blood samples were collected and a dual-energy X-ray absorptiometry was used for determining body composition at baseline and after 12 weeks in each group. Results There was a significant time by group interaction effect for MCP-1, soluble E-selectin and sVCAM-1 after 12 weeks ($p = 0.036$, $p = 0.005$, $p = 0.001$, respectively). There was a significant time by group interaction effect for total fat mass, glucose and C-reactive protein (CRP) after 12 weeks ($p < 0.0005$ for all). Delta MCP-1, soluble E-selectin and sVCAM-1 were correlated with delta glucose and CRP (glucose, $r = 0.433$, $r = 0.487$, $r = 0.563$, respectively, $p \leq 0.05$ for all; CRP, $r = 0.504$, $r = 0.452$, $r = 0.444$, respectively, $p < 0.05$ for all). Delta MCP-1, soluble E-selectin and sVCAM-1 were not correlated with delta total fat mass. Discussion The findings of our study support the previous studies using aerobic exercise or resistance exercise training alone and demonstrate that concentrations of soluble inflammatory markers are reduced after performing combined exercise training in humans. Furthermore, although adipose tissue is the main regulator of soluble inflammatory markers, our findings suggest that exercise-induced glucose uptake and anti-inflammatory effects may also contribute to decrease concentrations of soluble inflammatory markers in elderly women. NON-RECIPROCAL INHIBITION IN THE REGULATION OF THE VOLUNTARY MOVEMENT IN PERSONS OF DIFFERENT AGE

Chelnokov, A.

Velikiye Luki State Academy of Physical Education and Sports

The purpose of our research was to study the role of non-reciprocal inhibition (NI) in regulation of a voluntary muscle contraction in person of different age. 9-12 year-old boys ($n=15$), 14-15 ($n=15$) and 17-18 year-old teenagers ($n=15$), and 22-27 year-old men took part in the research. NI was evaluated according to the degree suppression m. soleus H-reflex amplitude of a testing in conditioning stimulation of n. common peroneal (Pierrot-Deseilligny et al., 1979, 1982). The interval between the conditioning and testing stimuli in 9-12 and 14-15 year-old boys was 2 ms, in 17-18 year-old teenagers and 22-27 year-old men it 6 ms in rest and during isometric contraction on 1st, 15th and 30th seconds. The subjects performed a isometric muscle contraction (plantar flexion) with a 25% of maximal voluntary contraction effort in a sitting position in the dynamographic system Biodex (Biodex Medical System, USA). It is shown that without dependence from age at all groups in the conditions of static effort expression of NI decreased in comparison with the background data received in rest. The higher expression of NI at performance of isometric contraction throughout 30 seconds of effort is characteristic for 9-12 year-old boys, and most the least for 14-15 and 17-18 year-old teenagers. Unlike previous age groups of 9-12 year-old boys, 14-15 and 17-18 year-old teenagers, at of 22-27 year-old men's expression of NI at performance of any movement is characterized by weakening. This regularity is associated with the age peculiarities of supraspinal and proprioceptive excitatory and inhibitory effects on Ia and Ib interneurons of the spinal cord are changing the nature of the spinal inhibition ensure voluntary movements as the development of the organism. References Pierrot-Deseilligny E, Katz R, Morin C. (1979, 1982). Brain Res, 166, 233, 176-179, 400-403.

EFFECTS OF TRANSIENT CARDIOLOCOMOTOR COUPLING ON GAS EXCHANGE AND MUSCLE DEOXYGENATION DURING TREADMILL EXERCISE: A PRELIMINARY OBSERVATION IN AN ELDERLY SUBJECT

Niizeki, K., Hoshi, A., Saitoh, T.

Yamagata University

Introduction Cardiac-locomotor synchronization (CLS) has been documented in humans performing various rhythmic activities but its functional role remains largely unknown. Therefore, the aim of this study was to determine whether CLS is associated with gas exchange efficiency and whether CLS alters muscle O₂ utilization during treadmill walking exercise. Methods A healthy elderly subject (59 yr male) performed repeated incremental grade walking test on a treadmill at a constant speed for 20 min. The initial speed and grade were set

such that the heart rate intersected the cadence rate, and the grade was increased 0.5% every 1 min followed by a 3 min warming up. Breath-by-breath minute ventilation (VE), oxygen uptake (Vo₂), and carbon dioxide output (Vco₂) were measured and the ventilatory equivalent for O₂ (VE/Vo₂) was determined as a measure of gas exchange efficiency. Changes in deoxyhemoglobin (D[Hb]) and oxy-hemoglobin (D[O₂Hb]) at the lateral aspect of the soleus muscle were sampled each second by near-infrared spectroscopy (NIRS). These data were normalized to the peak amplitude of the response. The phase difference between heartbeat and cadence was calculated and then SD of the phase difference was computed over the 10 s time windows. CLS was defined as being present when the phase difference was fixed over 20 s with the SD being below 0.1. The changes in gas exchange and NIRS indices during CLS were evaluated as the differences between the observed and predicted values which were obtained by plotting each desynchronized parameter against time and fitted with a least squares regression line. Results The subject performed eight times of treadmill walking test at varying speed (4.8 - 5.5 km/h) on a separate day and CLS was found in all tests with the duration of 175±46 s. Lower levels of VE/Vo₂ (-3.4±1.7%), VE (-2.6±2.1%), and gas exchange ratio (-1.36±1.21%) were seen during CLS episode. Further, relative increase in D[Hb] (1.9±1.7%) and decrease in D[O₂Hb] (-6.4±5.6%) were observed. Discussion The reduced VE/Vo₂ could be accounted for by a decrease in VE. Since it has been shown that metabolite accumulation in skeletal muscle tissue drives ventilatory response to dynamic exercise (Whipp BJ, 1994), we assume that CLS might minimize the accumulation of ischemic metabolites that are produced during muscle contraction by impeding intramuscular arteries, which would, in turn, act to reduce ventilation. The observation of a relative increase in D[Hb] during CLS indicates a shift toward more aerobic oxidative metabolism. Whether these trends are consolidated among individuals needs further study. References Whipp BJ (1994). *Med Sci Sports Exerc* 26, 337-347. Contact lnzq@yz.yamagata-u.ac.jp

ENDURANCE TRAINING AUGMENTS HEMATOPOIESIS IN AGED BONE MARROW

Iacono, C., Baker, J.M., Joannis, S., Parise, G.

McMaster University

Introduction Recently it has been shown that endurance training increases medullary and circulating hematopoietic progenitor cell content in 14-week old mice. Additionally, our lab has shown that mesenchymal stem cells from endurance trained animals have decreases in adipocyte differentiation potential, and increased potential for osteoblast differentiation potential (Baker 2011). Therefore, the purpose of this study was to investigate the effects of endurance exercise on the age-related dysfunction of hematopoiesis and to identify mechanisms responsible for any observed changes. **Methods** Twenty-two month old C57Bl/6J mice underwent an 8 week progressive treadmill training protocol. Mice exercised 3d/wk for 40 min, training began at 8.5 m/min (wk 1) and increased to 15 m/min (wk 8); training was preceded by a warm-up at 6 m/min for 10 min and followed by a cool-down at 6m/min for 5 min. Tissues were collected 3 days post-exercise (n=3), 10-days post-exercise (n=4) and 28 days-post exercise (n=3). Sedentary mice served as controls (n=10). Cobblestone area-forming cell assay, the methylcellulose colony forming unit assay and the long term culture initiating cell assay (LTC-IC) were all used to assess medullary hematopoiesis and progenitor cells. **Results** Following endurance training, both cobblestone and long term culture initiating cell frequency tended to increase when compared to sedentary. Although, we did not see a significant increase in the early stage multipotent myeloid progenitor cell granulocyte erythrocyte monocyte megakaryocyte (CFU-GEMM) colonies with exercise when compared to sedentary. Furthermore, exercise increased total progenitor cell types by approximately 50%. Specifically; training increased late stage erythroid, granulocyte and monocyte progenitor cells when compared to the sedentary group. Discussion Aerobic training increased early multipotent progenitor cells as shown in the cobblestone and LTC-IC. Similarly, exercise increased all late stage unipotent progenitor cells when compared to the sedentary group. These findings are consistent with previous findings our lab has published in young mice. Even at a lower intensity of exercise an increase in progenitor cell content was observed. These findings provide evidence that even in advanced age, exercise-training can stimulate the HSC compartment and improve hematopoiesis in aging. **References** Baker, JM, M De Lisio, and G Parise. *FASEB*. 25.12 (2011): 4348-4357. THE RATING OF PERCEIVED EXERTION IN ANAEROBIC THRESHOLD INTENSITY IS SIMILAR IN CYCLE AND TREADMILL EXERCISE Bertucci, DR.1-2, Candido, FF.2, Sousa, NFM.2-3, Papini, CB.1, Barbosa, MR.2, Perez, SEA.2, Baldissera, V. 1-2. 1:UNESP (Rio Claro, Brazil), 2: UFSCar (São Carlos, Brazil), 3: FESV, (Vitória, Brazil) **INTRODUCTION** The anaerobic threshold (AT) is the best intensity to improve the aerobic capacity in several populations. However, the AT determination requires expensive equipment measurements and knowledge about testing (Simoes et al., 2010). It is necessary to investigate accessible ways for determining the AT. The aim of this study is to identify the ratings of perceived exertion (RPE) at AT in cycle and treadmill exercise. **METHODS** Thirty two women (mean ± SD age 32.5 ± 5.9 years, BMI 28.1 ± 2.8 kg/m²) performed an incremental Test (IT) on treadmill (TG), which consisted in stages begun in 3km/h with increasing speed of 1km/h every two minutes. Eighteen women (mean ± SD age 38.2 ± 4.0 years, BMI 22.6 ± 1.8 kg/m²) performed an IT of cycle ergometer (CG) using the Balke protocol, with initial load of 25 W and increase by 25 W every two minutes. Both ITs were conducted until voluntary exhaustion and all individuals were verbally encouraged. At the end of each stage of IT the RPE using Borg 6 – 20 scale were recorded. The AT was determined by the visual method using a gas analyzer (VO2000, Imbramed, Medgraphics, Porto Alegre, Brazil). The student t-test was used to compare the differences between groups and the statistical analyses were conducted using SPSS 17.0, with significance set at p<0.05. **RESULTS** The PSE and %VO₂max values in AT intensity was not significantly different, (TG, 12 ± 2 VS CG 12 ± 3, p = 0.43) and (TG 60 ± 8% VS CG 63 ± 11%, p = 0.22). The AT intensity was 6.2 ± 0.6 km/h for TG and 73.6 ± 2.5 W for CG. The VO₂max was significantly higher in TG (TG, 29.6 ± 3.4 VS CG, 25.2 ± 4.5 ml(kg.min)⁻¹, p = 0.001). **DISCUSSION** Although the groups in this study were with different subjects, classic studies found differences in VO₂max between treadmill and cycle due to the body mass involved in exercise (Carter et al., 2000). The relations between RPE and AT in cycle ergometer and treadmill are well reported in the literature (Garcin et al., 2006; Simões et al., 2010; Vieira et al., 2014) and this research confirm the knowledge that during endurance sports the RPE values between 10 – 12 are closely related to the AT intensity. Thus, for its simplicity, low cost and effectiveness in determining the exercise intensity, RPE can be an important tool in application of functional evaluations. **REFERENCES** Vieira, DCL. et al., (2014). *Rev. bras. cineantropom. desempenho hum*, 16(1), 106-115. THE PERFORMANCE EFFECT OF CENTRALISING A NATION'S ELITE SWIM PROGRAMME

Allen, S.V.1,2, Hopkins, W.G.3, Vandenbogaerde, T.J.1,2

1Auckland University of Technology, NEW ZEALAND 2High Performance Sport New Zealand, NEW ZEALAND 3Victoria University, AUSTRALIA

INTRODUCTION: The centralisation process in high-performance sport usually involves a nation's top athletes leaving home-training squads to join better resourced programmes. Although this process has been widely credited for the Olympic medal-winning success of teams such as British Cycling and Rowing New Zealand, the success of centralisation strategies in elite sport has rarely been evaluated objectively. Here we present a method for analysing the performance progression of swimming squads, which we have used to assess the effect of the centralisation of New Zealand's elite swim programme in 2002. **METHODS:** All official long-course performance times for New Zealand swimmers between 2002 and 2013 were downloaded from takeyourmarks.com. Best annual times of all swimmers with at least three years of performances in an event (276,000 times from 8226 swimmers) were analysed separately for males and females using a mixed linear model. The model produced estimates of mean annual performance for 176 swim clubs and mean estimates of the deviation of swimmers' performances from their individual quadratic trajectories after they joined the centralised high performance centre (HPC). Effects were evaluated using magnitude-based inferences with a smallest important change in performance time of 0.24%. **RESULTS:** Before 2009, the effects of HPC membership were mostly unclear and trivial to small in magnitude. Thereafter, both sexes showed clear additional enhancements in performance, increasing from large in 2009 (males 1.4%, $\pm 0.8\%$; females 1.5%, $\pm 0.8\%$; mean, $\pm 90\%$ confidence limits) through to extremely large in 2013 (males 6.8%, $\pm 1.8\%$; females 9.9%, $\pm 2.9\%$). Some clubs also showed clear trends in performance during the 12-year period. **DISCUSSION:** Swimming New Zealand's centralisation strategy took several years to produce substantial performance effects. Possible reasons for the increasing performance benefits for HPC swimmers from 2009 onwards include additional funding, recruitment of top coaches, and improvements in sport-science and medicine provision, all of which began to be introduced into the HPC in late 2006. Our study shows that a mixed modeling method to assess deviations from individual trends in competition performance can be used to evaluate performance-enhancement strategies introduced at club or national level. **CONTACT:** sian.allen@hpsnz.org.nz

DIFFERENT BOX SCORE STATISTICS DISTINGUISH WINS FROM LOSSES OF DIFFERENT TEAMS

Rimer, E.G.

University of Utah

Introduction Box score statistics have been used to discriminate between winning and losing basketball performances during quarters (1), games (2), and seasons (3). Such techniques clarify trends in the sport, but unique variables may distinguish winning from losing performances of individual teams. This study investigated if different box score variables separate winning and losing performances of different teams.

Methods 20 common box score variables from 108 Pac-12 Conference games played during the 2012-13 NCAA Basketball season were used: 2-point, 3-point, and total field goals attempted (2PA, 3PA, FGA), made (2PM, 3PM, FGM), and percentage made (2P%, 3P%, FG%); free throws attempted, made, and percentage made (FTA, FTM, and FT%); offensive, defensive, and total rebounds (OR, DR, REB); assists, steals, blocks, turnovers, and fouls (AST, STL, BLK, TO, PF). Game tempo was controlled by normalizing each variable to possessions (4). Independent samples t-tests determined which box score variables differentiated games won and lost for each team. Effect sizes (ES) were calculated to rank the magnitude of the effect of each team's statistically significant ($p < .05$) box score statistics.

Results Each team's wins and losses were separated ($p < .05$) by an average of 4.1 ($s = 2.8$) different box score variables (range: 2-12 variables). FG% was significant for six of the 12 teams. DR and PF were significant for five teams. FGM, 2P%, and FTM were significant for four teams. FGA, REB, and AST were significant for three teams. 3P%, FTA, OR, and BLK were significant for two teams. 2PA, 2PM, 3PM, and FT% were significant for one team. 3PA, STL, and TO were not significant for any team. The ES of significant variables ranged from 1.05 to 2.43, indicating moderate (.60 to 1.19) to very large (> 2.0) effects (5) on a team's wins and losses. Ranking variables by ES revealed which factor accounted for the largest variance in a team's wins and losses. DR had the largest effect for four of the 12 teams. FGM and FG% each had the largest effect for two teams. 2P%, FTM, REB, and BLK each had the largest effect for one team.

Discussion Different box score statistics distinguish wins from losses of different teams. This study is limited because each team played only 18 conference games, yielding lower statistical power while compromising further analysis using multivariate techniques. Insight can be gained from analyzing winning and losing performances across all teams, but this method provides objective information about individual opponents.

PASSING PLAYS LEADING TO PASSING AND DRIBBLING PLAYS IN THE 16TH FIBA WOMEN'S WORLD CHAMPIONSHIPS

Sakuragi, K., Aoyagi, O., Komure, I., Tagata, S.

Fukuoka University

Purpose Preceding passing plays are related to subsequent passing and dribbling plays in basketball games. The present study aimed to identify relationships between preceding passing plays and subsequent passing and dribbling plays. **Methods** We analyzed 1084 pairs of preceding passing plays and subsequent passing and dribbling plays implemented by six teams at the 16th FIBA Women's

World Championships. The following passing and dribbling plays were assessed: forward passes that moved the ball to the back court (cf); passes that changed the side or angle to create a scoring opportunity in the back court (cc); before-shooting passes (aa); passes leading to a one-on-one situation (ab); passes leading to a driving play (ac); passes to the postman (pa); passes to change the angle (po); passes from the top to the side to change the side (s); return passes to the guard or top (rt); passes to the corner (cn); hand-in passes (hh); throw-ins (p); dribbling to move the ball to the back court (cd); dribbling on the spot in the front court (fco); and so on. A cross-table of preceding passing plays with subsequent passing and dribbling plays was then generated. The χ^2 test was applied to the cross-table, and an adjusted residual was computed if a significant difference was identified. Significant relationships were found between preceding passing plays and subsequent passing and dribbling plays with a significantly larger adjusted residual. Results The results of the χ^2 test were significant at the 0.1% level ($\chi^2 = 5685.22$; $df = 260$). We found cells with >20 frequencies and a significant adjusted residual in $cf > cd$ (frequency, 94; adjusted residual, 7.31), $cf > cc$ (147, 19.20), $pa > aa$ (20, 5.25), $po > ab$ (24, 18.22), $po > pa$ (23, 13.82), $s > rt$ (133, 8.55), $s > cn$ (71, 11.88), $s > aa$ (55, 3.53), $s > pa$ (44, 3.83), $s > hh$ (38, 5.54) and so on. Discussion In the absence of defensive pressure, a long pass from the back court to the front court is considered to be most effective passing play ($cf > cd$, cc). When the ball was passed to the post player, the defensive player was obliged to focus on the post, but not their matching offensive player. This situation caused space to be created around all offensive players other than the post player, and each offensive player could thus easily assist their teammates ($pa > aa$). Changing the angle of the passing course is more effective for creating one-on-one situations and passing to the post player ($po > ab$, pa). An offensive team that wants to restart an offense often applies the strategy of changing the ball-side ($c > rt$ and cn). On the contrary, changing the offensive ball-carry side is more effective for breaking through a defense, and thus offensive players can easily perform aa , hh , and pa ($s > aa$, hh , pa).

THE IMPACT OF MATCH STATUS ON GAME RHYTHM IN NBA BASKETBALL.

Courel, J.I, McRobert, A.P.2, Ortega, E.3, Cárdenas, D.1

1: UGR, (Granada Spain), 2:LJMU (Liverpool, UK) 3: UM (Murcia, Spain).

Introduction Faster-paced attacks in basketball increase the likelihood of scoring. Furthermore, teams and players change their activity as a response to the match situations (Gómez et al., 2013). However, there is scarce information on game rhythm when there are varying degrees of match status (i.e. the difference in points). Therefore, this study aimed to analyse differences on ball possession duration and attack effectiveness when match status varied during the game. Methods In total, 4207 ball possessions from 25 matches (NBA Playoffs, 2011) were analysed and classified as "moderate advantage" (4 to 10 points advantaged), "balanced" (3 points advantaged to 3 points disadvantaged) and "moderate disadvantage" (4 to 10 points disadvantaged) using the k-means cluster procedure. Binomial logistic regression analysis was performed to estimate the predictive weight of ball possession duration on attack effectiveness. Student t-test and one-way ANOVA for independent samples were used to detect mean differences in ball possession duration, attack effectiveness, and match status situations. Results Playing shorter ball possessions was associated with higher attack effectiveness. Specifically, winners ($M = 3.96s$, $SD = 1.38s$) played shorter and more effective fast breaks compared to losers ($M = 4.73s$, $SD = 1.61s$) in "moderate advantage" situations ($t(89) = 2.46$, $p = 0.02$). Moreover, losers played longer set offence possessions in "moderate disadvantage" ($M = 14.05s$, $SD = 5.24s$) compared to "balanced" ($M = 12.97s$, $SD = 5.75s$) and "moderate advantage" ($M = 12.92s$, $SD = 5.59s$) situations ($F(2) = 4.20$, $p = 0.02$). In contrast, there was no significant differences between match status for winners ($F = 0.50$, $p = 0.61$). Discussion Results reinforce the importance of playing faster-paced attacks to increase the likelihood of scoring in basketball (Bazanov et al., 2006; Csataljay et al., 2011; Sampaio et al., 2010). Moreover, there were significant differences in the duration of ball possession when match status altered. First, winner's played shorter fast breaks that allowed them to keep and/or increase their scoring advantage. Second, loser's increase in ball possession in the "moderate disadvantage" situation might be due to the winner's defensive performance. In conclusion, increasing fast break intensity and adopting strategies to slow down opponent's game rhythm appears to be a crucial factor used to achieve and/or increase advantages in the score and winning the game. ANALYSIS OF DEFENSIVE GAME SITUATIONS IN TEAM HANDBALL BY MEANS OF ARTIFICIAL NEURAL NETWORKS

Schrapf, N., Rudelsdorfer, P., Tilp, M.

University Graz

Introduction For the identification of game tactics and the selection of successful playing strategies analysis of game situations is very important. Previous own studies focused on identification of offensive playing patterns in team handball (Schrapf & Tilp, 2013). In order to get deeper insight into team and player tactics, the behavior of the defensive teams also has to be considered. Therefore, the aim of the present study was to classify defense situations. Methods For the present study 12 games from the EHF EURO Men 18 in Hard (Austria) were captured by 8 cameras. Subsequently, shot-actions were annotated with custom-made software. Every annotation includes the ground position of the player performing the shot and of all defensive players at the instant of the shot. In total, 728 actions were annotated which were then analyzed by artificial neural network software (Perl, 2002). In order to obtain suitable entropy, data was enlarged by multiplication to a quantity of 7280 datasets with a noise of 5% and subsequently permuted to minimize unwanted learning effects due to duplication. Position data of the shot and the defensive players were used to train the neural network with a dimension of 400 neurons. Each neuron represents a pattern of defense action. Hereafter, similar neurons are grouped to clusters which represent similar defense behavior. The similarity resolution, which defines selectivity between similar and dissimilar neurons, was set to 75%. Results The artificial neural network recognized 18 clusters and 3 single neurons which could not be assigned to a cluster. Thus, we found 21 different patterns of defense positions. The different defense patterns coincide very well with the usual used shot position areas in team handball. The network determined two different patterns for the right wing and left back position, three from the left wing, the right back, and the pivot position, and five for shots from the center back. Discussion The analysis revealed the applicability of artificial neural networks for identifying defense patterns in team handball. As expected, the orientation of the defense coincides with the position of the shot. Differences between the single defense patterns mainly consist in the distance to the goal and the width and orientation (center, right, or left) of the defense. Furthermore, the neural network determined five defensive patterns where one player takes over an offensive role. Further analysis including action sequences preceding the shot positions instead of considering only the single shot position have to be done in order to observe the team tactics in its entirety. PRECEDING SKILLS AND GENDER DIFFERENCES IN THE ACCURACY OF THE BASKETBALL JUMP SHOT

Arguriou, M.1, Rousanoglou, E.2, Boudolos, K.2, Bolatoglou, T.H.1

National & Kapodistrian University of Athens, Greece.

Introduction The preceding technical and tactical skills aim to create the most favorable shooting conditions. Limited data report the effect of preceding technical skills (pass and dribble) in jump shot accuracy (JSA) (Oudejans et al., 2012). Gender differences are reported for game experience, game pace and game tactics (Gómez et al., 2007). However, there is lack of research integrating both technical and tactical skills as well as both genders regarding the JSA. The study examined the gender differences in JSA under the perspective of the preceding technical and tactical skills. **Methods** A notational analysis was used in 30 men's and 27 women's games (A1 league championship - first 6 ranking teams, respectively). The technical (shooting distance, way of ball pick-up, dribble number, last dribble hand, pass receiver's movement, and footwork) and tactical skills (on-ball and off-ball screen, side and area of pass origin and direction) preceding the attempted (JS-attempted) and accurate (JS-accurate) JS were recorded. The gender difference in the JS-attempted and JS-accurate percentages was tested using the custom table module of SPSS ($p = 0.05$). **Results** Women had more JS-attempted and JS-accurate from a short distance, after a rebound or steal, and after a pivot stop (front and back), when no screen was applied (on-ball and off-ball) and when the assist pass was directed close to the basket ($p < 0.05$). Women had less JS-attempted ($p < 0.05$) but similar JS-accurate ($p > 0.05$) when the pass receiver was already in motion and after a stride stop. Women had similar to men JS-attempted ($p > 0.05$) but less JS-accurate ($p > 0.05$), when the shooter received a screen (on-ball and off-ball). **Discussion** The JSA gender differences are possibly associated with the physical superiority of men (Ziv and Lidor, 2009), their better far aiming accuracy (Sykes-Tottenham et al., 2005), and their better response in intergroup conflict (Van Vugt et al., 2007) and in in-group cooperation (Bailey et al., 2012). Knowledge of the gender differences may help coaches for a more effective training and game guidance of women. **References** Bailey DH, Winegard B, Oxford J, Geary DC. THE INFLUENCE OF SCORING FROM THE NET ON GAME RESULT IN PADEL

Cañas, J., Courel, J.

University of Granada

INTRODUCTION Performance analysis has been widely applied to study a variety of aspects of racket sports (Lees, 2003), since it allows identifying critical factors of the game for players' development. Hughes and Barlett (2002) identified common performance indicators relating to net and wall games. However, information about practice requirements in padel (also known as paddle tennis) is limited. Carrasco et al (2011) found that volley strokes were the most used in padel, suggesting the importance of playing near the net. Therefore, the aim of this study was to determine whether scoring from the net increased winning chances in elite male padel players. **METHODS** In total, 2107 rallies were registered from 15 male matches (Masters Finals World Padel Tour, 2013). This competition gathered the top-16 best padel players, being the most important tournament of the world. Points were classified whether they were played in the net or not. Variables related shot effectiveness (points and errors), serve (serve and serve-return), and game result (winners and losers) were included in the analysis. A series of binomial logistic regressions were calculated to estimate main effects of shot effectiveness, serve, and game result in net points. **RESULTS** Important differences between winners and losers were found when playing near the net. Winners scored more points ($X^2(1) = 12.79$; $P < 0.01$; $OR = 1.50$), whilst losers committed more unforced errors ($X^2(1) = 3.80$; $P = 0.05$; $OR = 1.40$). These differences increased regarding serve and serve-return situations. Scoring odds from the net were three times higher for winners when they served ($X^2(1) = 47.03$; $P < 0.01$; $OR = 3.11$), whilst losers' likelihood of committing unforced errors increased when they served ($X^2(1) = 18.85$; $P < 0.01$; $OR = 2.93$). **DISCUSSION** Results highlighted the importance of scoring from the net in padel, since it increased winning chance. It might suggest that the more time spent in the offensive zone (i.e., net zone), the more chance to scoring. Conversely, keeping a defensive location (i.e., baseline zone) for a long time will increase the likely of receiving a point. Thus, developing strategies to dominate the net zone seems to be a crucial factor in padel (Ramón-Llin et al., 2009). Moreover, best players appear to be highly consistent in the net when serving. This might be explained by a better location when approaching to the net after serving (Ramón-Llin et al., 2013). Future research might be focused on exploring game strategies to improve success when playing near the net in padel. **REFERENCES** Hughes M, Barlett R. (2002). *J Sports Sci*, 20(10), 739-754. SIDE-OUT INFLUENCE IN HIGH LEVEL VOLLEYBALL SKILLS

João, P.V.1,2, Mota, M.P.1,2, Ribeiro, B.2, Vaz, L.1,2, Stamm, R.3, Pereira, A.1,4

1: CIDESD-UTAD (Research Center for Sports Sciences, Health and Human Development, Vila Real, Portugal), 2: UTAD; 3:Tallinn University – Estonia, 4: Polytechnic of Setubal.

Introduction Match analysis is crucial to achieve a good performance in volleyball (João et al., 2010). The analysis of athletes' different skills will provide important information about opponents' weaknesses, allowing the selection of more appropriate strategies to overrides them winning the game. The aim of this study was to search for the skills that most contribute to the result (win or lose) in the Side-out or complex I context (reception, setting and attack), in high level volleyball players. **Methods** A total of 74 games on the 293 sets of Volleyball World Championship Men 2010 in Italy were analysed, recording different skills in side-out. Data analysis was performed by Data Volley software. Discriminant function analysis (DA) was used in order to identify the skills that most contribute to establish the maximum difference between wins and losses results. We considered as relevant to the interpretation of the linear composites the $|SC| \geq 0.30$. The significance level was set at 5%. The calculation of the results was performed by SPSS version 17.0. **Results** Our results pointed out that the attack point ($SC = 0.42$), the excellent reception ($SC = 0.35$) and the attack error ($SC = -0.30$) contribute to the discrimination between defeat and victory, in the context of side out in volleyball game. **Discussion** The present study revealed possible predictors of success in a side-out situation: the excellent reception and attack point. Furthermore, the variable possibly associated with the failure, seems to be the attack error. In this sense, volleyball teams should maintain consistency in the side-out through an excellent reception and efficacy in attack, and prevent the attack of the opposing team, keeping an efficient block. Together, these results suggest that more importance should be taken in training situations to reception and attack skills in order to improve performance in competition, especially in side-out.

A TECHNICAL PERFORMANCE ANALYSIS OF SOCCER GAMES

Espinosa Sanchez, M.

National University of Mexico

Introduction Biomechanical aspects in the technical performance of soccer players defined the characteristics of their skills (Luhtanen, 2004). These allow the identification of determinants of successful technical performance during the game. For this study, the set of technical elements are actions with and without the ball and those of the goalkeeper (Bruggemann, 1996; Cantarero, 1995; Vidinic, 1988), which are hierarchically organized to facilitate the analysis (Brown, 1992; Espinosa, 2002; Koch, 1998; Vidinic, 1988). The semifinal (MEX vs JAP) and final (MEX vs BRA) of London 2012 were analyzed. Methods A careful observation was made, using the program Utilius Fairplay 5 © of the official video broadcast in TV. The following apparent aspects had been considered: a rating of three height ranges in the displacement of the ball, three force ranges of the player, two ranges of the distance of the ball, and the player's displacement with or without the ball taking into account the permitted and probable body parts. It is almost impossible to identify which zone of the ball is struck, and some times either which is the part of the foot that makes contact. Results The technical elements were summed for every 15 minutes of the game, and in each soccer field side. Examples of actions (semifinal/final) are: Hitting the ball (487/311) with the inside of the foot (267/146) of these 17 were carried out during the first 15 minutes at the final game, 11 moved the ball with the floor, 2 with poor force, 4 for a short and 6 large distances; with the outside of the foot (34/47) and with the head (30/52) of these 29 jumping during the fourth 15 minutes at the semifinal game. Receptions (468/282) with the inside of the foot (187/132), hitting at reception (88/66). Change of direction (69/75); feint with body rotation (89/58); sprint run (34/72); defensive blocking (285/386), of these from front (128/110). Goalkeeper action's (74/130), trapping the ball with both hands (1/8). Discussion This study would be an assessment to the technical movements. The results could be an indication of the technical preparation of the team's players, the intensity of the game, but probably also the coach strategy proposed to address the opposing team. EXAMINING THE GENDER DIFFERENCES OF SCORING SKILLS PERFORMANCE IN HIGH LEVEL VOLLEYBALL GAMES

Chang, C., Liu, Y.

National Taiwan Normal University

Introduction There are gender related performance characteristics in men and women's volleyball games. Volleyball coaches adopt different training programs and game tactics when coaching volleyball teams of different genders. However, few studies have examined the performance difference between men and women's volleyball games. Therefore, the purpose of the study was to examine the gender difference of the performance of the scoring skills in high level volleyball games. Methods One hundred and eight games from the Women's World Grand Prix final round and eighty eight games from the Men's World League final round between 2007 and 2013 were analyzed. The official match statistics of FIVB P3 reports from these matches were retrieved through the FIVB website. Performance ratio (score, fault, and continue) for services, spikes, and blocks were calculated for statistical analyses. Independent t tests and paired t tests were used to examine the gender effect and the effect of game result, respectively. Results The scoring ratio was higher for men than women in spikes, whereas women were higher than men in blocks. Men were higher than women for the fault ratio in all 3 skills, but women were higher than men for the ratio of continue. The winning teams had the higher scoring ratio compared to the losing teams for both men and women, but only the winning teams of the women's games had the lower ratio of fault than the losing teams. Discussion The results show that there are gender differences in the performance of spikes, blocks, and services in high level volleyball games. The higher ratio of scoring and fault for men in spikes indicates that men's volleyball games tend to score in just a short rally. Women's games, however, with the high ratio of continue (neither score nor fault), tend to score usually after a long rally (Bergeles et al., 2009). The results of the study provide the basis for different training and game tactics in men and women's volleyball games. Future studies will extend the scope to examine the performance difference between men and women's volleyball games in non-scoring skills. References Nikos, B., Karolina, B., & Elissavet, N. M. THE INFLUENCE OF TEACHING BEHAVIOR OF PHYSICAL EDUCATION ON LEARNING ATTITUDE IN MIDDLE AND HIGH SCHOOL STUDENTS

Hwang, Y.1, Kwon, O.1, Park, H.3, Park, S.1, Park, J.2, Yoo, H.1, Jang, S.1, Jeong, H.1, Kim, S.1, Lee, S.1, So, H.4

1: Pusan National University (Busan, South Korea), 2: Youngsan University (Busan, South Korea), 3: Chon Nam National University (Gwangju, South Korea), 4: Dongseo University (Busan, South Korea)

Introduction The purpose of this study is to investigate how teacher's teaching behavior affects students' learning attitude to control their behavior, individualization, enthusiasm, sincerity and clarity in the process of learning. We also we analyzed teacher's teaching behavior on students' learning attitude according to student's gender and grade in middle and high school student. Methods For this study, 960 of middle school students (240 boys, 240 girls) and high school students (240 boys, 240 girls) in Busan, Korea were surveyed. Among these,

898 questionnaires were included and 62 untrustworthy questionnaires were excluded in this study. Multiple regression analysis and t-test were used to analysis data. A statistical significant level was set at $\alpha=.05$. Results The satisfaction about learning in middle school students was significantly affected by teaching behavior of physical education teacher in the order of individualization, enthusiasm, sincerity, and clarity. The preference and concentration of students for learning were affected by teacher's behavior in the order of enthusiasm, sincerity, and clarity. In high school, student's satisfaction about learning was significantly affected by teaching behavior of physical education teacher in the order of enthusiasm, sincerity, and clarity. The student's preference and concentration for learning were affected by teacher's behavior in the order of enthusiasm and clarity, and clarity, behavior management and of individualization, respectively. The effects of teaching behavior of physical education teacher on the satisfaction, preference, and concentration of student for learning were significantly higher in male than female students in both middle and high school. Also, these effects were not different between middle and high school students. Conclusion Teaching behavior of physical education teacher including individualization, enthusiasm, sincerity and clarity significantly influences the satisfaction, preference, and concentration of student for learning. There was no difference in these effects between middle and high school students. However, these effects were larger in male than female students. References French, K. E. & Thomas, J. R. PUPIL PERCEPTIONS OF THE ATTRIBUTES FOR AN EFFECTIVE PHYSICAL EDUCATION TEACHER.

Cunliffe, D., Gundry, L.

Southampton Solent University

Introduction The growing number of school aged children dropping out of sport has risen steadily over the past few years (Cote & Deakin, 2008) with a variety of reasons being cited, including the quality of teaching being implemented or pupil's not being fully engaged in physical education (PE) lessons (Bevans et al., 2010). Equally, previous papers regarding the attributes of successful sports coaches have been written (Passmore, 2010) but limited research pertaining such qualities of an effective physical education teacher (Mowrer-Reynolds, 2008). Therefore, the purpose of this paper is to examine and establish pupil perceptions of key attributes a PE teacher should possess for effective teaching to encourage pupil engagement within PE classes. Methods Appropriate ethical clearance was sought and granted from a University's ethical committee, before gatekeeper permission was granted from a school on the south coast of England. Furthermore, written informed consent from parents and assent from children were also gained prior to commencement of the study. A total number of pupils (n=207) across UK school year 7 (male n=65; female n=39) and UK school year 11 (male n=57; female n=46) participated in the study. In addition to five physical education teachers (male n=4, female n=1). Each participant completed an adapted version of Gould et al. (1982) Questionnaire for Reason for Attrition, before participants were requested to apply rank order to the 22 common and reoccurring attributes associated with effective teaching. Results The data was analysed using PASW (version 18) involving both the Kruskal-Wallis test and Man Whitney tests. Results of findings suggested attributes of: confidence; being skilful; and being a leader were most important from the pupil perception. Whereas, findings from five PE practitioners found attributes such as: enthusiasm; confidence; and being a leader were the perceived attributes for an effective teacher of PE. Discussion From this small scaled study, the exploratory analysis led to the initial conclusion that pupils perceiving the attributes of confidence, being skilful and being a leader as being important for effective teaching of PE. Furthermore, and in slight contrast, the physical education teachers perceive the attributes of enthusiasm, confidence and being a leader as contributing factors associated with an effective lesson of physical education. Although there were slight contrasts between year groups and between sexes of participants, such differences were of non-significant values. Therefore, the findings of this study can tentatively be used for physical education practitioners to promote pupil engagement in class. References Bevans et al., (2010). *J. Teach. Phys. THE SUBJECT OF PHYSICAL EDUCATION AND HEALTH – IN SCHOOL AND TEACHER EDUCATION

Ekberg, J.

Malmö University

Introduction Although many studies have found that Physical Education (PE) is a popular subject there is an on-going discussion about its aim and what legitimizes it as a school subject. What knowledge appears as legitimate within the subject of PE is, however, hard to identify, which creates controversies within the field. Therefore this study aims to contribute to the discussion by increasing the understanding about what knowledge appears as valid in PE in the perspective to other subjects in Sweden. Theoretical and methodological perspectives The conceptual framework used is curriculum theory, inspired by Bernstein's (2000) and Lundgren's (1981) theoretical work on the social construction of knowledge. The focus is on selection processes of knowledge in the educational system. According to Bernstein, education is a field, like any other field, where there is a struggle between interests and actors competing to define the field but also arguing about what knowledge is to be counted as legitimate. In this study I will use different empirical material. The first material comprises applications to the government in 2011 about starting teacher education programmes in Sweden and, further, subject descriptions from six departments of teacher education as well as various policy documents for the subject in the compulsory school. The second material contains interviews with actors who have influence over how the subject is formulated for teacher educations as well as for the compulsory school. As a basis for comparison and analysis, material from four different teacher education and school subjects will be gathered. The subjects include PE, music, English and mathematics. The selection is based on the different traditions that these subjects represent. Expected results The result will contribute with knowledge about similarities and dissimilarities according to what knowledge appears as valid in different subjects and how this is defined. Moreover, the result will provide knowledge about how different subjects relate to the primary field of production and how this relation is expressed in these subjects. The study is most likely to offer an understanding about the identity problem of the subject of PE in the perspective of what knowledge appears as legitimate in relation to other subjects, but also about the character of these different subjects as well as how they relate to the primary field of production. The first part of the study will be implemented during 2014 and the second during 2015. THE PATTERN OF THE CONFLICT MANAGING CULTURE OF JUNIOR CLASS FOOTBALL COACHES

Németh, Z.

University of Pécs, Institute of Sport Sciences and Physical Education

Introduction In today's hasty, stress-ridden world we have less and less time to pay attention to each other, listen to the opinions of others and take them into account during decision making. In the special environment of sport – and inside that, the sport of my chosen topic, soccer – this effect is also sensible, and because of competition situations the emerging conflicts are more severe. According to one of America's best-known authority on coach-training, Rainer Martens, successful coaches are not only masters of their profession, but also masters of conflict managing (Martens, 2004). **Methods** As the first step of my research I focused on the stories of conflict, which I collected from the interviews with coaches. In November 2010 I made a written standard interviewing among the Hungarian professional football league (NB I, NB II, NB III) junior team coaches (n=582) which had questions focusing on the conflict management strategies of coaches. The questionnaire included 10 conflict-situations about the conflict management strategies (Thomas – Kilmann, 1974). Hungarian conflict research professionals controlled the validity of conflict strategies, which were hidden in the answers. For processing and evaluation I used mathematical-statistical methods and SPSS software. For the categories (U6-12; U13-U19) I created cross-tables, then I evaluated the results found with the help of the chi-square test. **Results** The distribution of the conflict management strategies according to age groups show us that coaches of younger generations use the problem solving strategy in 65,4% while coaches of older generations use it in 61,2%. Coaches of younger generations use the winner/loser strategy in 3,6%, while coaches of older generations used it in 4,8%. Regarding the conflicts with parents, it can be stated that the problem solving strategy is more efficient with parents of younger athletes (65,9%) than with parents of older athletes (62,6%). **Discussion** A soccer coach may encounter several conflicts during his/ her relationship with players and their parents. This process is obvious, because it is in the nature of interpersonal relationships. It is up to the soccer coaches' creative conflict management ability, how effective they can solve the problems. The conflict management process is largely influenced by: the circumstances of the situation the given, the character of the participants, their relationship with each other, and the participants' momentary state of emotions and their current style of communication. I experienced in practice that not every soccer coach is able to choose the appropriate conflict management strategy that suits the given situation and the age-specific characteristics of children. **References** Martens, R. IDENTIFICATION OF CONFLICTS CAUSED BY STUDENTS DIAGNOSED WITH ADHD IN PHYSICAL EDUCATION: PROJECT DESIGN

LABRADOR ROCA, V., HERNÁNDEZ VÁZQUEZ, F.J.

INEFC BARCELONA

Introduction Nowadays, an over diagnosis of Attention Deficit Hyperactivity Disorder (ADHD) exists. In Spain, more than a 9% of the pupils (5 - 15 years old) are diagnosed with ADHD (Lavigne et al., 2010). During physical activities, children with ADHD exhibit age-inappropriate features of hyperactivity, excessive impulsivity or problems in lateralization (Reid & Norvilitis, 2000). Despite the fact that physical educators have a privileged position in observing children in many settings, they can be important informants for children's deviant behavior (Efstratopoulou, Janssen & Simons, 2012). We show the results of a first pilot study of the research work entitled 'Identification, intervention and conflict resolution strategies with student diagnosed with ADHD in physical education classes.' Its objective is to identify the conflicts that arise in physical education classes when there are students with ADHD in it. **Methods** Indirect nonparticipative observation instrument (field notes and data log sheet) was used. 5 entire Physical Education sessions (1 hour each) were observed. The sample consisted of a student diagnosed with ADHD (diagnosis based on DSM -IV- TR) in a public school (upper primary school, 9-10 years old). **Results** 29 different conflict situations were observed. They have been structured in 5 variables: lack of self-control and impulsiveness, inattention, frustration and desire for recognition, organizational skills and difficulties in relationships with peers. A total of 101 situations of conflicts occurred, with an average of 20.2 per session. Conflicts that most frequently occurred were those that compose the variable of relationship difficulties with classmates (50.5%); low tolerance to frustration and the desire for recognition (20.79%); lack of attention and working memory (18.81%); lack of self-control and impulsiveness engine (6.93%) and capacity of organization and planning (2.97%). **Conclusions** Personality of those diagnosed with ADHD is conditioned by this disorder. Symptoms of inattention, hyperactivity and impulsivity involve attitudes and behaviors which often turn into conflicts: disturbing classmates, inattentiveness, striking, insulting... The PE class is usually carried out in a particular context, in which each individual is expressed as he/she is: that is why students with ADHD are shown as they are. **References** Efstratopoulou, M., Janssen, R. & Simons, J. THE SWEDISH RIDING SCHOOL – FROM A CHILD AND YOUTH PERSPECTIVE

Thorell, G., Hedenborg, S.

The Swedish national Equestrian centre & Malmö university

Introduction The purpose of this presentation is to analyze learning outcomes and attitudes to equestrian sports for children and youth at Swedish riding schools. The study uses a child rights perspective in order to analyze the and by using Lave & Wengers concept "situated learning" (1991). The use of the concept situated learning makes clear that the results have to be analyzed from the perspective of that learning is situated in a specific context. Learning and development are supposed to take place through participation in social practices and communicative processes become an important part. Previous research on equestrian sports is scarce, despite the fact that horse riding is one of the largest sports for children and young people in Sweden. The child rights perspective can be used to highlight children and youths own opinions about sport activities (SOU 2008:59). This can also help to shape the sports movement in the future by meeting young people's perceptions (Hedenborg & Glaser, 2013). Education at riding schools has a military background and the stable culture have is still many cases characterized by military exercise (Hedenborg 2008). In addition, it has been pointed out that riding schools is a place where girls and young women learn nurturing as well as leadership competences (Forsberg & Tebelius, 2011). This stable culture

affects children and young people in the way they learn how to ride and take care of horses. The Swedish Equestrian Federation has initiated the need for a project based on children and young people's perspective because there is not so much knowledge about it. Method Focus group interviews will be used to highlight children and youths perceptions about the riding school they participate in. Four different riding schools located in various district in Sweden is planning to be visit for conducting data. Riding instructors are to be contact for select and ask about 6-8 girls and boys aged 10-18 years (total n = 32), if they want to be involved and participate in the study. Results & Discussion Will be continue and compile during this spring. References Forsberg, L & Tebelius, U. (2011). MO-PM26 TT Small Sided Games

KNOWLEDGE OF BOUT DURATION INFLUENCES PACING STRATEGY DURING SMALL-SIDED GAMES

Sampson, J.A.1, Fullagar, H.H.K.1,2,3, Gabbett, T.J.

1 University of Wollongong; 2 Australian Catholic University; 3 The University of Queensland

Introduction The present investigation examines pacing during intermittent team sports by manipulating, and providing pertinent information regarding a time-dependent end-point for the exercise period. **Methods** Sixteen junior Rugby players participated in eight small-sided offside touch games. All games were 24 minutes, but differed with respect to bout duration (1 × 24, 2 × 12, 3 × 8, 4 × 6, 6 × 4, 8 × 3, 12 × 2 and 24 × 1 minutes). Repeat bout games were interspersed by 2 minutes of passive rest. Participants were informed of the bout duration immediately prior to the game. Each participant wore a 10 Hz global positioning system (GPS) located within a vest, positioned on the upper back. Heart rates were gathered from ventricular depolarisation and integrated with the GPS software, and ratings of perceived exertion (RPE) were examined. Speed zones were categorised as low (0-25%), moderate (25-50%), high (50-70%) and very high (>70%); acceleration zones as low (20-45%), moderate (45-85%) and high (>85%); and heart rates as low (<75%), moderate (75-85%), high (85-90%) and very high (>90%) relative to each individuals peak speed (m.s-1, 10-20 m), peak acceleration (m.s-2, 0-10 m) and maximum heart rate. Data analysed in one minute blocks and averaged to reflect four six minute quarters. **Results** Heart rate and RPE were reduced ($P \leq 0.05$) during shorter bout duration games, and a progressive increase was observed as bout durations increased. The distance covered at low, moderate, high and very high speed differed across quarters within- and between-games, yet the total distance was similar in all games. The greatest differences were observed in the first and second quarters of the 24 × 1 minute game, where low speed distances were reduced ($P \leq 0.05$) and high speed distances increased ($P \leq 0.05$). The majority of games started with increased high and very high speed distances in the first quarter, followed by more constant pacing. However, a rapid decline in high and very high speed distance and increase in low speed distance was observed during the 24 × 1 minute game, indicative of an all-out or fast-start pacing strategy. **Discussion** This investigation provides novel evidence to suggest that the pacing strategies employed during high-intensity, intermittent team sport activities are influenced by knowledge of the exercise bout duration. Practitioners should consider the bout duration when prescribing game-based activities to improve the aerobic capacities of team sport athletes. Contact jsampson@uow.edu.au

HEART RATE RESPONSES AND TECHNICAL DEMANDS IN FOOTBALL SMALL SIDED-GAMES TRAINING. A DESCRIPTIVE DESIGN

Beato, M., Schena, F.

University of Verona

Introduction Interval training using small sided-games (SSGs) is an effective training-method for improving together physical and technical skills (Kelly et al., 2009). SSGs are considered as modified games played on reduced pitch areas, often using suited rules and involving a smaller number of players than traditional football games (Hill-Haas et al., 2011). This study investigates the impact of high volume of SSGs on heart rate (HR) response and technical skills. **Methods** A descriptive design was used. 12 male football players (age 22.5 ± 1.8 years, weight 72.6 ± 6.3 kg, height 1.76 ± 0.06 m, HRmax 193.8 ± 5.2 bpm, VO2peak 49.7 ± 3.5 mL Kg-1 min-1, performed two different types of indoor SSGs: 3vs3 and 4vs4, (pitch size 30 x 20 m). The experimental design included 6 sets of 4 minutes, bouts with 2 minutes of passive recovery. The work intensity was evaluated through rating of perceived exertion (RPE) and HR measurements. Technical actions carried out during training games were recorded by means of a camera. **Results** No significant differences were found during the protocol between the two groups (3vs3 and 4vs4) in average HR, although RPE was heavier in 3vs3 compared with 4vs4 ($p < 0.05$). Technical actions (i.e. number of passages, passage in target and dribbling) decreased linearly with the sequence of repetitions ($p < 0.05$) and statistically differences were found in game 5 and 6 compared to game 1. In others technical actions counts (shots, interceptions and tackles) were not found any significant difference. **Discussion** The 3vs3 and 4vs4 SSGs appear to guarantee similar conditional and technical stimuli even if the 3vs3 is perceived as heavier modality of training. Moreover, with the sequence of games, the players reduce the number of technical actions, in both 3vs3 and 4vs4, and this could invalidate the technical purpose of SSGs (over 4 sets of 4 minutes). **References** 1. Hill-Haas SV, Dawson B, Impellizzeri FM, Coutts AJ. (2011). *Sports Med* 41(3), 199-220. 2. Kelly DM, Drust B. (2009). *J Sci Med Sport*, 12(4), 475-479. Contact Email: marco.beato@univr.it

THE INFLUENCE OF PLAYING SURFACE ON THE MOVEMENT CHARACTERISTICS OF SMALL-SIDED GAMES IN HIGHLY TRAINED PRE-PUBERTAL SOCCER PLAYERS

Fenner, J.1,4, Iga, J.2,3, Drust, B.3, Barrett, S.5, Unnithan, V.4

1:Wolverhampton Wanderers FC (UK), 2: The FA (UK) 3:, LJMU (UK) 4:, Staffs University (UK) 5:Perform Better Ltd (UK)

Introduction Small-sided games (SSG's) are commonly used training modality and recently adapted for use as a talent identification model (Unnithan et al. 2012). In youth soccer, training schedules are organised on a large scale and, therefore, require significant artificial turf usage, as natural turf pitches are sensitive to frequent use and cold climates. Movement characteristics and physiological responses on natural and artificial turf are noted to be similar in full-sized adult games; however no study has investigated these effects during SSG in pre-pubertal players. The aim of this study was to assess movement characteristics and physiological responses during multiple SSG on artificial turf compared to natural turf. **Methods** Eight pre-pubertal soccer players (age: 10.4 ± 0.2 yrs) from a professional youth soccer academy were recruited. Three, 4 vs. 4 SSG games were played on both artificial and natural turf. Each game was 5 min in duration, interspersed with 3 min rest. The same combination of players was used for each game, on each playing surface. Pitch size was identical for both surfaces (18.3 m x 23 m). Movement characteristics were captured using micromechanical devices (MEMS). Heart rate (HR) was recorded using short-range radio telemetry. A two factor, mixed design analysis of variance (ANOVA) was used to analyse the data. **Results** Mean HR was not significantly different between the surfaces (Game 1: Natural 152 ± 15 bpm vs Artificial 158 ± 33 bpm, Game 2: Natural 151 ± 16 bpm vs Artificial 156 ± 20 bpm, Game 3: Natural 157 ± 16 bpm vs Artificial 156 ± 25 bpm). Player load was not significantly different between the surfaces (Game 1: Natural 52 ± 3 Au vs Artificial 58 ± 6 Au, Game 2: Natural 52 ± 5 Au vs Artificial 55 ± 6 Au, Game 3: Natural 53 ± 6 Au vs Artificial 53 ± 4 Au). **Discussion** There was no significant difference in either internal physiological load or movement characteristics in SSG when played on artificial or natural turf in this age group. This indicates that artificial turf does replicate natural turf, with regard to the consistency of the movement characteristics and the internal physiological load when playing multiple SSG, but the findings are delimited to this particular age group. Consequently, the use of artificial pitches can be advocated as an appropriate surface for achieving training or talent identification-related objectives from SSG in pre-pubertal players. **References** Unnithan V, White J, Georgiou A, Iga J, Drust B. (2012). J Sport Sci, 30(15), 1719-1727. Contact Jonathanfenner@wolves.co.uk

TACTICAL BEHAVIOR DURING FOUR SMALL-SIDED FOOTBALL GAMES

Aguiar, M.1, Gonçalves, B.1, Botelho, G.2, Lemmink, K.3, Sampaio, J.1

1: UTAD, (Vila Real, Portugal), 2: CERNAS-ESAC-IPC (Coimbra, Portugal), 3: RUG (Groningen, Netherlands)

Introduction Performance in team sports is the result of a long-term training process designed to prepare the players for complex requirements of competition with special emphasis on self-organizing properties and dynamic adaptive behaviour to environmental constraints (Sampaio & Maças, 2012). The aim of this study was to describe tactical behaviour in small-sided games (SSG) in football using positional data. **Methods** Ten professional U19 players participated in 2-, 3-, 4- and 5-a-side SSGs, played 3 bouts of 6 min with 1 min rest in between. Positional data were collected at 5Hz using GPS and used to calculate team centroids. Besides, distance from each player to both team and opponent team centroid, distance between centroids and angle between two players and the own centroid were calculated and analysed. Approximate entropy (ApEn) was used to identify the time series regularity. **Results** The effect sizes of absolute distances increased with the number of players from small to perfect differences. The absolute distance to team centroid increased significantly and the absolute distance to the opponent team centroid decreased significantly with an increasing number of players. The variability among the 3 bouts within each SSG format was very small. ApEn values suggested that in the 5-a-side SSGs, the distance to both own and opponent team centroid was more regular than in the 2-a-side SSGs. The distance between centroids decreases marginally from 2- to 4-a-side SSGs and substantially to 5-a-side SSGs. ApEn values suggest higher regularity in angle distribution in the SSGs with more players. **Discussion** A higher number of players was associated with higher regularity, suggesting higher positional organization in SSG with more players. The higher regularity found in 4- and 5-a-side identified these formats as more adequate to promote emergent and self-organized behaviours. A relationship between the angles performed by players' dyads with the own team centroid suggests the existence of different relationships between players. **References** Sampaio J, Maças V. (2012). MONITORING FATIGUE IN TRAINED SOCCER PLAYERS DURING SPECIFIC WORKOUTS

Del Aguila Ruipérez, A.1, Castaño, A.1, Martínez, A.1, Capelo, F.1, Peñalver, A.1, Jiménez Reyes, P.1

Catholic University of San Antonio

Introduction Soccer is a complex sport requiring the repetition of many different activities such as jogging, sprinting and jumping (Bloomfield et al, 2007). The combination, managing and adjusting of these activities is essential in order to organize the well known "Small Side Games" (SSG). Besides, the ability to sprint is a key parameter (Faude et al 2012) and is the most frequent action in goal situations. To our knowledge, no one date has examined the influence of repetition of SSG sequences, neither if the degree of fatigue due to the accumulation of actions performed is associated with simple mechanical parameters related to fatigue. Thus, the aims of this study were: 1) to investigate relationships between mechanical parameters related to jump and maximal sprint running before and after a specific SSG, and 2) to quantify changes in these data due to fatigue induced by SSG. **Methods** Sixteen trained soccer players performed a maximal sprint of 30-m before the specific SSG. Instantaneous running velocity (v in m·s⁻¹) over time and distance was recorded with a radar Stalker ATS SystemTM (Radar Sales, Minneapolis, MN, US). As well, a countermovement jump (CMJ) and a standing long jump (SLJ) were performed before the SSG. The SSG was composed by 4 repetitions of: a straight sprint over 15-m (without ball), a change of direction and 15-m of 2-on-1 situation finishing with a shot. Immediately after the SSG, players performed a 30-m maximal sprint, CMJ and SLJ in order to check the decrease in performance. **Results** CMJ height and SLJ performance loss pre-post SSG were highly significant and were strongly correlated ($r = 0.86$; $p < 0.001$). The speed losses produced by the specific SSG presented a high relation with CMJ and SLJ exercises ($r = 0.77 - 0.88$; $p < 0.001$). Besides, top speed and the moment which is achieved in the maximal sprint running significantly decreased ($p < 0.001$). **Discussion** The high correlations found between mechanical responses (speed, CMJ height and SLJ performance losses) and the marked alterations observed in this study during a specific SSG, could be useful as indicators of fatigue and this could highlight the utility and validity of using CMJ and SLJ to monitor training load in different specific workouts, as has been proposed by Jiménez-Reyes et al (2013) in other activities. Such data would provide new information on the mechanical manifestation of fatigue during specific SSG sequences, which would then be used to design optimal training routines to improve players's training session. **References**

ANALYSIS OF ENERGY CONTRIBUTION DURING VARIOUS SMALL-SIDED GAMES

Oh, S., Hartmann, U.

Institute of Movement and Training Sciencell

Introduction Based on previous studies (Rampinini et al., 2007) the training intensity during small-sided game (SSG) was measured using heart rate and blood lactate (BLa). However, there are no findings concerning energy contributions (EC) during SSG, when changing number of players. Therefore, the aim of this study is to investigate the difference in EC between various game formats. **Methods** Six U-16 elite junior soccer players (15.3 ± 0.7 yrs, 62.3 ± 7.4 kg, 172.9 ± 5.7 cm) participated in this study during in-season period. 3 different game formats, 2 vs. 2 (2SG), 4 vs. 4 (4SG) and 6 vs. 6 (6SG), were conducted on the constant relative pitch size per player separated by two or three days. Each game formats involved 4 bouts of 4 min with 3 min recovery between each bout except for 2 vs. 2 with 2 min playing time. To ensure the phase of fast and slow components 6 min recovery was set only after the first bout of each game formats. During and after the playing time oxygen uptake and BLa were measured by portable gas analyser (MetaMax 3B, Cortex Biophysic GmbH, Leipzig, Germany) and BLa analyser (BIOSEN 5 line, EKF Diagnostic, Barleben, Germany). The EC were calculated based on the accumulated oxygen uptake above rest during SSG (aerobic [Aer]), fast component of the post-exercise oxygen uptake (anaerobic alactic [AnaLa]), maximum net accumulation of BLa (anaerobic lactic [AnLa]) (Beneke et al., 2004). The data were analyzed with a two-factor repeated measures ANOVA. **Results** During 2SG the Aer was lower (76.3 ± 2.9 % (101.5 ± 21.8 kJ) vs. 84.3 ± 5.2 % (189.2 ± 29.4 kJ), $p < 0.05$), but AnaLa was higher (17.1 ± 2 % (23.5 ± 9.0 kJ) vs. 12.5 ± 2 % (27.8 ± 4.9 kJ), $p < 0.05$) than during 4SG. During 6SG the mean Aer (93.7 ± 2.6 % (213.9 ± 30.0 kJ)) was higher, but AnaLa (3.5 ± 1.6 % (8.4 ± 4.6 kJ)) and AnLa (2.8 ± 1.2 % (6.7 ± 2.9 kJ)) was lower than during 2SG and 4SG (not statistical analysis because of few subjects). **Discussion** The previous studies have determined that the anaerobic fraction increases, as the number of players during SSG decreases (Rampinini et al., 2007). Indeed, in this study it was shown that 2SG led to the higher anaerobic EC and lower aerobic EC compared to the 4SG. However, in all the studied SSG, almost all the EC were from the aerobic energy system. Therefore, the short duration of a bout should be considered to stimulate the high rate of anaerobic energy system during the 2SG. **References** Beneke R, Beyer T, Jachner C, Erasmus J, Hütler M. THE DIFFERENCES IN MOVEMENT PATTERNS AND EXERCISE INTENSITY BETWEEN THE FOOTBALL REFEREE AND ASSISTANT REFEREE DURING GAMES

Hasegawa, M., Miyashita, M.

Tokyo Gakuji University

Introduction In recent years, the physiological characteristics of football referees have received special attention in the literature. However, few studies have compared the physiological characteristics of football between the referee and assistant referee. Therefore, the evaluation of game activity profiles between the referee and assistant referee is needed for providing a new specific training protocol for football referees. The purpose of this study was to compare the movement patterns and exercise intensity between the referee and assistant referee during the football game. **Methods** Thirty-three football referees registered with Japan Football Association were participated in this study. Twelve football games in the U-15 league (i.e. a 70 min game) were used to evaluate for the data analysis. The heart rate monitor (RS800CX, POLAR) and acceleration sensor (s3+Stride Sensor W.I.N.D., POLAR) were used to evaluate the heart rate (beat/min), the total distance covered (m/game), and the total time spent distance covered accelerating (km/h/s). Exercise intensity and acceleration were classified according to the previous studies (American College of Sport Medicine, 2009; Young et al., 2012). **Results** The referees covered more distance during games than the assistant referees (7053 ± 1185 m vs. 3367 ± 169 m, $p < 0.0005$). The assistant referees significantly engaged in low intensity activities than the referees during games (32 ± 15 min vs. 8 ± 7 min, $p < 0.0005$). The referees significantly engaged in high intensity activities than the assistant referees during games (49 ± 19 min vs. 14 ± 12 min, $p < 0.0005$). The percentage of the time spend distance covered low accelerating and low decelerating were higher in the referees than the assistant referees (32.4 ± 2.7 % vs. 21.7 ± 3.5 %, 25.7 ± 4.2 % vs. 18.1 ± 3.4 % respectively, $p < 0.0005$). The percentage of the time spend distance covered high accelerating was higher in the assistant referees than the referees (1.4 ± 0.5 % vs. 0.7 ± 0.3 %, $p < 0.0005$). **Discussion** These findings may suggest that the football referees are required to maintain a high heart rate, and the football assistant referee are needed high degrees of agility and mobility. It is necessary to plan an appropriate training programme to improve such capabilities for each football referee and assistant referee. **References** Young WB, Hepner J, Robbins DW. (2012). VALIDATION OF A NEW SOCCER-MOVEMENT SPECIFIC SPRINT TEST MEASURING BOTH ACCELERATION AND CHANGE OF MULTIDIRECTIONAL SPEED

Kristoffersen, M., Nilsen, A.K., Iversen, V.V., Gundersen, H.

Bergen University og College

Background: Sprinting abilities are very important in soccer, both linear acceleration and change of direction speed (CODS). The aim of this study was to evolve and validate a test measuring soccer-movement specific (SMS) sprint abilities. **Methods:** 12 male elite junior soccer players (17 ± 1 years, 77 ± 2 kg) performed both a 30m linear sprint test and the 30m SMS sprint test at three different days within one week. All participants performed three runs with maximal effort at each test day, and the best result was used in the statistical analysis. The SMS test contains turns of 45° , 90° and 180° , in addition to linear sprints of 5 and 10m. Times between 0–10m (T10), 10–20m (T10–20), 20–30m (T20–30) and 0–30m (T30) were recorded using Brower timing system (Utah, USA). All tests were performed at an indoor area with synthetic grass (Fieldturf Tarkett Playfoot xm 40, granules from Terra XPS, and 12mm Pad beneath the grass, UNISport Scandinavia), and the same procedures were followed for all tests. **Results:** No significant differences were seen between the mean results achieved at the three different test days, nor in total time (T30: 7.15 ± 0.23 , 7.05 ± 0.20 ; 7.13 ± 0.19), or at T10, T10–20 or T20–30. **Conclusion:** Our results indicate that there is no learning effect of repeated testing, and thereby it can be used as a valid and reliable test. The SMS sprint can be used for testing of acceleration and change of multidirectional speed in soccer.

IS CHUNKING THE EXPLANATION FOR THE BENEFITS OF ANALOGY INSTRUCTIONS IN LEARNING?

Van Duijn, T.1, Koedijker, J.M.1, Poolton, J.M.2, Masters, R.S.W.2

University of Bern

Introduction Analogies or metaphors are often used by coaches to teach new movements. Several studies demonstrated advantages of an analogy instruction, such as robust performance under dual-task conditions (e.g. Liao & Masters, 2001). Yet, the question of how an analogy exactly works is still open. One possible explanation is that an analogy chunks task-specific information into higher-level units, which leaves the learner with less chunks to process during movement execution. The current experiment examined this theory by comparing rule accumulation during learning with performance under dual-task conditions. It was hypothesized that participants who accumulated rules that are subsumable under the analogy would show the benefits of analogy learning in their performance measures.

Methods Fifty-one novice participants performed 5 blocks of 20 practice trials in order to learn a table tennis topspin forehand. After each block participants wrote down all the movement-specific rules they were aware of using during learning. After acquisition, the "hand up the mountain" analogy was introduced. Participants were required to perform the task under dual-task conditions (tone-counting), both before and after introduction of the analogy. The rules acquired during learning were rated as subsumable or non-subsumable. On the basis of performance in the first dual-task condition participants were grouped into a Breakdown group (performance decrement in the dual-task more than 5% of single task performance, $n=27$) and a No Breakdown group (performance in the dual-task equal or better than single task, $n=24$). The Breakdown group was further split into a Benefit group (more than 5% improvement from first to second dual task performance) and a No Benefit group (less than 5% improvement). Results The Breakdown group reported a significantly lower proportion of subsumable rules compared to the No Breakdown group, $t(49) = -3.33$, $p = .002$. Further, the Benefit group and No Benefit group did not show any differences in number of subsumable rules, $t(25)=0.41$, $p=.69$, and proportion of subsumable rules, $t(25)=0.82$, $p=.42$.

Discussion In contrast to our main hypothesis, performance improvements after the introduction of the analogy did not depend on whether the acquired rules were subsumable under the analogy. Therefore, our data does not support the chunking hypothesis of implicit motor learning. Interestingly, a higher proportion of subsumable rules seem to lead to a higher robustness under dual-task conditions, suggesting that these rules are more useful in learning than other rules. CONTEXTUAL INTERFERENCE AND DIFFERENTIAL LEARNING COMPARED IN A GRIP-FORCE-REPRODUCTION TASK

Hegen, P., Kubly, M., Horst, F., Schöllhorn, W.I.

Johannes Gutenberg University Mainz

Introduction Different approaches with changing emphasis on variations have been suggested for successful learning. The Contextual Interference (CI) approach (Battig, 1966) focuses on adding a context to a to-be-learned task during the training phase and theoretically results in increased learning rates after interfered acquisition phases. The differential learning (DL) approach relies on the rise of fluctuations during phase transitions in dissipative systems (Schöllhorn, 2000). The space of the to-be-learned "text" is given up and enlarged thru increasing fluctuations by adding stochastically self induced perturbations to the test task for improved acquisition and learning rates (Schöllhorn et al., 2013). For a first comparison of these two approaches a force grip experiment from Shea et al. (1990) was adapted. Beside a low (blocked) and a high (random) CI group a third group was added with DL content, which is mainly changing a movement by slight changes of the test movement. Methods 24 subjects (22 male, 2 female; 27.1 ± 3.1 years of age) were randomly assigned to one of three intervention groups (CIL, CIH and DL). Each subject completed three training sessions (TS) with 30 trials in each. The time to recover between each TS was one hour. The ability to head onwards 60% of the individual maximum grip strength was examined in a pre- and a posttest for each TS as well as 24 hours after the last TS (retentiontest). A repeated measurement ANOVA was used to analyze the immediate (pretest – posttest) and outwear effect (retentiontest) of the three intervention groups. Results The three groups developed very differently. Both CI-Groups decreased their performance in the grip strength task during the training phase. By contrast the DL-Group increased its performance in the grip strength task during all training sessions. All groups increased their performance in the retention test. The repeated measurement ANOVA showed significant results ($p=.043$) over the time. The interaction of group and time is not significant ($p=.359$). Moreover the between-subject effect is not significant ($p=.202$).

Discussion All groups were able to increase their performance from pre- to retentiontest. The development of the DL group differs distinctively in comparison to the CI groups in the training phase, therefore different mechanisms seem to underly these two learning approaches. OBSERVATIONAL LEARNING OF A BASEBALL PITCH: WHICH KIND OF INFORMATION IS EXTRACTED?

Ghorbani, S.1, Bund, A.2

1:CVO (Oldenburg, Germany) 2:UL (Luxembourg)

Introduction A main issue in observational learning is to identify the nature of information extracted by observers from demonstration. Visual perception perspective (Scully & Newell, 1985) proposed that relative motion is picked-up and used for action reproduction. According to visual perception perspective, making salience relative motion information within a demonstration, e.g. by creating point-light or stick-figure displays, would be more effective than a classic video display on observational learning. This proposition was examined in this study by using a Baseball pitch as learning task. Methods Forty one novice female and male adults ($M = 24.2$, $SD = 3.3$ years) were randomly assigned to video, stick-figure, point-light and control groups. Subjects performed 5 familiarization trials, three blocks of 10 acquisition trials, and two retention tests of 5 trials in 10 min and 7 days later. Demonstration groups observed respective videos three

times before each acquisition block. Subjects' performances were independently rated by two experienced Baseball coaches both at level of overall motion and level of individual phases (inter-rater reliability = 0.87). One way and repeated measures ANOVAs were used for statistical analysis ($P < 0.05$). Results Results showed that subjects improved significantly their performance scores from pretest to acquisition phase ($F = 5.54$, $p < .01$), however, regardless of type of model demonstration. Video group performed significantly better than stick-figure group in late retention test ($F = 3.43$, $p < .05$). Analysis of movement phases revealed a significant improvement in stride ($F = 5.12$, $p < .01$), and follow-through ($F = 4.41$, $p < .01$) phases from pretest to acquisition blocks. Moreover, stick-figure group showed a significantly worse performance in late retention test than point-light and video groups in arm cocking ($F = 5.47$, $p < .01$) and arm deceleration ($F = 3.08$, $p < .05$) phases. Discussion The proposition of visual perception perspective was not confirmed by the results, because no superior performance was observed for the subjects in point-light or stick-figure groups over video group. Moreover, lacking a superiority of model observation over no-observation might be due to information the subjects were given prior to pretest and number of times the subjects were presented with model demonstration. Improvements in stride and follow-through phases from pretest to acquisition blocks may indicate that these are most practice demanded phases of the pitch. References Scully, D. M., & Newell, K. M. (1985). Observational learning and the acquisition of motor skills: Toward a visual perception perspective. *Journal of Human Movement Studies*, 11, 169-186.

IMPLICIT MOTOR LEARNING IN YOUTH ELITE SOCCER PLAYERS

Verburgh, L., Scherder, E.J.A., van Lange, P.A.M., Oosterlaan, J.

VU University Amsterdam

Introduction: Neurocognitive functions such as motor inhibition and attentional skills may underlie success in sports and distinguish between elite and amateur players. One ability that has not been studied in relation to sports performance is the ability to learn motor sequences. The current study investigated implicit and explicit motor learning in elite youth soccer players as compared to amateur soccer players. Method: Thirty-eight youth elite soccer players, and thirty-two amateur soccer players between 10 and 12 years of age performed a serial reaction time task (SRTT) with two sequences of eight keys. One of the sequences must be learned explicitly, the other was implicitly learned. A total of five blocks with 25 trials for both sequences in each block was administered. Differences between implicit and explicit learning were tested using repeated measures analysis of variance with sequence and block as within-subject variables and group as between-group variable. Group differences were tested using two separate repeated measures analysis of variance, with group as between-factor and mean reaction time of each block as dependent variable. Results: No difference across groups was found between implicit and explicit learning ($(F(1,68)=.80, p=.53)$). Interestingly, youth elite soccer players showed superior reaction times on both the implicit and explicit learning sequence ($F(1,68)=4.9, p<.05$ and $F(1,68)=3.8, p<.05$, respectively) as compared to amateur soccer players. An interaction effect was found between group and block for the implicit sequence, between block 3 and 4 ($F(1,68)=4.4$, $p<.05$) where the elite youth soccer players showed constant performance of the implicit motor sequence and stopped learning, whereas the amateur soccer players were still learning. For the explicit sequence, no interaction effect was found ($F(1,67)=.26$, $p=.61$), indicating similar learning curves for both groups. Conclusion: Youth elite soccer players outperform youth amateur soccer players on implicit motor learning, and also showed faster reaction times across the SRTT on both sequences. These findings may be important for talent identification in soccer because children with superior implicit learning abilities may learn more rapidly and develop better motor abilities leading to superior sports performance.

EXAMINING THE ROLES OF CONSCIOUS MOTOR PROCESSING AND MOVEMENT SELF-CONSCIOUSNESS IN PERFORMANCE OF A GOLF-PUTTING TASK

Malhotra, N.1, Poolton, J.M.1, Wilson M.R.2, Masters, R.S.W.1,3

1.The University of Hong Kong, 2.University of Exeter, 3.University of Waikato, New Zealand

Objective This study investigated the influence of two dimensions of movement specific reinvestment (conscious motor processing and movement self-consciousness) on performance of a golf-putting task during early-learning and late-learning. Background The influence of individual personality differences on performance has been extensively examined in a range of motor skill-learning domains. 'Reinvestment' is a characteristic of personality that has been shown to negatively influence motor-skill performance under pressure (Masters & Maxwell, 2008). The propensity for 'reinvestment' can be quantified using an updated version of the original Reinvestment Scale, the Movement Specific Reinvestment Scale (MSRS). The MSRS has two subscales that represent dimensions of movement specific reinvestment, which reflect an individual's propensity to consciously control movements (conscious motor processing) or to consciously monitor the 'style' of movements (movement self-consciousness). Understanding the unique influence of the dimensions during the different stages of learning may inform development of more fine-tuned training paradigms in sport. Design Participants ($n = 30$) with no prior experience in golf were recruited to practice 300 golf putts during a learning phase over the course of two days. Methods Trait measures of movement specific reinvestment were obtained from participants using the MSRS. Performance accuracy and quality of performance were assessed on the basis of number of putts holed and consistency of putting strokes, respectively. Multiple regression analyses were conducted to test if conscious motor processing and movement self-consciousness predicted putting accuracy and stroke consistency during early-learning and late-learning. Results Movement self-consciousness, but not conscious motor processing, uniquely predicted putting accuracy during early-learning and late-learning. Higher propensity for movement self-consciousness was associated with greater putting accuracy early and late in learning. Movement self-consciousness, but not conscious motor processing, predicted stroke consistency early in learning such that higher propensity for movement self-consciousness was associated with greater consistency in putting strokes. During late-learning, neither movement self-consciousness nor conscious motor processing predicted stroke consistency. Conclusion The findings suggest that higher propensity for movement self-consciousness is beneficial early and late in learning. A higher propensity for movement self-consciousness seems to be associated with a more consistent style of movement, which benefits performance, especially early in learning. The lack of influence of conscious motor processing on performance during learning will be discussed within the framework of the Theory of Reinvestment. References Masters, R. S. W., & Maxwell, J. (2008). The theory of reinvestment. *International Review of Sport and Exercise Psychology*, 1(2), 160-183. doi: 10.1080/17509840802287218

VERBAL OVERTHADOWING CAUSES A PROCESSING SHIFT IN INDIVIDUALS WITH LOW BUT NOT HIGH CONSCIOUS CONTROL OF THEIR MOVEMENTS

Uiga, L.I., Poolton, J.M.I., Wilson, M.R.I., Masters, R.S.W.I,3

1.Institute of Human Performance, The University of Hong Kong, 2.College of Life and Environmental Sciences, University of Exeter, 3.Department of Sport and Leisure Studies, University of Waikato

Objectives: Balance is a fundamental ability that underlies successful motor performance. Balance is generally controlled automatically, with little conscious involvement, but what happens when people are made to describe their balancing performance? Trying to verbalize a perceptual memory disrupts the subsequent recognition of that memory. This verbal overshadowing phenomenon has been shown in cognitive tasks and also in a motor task (golf putting; Flegal & Anderson, 2008). The transfer inappropriate processing shift explanation of overshadowing proposes that performance is disrupted when processing operations used to encode and to retrieve a memory differ from each other. Therefore, verbalizing a relatively automatic balancing task potentially induces a shift to verbal processing. Theoretically, however, for people who already tend to involve consciousness in the control of their movements (see Masters & Maxwell, 2008) a processing shift, and the associated decline in performance, would not occur. This experiment examined verbal overshadowing of a simple balance task in individuals with lower or higher propensities for conscious involvement in the control of their movements. **Design and Method:** Propensity for conscious involvement in the control of movement was assessed in 53 students, using the Movement Specific Reinvestment Scale. The participants were classified as low or high reinvestors using a median split of their scores on the Scale and performed a quiet standing pretest and posttest on a force plate (1 min). Between the tests, participants either described in writing for 4 mins their pretest balancing (verbal overshadowing) or listed different animals (control). Postural stability was assessed using path length, area of sway and sway variability in anterior-posterior (SD of sway in x axis), and medio-lateral (SD of sway in y axis) directions. **Results and Conclusion:** Verbalization significantly increased the area of sway of low reinvestors but not high reinvestors. For low reinvestors, a transfer inappropriate shift to verbal processing may have occurred, but for high reinvestors, who are more accustomed to verbal processing, no such shift was evident. A second phase of this experiment will focus on the elderly who are likely to be more aware of their balance than young adults. **References** Flegal, K.E., & Anderson, M.C. (2008). THE EFFECT OF ERRORLESS VERSUS ERRORFUL LEARNING ON GENERALIZED MOTOR PROGRAM LEARNING AND PARAMETERIZATION LEARNING

Van Ginneken, W.F., Capio, C., Poolton, J.M., Choi, C., Masters, R.S.W.

The University of Hong Kong

Objectives A contradiction exists between the mechanisms associated with errorless learning (EL) and those attributed to contextual interference (CI). EL discourages conscious attempts to modify technique (Maxwell, Masters, Kerr & Weedon, 2001), while the CI literature suggests benefits of practice structures that encourage conscious engagement in (trial-to-trial) movement variability (e.g., variable practice). This paradox was explored by applying measures reported in the CI literature to an EL paradigm. The main goal was to dissociate variability in Generalized Motor Programs (GMPs) and parameterization in EL. **Design and Method** University students learned a darts-like ball throwing task over 300 trials under either errorless or errorful conditions and performed 150 retention and transfer trials. In a learning session, both groups threw golf balls towards a target at 4 m distance for 6 blocks of 50 trials. The errorless group started with a target size of 95x95 cm. After each block of trials the dimensions of the target were decreased by 15 cm. The errorful group threw at smallest target of 20 x 20 cm exclusively. More than one day after the learning session, participants performed a total of 150 (3 blocks of 50) trials to targets at distances of 3.5, 4 and 4.5 m respectively. During the test session only the smallest target size was used. Trial-to-trial GMP variability was quantified as the Euclidean distance of the time- and amplitude normalized kinematic data (Jaitner, Mendoza & Schöllhorn, 2001). In line with Wulf and Schmidt (1994) the scaling factors of time and amplitude represented parameter settings. **Results and Conclusion** The errorless group committed fewer errors during both learning and test sessions. Preliminary analyses showed that the errorless learning group combined low GMP variability with high variability in parameterization. It is concluded that errorless learning yields more effective generalized motor program learning and parameterization learning. **References** Jaitner, T., Mendoza, L., & Schöllhorn, W. I. (2001). A MOBILE SYSTEM TO INVESTIGATE PUTTING KINEMATICS IN MOTOR LEARNING

Jensen, U.I., Dassler, F.I., Schmidt, M.I., Hennig, M.I., Jaitner, T.I., Eskofier, B.M.I

1: University Erlangen-Nuremberg, 2: adidas AG Herzogenaurach, 3: TU Dortmund University

Introduction Numerous monitoring and training tools for golf putting exist (Marquardt, 2007). However, they are mostly lab-based or stationary. This work presents an improved version of a mobile golf putt system and describes a research application that such a system can be used for. The system was capable of automatic putt detection and kinematic parameter extraction. Using 31 kinematic parameters, the system was used to monitor training effects and to identify relevant group differences. This knowledge delivered further insight in the process of motor learning. **Methods** The presented system is an improved version of a 6-D IMU (3-D accelerometer, 3-D gyroscope) instrumented golf club with real-time analysis capabilities (Jensen et al., 2012). The sensor and the club head coordinate system were aligned and an advanced putt detection based on a Hidden Markov Model was established (Rabiner, 1989). We trained the system with data from 15 subjects putting from various distances (1.5 m, 3 m, 5 m) with two different putters. Overall, 272 putts and the same amount of training swings were collected to train the system. The final system was used in a research study to investigate motor learning. Beside the kinematic putt parameters, average hit ratios and minimal distance to hole were collected. Therefore, 11 non-experienced students completed eight training sessions within four weeks that contained an overall amount of 288 putts. All subjects passed pretest, posttest and two retention tests (one week and three weeks after posttest) with ten putts each. Furthermore, transfer capabilities regarding floor material were tested together with post and retention tests. **Results** The cross-validated putt detection evaluation on the training set resulted in a putt detection rate of 96.0 %. The sensitivity was 88.8 % as 22 misdetections occurred during data collection. Misdetected putts mainly coincided with training swings. The research study targets the identification of parameters that change with training. **Analysis**

sis will be performed in an intra- and inter-individual manner to identify individual as well as group-wide effects. Data mining methodologies like classification, feature selection and regression will be used to analyze the training effects. Discussion The improved mobile golf putt system showed a high putt detection rate on the collected training data. The disjoint training group will allow insight in the true performance on previously unseen subjects. The continuous monitoring of putt parameters and hit ratios will reveal motor learning effects of the specific training program used. References Jensen, U. et al. (2012). THE EFFECT OF CONTEXTUAL INTERFERENCE WITH CONSTANT, INCREASING AND DECREASING VELOCITIES ON ACQUISITION, RETENTION AND TRANSFER OF COINCIDENCE ANTICIPATION TASKS

Zamani Sani, S.H.1,2, Fathirezai, Z.1,2, Farsi, A.1, Brand, S.2, Pühse, U.2, Gerber, M.2

1: University of Shahid Beheshti, Tehran, Iran, 2: University of Basel, Basel, Switzerland

Introduction The aim of the present study was the effect of contextual interference with constant, increasing and decreasing velocity on acquisition, retention and transfer of coincidence anticipation tasks. **Methods** To do this, three separate experiments with different contextual interference were used. First experiment with constant, second with increasing and third used decreasing velocities (Millsag, 2008). 36 male students randomly selected in three groups (blocked, serial and random, each 12 subjects) and performed coincidence timing task with Bassin Anticipation Timing. After pre-test, in acquisition phase, participant performed 90 trials under three conditions (blocked, serial or random). Assessments of retention of learning were made in situations of blocked and random condition and transfer test after 24 hours. Analysis was conducted on temporal absolute error. Data were analyzed by SPSS 18. **Results** Results in the first experiment with constant velocities in the acquisition stage shown the blocked group, had significantly lower absolute errors than the other two groups ($p < 0.05$). In retention under random condition, random group had significantly lower absolute errors than two other groups ($p < 0.05$). In transfer, also, the random group had significantly lower absolute errors than blocked group ($p < 0.05$). In the second experiment with increasing velocities, in the acquisition stage, blocked group had significantly lower absolute errors than random group ($p < 0.05$). In retention, no significant difference was in absolute error between groups ($p > 0.05$). In transfer test, no significant difference was in absolute error between groups ($p > 0.05$). In the third experiment with decreasing velocities, in acquisition stage, random group had significantly most absolute errors than two other groups ($p < 0.05$). In blocked retention, the blocked group had lower absolute errors than random group ($p < 0.05$). In transfer stage, no significant difference between groups was found ($p > 0.05$). **Discussion** Results were interpreted using cognitive difficulties created due to decreasing velocities and also double difficulty of the problem solving process of random arrangement in decreasing velocities, and reduce the effect of timing errors with increasing velocities.

MOTOR ABILITIES OF THE HAND IN JUDO AND KICK-BOXING ATHLETES

Karaleic, S.1, Puzovic, V.2, Milenkovic, V.1, Savic, Z.1, Andjelkovic, I.1

1. Faculty of Sport and Physical Education, University of Pristina, Serbia; 2. Faculty of Medical Sciences, University of Kragujevac, Serbia

Introduction: Motor abilities of the hand are considered as important factor for successful task performing in combat sports. The aim of this study was to evaluate differences in hand motor abilities of athletes from two combat sports with different style of fighting, judo and kick-boxing. **Subjects and methods:** This study included 36 male athletes, age 16-17 years old. They were divided in two groups per 18 athletes, by the sport they train, judo and kick-boxing group. All the athletes compete in the first league for their age category. Criteria for including in the study was that they train their sport at least 4 years, and that height of the athlete is between 178-184 cm, and weight between 65-72 kg. Under motor abilities of the hand we tested grip force, pinch force and hand and fingers coordination. Grip and pinch force were evaluated with Lafayette hydraulic dynamometers, while hand and fingers coordination were evaluated with Minnesota rate of manipulation test and Nine-hole peg test. All tests were done with dominant hand. Statistical procedures were done with statistical package PASW 18. **Results:** Judo athletes had a significantly higher grip (46.8 ± 6.2 kg) and pinch force (7.7 ± 0.9 kg) in comparing with results from kick-boxing athletes, 38.4 ± 5.4 kg and 6.1 ± 1.1 kg for grip and pinch force respectively, with $p = 0.001$ for both tests. In Minnesota rate of manipulation test, which we used to evaluate speed and coordination of the arm, hand and fingers, kick-boxing athletes had significantly better results in comparing with judo athletes, with $p = 0.001$. However, in Nine-hole peg test for evaluation of fingers and hand coordination judo athletes had better results but without statistical significance, $p = 0.078$. **Conclusion:** In conclusion we can say that majority of results from this study goes along with specific sports requirements for these two combat sports. However, we expected better pinch and grip force results from kick-boxing athletes, because weak hand muscle in this sport may lead to the injury. DEVELOPMENT OF AEROBIC CAPACITY IN SWIMMERS – CRITERIA FOR THE PRESCRIPTION AND CONTROL OF SETS ORIENTED TOWARDS BASIC AEROBIC INTENSITY

Cunha, P.1, Proença, J.1, Rama, L.2

(1)U.Lusófona H.T. – Lisbon-Portugal. (2) FCDEF-UC- Coimbra-Portugal

Introduction Most of the training volume in Competitive Swimming (CS) aims for the consolidation of a consistent aerobic development using training loads corresponding to the metabolic zone of the Lactic Threshold or Aerobic Threshold or A1 [1] and Anaerobic Threshold or A2 [2,3]. Swimmers must perform these tasks at optimal velocities, corroborating the development of the aerobic capacity as one of the determining goals for the success in CS [4]. The aim of this study was to identify the training tasks most often used by Portuguese

swimming coaches working with elite athletes in CS following this orientation. **Methods** The sample is composed of 51 Portuguese top level coaches who answered an online questionnaire. In the questionnaire there were 3 groups of closed questions where, for each question, each coach was to select up to 3 answers which corresponded to their favorite methodologies. The groups related to: I – Methods of load control; II – Sets for the development of A1; III – Sets for the development of A2. **Results** The methods of load control most commonly used are: 1st–Heart rate (90.2%); 2nd – percentage of best time (70.6%); 3rd– T-30 mean velocity (37.3%); 4th– lactate accumulation (23.5%). A1 tasks often prescribed are: 1st - 8x400m (70%) with 40" rest (58.8%); 2nd - 30x100m (65%) with 10"rest (41.2%); 3rd - 15x200m (65%) with 20-30" rest (39.2%); 4th - 6x500m (70%) with 45" rest (31.4%). A2 sets more often prescribed are: 1st - 2x(7x200 (80%) 30" rest) 3' between sets (78.4%); 2nd- 3x(10x100m (75%) 15" rest) 3' between sets (74.5%); 3rd - 2x(4x400 (85%) 45" rest) 3' between sets (52.9%); 4th - 2x(30x50m (70%) 10" rest) 3' between sets (23.5%). **Discussion** A considerable variability of the results was confirmed, with the exception of heart rate as the preferred method for monitoring training load (90.2%), which is corroborated by others [2]. The results obtained point towards a massive use of interval training, with the continuous methods coming as a distant second. The variation in the standard distances commonly used –from 100m to 500m for the A1 and from 50m to 400m for the A2 — mostly relate to the event each swimmer specializes in. **Bibliography** 1. TECHNICAL-TACTICAL ANALYSIS OF ELITE MALE KICKBOXING

Sanhueza Alfaro, S.P.1, Rodio, A.1, Giancotti, G.F.1, Lecce, D.1, Capranica, L.2, Cortis, C.1

1 University of Cassino and Lazio Meridionale; 2 University of Rome "Foro Italico"

Introduction During kickboxing competitions the aim is to score more points than the opponent, through the execution of kicking and punching techniques within the target area (above the waist) or through the execution of a knockout (Silva et al 2011). Although success in kickboxing competition results from a combination of several aspects, little information is available regarding the different techniques performed by the athlete during real matches. Thus, the aim of this study is to analyze the technical and tactical aspects of elite kickboxing competition. **Methods** Six matches of 12 elite male Italian Kickboxing athletes (weight categories from -57 to 91+kg) were recorded during the 2012 National Tournament (organized as a selection for the upcoming European Championship). All matches (3 2-min rounds) were analyzed in relation to type of action and limb used with Dartfish TeamPro Software. Differences ($p < 0.05$) with respect to type of action (attack vs defense) and between limbs (upper vs lower vs upper-lower combination) were analyzed in relation to match outcome (winners vs losers) and to rounds (rounds1 vs rounds2 vs rounds3) through repeated measures ANOVA. Results Data are presented as mean values and SDs of total number of occurrences. No differences emerged in relation to rounds and limbs used in attack and defense actions, while a different trend was found with respect to match outcome. In particular, winners showed differences ($p < 0.05$) with respect to limbs, with a greater use of upper (24.1 ± 11.1) and lower (27.6 ± 15.8) limbs than combinations (2.1 ± 1.1) during attack, and upper (10.1 ± 10.2) limbs more used than lower (1.8 ± 1.7) ones and combinations (1.0 ± 1.0) during defense actions. Losers showed difference ($p < 0.05$) only during the attack phase, with a greater use of upper (34.0 ± 15.1) limbs with respect to lower (15.6 ± 5.8) ones and combinations (5.0 ± 2.9). **Discussion** Findings indicate no differences between winners and losers for limbs used, probably depending on the high technical skills that characterize elite athletes. Winners attack more with the upper and lower limbs and defend more with the upper limbs. Conversely, losers use more often upper limbs during the attack while limbs were used to a lesser extent during the defense phase. This could depend on the adoption of a more effective strategy by the winners using a balance between attack techniques to hit the opponents and defense techniques to ensure their integrity compared to the losers (Ouerghi et al 2013). COMPARISON OF THE APPLIED 2 MIN MODIFIED LABORATORY TEST IN THE GYMNASTICS DISCIPLINES DURING PRE-PARATORY PERIOD

Gateva, M.1, Tarnichkova, M.1, Ivanov, N.1, Andonov, K.1

National Sports Academy

Introduction Due to the specifics of the gymnastics disciplines it is difficult to determine the dosage and also the effect of the applied load on the athletes. Commonly used tests, such as the VO₂max, register only the aerobic capacity of the gymnasts. Gymnastics, as a complex noncyclic structured sport is proved (Gateva, 2009; Jeliakov and Dasheva, 2002) to be in the anaerobic regime of work during the performed competitive programme – the routine. For that reason, the aim of this study is to create a laboratory model of the loading similar in intensity and duration to the gymnastics routines in order to compare the results between gymnastics disciplines. The test should cause the cardiovascular system to respond with 95% of the maximum HR which is the real value when executing a gymnastics routine (Gateva, 2009; Mineva et al. 2003). **Methods** 60 high level athletes from 4 gymnastics disciplines (Rhythmic, Acrobatics (male & female), Aerobics and Aesthetic gymnastics) were tested in total. Step one: the gymnasts performed a maximal test (Modified Balke Treadmill Protocol – Athlete) with a constant speed of 8,4 km/h, 0% starting incline and increment of the incline with 0,6% every 30 sec. Step two: 2 min modified laboratory test (authors' test) with constant speed of 8,4 km/h with incline set up individually for each athlete through extrapolation of the HR towards 95% of its maximum. The indicators measured were VO₂, HR, blood La, EPOC and related others. **Results** The maximum HR reached at the end of the test varied from 181 to 186 b/min, the oxygen consumption was from 42 to 49 ml/kg/min and the blood lactate concentration went up to 10 mmol/l for all gymnastics discipline. **Discussion** Applying test, same in duration and glycolytic requirements as the routine, shows the real effect of its execution. Attempts have been made in the past to calculate the energy cost of a gymnastics routine (Guidetti et al., 2000) but with extrapolation of the data from VO₂max test. The results we gathered show that the different gymnastics disciplines require similar effort and energy consumption. References Gateva M, Andonov K. (2009). PHYSICAL CHARACTERISTICS OF RECREATIONAL FEMALE GYMNASTS: A FOLLOW UP STUDY

Moustogiannis, A., Theos, A., Lafkas, A., Savvadi, A., Maridaki, M.

National and Kapodistrian University of Athens

Introduction Physical (strength, flexibility) and anthropometric (body height, body weight) factors seem to influence performance in gymnastics. In particular, performance in gymnastics depends on the ability to produce maximal power which, in turn, is influenced by maximal strength, balance and flexibility. The purpose of the present study was to investigate differences in physical characteristics of recreational female gymnasts after one-year training period. **Methods** Eighty six amateur female gymnasts participated in this study. Measurements of flexibility (sit and reach), lower limbs strength (squat jump), wrist strength (handgrip) of both hands and agility (agility T-Test) were first performed at the age of 9.0 ± 1.9 yrs and repeated one year later. Differences between the repeated measurements were analyzed using student's T-test. Results are presented as mean \pm SD. Results No significant differences were observed in body mass and body height (mass: 30.0 ± 7.9 kg vs. 33.2 ± 9 kg, height: 130.3 ± 12.6 cm vs. 135.4 ± 13.1 cm), while body mass index (BMI) differed significantly (17.2 ± 2.2 vs. 17.6 ± 2.6 kg/m²; $p < 0.05$) between the repeated measurements. Agility (16.5 ± 5.3 vs. 15.5 ± 2 sec, $p < 0.05$) and flexibility (26.7 ± 5.4 vs. 28.2 ± 4.7 cm, $p < 0.05$) also differed significantly between the two measurements. Similarly, lower limb strength (25.1 ± 7.9 vs. 27.3 ± 6.3 cm, $p < 0.05$) as well as wrist strength in both hands was significantly increased in the second measurement (right hand: 6.4 ± 4.8 vs. 9.9 ± 5.3 kg, $p < 0.05$; left hand: 6 ± 4.3 vs. 9 ± 4.7 kg, $p < 0.05$). **Discussion** The findings of the present study indicate that gymnastics training has a significant impact on all the physical parameters measured and promotes their symmetrical development in young female children followed a gymnast training. **References** Cagno A.D, Baldari C, Battaglia C, Monteiro M.D, Papalardo A, Piazza M, Guidetti L. EXPLORING THE RELATIONSHIP BETWEEN FUNCTIONAL MOVEMENT COMPETENCE, STROKE TECHNIQUE AND COMPETITIVE SWIMMING PERFORMANCE IN BOTH ELITE AND AMATEUR SWIMMERS

Oguz, H., Rolt, C., Nolte, K., Bathgate, A.

University of Pretoria

Aim. The Functional Movement Analysis (FMA) is a grading system which theoretically screens movement patterns and provides quantitative data about the mechanics of the musculoskeletal system during the execution of a motor task, whereas swimming performance is evaluated in terms of performance times and technique analysis. The primary objective of this study was to explore the relationship between functional movement screen competence and swim stroke technique, with a secondary objective of determining whether these scores are correlated with swimming competition performance, in both elite and amateur swimmers. **Methods.** Twenty six male and female swimmers (ELITE, n=12; and AMATEUR, n=14) took part in the study. There were two test days each separated by 24 hours. On test day one, 2D video analysis was used to record each swimmer's functional movement ability, which included movements that test trunk stability, overhead squat, rotational stability and shoulder external rotation. The third attempt of each movement was used in analysis. On test day two, underwater 2D video analysis was used to collect 100m freestyle swim from each swimmer which was later used for analysis. Three subdivisions were used; body position in the water, stroke analysis and kick analysis on both the right and left side of the swimmer, and scored using the USA stroke technique score card. Finally each swimmer's competitive performance was determined by the FINA points received for best race swim in that current year. **Results.** Right and Left side stroke analysis scores significantly correlated with trunk stability FMA score ($r=0.383$ & $r=0.419$ for right and left side respectively, $p < 0.05$). Right side kick analysis significantly correlated to the swimmers right side shoulder external rotation ($r=0.407$, $p < 0.05$), however the correlation was not strong enough on the left to be significant. Right and left side body position scores from the swim analysis showed no significant correlation with any of the functional movements tested. No significant correlations were found between the swimmers competitive performance scores, and their function movement overall scores, however there were significant positive correlations with right and left side stroke analysis scores. **Conclusion.** The results indicate that problems identified in a swimmers stroke could be rectified by improving swimmers trunk stability. From this study we cannot reveal that a poor functional movement score will determine a poor performance in the pool, and or vice versa. However, future research is recommended to investigate these correlations further with a larger subject pool, to enhance the relationships found within certain functional movements and stroke analysis which showed weaker correlations which perhaps could be further linked with performance output.

ANALYSIS OF THE ENTRY SPEED IN THE SWIMMING START

Caspani, M., Romagioli, B., Ciapparelli, C., Invernizzi, P.L.

Università degli Studi di Milano

INTRODUCTION The ability to perform a fast start is a fundamental factor to obtain a high performance in swimming sprint events, such as 50 m distance. For an optimal start, the swimmer must be able to limit the loss of speed subsequent to the impact to the water. A poor management of the dive technique and entry leads to a disadvantageous losing of speed. When the hands enter the water, swimmers still have the high speed gained in the pushing from the starting blocks, plus the gravity acceleration. Therefore the flight phase and the entry speed are very important. The aim of this study was to evaluate the effectiveness of a specific training to improve the pushing and the flight phases of the start, by high definition cameras and Speed RT device, which allow to accurately assess the swimmers' speed and the distance from the wall of the entry. **METHODS** Ten male sprint swimmers (age 22.6 ± 2.02 years; height 184.6 ± 3.9 cm; weight 77.5 ± 3.8 kg) participated in the study. The start's analysis was assessed by two synchronized cameras, placed in line with the starting block and at 3.5 m of distance. Speed RT device was used for real-time sampling data of the swimmers' speed during the start. Measurements were carried out before and after a specific training program addressed to improve the strength of the lower limbs (4x6 rip. 75% max, for two months) and the buoyancy improvement, assumed by swimmers during the flight phase. The effectiveness of the training program to improve the entry speed and the length of the flight phase was evaluated. Data analysis was performed with the Student's t-test, whose significance was placed at $p < 0.05$. **RESULTS** Training improved the distance covered by swimmers during the flight phase from 3.36 ± 0.15 to 3.51 ± 0.16 m ($p < 0.01$). The specific training also improved the swimmers' speed at the entry, from 5.49 ± 0.12 to 5.58 ± 0.15 m/s ($p < 0.001$). **DISCUSSION** The specific strength and high-intensity training produced a positive effect on the start performance. Therefore, for sprint swimmers, we propose modifications to the current start training methodology, with particular attention to strength and high-intensity training. The analysis of the technique's details is essential to improve performance. If a higher strength of the lower limbs may induce a farther start, perfect position during the flight is also very important to keep a high entry speed. **REFER-**

EFFECTS OF RESPIFIT S INSPIRATORY MUSCLE TRAINING IN ACUTE EXACERBATION COPD PATIENTS

Simi, H.1, Wallner, D.1, Hofmann, P.2, Wurzingner, G.3

1FH JOANNEUM, 2University of Graz, 3LKH Hörgas-Enzenbach

Introduction Several studies have proven that inspiratory muscle training (IMT) increase force of inspiratory muscles (Loetters et al., 2002). Long-term studies have shown a positive effect on health related quality of life (HRQL) in COPD patients (Vale et al., 1993). Significant improvements of HRQL and endurance were shown for short-term treatment in these patients (Kirsten et al., 1998), however, no studies investigated the short-term treatment including IMT. **Aim** The aim of this study was to examine the effect of an IMT additional to standard care in COPD patients during an acute exacerbation hospitalization. **Method** 24 COPD patients (41.12 ± 15.04 FEV1, 68.0 ± 7.8 years), were investigated during an in-patient hospitalization after acute exacerbation in a prospective, randomized and controlled trial. The training group (TG, n=7) received 4 to 5 IMT units, using RESPIFIT S (E.Biegler GmbH, Mauerbach, Austria), in addition to a standardized therapy program. IMT was performed at 80% of maximal inspiratory pressure (PImax), and inspiratory endurance training at 60% of PImax. The control group (CG, n=7) underwent only the standardized therapy program. The development of the inspiratory strength and endurance (Tlim), walking distance (6MWT), the associated effort tolerance (BORG scale) as well as HRQL were observed. **Results** PImax significantly improved from 58.71 ± 6.18 mbar to 78.14 ± 9.26 in the TG. The inspiratory endurance (Tlim) (200.85 ± 33.66 sec vs. 402.42 ± 55.78 sec) and the walking distance (6MWT) (307.07 ± 37.02 m vs. 356.42 ± 36.21 m), improved significantly in the TG whereas in the KG no significant improvements were observed. HRQL significantly increased in the TG for unpleasant chest sensations (0.026), fatigue and exhaustion (0.042), shortness of breath (0.039) and mental perception (0.023). Improvements in the KG were only observed for perception of medical therapy applied by the physician (0.046) and emotional stress (0.041) ($p = 0.5$). **Conclusion** IMT is suggested a beneficial complement to standard therapy during inpatient or outpatient rehabilitation as well as an addition in short in-patient hospitalization after an acute exacerbation.

PHYSICAL CHARACTERISTICS OF PREPUBERTAL GIRLS INVOLVED IN RHYTHMIC GYMNASTICS TRAINING

Drivas, A.1, Karanastasis, G.2, Maridaki, M.2

National and Kapodistrian University of Athens

Introduction Rhythmic gymnastics is a multi-factorial sport and, thus, young athletes should train to develop skills such as flexibility, agility and muscle strength in order to improve their performance. Combination of these skills is also a key factor so as elite rhythmic gymnastics athletes to be able to stand at high level. The aim of this study was to assess and correlate the flexibility, agility, vertical jump and upper limbs strength in rhythmic gymnastics young athletes. **Methods** Ten (n=10) female athletes (age: 9 yrs \pm 1) participated in the study. Somatometric characteristics were measured including height and weight, and body mass index (B.M.I.) was calculated. The subjects performed tests for agility (T-test), flexibility (Sit'n'Reach), lower limb strength (vertical jump; Abalakov test) and wrist strength (Handgrip). Pearson correlation coefficient (r) was used to assess possible relationships between the variables. The level of statistical significance was set at $p < 0.05$. **Results** The somatometric characteristics of the participants were: height 142 ± 10 cm, weight was 35.7 ± 8.1 kg, and B.M.I. 17.33 ± 2.23 kg/m². The performance of the participants in the tests conducted were: Vertical Jump 30.4 ± 2.7 cm, Sit'n'Reach 27.5 ± 6.3 cm, Handgrip 10.8 ± 4.9 and T-test 16.6 ± 1.9 sec. Statistical analysis showed significant correlations between weight and wrist strength of the subjects ($r=0.71$). No correlations were found between Sit'n'Reach and B.M.I. ($r=0.32$), as well as between Vertical Jump and T-test ($r=0.24$). **Discussion** Conclusively, the skills of those rhythmic gymnastics athletes seem not to be highly developed (Douda et al., 2008). Flexibility and agility are developed at a higher level than upper limb strength. An explanation for that could be that rhythmic gymnastics is a sport based mainly on the combination of the first two skills (Cagno et al., 2008). It should also be noted that, these subjects had about 2 years of experience in this sport while performance in rhythmic gymnastics requires more years of practice and training that starts at the early age of 6 years and continues until adolescence (Zhumanova, 2013). **References** Cagno A., Baldari C., Battaglia C., Guidetti L., Piazza M (2008). *Italian J Anatomy and Embryology*, 113, 29-36. AN EVALUATION OF BREATHING FUNCTION TESTS BY SWIMMERS AND BY ACADEMIC LEVEL BLOWING INSTRUMENT USERS

Koparan, Ş., Sungurtekin, M., Coşkun, F., Sungurtekin, Ş.

Sport science

Introduction As it is the case in sports where skills and competences are priorities and special talents are required, it is quite crucial to determine an organism's functional readiness level in the field of music as well. Besides, an exhaustive literature review did not reveal any similar study on this issue. The present study aims to compare the findings obtained from the pulmonary function tests of university students both from the blowing instrument education branch in the Music department and the swimming education branch in the Physical Education and Sports department. **Methods** 11 swimmers and eight blowing instrument performers participated in the study voluntarily. The types of pulmonary function tests used in the study were ventilation, perfusion, diffusion and respiratory control tests. The tests were conducted as incremental tests on Ergospirometer by the use of VMAX Encore system. Mann-Whitney U test was used to investigate the differences between the two groups. **Results** The findings of the study did not indicate any statistically significant differences in the volume level exhaled on the first second of forced expiration, forced vital capacity measurements, total lung capacity, residual volume, and diffusion capacity between the instrument performers who are receiving training in blowing instrument education and the swimmers who are receiving training in swimming education. However, differences were found in relation to swimmers in maximal oxygen consumption ($p=0.001$) and maximal carbon monoxide production ($p<.01$). **Discussion** The results of this study revealed that the students receiving training in blowing instrument education have dynamic and static lung respiratory capacities that are very similar to swimmers who are training rigorously. From this point of view, it could be thought that when swimmers, who used too lots of heavy training, had to stay away training for any health reason, the kind of training with a blowing instrument, which does not require any physical activity, would contribute to their either dynamic or static lung breathing capacity and shorten the process of reclamation for

competition and adaptation and prevent any negative consequences of this set back. Similarly, based on the findings from the tests in the study, the blowing instrument performers' levels of proper breathing and effective use of breath were evaluated objectively. Besides, it is considered that a right and proper use of breath might be an indicator of what levels of development can be attained both at practices that require technical exercises and at performances of a piece of music. This study is significant not only for the evaluation of performance development of the participant groups but also for increasing their levels of professional motivation. References Kenney, L. W. THE DIFFERENCES OF MUSCLES CO-CONTRACTION AROUND THE SHOULDER AT VARIOUS POSITION AND VELOCITIES IN BASEBALL PLAYERS

Ko, H.T., Lin, S.H., Hu, C.Y., Lin, H.T.

Department of Sports Medicine

Introduction Muscle co-contraction is important for motion accuracy, and maintains joint stability (Enoka, 1997; Baratta et al., 1988). Therefore, muscles around the joint should have different co-contraction to keep joint stability in different motion situation, especially for the baseball players with heavy loading of the shoulder. The purpose of this study is to investigate the effect of joint abduction and rotational velocity in muscles co-contraction during shoulder rotation in the baseball players. **Methods** Eight baseball players including 3 outfielders and 5 pitchers, aged 20-22 yrs, without any upper limb injuries within six months were recruited in the study. The activation of seven muscles including anterior deltoid, posterior deltoid, pectoralis major, supraspinatus, infraspinatus, teres major and teres minor were investigated. Before testing, the subjects were asked to warm up the shoulder and measured the muscle maximum voluntary contraction (MVC). The shoulder isokinetic internal and external rotation was tested, and the testing velocities were 60°/sec, 120°/sec and 210°/sec at three various shoulder abduction 45°, 70° and 90° positions. **Results** The outfielders' pectoralis major and anterior deltoid were more activated than the pitchers both in internal and external rotation ($P < 0.05$). Only the pitchers' posterior deltoid was more activated than outfielders ($P < 0.05$). Analyzed the effect of shoulder abduction angle in muscle activation, the posterior deltoid, teres minor, supraspinatus and infraspinatus had largest activation at shoulder abduction 70° in internal rotation, however, the pectoralis major, supraspinatus, posterior deltoid and anterior deltoid were more activated at shoulder abduction 90° during external rotation, these were reached significant differences in both groups. The effect of rotational velocity, the pectoralis major, teres minor, posterior deltoid and teres major have significant higher activation at 60°/sec ($P < 0.05$). **Discussion** The shoulder position and rotational velocity did affect muscles activation during internal and external rotation due to the muscle length change and physiological characteristics. Pitchers need precise pitching control, while outfielders often training for throwing long distance, these differences may make players have various muscle contractions even at same exercise condition (Noffal, 2003). However, only 3 outfielders and 5 pitchers was the limitation for the study and need more subjects to confirm the muscle co-contraction change at these exercise condition change. These results could help for design more efficient training program and prevent injury. **References** Enoka RM. (1997). *J Biomech*, 30(5), 447-455. COMPARED TO LASER WATI CAPACITY AND THERMAL DEVICES IN THE REHABILITATION OF INJURED ELBOW AND RESTORE STRENGTH AND RANGE OF MOTION TO THE PLAYERS JAVELIN

Mohammed, W., Hamadulla, H.

University of Muthanna.

The (Golfer Elbow) to the elbow joint of more and more complicated injuries that afflict throwers spear and players of the tennis racket, often Tinea life more Sporting through this injury if not treated and rehabilitated in a scientific and fast, where the study aimed to identify the impact of the laser and the Aiti capacity and thermoelectric devices in the rehabilitation of injured elbow joint and restore strength and range of motion is normal. Because the hardware is thermal, laser and Aiti ability of more ways physical therapy influential in the belief of the researchers, as well as the study assumed there is a preference in the influence of the laser and the Aiti ability in the rehabilitation of injured elbow joint and restore strength and range of motion of natural Aladz thermal. The sample consisted of four archers shaft infected infecting (Golfer Elbow) has been diagnosed by a physician specialist physiotherapy and determine the degree of injury, was a pre-test, which included grip strength by Aldainmomiir, and test the range of motion of the elbow joint, was split sample randomly into two groups each set consists of two players, has been rehabilitating the first set by a laser at low power, and the second group apparatus heat for a period of eight weeks, and then was a post-test and were processed results and discuss style and scientific researchers concluded that the laser at low power and thermoelectric devices Sihaman in the rehabilitation of injured attachment (Golfer elbow) and restore strength and range of motion of the joint and through the results show that there is a preference for the laser and sessile ability to restore strength and range of motion of the elbow joint of thermoelectric devices, so the researchers recommended using laser and Aiti ability to treat wounded attachment (Golfer Elbow), and conduct similar studies for other injuries similar.

TRUNK MUSCLES ACTIVITY DURING PIVOT MOVEMENT

Akie, U.1, Yu, O.2, Mai, Y.1, Koji, K.1

1 Faculty of Sports Science, Waseda University, Tokorozawa, Saitama, Japan. 2 Saitama Medical University, Saitama, Japan.

Background: Recently, many studies focus attention on trunk muscles activity during daily performance or sports activities. However, the pattern of trunk muscles activity during the turning movement is not clear. **Objective:** To elucidate the pattern of trunk muscles activity

during a one-legged turn of the body while swinging the free leg. Methods: Subjects are 7 female collegiate rhythmic gymnastics players (age, 19.3 ± 1.7 years; height, 157.8 ± 10.0 cm; weight, 47.5 ± 5.4 kg). Electromyographic data were bilaterally obtained from rectus abdominis (RA), external oblique, internal oblique (IO), and erector spinae muscles. The Subjects performed the "passé pivot," which is the basic pivot in rhythmic gymnastics. The pivot is a turn wherein the toe of the free leg is placed at the knee of the standing leg. The subjects turned as possible as they could. The left leg was the standing leg and the subjects turned towards the right means posteriorly. We analyzed the first turn, and we divided the pivot into 3 phases; namely, the preparation phase (Pp), the early phase (Ep), and the later phase (Lp). The Pp lasts from the 0.5 seconds before the free leg leaves the floor to the time the leg leaves the floor, the Ep lasts from when the leg leaves the floor till the time the subjects turns 180° , and the Lp lasts from the 180° point to the 360° point. The muscle activity (%MVC) was compared between muscles and phases by using repeated two-way analysis of variance ($p < .05$) Results: As the results of the two-way ANOVA, there is no interaction. IO activities on both sides were high in all phases. The IO activity on the free leg side for each phase was 87.5 %MVC during the Pp, 60.5 %MVC during the Ep, and 69.7 %MVC during the Lp, respectively. Additionally, the IO activity on the standing leg side for each phase was 51.2 %MVC during the Pp, 58.2 %MVC during the Ep, and 87.3 %MVC during the Lp. A major finding during the comparison of the muscles was that the activity of the IO on the standing side was significantly higher than the RA of the free leg. Discussion: The IO muscle activity was highest among all the other muscles and was high value in all the phases. Therefore, the IO may have a significantly affect postural maintenance in turning. The IO activity in the free leg was higher value from the preparation. It is suggested that the IO of the free leg contributed by providing the necessary power for the turn. Although the IO activity in the free leg was high during Pp, the IO activity in the standing leg was higher than that in the free leg during Lp. The results might suggest that the IO in the standing leg provides postural maintenance that prevents the body being pulled in the direction of the free leg by the centrifugal force. Conclusions: This study indicated that the IO showed higher activation than the other trunk muscles during the pivot movement. There is the possibility that the IO of the free leg provided the power for the turn, and the IO of the standing leg provides postural control.

EFFECTS OF TRANSVERSE ABDOMINAL MUSCLE ACTIVITY HAS ON THE ACTIVITY OF THE ERECTOR SPINAE IN TRUNK EXTENSION

Iizuka, S.I., Matsunaga, N.I., Kaneoka, K.I., Okubo, Y.I.

1: GRADUATED SCHOOL OF SPORT SCIENCES, WASEDA UNIVERSITY, 2: FACULTY OF SPORTS SCIENCES, WASEDA UNIVERSITY 3.SAITAMA MEDICAL UNIVERSITY

Introduction In previous study, it has been reported that the activities of the internal oblique muscle and is decreased when it has a weight as compared to healthy subjects with chronic low back pain patients. Therefore, we thought function of local trunk muscles are related to the occurrence of low back pain. So, The purpose of this research was to reveal the influence of erector spinae (global muscle) activity on transverse abdominal muscle (local muscle) activity in trunk flexion-extension movement. Methods Subjects of this study was eight female college students. The three EMG signals were collected using disposable surface electrodes. The pairs of electrodes were positioned onto the rectus internal oblique and erector spinae on right sides of the body in the direction of the muscle fibers. Erector spinae muscles were divided into two of lumbar (level of L3 spinal process) and thoracic (level of T7 spinal process). The subjects were two tasks trunk flexion-extension movement with draw-in and without draw-in. Trunk flexion angle was three: 45 degrees, 90 degrees and maximum. The movement was divided into five phases: Standing position(Prel), Flexion, Flexion action, Flexion position, Extension action, and Standing position(Post) Results In the task of flexion 45 degrees, No significant differences were shown for EMG between with and without draw-in for lumbar erector spinae and thoracic erector spinae, in all phases. However, in flexion task 90 degrees with draw-in, EMG of the lumbar erector spinae was significantly smaller than in the extension phase ($p < 0.05$). Discussion Rigid body of the trunk result from the activation of both the local and global muscle. As a result, the increased stability of the trunk can be considered. In this study, the rigidity of the lumbar region has increased by draw-in, EMG of the lumbar erector spinae has been reduced in the extension phase of 90 degrees flexion task. In fact, this study shows the possibility that burden of other global muscles would decrease by activating the local muscles of the trunk. Therefore, it was thought that it might be alleviating chronic low back pain due to overuse of the global muscles in activating a local muscle during movement. Conclusion It has been shown by this study is that the burden of global muscle is reduced by the activities of local muscle.

HIP AND TRUNK NEUROMUSCULAR TRAINING TO REDUCE RISK OF ACL INJURY IN SPORT: RESPONDERS AND NON-RESPONDERS IN ELITE FEMALE TEAM SPORT ATHLETES

Weir, G.J., Cantwell, D., Alderson, J.A., Elliott, B.C., Donnelly, C.J.

University of Western Australia

Introduction The aim of this study was to determine if body-weight based (BWB) neuromuscular training targeting the hip and trunk is effective in altering the activation of the muscles crossing the hip and knee, reducing peak knee joint loading and anterior cruciate ligament (ACL) injury risk among elite female field hockey players. A secondary objective was to determine if all athletes within this cohort responded in a similar manner to training, or when clustered into sub-groups based on response to training (i.e. reductions in peak knee loading) displayed unique biomechanical and/or neuromuscular adaptations that could explain these differences. Methods Sixteen elite female hockey players participated in eight weeks of BWB neuromuscular training, targeting the hip and trunk. Hip, knee and ankle moments, support moment and the activation of nine lower limb muscles were calculated during weight acceptance of unplanned sidestepping prior to, and following training. Athletes were then classified as 'responders' ($n=4$) and 'non-responders' ($n=12$). Total muscle activation (TMA) of all lower limb muscles and individual muscle groups (gluteal, quadriceps, hamstrings and gastrocnemii) were calculated. A split-plot ANOVA was used to assess changes in lower limb kinetics ($\alpha=0.05$) and Cohen's d for muscle activation changes following training. Results As a group ($n=16$), no differences in lower limb kinetics were observed. Responders displayed reductions in peak knee valgus (-28% ; $p=0.003$) and extension (-10% ; $p=0.005$) moments following training, and interestingly displayed higher peak knee valgus moments relative to non-responders prior to training. No change in support moment existed pre to post training for both groups, however an increase in peak hip extension moments ($+18\%$; $p=0.046$) were observed in responders. A large effect was observed for increased TMA-gluteal for responders ($+29\%$; $d=1.4$). Discussion Following hip and trunk focused BWB neuromuscular training, responder athletes better utilized their hip musculature to generate their support moment. This is thought to be related to the reduced peak extension and valgus moments observed at the knee, therefore effectively reducing ACL injury risk (Donnelly et al., 2012; Markolf et al., 1995). The analysis of responding athletes is important for improvement of the effectiveness of injury prevention protocols (Myer et al., 2007). THE EVALUATION OF RUNNING ECONOMY IN ABOVE LT INTENSITY RUNNING

Tanji, F., Shirai, Y., Kurokawa, K., Kawai, K., Nabekura, Y.

University of Tsukuba

Introduction Running Economy (RE) is a factor that determines middle-long distance running performance. Generally, RE is evaluated by aerobic energy metabolism ($\dot{V}I \cdot \dot{V}O_2$) below lactate threshold (LT) intensity. This is because, at exercise intensities above LT, anaerobic energy metabolism increases and thereby it becomes complicated to evaluate RE. However, race pace in middle-long distance, except the marathon, is more than LT intensity. Moreover RE below LT intensity might be inconsistent with the one above LT intensity. Therefore, the aim of this study was to evaluate the running economy above LT intensity and examine a relationship between running economy and its performance. **Methods** Kyröläinen et al. (2001) determined energy expenditure by combining aerobic energy metabolism, calculated from $\dot{V}I \cdot \dot{V}O_2$ and respiratory exchange ratio, with anaerobic energy metabolism, calculated from the amount of change in blood lactate concentration. By using this method, we evaluated university student middle-long distance runners ($n=40$). These student runners ran at 13.8, 15.0, 16.2, 17.4 and 18.6 km/h, and we determined energy expenditures at each running pace. We also evaluated their RE by $\dot{V}I \cdot \dot{V}O_2$ at or below LT intensity. We clarified the relationship between their personal bests in 1500m and 5000m, energy expenditures and conventional REs at each velocity. **Results** There are significant positive correlation between 1500m and 5000m personal best time and energy expenditure at each velocity, except 1500m at 18.6 and 5000m at 17.4 km/h. This results showed a stronger correlation than conventional RE evaluation method, and this stronger correlation was also maintained when the intensity is above LT. **Discussion** The significant characteristic of the evaluation of RE in this study was not only to evaluate aerobic energy metabolism by $\dot{V}I \cdot \dot{V}O_2$ and respiratory exchange ratio but also to consider anaerobic energy expenditure. This evaluation method showed a stronger correlation than conventional RE evaluation, because it was able to consider whether energy source is from carbohydrate or fat, at below LT intensity (Kyröläinen et al. 2001). We also suggested that this stronger correlation was also maintained when the intensity was above LT, because this method was able to consider lactate acid utilization. Furthermore, we reacknowledged that the RE is a key factor for middle-long distance running. **References** Kyröläinen, H., Pullinen, T., Candau, R., Avela, J., Huttunen, P. and Komi, P.V. SPRINT ORIENTEERING: TEST RUNNING ON AN INDOOR COURSE, IN THE FIELD AND IN THE LABORATORY

Gullstrand, L.I., Andersson, G.I., Öberg, P.2

Swedish Sports Confederation 1, Swedish Orienteering Federation 2

Introduction Sprint orienteering (SpO) was for the 1st time a part of the World Championships in 2001 in Finland and Swedish orienteers are internationally successful. The recommended winning time is 12-15 min and is not a sprint event from a physiological view (1). The course is characterized by 20-30 controls with distances of 50-500m in between. The aims were to study how cardiopulmonary variables ($\dot{V}O_2$, VE, HR, RER) blood lactate and RPE correspond between treadmill test (TM), an indoor test course (ITC) and outdoor sprint orienteering (oTC) and whether a standardised indoor course is useful for evaluating SpO capacities. **Methods** Seven national team orienteers (3 male, 4 female) took part in the study. The TM test was a standardised protocol with 1 individual velocity and increased inclination leading to exhaustion after 5-8 min. The ITC with controls was prepared in an indoor football hall (65 x 110 m). A typical outdoor sprint course with controls was also used. Cardiopulmonary data were collected with a validated (2) portable Oxycon Mobile device (CareFusion GmbH, Germany) at all occasions. Moreover, both courses were timed regarding total- and "approach-punch-go" times for selected controls. **Results** ANOVA showed no significant differences in any of the cardiopulmonary variables between the 3 modes of running. Between ITC and oTC, $\dot{V}O_2$, HR, VE and lactate corresponded significantly with $r^2=0.97, 0.99, 0.94$ and 0.78 respectively. Average running velocity, as well as max 30 m time had r^2 of 0.97 and 0.91. Punching time also correspond sign. with 0.66 between ITC and oTC. **Discussion** Earlier studies have revealed that world class orienteers have a high aerobic and anaerobic capacity (3-5). $\dot{V}O_2$, HR, Hla and high RPE values support similar findings for SpO on indoor and outdoor courses. There was a tendency of higher anaerobic demands (Hla, RER) during TM test, possibly due to a 5-8 min constant running leading to exhaustion on 3-4 degrees inclination, being a different work compared to the 2 courses. The high physiological and running correlations indicate that ITC may serve as a valid test for real SpO. Coaches and athletes were positive to use the standardised indoor course for analysing both metabolic and running strategic factors for real SpO. **References** 1. SIMILAR RELATIVE AEROBIC CONTRIBUTION IN HIGH INTENSITY RUNNING AND CYCLING

Li, Y., Götz, J., Niessen, M., Hartmann, U.

University of Leipzig, Ruhr University

Introduction An exponential relationship between relative aerobic contribution (WAER%) and duration in high intensity exercises was found by summarizing the corresponding investigations with various exercise models/sports (Gastin, 2001). However, the independence of WAER% on exercise model/sport was not verified. Therefore, the aim of this study was to examine the WAER% with selected exercise

models (i.e. running and cycling) of high intensity. Methods 24 adults (33 ± 9 yrs, 177 ± 10 cm, 73 ± 11 kg, 56.1 ± 8.0 ml/kg/min) from endurance sports (running, cycling, and triathlon) participated in this study with written consent. Each subject performed two maximal-4-min exercises (running and cycling) on separate days with self-chosen pacing strategy. Energy contribution was calculated with the method implemented by Beneke et al. (2004), using accumulated oxygen consumption and net blood lactate production during exercise, as well as the fast component of oxygen debt during recovery. Spirometric data were registered by MetaMax 3B (Cortex Biophysic, Germany), and blood lactate was measured by Biosen S_line (EKF Diagnostic, Germany). Three-phase model was utilized to calculate the oxygen uptake kinetics in exercises (Poole & Jones, 2012). Differences in energetics between running and cycling were analyzed using paired t-tests. Results WAER% were similar during 4-min maximal running and cycling ($76.7 \pm 4.4\%$ vs. $75.2 \pm 3.3\%$, $p > 0.05$). Time constants of fast component in oxygen uptake kinetics were also similar in the two exercise models (16.2 ± 3.7 s vs. 14.5 ± 4.8 s, $p > 0.05$). Discussion The primary finding of this study was an approximate WAER% of 75% during 4-min maximal running and cycling, which was in line with existing reports (Gastin, 2001). It seemed that WAER% was independent of exercise model during certain duration (as 4-min in this study) of high intensity. The exponential relationship between WAER% and duration of high intensity exercise drawn from various reports (Gastin, 2001) could be applied to a given exercise model with high intensity. Similar time constants of fast component in oxygen uptake kinetics could be attributed to the involvement of similar muscles during running and cycling. Comparison of WAER% between exercise models/sports using different muscles (e.g. upper-body vs. lower-body) are needed to be investigated in the future. PHYSIOLOGICAL FACTORS AFFECTING PERFORMANCE IN ROWING

Miller, T.F., Popov, D.V., Saraev, O.A., Vinogradova, O.L.

SRC RF Institute of Biomedical Problems RAS

Introduction Revealing factors limiting the performance is one of the main tasks in training of elite athletes. Knowing these factors we may find optimal training impacts for increasing athlete's performance. The aims of our work were to identify physiological parameters, affecting the special performance in rowing and to predict performance using physiological tests. Methods 298 rowers (open category: 181 men, age 15-38 and 117 women, age 14-37) participated in 14 test sessions. In these test sessions absolute and relative fat and muscle mass, isokinetic force of the knee extensor muscles (angular velocity 300, 240, 180, 60 deg/s), as well as maximum oxygen consumption, oxygen consumption at anaerobic threshold, maximum aerobic power and power at anaerobic threshold were measured. Results of physiological tests were compared with the rowing ergometer (Concept II) 2000 m time trial. Results Regression analysis revealed that the absolute values of muscle mass, knee-extensors force, maximum aerobic power, power at the anaerobic threshold, maximum oxygen consumption, and oxygen consumption at the anaerobic threshold were significantly associated with the 2000 m time trial for both men and women. Simultaneous influence of knee-extensors muscle strength and aerobic capacity of organism on 2000 m time trial was evaluated by multiple regression. It was found that the anaerobic threshold had a greater influence on rower's performance than the knee-extensors muscle strength. Discussion Our work revealed significant relationships between 2000 m time trial and absolute, but not relative physiological indices. Multiple regression analysis allowed to calculate the individual values of the power at anaerobic threshold and the knee-extensors strength required to achieve a desired result/2000 m time trial. PERFORMANCE CHANGES IN ROWERS AFTER TRAINING AIMING FOR IMPROVEMENT OF THE INDIVIDUAL PHYSIOLOGICAL PROFILE ESTIMATED BY FIVE PERFORMANCE TRIALS IN FOUR DAYS

Jensen, K., Lippiits, R., de Boorder, D.

Institute of Sports Science and Clinical Biomechanics, SDU (Odense, Denmark), TU/e (Eindhoven, Holland), Tilburg University (Tilburg, Holland)

Introduction Rowers perform over 2000m (5.3-7.5 min), but although they follow the same training program and look similar from a physical performance point of view, genetics and training history may have a great influence upon their individual physical profile and adaptation to training. It might be hypothesized that individual terms should be taken, i.e. that rowers with low max power should be motivated to do special power sessions, and equivalent, less powerful rowers, a program based on steady aerobic work. Hence, they should develop against a more balanced profile. Therefore, the aim of the current study was 1) to evaluate performance changes during a winter season and 2) focus on individual based training for development of performance aiming a more balanced profile in a group of young talented rowers. Methods Twenty Dutch university rowers, 14 males and 6 females: age 21.2 ± 2.0 years, systematic rowing experience 2.2 ± 1.2 years, from Regional Talent Center, Rowing (Brabant) were tested at the beginning of the winter season and after 16 weeks. Average power was measured during five all out tests on a Concept II rowing ergometer on four consecutive days: 1: 6km (W6k) and best of 3 times 100m (W100m); 2: 2km (W2k); 3: 1 min (W1min); 4: 60 min (W60min). Free stroke rate and drag factor setting were allowed. W2k was used as reference, resulting in a relative intensity in relation to work time: "the power endurance curve" (Jensen, 2007). Training consisted of 30 min in a rowing ergometer, 6 days per week, alternating between intensities defined by each rower's individual performance profile (70-170% W2k). Each session was followed by 45 min in the boat with low intensity (~60-75% W2k). Results The performance increased by 3.5, 5.9, 8.5, 9.5 and 10.1% in W100m; W1min; W2k; W6k; and W6min, respectively ($p < 0.05$) bringing the group from 22% to 15% below the selection criteria for the national team. The different relation between high intensity performance and endurance was indicated by W100m relative to W60min: 2.39 ± 0.21 vs 2.55 ± 0.29 ($P < 0.05$) while other relations between performance tests remained unchanged ($P > 0.05$). The relative changes between short and longer tests indicate that the profile is balanced more in direction of the golden standard (Jensen, 2007) Discussion This study demonstrated that aerobic endurance increased by 9-10% during winter season in this group of relative unexperienced (<23years) rowers after 16 weeks and by only 6-8 hours of weekly training. More importantly the rowers changed their profile from more strength and power dependent to be more aerobic trained. References Jensen K. (2007) Rowing, 96-102. Blackwell Publishing. EFFECTS OF RUNNING ECONOMY ON PACING STRATEGY IN A 10-KM RACE

Do Carmo, E.1,2, Bertuzzi, R.1, Ribeiro, N.1, Gil, S.1, Lasevicius, T.1, Afonso, H.1, Barroso, R.1,3, Tricoli, V.1

1: USP (São Paulo, Brazil), 2: Senac (São Paulo, Brazil), 3: Unicamp (São Paulo, Brazil)

Introduction The overall approach of work distribution during an exercise task has been termed pacing strategy (PS). PS in running events seems to be affected by different variables (Gibson et al., 2001) such as running economy (RE). The effects of RE on performance have

already been demonstrated. However, RE effects on PS are still unknown. It is conceivable that changes in RE affects PS. Plyometric training (PT) can be used to improve RE (Spurrs et al., 2003). Thus, the aim of this study was to verify the effects of RE improvement on PS of a 10-km race. Methods Twenty-eight runners were randomly divided into control (C, n=13) and PT (n=15) groups. PT was performed twice a week for 8 weeks in a periodized fashion. Running velocity (GPS Polar, RS800CX) was measured during a 10-km race every 400m. The race was divided into start (first 400m), middle 1 (M1=from 400m to 5200m), middle 2 (M2=from 5200m to 9600m) and end spurt (final 400m) to PS analysis. VO₂max, peak velocity (PV), vVO₂max were obtained during a maximal incremental test. RE was assessed at two different speeds (10km.h⁻¹ and 12km.h⁻¹). Mixed model analysis was used for statistical analysis and significance was set at p≤0.05. Velocity-time curve was also visually inspected to assess PS. Results PT and C groups were not different at baseline. VO₂max, PV, vVO₂max did not change in both groups. RE and 10km performance were not altered in C group. Subjects from PT group improved their RE both at 10km.h⁻¹ (38.3±3.6 vs 37±3 ml.kg⁻¹.min⁻¹, p=0.05) and at 12km.h⁻¹ (44.5±3.4 vs 42.4±3.4 ml.kg⁻¹.min⁻¹, p=0.02). However, from the 15 participants in PT, 11 presented an improvement >3.6% and were selected for an additional analysis. This subgroup improved 10-km performance (41:29±2:30 vs 40:49±2:26 min:s, p=0.01) and M2 speed (14.2±0.9 vs 14.5±1 km.h⁻¹, p=0.04), but there were no differences in PS. Discussion We aim at investigating if RE would affect PS. From the 15 athletes in PT, 11 improved RE, 10-km performance and M2 speed. The 10-km performance improvement seems to be related to higher speeds during M2. It is possible that improved RE is responsible for the higher speeds during M2. In addition, velocity-time curve was slightly shifted upwards with improved RE. We concluded that despite the positive effects of PT on RE improvement, PS of a 10-km race was not affected. ASSESSMENT OF PHYSICAL PREPAREDNESS LEVELS IN CROSSFITTERS

Volkov, V., Eryomin, S., Seluyanov, V.

Russian State University of Physical Education, Sports and Tourism

Introduction CrossFit has recently gained popularity on a global scale. Competitions include exercises that require strength, strength endurance and general endurance. Training consists of many global and local strength exercises. To manage athlete preparation effectively, it is necessary to compare individual athletes to elite profiles. Purpose: to assess local capacity of arm and leg muscles, and cardiovascular endurance of Russia's elite CrossFit athletes. Methods The study consisted of 10 elite athletes: 5 male (29 yo) and 5 female (23 yo). These tests were conducted: cardiac ultrasound, osteo densitometry, and body composition analysis. Speed-strength and aerobic capacity of the leg, shoulder girdle, and arm muscles were measured. Body composition analysis involved the dual energy X-ray absorptiometry by the densitometer Lunar Prodigy (USA). Heart stroke volume was measured by the high resolution ultrasonic scanner Logiq E9 (USA). Aerobic threshold (AeT), anaerobic threshold (AnT) and maximal oxygen uptake (VO₂max) were assessed by the leg and arm ergometers Lode (Netherlands) and the gas-analyser Cosmed (Italy). The following parameters were measured: lung ventilation, oxygen uptake, carbon dioxide expiration and heart rate. Maximal anaerobic capacity was determined in accordance with Seluyanov's (2008) guidelines. Feofilaktov et al. (2013) research constituted as the control group. Results Fat mass and bone mineral density were 11±1.4% and 1.4±0.03 g/cm³ for males, and 20±6% and 1.3±0.2 g/cm³ for females, respectively. Heart stroke volume at rest for males was 112±8.3 ml, and 77.6±13.8 ml for females. Oxygen uptake during leg-veloergometer at AeT, AnT and VO₂max were 22±3.9 ml/kg/min, 38±2.8 ml/kg/min, 46±3.7 ml/kg/min for males, and 24±2.8 ml/kg/min, 36±1.5 ml/kg/min, 42±2.8 ml/kg/min for females, respectively. Oxygen uptake during arm-veloergometer at AeT, AnT and VO₂max were 21±3.2 ml/kg/min, 33±3.9 ml/kg/min, 42±5.3 ml/kg/min for males, and 19±3.7 ml/kg/min, 30±3.6 ml/kg/min, 38±3.7 ml/kg/min for females, respectively. Discussion The level of Crossfit athletes' physical preparedness is higher than the control group due to the following adaptations: muscle mass growth, increased bone mineral density, and significant myocardium development. Leg and arm muscle capacity was significantly higher than the control. These results reflect specific adaptations in response to exhaustive training. Bibliography 1. Seluyanov V. et al. (2008). REPEATED SPRINT TRAINING IN HYPOXIA DOES NOT INFLUENCE MUCOSAL IMMUNE FUNCTION TO A GREATER EXTENT THAN IN NORMOXIA

Born, D.P.1, Faiss, R.2, Willis, S.3, Strahler, J.4, Holmberg, H.C.3, Millet, G.P.2, Sperlich, B.1

University of Wuerzburg

1 University of Würzburg, Department of Sport Science, Würzburg, Germany 2 ISSUL-Department of Physiology, Faculty of Biology and Medicine, University of Lausanne, Switzerland 3 NVC, Swedish Winter Sports Research Centre, Mid Sweden University, Östersund, Sweden 4 University of Marburg, Clinical Biopsychology, Marburg, Germany Introduction Stress due to repeated exposure to hypoxia affects the mucosal immune system, as reflected in a reduced salivary concentration of immunoglobulin-A (sIgA) (Tiollier et al. 2005). Moreover, adding a hypoxic stress to a very intensive form of training (i.e. repeated sprint training in hypoxia (RSH)) induced superior performance benefits compared to repeated sprint training in normoxia (RSN) (Faiss et al. 2013). With a positive correlation between decrease in sIgA and incidence of respiratory tract infection, we hypothesized that RSH may alter immune function and increase infection risk to a greater extent than RSN in elite cross-country skiers. Methods Within a two-week period 17 elite cross-country skiers performed 6 sessions on a double-pole ergometer (Concept2), under either normobaric hypoxia (RSH, FiO₂=13.8%, 3000m, n=9) or normoxia (RSN, FiO₂=20.9%, 300m, n=8). Each session consisted of 10-s repeated sprints (4 sets of 5) interspersed with 20 s of recovery. Before (Pre-) and after (Post-) training, performance was assessed by a repeated sprint test (RSA) with 10s all-out sprints interspersed with 20 s of recovery until peak power output fell below 70% of the best sprint. Saliva was collected on a rest day before Pre- and the first and sixth training day in specific polyethylene tubes (SaliTubes, Eppendorf) at five times during the day: immediately and 30 min after awakening, before and after the training session as well as immediately before going to bed. These samples were stored at -20°C until being analyzed for sIgA (DRG Instruments). Results In Post- compared to Pre-, power output in RSA was improved (p<0.01) similarly in both groups (25% vs. 21%, NS), whereas the number of sprints completed before task failure was increased in RSH (10.9±5.2 vs. 17.1±6.8, p<0.01) but not in RSN (11.6±5.3 vs. 11.7±4.3). Groups did not differ in any measured parameter on the rest day (p=0.35). Further, in RSH vs. RSN, saliva flow rate (0.50±0.10 vs. 0.54±0.07 and 0.51±0.04 vs. 0.52±0.08 mL/min, NS), sIgA (103.1±59.1 vs. 89.8±31.3 and 121.3±57.1 vs. 99.9±59.5 µg/mL, NS), and sIgA secretion rate (47.9±25.4 vs. 45.2±12.1 and 61.1±30.6 vs. 50.8±31.1 µg/min, NS) were unaffected on the day of the first and sixth training session, respectively. Conclusion We conclude that for elite cross-country skiers repeated sprint training in hypoxia is more beneficial than identical normoxic training without compromising mucosal immunity.

MUSCLE DAMAGE AND STRENGTH LOSS AFTER A CONTINUOUS AND INTERMITTENT RUNNING UNTIL EXHAUSTION

Dittrich, N., de Lucas, R.D., Maioral, M.F., Diefenthaler, F., Guglielmo, L.G.A.

Federal University of Santa Catarina

Introduction The maximal lactate steady state (MLSS) represents the higher exercise intensity that can be maintained over time without continuous lactate accumulation (BILLAT et al., 2003). Because of its relationship with performance, MLSS has been frequently used as reference intensity for continuous and interval training (PHILP et al., 2008). Prolonged running, due to repeated muscle contractions, is also known to elicit muscle fatigue and induce deleterious effects on neuromuscular functions (MILLET et al., 2003). However, considering that the magnitude in the decline of force-generating capacity depends on the characteristics of the task being performed, the aim of the study was to verify and correlate the neuromuscular and biochemical responses of running until exhaustion at MLSS continuous and intermittent in trained runners. **Methods** Twelve runners performed an incremental treadmill test, several constant speed tests to determine the MLSS at continuous and intermittent (5:1 ratio) models and two randomized tests until exhaustion at such intensities. Knee extension torque and blood sampling were collected before and immediately after the time to exhaustion tests (TTE). Serum creatine kinase (CK) was determined from blood samples. ANOVA two-way with post hoc testing was used to compare the changes between exercises performed in continuous and interval model. Significance level was $p < 0.05$. **Results** The intermittent MLSS velocity (15.26 ± 0.97 km.h⁻¹) was higher than MLSS continuous (14.53 ± 0.93 km.h⁻¹), while TTE at MLSS continuous was longer (68 ± 11 min and 58 ± 15 min, respectively). Regarding the neuromuscular responses, results showed a significant decrement in torque production (~15%) after TTE for both exercise models. In addition, an acute increase of 65% and 38% was observed for creatine kinase (CK) after TTE continuous and intermittent, respectively. No significant correlation was found between CK and strength loss for both exercise models. **Discussion** The results showed that the TTE and distance covered at intermittent MLSS were longer than continuous MLSS running, suggesting references to prescribe endurance interval training sessions. Further, it was observed that independent to the exercise model (i.e. continuous or intermittent), there was a significant deleterious effect on muscle strength and an increase in muscle damage (CK) in trained runners. These results indicate how stressful a single training session until exhaustion at MLSS can be. Therefore, it should be considered and applied carefully when designing endurance training, whether continuously or intermittently. **References** Billat VL, et al. (2003) *Sports Med* 33: 407-426. MEASUREMENT ACCURACY OF GAS EXCHANGE PARAMETERS FROM TWO SPIROERGOMETRIC SYSTEMS

Potreck, H.1, Herhaus, B.1, Thys, S.1, Schaar, B.2

1: GSUC (Cologne, Germany); 2: UFAB (Munich, Germany)

Introduction: Open spiroergometric systems with the aim of investigating the endurance performance get more and more access to the fitness market intending to give implemented exercise recommendations as part of the training routine. In open systems, it is important to note that the results may partially differ clearly in dependence of the operating principles in the range of accuracy, comfortableness, handling of masks and mouthpieces and maintenance as well as calibration. For a controlled endurance training, the reliability of the reproducibility and a small margin of error is a prerequisite. The aim of the study was to investigate the accuracy of two spiroergometric measuring systems after the implementation of a standardized test procedure. **Methods:** In a cross-sectional study, cardiopulmonary exercise tests were performed on 21 male subjects (age: $x = 24 \pm 2.78$ years; bodyweight $x = 80.42 \pm 5.58$ kg; body height: $x = 183.38 \pm 5.03$ cm) within eight working days. For the study, two spiroergometric systems (Meta control 3000, Cortex, aeroman® professional, Aerolution®) were used and compared in an experimental laboratory study with the identical test protocol by Hollmann and Venrath (1982). Both systems use electrochemical cells for O₂ measurement but differ in the measurement type of CO₂ concentration and volume flow. Cortex utilizes infrared absorption and turbines, Aerolution ultrasonic sensors. For comparison, the ventilatory and cardiopulmonary parameters VE, VO₂, VCO₂ and RER were analyzed. **Results:** The Meta control 3000 was not significantly different from the aeroman® professional at any work rate for VE ($P \geq 0.05$) and VO₂ ($P \geq 0.05$). In contrast, there were significant systematic differences in gas exchange values of VCO₂ and RER across all workloads ($P < 0.05$). **Discussion:** Significantly different results may lead back to different measuring principles of the systems. A controlled endurance training by considering the compared parameters would produce different exercise recommendations due to widely divergent values in VCO₂ and RER. **References:** Carter, J. & Jeukendrup, A.-E. 14:00 - 15:00**Mini-Orals****MO-PM30 Health & Fitness****CARDIORESPIRATORY FITNESS IN INDIVIDUALS WITH INTELLECTUAL DISABILITIES**

Oppewal, A., Hilgenkamp, T.I.M., van Wijck, R., Evenhuis, H.M.

Erasmus MC

Introduction Poor cardiorespiratory fitness is a major independent risk factor for cardiovascular diseases and all-cause mortality. Low cardiorespiratory fitness levels have been found in people with intellectual disabilities (ID), which puts them at higher risk for cardiovascular diseases and all-cause mortality. To assess cardiorespiratory fitness levels of people with ID, the tests used in the general population, may not all be applicable in the same way for people with ID. **Methods** Therefore, the aims of our review were to review the literature about (a) the cardiorespiratory fitness levels and their determinants in individuals with ID, and (b) the validity and reliability of cardiorespiratory fitness testing in individuals with ID. We searched the databases of Pubmed and Embase for relevant studies, resulting in 31 included articles. **Results and discussion** The studies mainly included younger participants with mild to moderate ID. Results confirmed findings

of low cardiorespiratory fitness levels in individuals with ID. Cardiorespiratory fitness levels of children and adolescents with ID are already low, with further decline with increasing age. Furthermore, females have lower cardiorespiratory fitness levels than males. Physical inactivity and chronotropic incompetence are most likely to contribute to low cardiorespiratory fitness levels. Peak cardiorespiratory fitness levels of individuals with ID can be assessed with maximal treadmill protocols in laboratory setting, after allowing for familiarization sessions. Although, predicting maximal oxygen uptake from field tests is problematic, field tests have been found valid and reliable as indicators of cardiorespiratory fitness. FAMILIAR CORRELATES OF PHYSICAL ACTIVITY IN ADOLESCENTS WITH DOWN SYNDROME. THE UP&DOWN STUDY.

Izquierdo Gomez, R., Veiga, O.L., Sanz, A., Diaz Cueto, M., Villagra, A.

Universidad Autonoma de Madrid

Introduction There is compelling evidence that regular physical activity (PA) contributes to health benefits in children and adolescents (Ruiz & Ortega, 2009). Despite this evidence, it is well documented that PA is quite low in adolescents with Down syndrome (DS) (Matute-Llorente, et al., 2013). Thus, it is important to understand family factors associated with PA in this target population in order to design effective intervention programs. **Methods** PA was measured using accelerometers in 98 adolescents (63 males and 35 females) aged 11-20 years old (15.43 ± 2.54) as a part of the UP&DOWN study. A total of 11 family factors were measured by proxy-report questionnaires and examined for association with total PA, moderate PA, vigorous PA and moderate-vigorous PA, using analysis of variance (ANOVA) and analysis of covariance (ANCOVA) with Bonferroni's. Three models were used to test association between potential correlates and PA levels. Model 1 tested crude association between factors and PA variables, model 2 was controlled for sex and age and model 3 was additionally controlled for socio-economic status (SES). **Results** The crude model showed that the father's low-medium work status was inversely associated with total PA, VPA and MVPA level, as well as the father's MPA were inversely associated with MPA, VPA and MVPA level ($p < 0.05$). The model 2 shows that adolescents with fathers who did not practice MVPA spent more time in VPA and MVPA after controlling for sex and age, and these associations remained significant in model 3 after controlling for SES ($p < 0.05$). **Discussion** Only one family modifiable factor was associated with PA levels in adolescents with DS in the final model. In future studies, it will be necessary to examine multiple factors associated with adolescents PA within an ecological framework (Sallis et al., 2006) to identify potential factors and to increase opportunities for PA in adolescents with DS. **Reference** Matute-Llorente, A., González-Agüero, A., Gómez-Cabello, A., Vicente-Rodríguez, G., & Casajús, J. THE FEASIBILITY AND RELIABILITY OF PHYSICAL FITNESS TESTS IN CHILDREN WITH A MODERATE TO SEVERE INTELLECTUAL DISABILITY

Wouters, M., Hilgenkamp, T.I.M., Evenhuis, H.M.

Erasmus MC

AIMS: Physical fitness is an important marker for health and can be measured using field tests. However, little information is available on suitable and reliable tests for children with moderate to severe intellectual disability (ID). In this study we investigate the feasibility and reliability of physical fitness measurements in these children. **METHODS:** A sample of 42 children with a moderate to severe ID, aged 4 to 18 year, will be tested in March this year. Tests include four strength tests of the Functional Strength Measurement (upperhand and underhand throwing, chest pass, standing long-jump) and the 6 minute walk test. Body composition will be assessed with the body mass index and waist circumference. The children will perform the fitness tests four times and the interrater and test-retest reliability of the above mentioned fitness tests will be determined. **RESULTS:** Results will include the feasibility (expressed in percentage withdrawal and reason of withdrawal) and reliability (Intraclass Correlation Coefficients, ICC) of the physical fitness tests. **CONCLUSION:** Conclusion will be drawn based on the results.

SPORT CLIMBING AND HEALTH ORIENTED FITNESS

Balas, J.

Faculty of Physical Education and Sport

The aim of the study was to determine the association between the number of metres climbed per week and the health oriented fitness. The total of 257 male and 126 female climbers volunteered in the strength testing and completing a questionnaire. Twenty seven males and fourteen females from these subjects took part in the energy expenditure assessment. The results showed a strong relationship ($R^2 = 0.45$) between the number of vertical metres climbed and grip strength in females, however, this relationship was not practically significant in males ($R^2 = 0.15$). A high level of association between climbing volume and the bent-arm hang was stated for females ($R^2 = 0.33$) and males ($R^2 = 0.27$). The average energy expenditure in vertical climbing was $0.594 \pm 0.077 \text{ kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ in males and $0.527 \pm 0.048 \text{ kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ in females, at the overhanging inclination $0.678 \pm 0.094 \text{ kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ in males and $0.579 \pm 0.056 \text{ kJ} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ in females. The results demonstrated that sport climbing may lead to maintain or to increase the upper-body strength with the climbing volume from around 80 vertical metres climbed per week. The energy cost of recreational climbing corresponds to the other aerobic activities as running, swimming or cycling. To maintain or to increase the cardiovascular fitness, the volume of 400-500 vertical metres climbed per week at least has to be completed.

DESIGN AND VALIDATION OF A QUESTIONNAIRE ON THE WORKING PROCEDURE OF FITNESS CLASSES INSTRUCTORS IN SPAIN

Juan Llamas, C.

Universidad Camilo José Cela

DESIGN AND VALIDATION OF A QUESTIONNAIRE ON THE WORKING PROCEDURE OF FITNESS CLASSES INSTRUCTORS IN SPAIN (CFTICC) Juan-Llamas, C. Universidad Camilo José Cela (Madrid, Spain) **Introduction** The objective of this research was to design a questionnaire, and check their validity and reliability, in order to know the different methodological strategies used by fitness instructors. **Methods** Validation

was achieved through 14 expert judges ratings and its reliability through the application of the test-retest procedure to a sample of 62 instructors of different sports centres in Madrid (Spain) twice with an interval of two weeks. The questionnaire has three parts: the first one of general information, experience and dedication; the second one referring to the habits of lifelong training; and the third one to learn their routines and programming methods for classes. Results After modifications proposed by experts, mainly changes in content, and in accordance with the results of the study, we can assume that the Cuestionario sobre la Forma de Trabajo de los Instructores de Clases Colectivas, entitled from here on CFTICC, has reached high levels of validity and reliability, in such a way that it provides sufficient guarantees of use for the knowledge of how do the fitness instructors work. EFFECTS OF A SIX-MONTH EXERCISE INTERVENTION PROGRAMME ON ASPECTS OF BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Stavropoulos Kalinoglou, A., Metsios, G.S., Veldhuijzen van Zanten, J.J.C.S., Kitas, G.D., Koutedakis, Y., Jamurtas, A.Z.
University of Thessaly

Introduction: Rheumatoid Arthritis (RA), the most common inflammatory arthritis, is accompanied by significant loss of muscle mass. RA patients experience unexplained reduction of their muscle mass even in the first few years following diagnosis. This condition is termed Rheumatoid Cachexia (RC) and associates with significant disability and poor quality of life in addition to that caused directly by RA. Despite the dire consequences of RC, no valid intervention against muscle wasting in RA exists in clinical practice. **Aim:** The aim of this study was to assess the effectiveness of a six-month combined (aerobic+ resistance) exercise intervention on improving aspects of body composition in RA patients **Methods:** Participants: A total of 40 patients with RA participated in the study. They were assigned to either an intervention or a control group. **Assessments:** All patients were assessed for: Body composition, markers of inflammation, and disease characteristics **Intervention:** Patients in the intervention group received an individualised six month exercise programme based on their physical fitness test results. They exercised three times per week. Their heart rate was recorded during each exercise session for the duration of the programme. **Results:** Attendance (i.e. number of visits) was 88%, and adherence (i.e. achieving prescribed goals in each of the exercises during each session) 76%. Inflammation and disease characteristics improved significantly during the intervention period in the exercise group while they remained relatively unchanged in the control group. Similarly, patients in the exercise group experienced significant reductions in BMI (baseline BMI: $28.7 \pm 5.1 \text{ kg/m}^2$ vs 6-month BMI $28.0 \pm 4.8 \text{ kg/m}^2$) while in the control group BMI was slightly increased (baseline BMI: $28.8 \pm 5.3 \text{ kg/m}^2$ vs 6-month BMI: $29.1 \pm 5.4 \text{ kg/m}^2$). Interestingly, the above mentioned changes were a result of change in fat mass; in the exercise group Body Fat (BF) was reduced from $36.1 \pm 8.4\%$ to $33.6 \pm 7.9\%$ while in the control group it was increased from $37.2 \pm 8.7\%$ to $38.3 \pm 7.9\%$. More importantly, Fat Free Mass (FFM) was slightly but significantly increased in the exercise group (baseline FFM: $48.9 \pm 10.8 \text{ kg}$ vs 6-month FFM: $50.8 \pm 12 \text{ kg}$) while it was reduced in the control group (baseline FFM: $48.3 \pm 7.8 \text{ kg}$ vs 6-month FFM: $48 \pm 7.3 \text{ kg}$). **Conclusions:** RA patients are able to perform purposeful exercise that elicits significant benefits for their body composition by reducing body fat and increasing fat free mass. Concomitantly, this form of exercise does not adversely affect disease activity.

CLINICAL MARKERS OF BODY COMPOSITION AND BODY FAT DISTRIBUTION ARE RELATED WITH CARDIAC AUTONOMIC CONTROL IN NAFLD PATIENTS

Pimenta, N.1,2, Santa Clara, H.1, Cortez Pinto, H.3, Silva Nunes, J.4, Rosado, M.1, Sousa, P.5, Calé, R.5, Melo, X.1, Sardinha, L.1, Fernhall, B.6

1: CIPER, FMH-UL (Lisbon, Portugal), 2: ESDRM-IPS (Rio Maior, Portugal), 3: Santa Maria Hospital, FM-UL (Lisbon, Portugal), 4: Curry Cabral Hospital (Lisbon, Portugal), 5: Santa Cruz Hospital (Lisbon)

Introduction Body composition (BC), particularly central body fat (BF), is a major issue in Non-alcoholic Fatty Liver Disease (NAFLD). Decreased vagal activity, as assessed by heart rate recovery (HRR), is known to be a marker of imbalanced cardiac autonomic control and a risk factor for death. HRR was shown to be inversely associated with BF content and distribution, but the association with BC clinical markers has not yet been tested. The aim of this study was to determine if, and to what extent, clinical markers of BC and BF distribution, are related with HRR, in NAFLD patients. **Methods** We assessed 25 NAFLD patients (19 males, 51 ± 13 yrs, and 9 females, 47 ± 13 yrs), who were diagnosed through liver biopsy or ultrasound, after exclusion of other causes of liver disease. BC and BF distribution assessment consisted of anthropometry, specifically: body circumferences (C), including arm-C, waist-C, hip-C, thigh-C and calf-C; and body indexes (body mass index; body adiposity index [BAI = (hip circumference / height^{1.5})-18]; waist-to-hip ratio [WHR] and waist-to-height ratio [WHtR]). All subjects underwent a maximum graded exercise test (GXT) on a treadmill monitored by 12 lead ECG. HRR was measured as the difference between peak exercise heart rate and the heart rate recorded 1 (HRR1) and 2 minutes (HRR2) immediately after GXT. Partial and semipartial correlations were used to test associations. Only $r \geq 0.5$ were considered to attain statistical significance ($\alpha = 5\%$ and $\beta = 20\%$). **Results** Partial and semipartial correlations, controlled for age and sex, showed that WHtR was the only body index correlated with HRR1 ($r = -0.59$ and $r = -0.56$; respectively, $p < 0.01$). None of the studied body indexes were correlated with HRR2. In partial correlations Waist-C ($r = -0.66$, $p < 0.01$), Hip-C ($r = -0.54$, $p < 0.01$), Thigh-C ($r = -0.51$, $p < 0.05$) and Calf-C ($r = -0.53$, $p < 0.05$) were correlated with HRR1, but only Waist-C ($r = -0.63$, $p < 0.01$), Hip-C ($r = -0.52$, $p < 0.01$) and Calf-C ($r = -0.51$, $p < 0.05$) were also correlated with HRR2 in semipartial correlations. Waist-C was the only independent variable found to be correlated with HRR2 ($r = -0.51$, $p < 0.05$), using partial correlation. **Discussion** WHtR was the only body index associated to HRR variation in NAFLD patients. Accordingly, Waist-C was somewhat better associated with HRR than the studied peripheral BF clinical markers. However, unlike previous findings, that showed body fat distribution to be the strongest body composition correlate with HRR, regardless of body fat content, in the present study, WHR ratio was not associated with HRR. This rather conflicting result warrants further study. Do not insert authors here

RENAL FUNCTION IN TRANSPLANT RECIPIENTS COMPARE TO HEALTHY SUBJECTS AFTER A MARATHON CYCLING

Totti, V., Zancanaro, M., Di Michele, R., Mosconi, G., Beltrandi, E., Nanni Costa, A., Roi, G.S.

Non Profit Foundation for the Advancement of Organ and Tissue Transplantation

Background Few studies have evaluated the changes in renal function of transplant recipients (TR) after intense physical activity. **Methods** The purpose of this study was to investigate some aspects of renal function in TR participating in a road cycling race (CR) of 130km long (total climb: 1871m, uphill 50km, downhill 46km and 34km flat). Venous blood and urine samples were collected: i) the day before (Pre), ii) at the finish (Post), iii) 24 hours (24h) after CR from 20TR (mean \pm SD age 52 ± 10 yrs, $72 \pm 11 \text{ kg}$, $173 \pm 0 \text{ cm}$, $24.1 \pm 2.9 \text{ kg/m}^2$), who underwent transplant (2 heart, 5 liver, 11 kidney, 2 bone marrow) 8.8 ± 4.9 yrs before. Forty-four healthy subjects (HS) (52 ± 9 yrs, $73 \pm 9 \text{ kg}$, $175 \pm 0 \text{ cm}$, $23.8 \pm 2.2 \text{ kg/m}^2$) participating to the same race were recruited as control group. From the group of TR, we also collected data from 6 TR

who have participated in two editions (2012-2013) of the same race. Results All the participants completed CR without problems. No significant differences were found in the mean race time in both groups ($6.36.49 \pm 1.15.14$ vs $6.03.27 \pm 0.47.24$ hh.mm.ss). Significant differences were found between Pre-Post and Post-24h in TR and HS in urea (Pre 45 ± 14 , Post 68 ± 20 , 24h 62 ± 16 vs Pre 38 ± 8 , Post 55 ± 11 , 24h 51 ± 7 mg/dL; $P < 0.05$), creatinine (Pre 1.12 ± 0.36 , Post 1.37 ± 0.42 , 24h 1.16 ± 0.38 vs Pre 0.92 ± 0.16 , Post 1.09 ± 0.22 , 24h 0.94 ± 0.15 mg/dL; $P < 0.05$), urinary proteins (Pre 148 ± 99 , Post 341 ± 345 , 24h 126 ± 133 vs Pre 73 ± 40 , Post 116 ± 79 , 24h 104 ± 35 mg/die $P < 0.05$) and microalbuminuria (Pre 54 ± 75 , Post 192 ± 278 , 24h 35 ± 59 vs Pre 11 ± 18 , Post 36 ± 44 , 24h 8 ± 4 mg/L; $P < 0.05$). In both groups values significantly increased between Pre-Post and decreased between Post-24h. In the urine specific gravity values significant differences were found between Pre-24h in both groups (Pre 1.015 ± 0.004 , Post 1.017 ± 0.005 , 24h 1.016 ± 0.006 vs Pre 1.018 ± 0.005 , Post 1.020 ± 0.005 , 24h 1.027 ± 0.005 ; $P < 0.05$) and between groups in 24h ($P < 0.05$). Longitudinally there was no significant difference in Pre, Post and 24h in the two editions of the race. Conclusions TR in good clinical conditions and properly trained, were able to face intense physical effort with transient changes in renal function. The variations observed are superimposable in TR and in HS and have a similar trend. The lower urine specific gravity in TR is related to a tubular dysfunction partially due to immunosuppressive therapy. The increase of proteinuria resolves after rest. More longitudinal studies are necessary to understand the eventual risk of endurance sports activities (CR) for renal function of TR.

EFFECT OF A NEUROMUSCULAR DENTISTRY-DESIGNED MOUTHGUARD ON SPRINT PERFORMANCE

Fischer, H., Weber, D., Bäumchen, F., Hahn, F., Lotzmann, U., Beneke, R.

Philipps University Marburg - Germany

Introduction Athletes of various sports require mouthguards for protection against orofacial and dental injuries during training and competitions. Customization or dentistry-fitting of those mouthguards shall additionally optimize mandibular position with positive effects on neuromuscular function of jaw muscles and physical performance. Selected studies suggesting favourable effects of corresponding splints on explosive performances remain inconclusive (1,2,3). Purpose of this study was to investigate potential splint-related effects on selected components of cycling sprint performance. **Methods** 23 physically and dentally healthy young men (26 ± 1.9 yr; 182 ± 6 cm; 79.7 ± 7.6 kg) performed an Anaerobic Wingate Test (WAnT) ($7.5\%/kg$) under three conditions in a double-blinded randomized within-subject study design: without mouthguard, with a habitual verticalized mouthguard and a neuromuscular dental splint, which was fitted in a special myocentric jaw position (4). Peak power (PP), time to peak power (TiPP), average power (AP), minimum power (MP) and power drop (PD) were analysed. Results PP (862.3 ± 111.9 W), TiPP (5.9 ± 0.8 s), AP (673.8 ± 80.1 W), MP (474.8 ± 66.7 W) and PD (387.6 ± 100.9 W) were not different between any testing conditions. PP, AP, MP and PD were highly correlated between all conditions (all $r \geq 0.86$; $p \leq 0.01$), but not TiPP. **Conclusion** Irrespective of habitual verticalization or myocentric positioning, dental splints have no effects on explosivity and fatigue in cycling sprint performance. The subjects performed well in comparison to age- and gender-matched active but untrained reference cohorts (5). Correlation coefficients of selected performance measures between the different conditions were similar to those of WAnT test-retest reliability studies. **References** (1) Arent SM, McKenna J, Golem DL (2010) Effects of a neuromuscular dentistry-designed mouthguard on muscular endurance and anaerobic power. *Comparative Exercise Physiology* 7(2), 73-79. PATTERNS OF OBJECTIVELY MEASURED PHYSICAL ACTIVITY AND SEDENTARY TIME IN SOUTH ASIAN WOMEN

Babakus Curry, W., Thompson, J.L.

University of East London

Introduction: South Asian (SA) women in the United Kingdom (UK) are at high risk for the development of chronic diseases such as cardiovascular health disease (CVD) and type 2 diabetes, and the few published studies with these groups indicate low levels of self-reported physical activity (PA). Increasing PA and reducing sedentary time (ST) are key factors to target in an effort to curb chronic disease morbidity and mortality. There is limited evidence documenting objectively measured PA and ST and their correlates in SA women. Therefore the aim of this study was to objectively measure and report patterns of PA and ST, and examine potential socio-demographic correlates of PA and ST, among SA women in the UK. **Methods:** 140 SA women from Cardiff, Wales wore an ActiGraph accelerometer for 7 consecutive days, and anthropometric measurements and self-reported socio-demographic information were taken. **Results:** Mean daily moderate-to-vigorous PA (MVPA) was 34.66 ± 21.52 minutes and mean daily ST was 530.20 ± 81.76 minutes; these variables were inversely correlated (Pearson $r = -.270$, $N = 140$, $p < .001$). Independent t-tests indicated a significant difference in MVPA between older (≥ 65 yrs) and younger women ($18-64.9$ yrs), with older women failing to meet PA guidelines ($t = 3.101$, $p < 0.05$). Women who were overweight or obese had higher levels of both MVPA and ST ($t = 2.01$, $p < .001$). Multiple linear regression analyses indicated that 19% of the variance in MVPA was explained by age and waist circumference ($F(2,138) = 6.84$, $p < 0.002$). 34.7% of the sample met PA recommendations when calculated using consecutive 10-minute bouts. There was a significant difference ($p < .001$) between daily mean ST and moderate-to-vigorous physical activity (MVPA) on weekdays and weekend days with more MVPA on weekdays and more ST on weekends. **Discussion:** Results indicate that older SA women perform less MVPA than younger women, and those classified as overweight or obese engage in more MVPA and ST than normal weight women. Differences in weekday and weekend PA and ST have important implications for timing of the implementation of interventions.

THE VIDEO TRACKING INTER-RATER RELIABILITY TEST OF OUTDOOR FITNESS EQUIPMENT USERS BEHAVIOR

Ryzhov, M., Chow, H.

Graduate Institute of Physical Education

Introduction Outdoor fitness equipment (OFE) has gained popularity in many regions worldwide to increase public's health. However, the effectiveness of installing the OFE is not fully determined. As direct observation of OFE user's behavior is not precise and cannot capture detail using information, this study has developed a system to adopt videotaping OFE user behaviors and video tracking analytical procedures. The objective of this study is to assess the reliability of the system. **Methods** The case study park was located in Tainan, Taiwan which has six pieces of OFE. OFE user behavior data were collected from both direct on-site observation logs and two video cameras clips. Each observation session lasted for 120 minutes during morning and evening peaks for 12 days in 3 weeks period. In this reliability analysis, two observed sessions were assessed. The free trial version of Noldus Observer XT software was used in analyzing video data. The inter-rater reliability tests were assessed with kappa value using SPSS and Observer build-in features. **Results** The agreement of individual subjects observed between log files and video identifying is low ($\kappa=0.338$). After eliminating the discrepancy subjects, we did inter-rater agreement test between direct observation log file and video recorded identifying, and the Kappa rate for agreement of each individual equipment use 0.84. We also have done inter-rater reliability test between two observers processing the video materials on the observation software for an agreement of two independent raters both using observation system software, Kappa rate for this test was 0.95. **Discussion** The results indicate the feasibility of the proposed system in this study as it was found to perform better than on-site observation techniques only that traditionally used and has high degree of inter-rater and test-retest reliabilities. Based on this system, further analysis of detail information OFE user behaviors such as the frequency and duration of using each equipment can be assessed to better evaluate if the effectiveness of using OFE in meeting the needs of promoting physical activity was achieved.

EFFECTS OF INCREASED PHYSICAL ACTIVITIES OF DAILY LIVING ON POSTPRANDIAL LIPAEMIA IN POSTMENOPAUSAL WOMEN

Edamoto, K., Jung, H.H., Takahashi, M., Miyashita, M.

Tokyo Gakuji University

Introduction Most laboratory-based interventions report that acute aerobic exercise attenuates postprandial triacylglycerol (TAG) concentrations, often termed postprandial lipaemia, in men. However, few studies examining the effect of exercise on postprandial lipaemia in the elderly and even less in postmenopausal women (Maraki and Sidossis, 2013). Furthermore, limited evidence was available to support the effect of self-selected activities performed under free-living conditions on postprandial lipaemia. Thus, the aim of our study was to examine the chronic effect of increased physical activity of daily living on postprandial lipaemia in postmenopausal women. **Methods** Twenty-eight postmenopausal women, aged 71 ± 4 years (mean \pm SD), were randomly divided into two groups: active ($n=14$) and control ($n=14$) groups. The participants in the active group were asked to increase their activities above their usual lifestyle levels for 4 weeks; freely deciding the duration and intensity of their chosen activities. The participants in the control group maintained their usual lifestyle for 4 weeks. All participants were asked to wear a uniaxial accelerometer for 4 consecutive weeks. At baseline and after 4 weeks, all participants rested and consumed a standardised breakfast and lunch after a 24-h period of physical activity avoidance. Blood samples were collected in the fasted state (0 h) and at 2, 4 and 6 h after breakfast. **Results** After 4 weeks, the participants in the active group increased their step counts by 600 steps/day (from 6979 ± 2057 steps to 7586 ± 2301 steps/day, $P = 0.047$). The moderate to vigorous physical activity during the study did not change significantly in either group after 4 weeks (Active, from 20 ± 12 min to 24 ± 14 min/day; Control, from 20 ± 9 min to 19 ± 10 min/day). There were no differences in the postprandial TAG total area under the curve between the active and control groups (9.9 ± 6.0 vs. 11.8 ± 4.5 mmol \cdot 6h/L for the active and control groups respectively). **Discussion** Postprandial lipaemia was not reduced after performing self-selected activities under free-living in postmenopausal women. A previous study has suggested that only recent exercise (i.e., 12h before but not 24 h before) appears to facilitate the exercise-induced postprandial TAG lowering effects (Zhang et al., 2004). Our data may suggest that physical activity must be frequent if persistent effects on TAG metabolism are to be gained. **Reference** Maraki MI, Sidossis LS. (2013). *Sports Med*, 43 (6), 463-481. LIFESTYLE, HEALTH HABITS AND RISK FACTORS AMONG YOUNG ADULT AT QATAR UNIVERSITY

Al Nakeeb, Y.1, Al Maadeed, A.1, Trad, W.1, Al Qahtani, A.1, Al Shammari, D.1, Al Ghanim, H.1, Ali, M.1, Eiss, L.1, Mansour, M.1, Lyons, M.2

1: Qatar University (Qatar), 2: University of Limerick (Ireland)

Introduction The Gulf Cooperation Council countries have witnessed significant lifestyle changes due to rapid urbanization, the introduction of labor-saving devices and the availability of high-caloric density food. This has impacted on the physical requirements of daily life by encouraging sedentary lifestyle that has led to a significant increase in non-communicable diseases (WHO, 2011). This study aims to explore the lifestyle and health habits of young adults at Qatar University. **Methods** The study utilized a cross-sectional mixed-method design and a random sampling technique. A representative sample of 426 young adult males and females aged 18-25 years from Qatar University took part in this study. Physical Activity (PA) and dietary habits were assessed using a validated self-report questionnaire. Total energy expenditure per week was calculated based on the metabolic equivalent values of each activity reported by the participant (Al-Nakeeb et al., 2012). Body Mass Index (BMI) was calculated and the International Obesity Task Force criteria for age and gender-specific BMI cut-off points were used for classification (Cole et al., 2000). **Results** Females had a higher prevalence of overweight/obesity than males (64% and 56%, respectively) and exhibited lower levels of PA than males (26% vs. 38% inactive). Generally, males were more physically active than females across all age groups. Three clusters were identified: "low risk" cluster with healthiest dietary habits, most active and the least BMI; "moderate cluster" with moderate dietary habits, PA and BMI; "high risk" cluster with unhealthy diet, low PA and high BMI. There were more females and senior students in the high and moderate risk clusters. **Discussion** The prevalence of overweight and obesity was evident among male and female university students. Moreover, inactivity and sedentary lifestyle was manifested in the limited recorded moderate intensity PA in both sexes. Generally, younger students exhibited healthier lifestyles and followed better dietary habits than their senior counterparts. The findings reveal a worrying picture of young people's lifestyle and identify some important practical implications that could be of interest to policy makers, teachers and health professionals. Furthermore, the findings confirm the notion that health practices tend to occur in clusters rather than in isolation and indicate that patterns within these clusters of behaviors

should be considered when planning policies and designing intervention strategies concerning PA and health habits. References WHO (2011). Al-Nakeeb, Y. et al., (2012). IJERPH, 9, 1409-1506. Cole, T.J. et al., (2000) Br Med J, 320, 1240-1243. Contact alnakeeb@qu.edu.qa

THE RELATION BETWEEN PHYSICAL ACTIVITY AND HEALTH AMONG HIGHLY AND MODERATELY ACTIVE STUDENTS

Daniuseviciute, L.

Kaunas University of Technology

Introduction Lack of physical activity is influenced by a number of chronic non-infectious, mental (Corbin et al. 2001; Golden et al., 2004) and other diseases (Katzmarzyk et al., 2003). Students' physical activity and nutrition research remains relevant, especially for those students the future profession of which is not related to physical activity and health. Research aim. The aim of the study was to estimate the relation between physical activity and health among highly and moderately active students. Methods All the subjects (n = 327) were grouped according to their physical activity levels. The group highly physically active students - female athletes (n = 32) and male athletes (n = 79) who were physically active more than 3000 minutes per week. The group of moderate physical activity included females (n = 47) and males (n = 169) who were physically active 600–3000 minutes per week (Ainsworth, Levy, 2004). The respondents filled in anonymous questionnaires: the International Physical Activity Questionnaire (IPAQ) and International Food Frequency Questionnaire (FFQ). Results The subjects in high physical activity group gave a subjective evaluation of their physical activity as high (53%) and moderate (32%). The subjects in the moderate physical activity group evaluated their physical activity as moderate (60%) and high (26%). All subjects in both groups indicated that their health was good. The headache symptoms, stomach, abdominal or back pains, sadness, depression, insomnia and dizziness were rare or not common at all to subjects in high (63%) physical activity group. Sadness, depression, nervous tension and irritability, and bad mood were common to subjects in moderate (59%) physical activity group. The subjects in high physical activity group had their meals three – four times per day (76%), but subjects in moderate group ate only two – three times per day (61%). Irregular lunch and dinner were common to subjects in moderate physical activity group (63%). Discussion Research results showed that subjects in high and moderate physical activity groups gave correct subjective evaluations of their physical activity forms. Also subjects in high physical activity group had breakfast, dinner and supper on regular basis and they had balanced diets more often (p < 0.05). Contact lauruka@yahoo.com

GREEN PRESCRIPTION SUPPORT PROGRAMMES IN CANTERBURY: INFLUENCE ON PHYSICAL ACTIVITY AND PHYSICAL AND PSYCHOLOGICAL WELLBEING

Draper, N., Marshall, H.C., Green, J., Calder, K., Wood, J., Vabulis, S., Renolds, C., Wensley, L.

University of Derby

Introduction New Zealand Green Prescription (GRx), a physical activity (PA) counselling programme, has been shown to increase short and long-term PA levels, and to improve perceived health benefits in sedentary individuals (Elley, et al., 2003; Lawton et al., 2009; Sinclair & Hamlin, 2007; Swinburn et al, 1998). The purpose of this study was to compare the short and long-term effects of the Be Active (BA) and Telephone Support (TS) versions of the GRx programme on physical activity and wellbeing. Methods Forty eight previously sedentary adults (mean 54.4 yrs, 68.8% females) referred to the GRx programme volunteered for the two group repeated measures intervention study. Following a face-to-face consultation, participants opted to take part in either a 10 week BA programme (1.5h weekly session of combined PA and education) (n = 28) or TS (15-20 min phone consultation every 4-6 wks for 4 months) (n = 20). Testing of the outcome measures – physical activity, % body fat, BMI, waist and hip circumferences, blood pressure, submaximal exercise efficiency, self-reported wellbeing – was carried out at baseline, 10 weeks, 6 months and 12 months. Outcome measures across these four time points were analysed using repeated measures ANCOVA modelling. Results Physical activity increases were significantly greater following the BA programme compared with the TS (p = 0.011), a behavioural change which was maintained at 12 months. Subsequently, body composition was improved over time with a decrease in body mass, BMI and waist circumference, adaptations which were sustained long-term. This improved body composition was greater in those exceeding the participation threshold (body mass p = 0.018, BMI p = 0.029) or those of a lower SES (BMI p = 0.046, waist circumference p = 0.006). More deprived individuals also had greater improvements in self-perceived general health (p = 0.012). Discussion These findings support the increase in short (Swinburn et al., 1998) and long-term (Elley et al., 2003) activity levels previously found following traditional GRx support and extends these findings, showing the Canterbury Be Active programme to increase physical activity levels to a greater extent. A lack of change in clinical outcomes has previously been reported (Elley et al., 2003; Swinburn et al., 1998), however, the current findings suggest improvements may be dependent on being provided with a minimal level of support and socio-economic status. OBJECTIVELY MEASURED HOURLY PATTERNS OF PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR UNDER FREE-LIVING CONDITIONS IN YOUNG AND MIDDLE AGED MEN AND WOMEN

Ayabe, M.1,2, Kumahara, H.2,3, Morimura, K.2, Tanaka, H.2

Okayama Prefectural University

Introduction The recent technological advances enable us to assess objectively the behavioral patterns under free-living condition. Although the accelerometer-based investigations have demonstrated the whole day habitual physical activity and sedentary behavior, the hourly patterns remains unclear. As the fields of the chrono-nutrition and the chrono-medicine have been developing rapidly, it is not doubtful that, in regard to the habitual physical activity, there are the time specific effects on the healthy lifestyles. Therefore, the purpose of the present investigation was to appear hourly patterns of the habitual physical activity and sedentary behavior under free-living conditions in young and middle aged men and women. Methods A total of 139 adults (97 Men and 42 women, 50±6 years of age, 165±6 cm of height, 67±13 kg of body weight, 24±4 kg/m² of body mass index) participated in the present investigation. All participants wore a pedometer with a one-axial accelerometer (Lifecorder, Kenz, Japan) during all waking hours for 7 days, in order to determine their frequency (bouts) and duration of physical activity (min), and physical activity was divided by the intensity (Sedentary; <1.7 METs, Light; 1.7-3.0 METs, Moderate; >3METs). The bout and min of physical activity evaluated in hour-by-hour, thereafter, the sum of the hourly values was defined as the 24-hour indexes. Results The hourly frequency and the intensity of the physical activity were significantly higher at 0700 to

0900 and 1700 to 1900 compared with that at other time periods ($p < 0.05$). Similarly the significantly shorter hourly duration of the sedentary behavior was also found within same time periods ($p < 0.05$). Although the absolute hourly frequency and the intensity of the physical activity significantly associated with age and gender at the several time of day, these statistical significances disappeared after the adjustments by the 24-hour levels of physical activity. Discussion The levels of the hourly physical activity would be higher at morning and late evening periods due to the transportations in middle-aged men and women. The significant role of the hourly physical activity independent from the 24-hour values remains unclear. References Davis MG, et al. Eur J Appl Physiol (2007), Hansen BH, et al. INVESTIGATING THE ENDOGENEOUS RELATIONSHIPS BETWEEN PHYSICAL ACTIVITY AND RESIDENTIAL ENVIRONMENT IN THE ELDERLY WITH AN APPLICATION OF TREATMENT EFFECT MODEL

Yeh, C.Y., Chang, C.K.

National Chi Nan University

This research examines the environmental factors affecting the physical activity of the elderly. A quantitative questionnaire is applied to collect the data of the elder citizens above 65-year-old in Taichung City, Taiwan. The Geographic Information System (GIS) is employed to generate residential environment of sport related facilities as the environmental data. The data examination indicates that there is an endogeneous relationship (or bi-causal relationship) between physical activity levels and the preferred location of doing regular exercise. In our case, the elderly in Taiwan prefer to exercise at local public parks. If the elderly live closer to parks, they tend to choose the parks for exercise and develop an exercise habit in a park, so that they tend to have higher physical activity levels. On the other hand, if the elderly have higher physical activity levels, they are also more likely to choose a residential location closer to parks and form the exercise habit in parks. Accordingly, in order to avoid the endogeneity problem of causing the biased estimation, Treatment Effect Model adjusted with appropriate instrumental variables is applied for the regression analysis. The results of this research show that the more and closer public parks are within the residential neighborhood of the elderly, the higher level of physical activity they achieve. Also, the elderly who have habits to exercise in the public parks have a higher level of physical activity. If the endogeneity issue is ignored, the Ordinary Least Squared Method (OLS) estimated park effect that is only 16% of the estimate in the Treatment Effect Model. As can be seen, the endogeneity problem is very significant in investigating the environmental effect. In conclusion, the public parks are important leisure and sport venues to the elder citizens in Taiwan as well as in many Eastern countries. Our study suggests that increasing the park accessibility is a crucial factor in promoting physical activity in the elderly for their physical fitness and health.

MUSCLE ACTIVITY AND SITTING COMFORT DURING PROLONGED COMPUTERIZED OFFICE WORK ON A STANDARD OFFICE CHAIR AND A CHAIR WITH UNSTABLE SEAT

Geržević, M.1, Mikuletič, V.2, Koren, K.1, Šimunič, B.1

University of Primorska

Introduction Sitting on stability balls or chairs with unstable seats are often recommended and promoted as "active sitting", which could increase muscle work, strength and blood flow as well as prevent or reduce low back pain, but little research has been done to evaluate this (Gregory et al., 2006; McGill et al., 2006; Schult et al., 2013). Therefore, it was the aim of this study to compare the activity of trunk muscles and sitting comfort during 1-hour of computerized office work on a standard office chair and a chair with unstable seat. Methods Fourteen healthy adult volunteers (43 % men; 22.4 ± 2.2 years, 65.0 ± 11.8 kg, 169.9 ± 11.6 cm) participated in the project co-financed by the Health Insurance Institute of Slovenia and PFEIFER s.p. and performed 4 computerized office work tasks for 15 minutes each on a chair with unstable seat (Active Chair). Before and immediately after each task the participants estimated the overall level of sitting discomfort on a visual analogue scale. While working, the EMG signal was continuously recorded from left and right lower trapezius (LT), erector spinae (ES), rectus abdominis (RA) and obliquus externus (OE) muscles. All measurements and the study protocol were performed according to Gregory et al. (2006), where working on a standard office chair and stability ball were compared. Therefore, the acquired data on the Active Chair were statistically compared to the office chair using one sample t-test, while the discomfort rates in time on the Active Chair were analyzed with RM ANOVA using Bonferroni's correction for post-hoc tests. Significance level was set at .05. Results The results showed that the trunk muscles' activity was relatively low (1.2 % MVC) during 1-hour sitting (working) on both chairs. On the Active Chair the activity of right ES muscles was lower ($p = .002$), while the activity of left OE muscles was significantly higher ($p = .026$) in comparison with the activity while working on the office chair. Furthermore, sitting discomfort on the Active Chair was significantly higher already at the beginning ($p = .001$) as well as after 1h work ($p < .001$) compared to the office chair, but it increased significantly only after 45 minutes ($p = .024$). Discussion Sitting on the Active Chair increases the activity of some abdominal muscles, but it is relatively low with respect to muscles' MVC. Moreover, the overall rate of sitting discomfort on the Active Chair is higher than on a standard office chair, which is somehow expected for these types of chairs, yet it could still be improved. EFFECTS OF ABDOMINAL MUSCLES IEMG AMPLITUDE DEPEND ON BODYBOLSTER APPLICATION, SITTING BODY POSTURE AND EXERCISE

Lee, B.K.1, Jung, D.C.2, Kim, W.T.3, Hwang, K.S.4, Kim, J.E.4, Kang, I.5, Shin, J.M.1, Oak, J.S.6, Kang, H.J.7

1: SMU (Korea), 2: CRC-I (Seoul, Korea), 3: NURY-Tec (Seoul, Korea), 4: Nature&Bio (Seoul, Korea), 5: AIM (Seoul, Korea), 6: DKU (Korea), 7: SCHU (Korea)

Introduction The purpose of the study was to analyse the effects of abdominal muscle iEMG amplitude depend on BODYBOLSTER application, sitting body posture and BODYBOLSTER exercise. Methods EMG signal was collected by QEMG-8(Laxtha, Korea). The electrode were attached on external oblique muscle of abdomen, rectus abdominis, and transversus abdominis both left and right sides. The material for application was BODYBOLSTER(Bolster Trading Pty Ltd., Australia). The subjects were healthy college male students. Participants performed 5 condition 1) sitting back attached wall on bolster(SBAW-OB) and 2) without bolster(SBA-WOB), 3) sitting back detached wall on bolster(SBDW-OB) and 4) without bolster(SBDW-WOB), and 5) sitting forward-backward exercise on bolster(FBE-OB). EMG responses were collected for 20 seconds, rectified, and transferred to iEMG average. Results iEMG were a small difference between 1) sitting back attached wall on bolster(SBAW-OB) and 3) sitting back detached wall on bolster(SBDW-OB) depending on back attached and detached. However, iEMG of 1) sitting back attached wall on bolster(SBAW-OB) were higher than 2) without bolster(SBA-WOB), and iEMG of 3) sitting

back detached wall on bolster(SBDW-OB) were higher than 4) without bolster(SBDW-WOB). iEMG of 5) sitting forward-backward exercise on bolster(FBE-OB) were 50-600% higher than 1) sitting back attached wall on bolster(SBAW-OB), and 2) without bolster(SBA-WOB). Discussion This study show that means iEMG on bolster posture were 10-30% higher than without bolster posture. It means posture on bolster need additional muscle activities to keep balance, and may enhance muscle strength after several weeks. iEMG during sitting forward-backward exercise on bolster(FBE-OB) were marvelously increased 50-600%. It means exercise on bolster were marvelously increased muscle activity, even low intensity exercise, and may enhance muscle metabolism. Contact 1: klee@smu.ac.kr

CHARACTERISTICS OF SPRINT MOTIONS FOR ELEMENTARY SCHOOL CHILDREN

Tatsumi, J., Kokudo, S.

Kobe university

Introduction There are various motions in children's sprint. It is important to elucidate the methods to estimate objectively sprint motion for making sure of the current mastery of sprint ability. The purposes of this study were to examine characteristics of sprint motions for elementary school children and to construct the simplified check points for evaluate children's sprint ability. **Methods** The samples were 3rd grade children, 43 boys and 49 girls, who perform 50m sprints. Their sprint forms were recorded from front and side with panning. Sprint times were also recorded during 10m (25-35m section) using photoelectric sensor timer. The sprint motions were analyzed based on 39 observational motion points, which have multi rating categories. The graded response model of item response theory (IRT) was applied in order to estimate the sprint ability of the children and item characteristics such as item difficulty (ID) and discrimination power (DP). From the IRT results, several motion points were picked up in order to evaluate sprint ability concisely. **Results and discussion** It is necessary to select motion points so that IDs are distributed wide range. In addition, it is desirable for them to have higher DP to evaluate children's ability. As a result of consideration, the simplified check points were constructed by 7 motion points such as 'bouncing motion (ID1=0.402, ID2=0.714, DP=2.524)', 'hip motion (ID1=-1.012, ID2=0.725, DP=1.942)', 'weighting motion (ID=-0.644, DP=1.752)', 'two-axis motion (ID=0.375, DP=1.675)', 'push direction at taking off (ID1=-1.570, ID2=0.381, DP=1.491)', 'pumping action of front arm (ID1=-1.179, ID2=0.160, DP=1.258)' and 'knee highest position (ID1=-0.152, ID2=2.378, DP=0.878)'. The correlation coefficient between the ability scores which from all motions ($\theta = -0.438 \pm 0.982$) and which from selected motions ($\theta = -0.228 \pm 0.978$) was $r = 0.958$ ($p < 0.01$). The correlation coefficient between the ability scores which from all motions and sprint times (1.97 ± 0.20 seconds/10m) was $r = -0.791$ ($p < 0.01$). The correlation coefficient between the ability scores which from selected motions and sprint time was $r = -0.805$ ($p < 0.01$). From the results, the simplified check points can evaluate children's sprint ability enough. **References** Kokudo S. (2013). 18th annual Congress of the European College of Sport Science, 917. A STUDY OF MORPHOLOGICAL EVALUATION OF SPRINT MOTION FOR ELEMENTARY SCHOOL CHILDREN

Kokudo, S., Tatsumi, J.

Kobe University

Introduction The purpose of this study was to establish a cycled morphological model of the sprint in order to develop some effective methods for teaching the sprint in the physical education class. **Methods** The morphological model of the sprint motion was drawn on the cycled causal model, which was applying cause and effect diagram or fishbone diagram, one of the quality control tools. The model covered the descriptive checkpoints of previous studies. It was composed 3 major motions; ground catching, driving, and swing action, which included 38 morphological observation points. Every morphological observation was categorized into 2-3 levels respectively. Intermediate sprint forms (25-35m of 50m sprint) of 92 5th-grade elementary school children, 43 boys and 49 girls, were shot by digital video cameras. Their forms were played in slow motion or frame-by-frame, and an investigator evaluated the checkpoints. Exploratory factor analysis was applied in order to investigate major factors of sprint motions. Structural equation modeling (SEM) was applied for constructing cycled structural models of sprint from the results of the factor analysis **Results and Discussion** Five factors, catch and push motion of grounded leg, swing motion of free leg, body axis configuration, body twisting motion and arm pumping motion, were extracted from the factor analysis. SEM of leg motion, which included causal relationship between the swing of free leg and the catch and push motion of grounded leg, was constructed as a circular condition, including swing motion, catching motion, weighting motion, elastic motion, and pushing motion. The fitting indices were chi-square=77.91(df=50, $P < 0.05$), RMR=0.020, GFI=0.886, AGFI=0.823 and RMSEA=0.078. The body axis-related model, which included body axis configuration, body twisting motion and arm pumping motion, was investigated (chi-square=37.71(df=26, $P > 0.05$), RMR=0.021, GFI=0.923, AGFI=0.867 and RMSEA=0.078). The leg-body combined model was also examined (chi-square=241.76(df=179, $P < 0.01$), RMR=0.025, GFI=0.819, AGFI=0.766, and RMSEA=0.062). The model explained that the arm pumping motion affected to swing motion of free leg and weighting motion. Elastic motion was affected to body axis motion and push motion of grounded leg. The model was easy to understand the casual relationship of time following sprint motions. Therefore these motion viewpoints are able to utilize the teaching method. **Conclusions** Sprint motion was able to evaluate with circular model of leg motions. Arm pumping motion was support the leg motions such as swing motion and weighting motion. We need to improve further aspect because the viewpoints did not reflect some of the observed motions. ITEM ANALYSIS OF TOE GRIP FOR PRESCHOOL-AGED CHILDREN

Ikededa, T.I, Aoyagi, O.2

1Fukuoka Prefectural University, 2Fukuoka University

Introduction Previous studies have focused on toe grip (TG) as a measure of fall-related physical function among the elderly (Yamaji & Demura, 2013) and as part of strategies for adapting to slippery surfaces (Fong et al., 2008). The reliability (Fukumoto et al., 2011) and validity (Hirahara, 2011) of TG as a measure of physical function have previously been examined; however, the samples included only young adults. Therefore, this study aimed to investigate the reliability and validity of TG as a measure of physical function in preschoolers. **Methods** Participants were 153 preschoolers. Each participant was measured using T.K.K.3360. In addition, all participants completed a motor ability test (MAT) that included six items. The reliability of the measurements was examined by Pearson's *r* and Cronbach's α using a test-retest method. The validity of TG as a measure of physical function was investigated by measuring the correlation between TG and each component of the MAT, the MAT principal component score, and a two-way layout ANOVA (gender and age). **Results** The mean TG for boys was 3.96 ± 1.30 kg (4yr.) and 5.38 ± 1.57 kg (5yr.). For girls, the mean was 3.92 ± 1.20 kg (4yr.) and 4.81 ± 1.11 kg (5yr.). The *r* for TG was .720 (right) and .740 (left), and the α was .837 (r) and .850 (l). Significant correlations were observed between TG and all components of the MAT ($p < .05$). In a two-way layout ANOVA, no sex interaction or significant age difference was observed. **Discussion** In the present study, TG was found to be a highly reliable measure of physical function in preschoolers. Fukumoto et al. (2011) reported that TG was highly reliable in young adults. Based on the significant correlations with all components of the MAT, TG is considered to be a valid indicator of physical development with age. The most significant correlation was observed between grip strength and TG. This is because the palmar grasp reflex exhibited by infants diminishes over time and is eventually inhibited by higher brain centers or is integrated into movement patterns as those centers develop (Malina & Bouchard, 1971). The plantar grasp develops in a similar manner, but the function of the hand and foot differ in humans. Therefore, grip strength and TG have the most significant correlation among all components of the MAT, but not the largest correlation coefficient. **References** Fong D.T. et al. GOALKEEPING IN FOOTBALL: FAST OR SLOW, HOW TO DECIDE?

Vicente, A., Fernando, C., Lopes, H.

University of Beira Interior, University of Madeira, CIDESD

Introduction It is easy to accept that football is about being fast to be successful. So it may be natural to believe that to score or prevent goals players need to be fast and act as quickly as possible. However, previous studies (e.g. Vicente et al., 2012, Vicente et al. 2013) showed that there are time relations between players that must be taken into account in football, that players need to be aware of the opponent's actions (stimulus) and possibilities in order to take decisions and make the right choice. In some football typical situations (feint, passing or shooting) the success is not about being fast, but to be slow enough to take advantage over the opponent reaction. Does the same occur to a goalkeeper? The aim of this study was to verify whether a correlation exists between the velocity of the stimulus in a penalty kick situation in football and the goalkeeper's response. **Methods** We've used a software (MeSiR1.4) designed to measure the relation between the velocity of the stimulus and the time to respond it. The test was based on a stimulus - a striker (ST) - that kicked a ball from the penalty kick spot to each side of the goal (left or right) at different ball velocities (± 40 km/h and ± 90 km/h) randomly. The players (75 university football players) had to press one of four matching letters in a keyboard, previously known, according to the ball trajectory to the goal (B or V when the ball was kicked to the left corner; N or M when the ball was kicked to the right one) for two possible ball velocities perceived (B, N for 40km/h and V, M for 90km/h) for 30 trials. Each test data was automatically collected by the software that provided the response time (and correspondent direction and perceived ball velocity) to each stimulus velocity. **Results** The results from the 2250 trials performed showed that players took the right decision (ball direction to goal) in 81% of the situations. In those, for the fastest stimulus the average response time was 378 milliseconds (ms), and for the slowest stimulus the average time to respond was 420 ms. Players perceived the fastest ball velocity in 78% of the fastest stimulus, and 86% of the times perceived the slowest ball speed in the parallel slowest stimulus. **Discussion** Data showed that the stimulus velocity influenced the response time and the response itself: as the stimulus (ball velocity) was faster or slower, the response (goalkeeper decision) was also correspondingly faster or slower. Results corroborate previous studies (Vicente et al., 2013) and other ecological studies that we are still carrying out. The findings led us to suggest that goalkeepers in football should be trained to relate with the opponents (strikers) being aware that they can influence their actions and their time to decide in order to take advantage and increase the chances of saving goals. **References** Vicente A., Fernando C., Lopes H., (2012). 17th ECSS, Bruges. RELATIVE AGE EFFECT – A STUDY OF NORWAYS, SWEEDENS AND PORTUGALS U17, U19, U21 AND ADULT TEAM

Hamnvik Sagelv, E., Nicolaisen Simonsen, J., Rafoss, K.

University of Tromsø

Introduction Since Grondin, Deshaies and Nault (1984) discussed a possibility of relative age effect, the phenomenon has been shown in many sports, especially in team sports with physical contact. Relative age effect (RAE) is a phenomenon when an athlete gets benefits of being more physically developed because of when he/she is born in the year, or after the cut-off date. We have been aware of the RAE in over 10 years now, and little is done about it. The consequences is that many talents, who is not that well physically developed yet, is lost due to the small sense of achievement in a young age, this is called drop-out. In adult sports the phenomenon does not occur as much as in youth sports (Musch and Grondin, 2001). **Methods** We checked the birth date of all male players who were called up for the U17, U19, U21 and the adult team in Norway, Sweden and Portugal from 2008 until 2012, in football. We divided them into 4 quarters and looked for any significant similarities or differences. We hypothesized that since Portugal is a better football nation than Norway and Sweden, Norway and Sweden should have more players born in the first and second quarter than Portugal. At the same time we checked the 1994- and 1998-world cup team for Norway, because Haulan and Saether (2011) meant that RAE did not occur in the time when the Norwegian national team qualified for the world cup in 1994 and 1998. **Results** The results showed no significant differences in the three nations. It also showed that RAE did not occur as much in adult sports as in youth sports. From 2008 until 2012 it seems that there are more players born in the first and second quarter in 2012 than 2008 for U17 and U19. It also showed that RAE did occur in the two Norwegian world cup teams (1994 and 1998). **Discussion** These results show that these three nations have not taken RAE under consideration when they call up youth players for the national team. Also, by comparing our results with Helsen et. al. (2012), Peter-

son(2004) and Ripegut and Eidel(2008), these nations have not taken any consideration for RAE from 2000 until 2012. We proposed three solutions to RAE. One is that you must have 25 % of the players you call up to the national team in each quarter. Another one is weight and height national teams instead of U16, U17 and so on. The last solution is rotating cut-off date. For each year the cut-off date is moved, in that way every month gets to be the first month after the cut-off date. This last solution is Helsen et. al.(2012) idea. References Since this is a Bachelor thesis, it is a lot of references. If you want to see them, please let me know and I will be happy to give them to you.

REVEALING RACE PATTERNS IN IRONMAN TRIATHLON USING PRINCIPAL COMPONENT ANALYSIS

Krieger, J.P.

ETH Zürich

Introduction The multidisciplinary nature of ironman (IM) triathlon races makes the analysis of performance more challenging. However, an analysis of race patterns (i.e., the real contribution of each discipline to a good ranking overall) is needed for athletes and coaches to plan training and race strategy. To our knowledge, only the timed contribution of each discipline to overall time is classically used to describe race patterns in ironman triathlon races but this data may not be of relevance as it strongly depends on the event and overall time. Here we proposed to analyze IM triathlon race results using a multidimensional descriptive approach and to provide a simple graphical representation of an athlete's race structure as well as its correlation with overall performance. This new method allows the identification of successful (and unsuccessful) race patterns. **Methods** We used race results of IM Hawaii 2012 to compute a principal component analysis (PCA) by group division (Pro and age groupers) and gender. All variables related to swim time, bike time, run time and transition time were taken into account and names of the competitors were replaced by their final ranking. All results and graphs were obtained with SAS 9.3 (SAS Institute Inc., Cary, NC, USA). Original data was taken from « slowtwitch enhanced results » (available online : <http://www.slowtwitch.com/enhancedresults/>). Results PCA of IM Hawaii triathletes revealed a strong correlation of bike-related variables with the 1st axis ($rc1=0.45$) while run-related variables and swim-related variables were respectively correlated and negatively correlated with axis 2 ($rc2=0.19$). When athletes were projected within those axis, a clear ranking-dependent pattern appeared : the best triathletes were characterized by a balanced performance in all three disciplines, with a high prevalence of top running performance. After a certain rank, race patterns were characterized by a slower time in one of the three disciplines, more than a moderate performance in all three disciplines. Finally, combining a slow bike split with another slow split in one of the 2 other disciplines (especially running) was the main reason for a low final ranking. Eventually, category-specific patterns were found such as the absence of data structure linking transition times and final ranking in the professional category, whereas this structure appeared in several age groups. **Discussion** PCA is a descriptive method that is not based on probabilistic assumptions but on a geometric model. Further investigation can be done using the race patterns described here using inferential statistics. However, the graphical data generated by PCA can be used to point out the existence of classical race patterns associated with performance as well as to describe an athlete's performance after the race. We believe that such data may be of relevance for triathletes and coaches to adapt their training programs.

RELATIONSHIPS BETWEEN PACING PARAMETERS AND PERFORMANCE OF ELITE FEMALE 800-M FREESTYLE SWIMMERS

Lipinska, P.1, Allen, S.V.2, Hopkins, W.G.2

1: University of Physical Education and Sport, Gdansk, Poland; 2: High Performance Sport NZ and AUT University, Auckland, New Zealand

INTRODUCTION: Evidence for the effects of changes in pacing profile on endurance performance is sparse. Here we report a method for characterizing pacing in 800-m freestyle swimming and for relating changes in pacing to changes in performance time. **METHODS:** The swimrankings.net website provided 50-m split and final race times for 192 swims of 20 elite female swimmers in 20 national and international competitions between 2006 and 2012. A plot of the log of lap time vs lap number for each swim indicated that the pacing profiles could be characterized parsimoniously by five parameters derived from a linear model: linear and quadratic coefficients for the effect of lap number, reductions in time for the first and last laps, and the residual standard error of the estimate (summarizing random and systematic deviations from the model). Each parameter was then included separately in a mixed model as a simple linear predictor of the log of final race time to determine the relationship between within-swimmer change in the parameter and change in final race time. The magnitude of the relationship was expressed as the effect on race time of two within-swimmer standard deviations of the parameter (a typically low to a typically high value) and evaluated by magnitude-based inference with reference to a smallest effect on swimming performance of 0.3%. **RESULTS:** The average quadratic profile represented a reduction in pace of 2.1% between the first lap and the nadir in the eleventh lap, followed by an increase in pace of 0.6% by the last lap. Times for the first and last lap were shorter by an additional $6.6\% \pm 1.0\%$ and $3.6\% \pm 1.6\%$ (mean \pm SD). The residual error was $0.6\% \pm 0.2\%$. The within-swimmer analyses showed that the linear and quadratic parameters had likely trivial effects on final time (0.2% and 0.1% respectively), while the first lap, last lap and residual error had possibly trivial-small effects (-0.3%, 0.3% and 0.2% respectively). Uncertainty in all these effects was $\pm 0.3\%$ (90% confidence limits). **DISCUSSION:** The surprising finding was the curvilinear shape of the pacing profile and the lack of any substantial effect of the slope or curvature of the profile on final time. At this elite level there is apparently nothing to be gained from changing the profile. The possibility of a small negative effect of the first lap presumably reflects the antagonism of strength and endurance fitness, while the possible positive effect of the last lap is of the expected magnitude and reflects the effect of changes in fatigue between races. Our study shows that a five-parameter mixed-modeling method can be used to assess pacing in distance swimming events.

ANALYSIS OF RACE TIMINGS FOR MEN'S, WOMEN'S AND MIXED CREW DRAGON BOAT AT THE 27TH SOUTHEAST ASIAN GAMES

Tay, C.S., Kong, P.W.

Nanyang Technological University

Introduction In team boat racing, the race timing of a boat depends on the collective performance of the individual crew members. Dragon boat racing provides a unique opportunity to examine the science behind team boat racing since on top of Men's and Women's events, Mixed crew events (at least 40% of the crew is female) are also contested internationally. The aim of this study was to compare race timings of Men's, Women's and Mixed dragon boat crews from the 27th Southeast Asian (SEA) Games, and its implications for team boat performance. The SEA Games included many top dragon boat crews such as the Myanmar, Indonesia and Thailand national teams. **Methods** We first compared the official race timings of the gold medal Men's, Women's and Mixed crews for 5 events, namely 20-crew 2000m, 20-crew 1000m, 20-crew 500m, 10-crew 1000m and 10-crew 500m. Taking the Men's timings as the basis for comparison, percentage differences for the Women's and Mixed crews were calculated and then modelled with a non-linear equation. Next, we

calculated the winning margins for each event to determine how much slower the 2nd and 3rd placed crews were compared to the gold-winning crew. Results Compared to the gold medal timings of the Men's events, Women and Mixed crews were slower by 9.6% (8.4-11.3%) and 2.1% (1.5-2.7%) respectively. The percentage difference (y) is modelled by the equation $y = 0.0743x^2 - 0.1707x + 0.0965$, where x is the percentage of men in the crew. For example, if $x = 90\%$, we expect that a 20-crew boat with 18 men (or a 10-crew boat with 9 men) would be 0.3% slower than a Men's crew. The winning margins for all events ranged from 0.16 to 1.45%, with 4 events at 0.3% or less. Although the winning margins for the Women's events were between 0.63 and 1.45%, the silver and bronze medallists for one event were separated by only 0.03s, or 0.02%. Discussion The timing difference of 9.6% between the Men's and Women's dragon boat crews is similar to the 9 to 10% differences reported in rowing (Yoshiga & Higuchi, 2003). By also considering the difference between the Men's and Mixed crews, we obtained a nonlinear equation modelling the effects of having more men in the crew. Assuming that men are stronger paddlers than women, this model may also be used to evaluate the performance effects of having "stronger" paddlers in a single gender crew. Based on our model, replacing one "stronger" person/pair with a "weaker" person/pair translates to a 0.30% slower timing. This timing difference, though small, is significant in the context of the winning margins and medals placing. Thus, for highly competitive dragon boat crews, the contribution from each paddler is crucial to successful boat performance. References Yoshiga CC, Higuchi M (2003). JUMPING ACCELEROMETRIC STUDY OF ELITE HANDBALL FEMALE ATHLETES WITH OR WITHOUT PREVIOUS ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Setuain, I.1, Millor, N.1, Gorostiaga, E.1, Garcia, I.1, Alfaro, J.2, González Izal, M., Izquierdo, M.3

1Research, Studies and Sport Medicine Center, Government of Navarre, Spain, 2 San Miguel Clinic, Department of Orthopaedics, Pamplona, Spain 3Public University of Navarre, Department of Health Science

Measuring movement-pattern related variables during the rehabilitation process would help to identify possible movement patterns associated with a previous ACL reconstructed limb. PURPOSE: To identify possible differences between previously ACL injured and uninjured athletes focusing on jumping performance and 3 orthogonal axis kinematic variables among a group of 20 female handball elite athletes in the vertical unilateral drop jump (VBDJ) task. METHODS: A cross-sectional descriptive study was carried out in order to analyze jumping performance and movement pattern among 20 female elite handball players (6 previously injured and reconstructed and 14 uninjured subjects) during the execution of a VBDJ. An inertial orientation tracker MTx attached over the L3 region of the subject's lumbar spine provided the kinetic data recorded in each trial at a sampling rate of 100 Hz. VBDJ was divided for biomechanical analysis into three phases (initial absorption phase; IA, drive phase, and final absorption phase; FA). RESULTS: Previously ACL reconstructed athletes displayed greater mediolateral, anteroposterior and vertical axis peak accelerations in the IA, DP and FA jumping phases but not in the Z axis, where the FA was not different ($p > 0.05$) (X axis IA 13.15 ± 6.26 vs 0.13 ± 11.93 ; DP 2.70 ± 1.10 vs -0.48 ± 3.55 ; FA 8.58 ± 6.06 vs -0.71 ± 11.47 ; Y axis IA 14.66 ± 7.48 vs -6.17 ± 22.61 ; DP 6.27 ± 1.92 vs -4.90 ± 13.47 ; FA 9.30 ± 3.22 vs -9.43 ± 18.82 ; Z axis IA 49.86 ± 8.45 vs 39.84 ± 11.1 ; DP 16.68 ± 6.16 vs 12.39 ± 5.75 m/s²). Significant relationships were found between Z axis peak acceleration in the IA phase and flight time ($r = 0.38$; $P < 0.05$), DP Z axis peak acceleration and drive phase time duration ($r = -0.50$) and Z axis peak acceleration in the IA and IA phase duration ($r = 0.48$) among the control athletes. In contrast only the correlation between IA Z axis peak acceleration and IA time phase ($r = -0.68$) time resulted significant among previously ACL reconstructed group. CONCLUSION: Previously ACL reconstructed athletes showed significantly different movement patterns during the execution of the VBDJ comparison to non ACL injured controls. It may suggest that some different supporting forces distribution strategies in comparison with non ACL reconstructed control players could persist among previously ACL reconstructed elite female handball players despite having return to elite competition. Furthermore, the fact that more significant correlations were found among non ACL reconstructed athletes could indicate a more reproducible movement pattern among this group. REFERENCES: 1. THE EFFECT OF ANKLE TAPING IN THE JOINT LOADING DURING JUMPING AND LANDING

Lung, Y.R., Chen, W.H., Kang, K.C., Lin, H.T.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction Jumping and landing are the most common motions in many exercises but easy lead to ankle sprain. Recently, ankle taping could restrict ankle motion and is often used to protect athletes from ankle sprain (Surve et al., 1994). These changes may alter the ankle joint motion, and also affect the joint proprioception (Eils et al., 2003). If the athletes apply the ankle taping to protect ankle during the exercise, they have to adopt the motion change from taping (DiStefano et al. 2008). Therefore, the purpose of this study was to investigate the ankle force and moment change after taping during jumping and landing. Methods Seven male volunteers aged 18-25 years without any lower extremity injury were participated in this study. All subjects had to test two conditions: with ankle taping and without taping. Six different ways of jumping were tested including two countermovement drop jumps and two bounce drop jumps from 35 cm height platform and just in front of plate. Another two tests were forward jumping with distance of subject's half leg length and a leg length. The motion capture system (Qualisys, Swiss) were used for motion data collection and the force plate (Kisterler, Switzerland) measured the ground reaction force during jumping and landing. Applied the inverse dynamic analysis, the joint loading in ankle could be quantified. The "Wilcoxon signed-rank test" was used to examine the ankle joint loading differences between taping and non-taping. Results In the ankle joint force analysis, the joint force was reduced after taping especially in the medial/lateral axis during countermovement drop jump from 35 cm height box and bounce drop jump in front of the force plate ($p < 0.05$). Moreover, joint force in vertical axis was also reduced in countermovement drop jump in front of the force plate ($P < 0.05$). The ankle moment changes after taping were found in dorsi/plantar moment during bounce drop jump in front of the force plate ($p < 0.05$), and eversion/inversion moment during countermovement drop jump in front of the force plate ($p < 0.05$).

ment drop jump from 35 cm height and in front of force plate, and bounce drop jump in front of the force plate ($p < 0.05$). Discussion From this study, the ankle taping may provide more rigid and stable condition for landing and jumping, the subjects could afford less force during landing, especially in the vertical direction and medial/lateral direction. Moreover, after taping, the subjects just applied less moment especially in dorsi/plantar moment to jump and reaching the same performance, this may represent better neuromuscular efficiency during the motion. This information suggested the athletes to have ankle taping during the motion to reduce the ankle loading. THE MUSCLE ACTIVATION CHANGE DURING JUMPING AND LANDING AFTER ANKLE TAPING

Chen, W.H., Lung, Y.R., Kang, K.C., Lin, H.T.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction Ankle Inversion sprain is the most common injury occurred in people doing physical activity. Ankle taping could restrict ankle range of motion and provide a force to prevent ankle over-inversion is usually used to protect athlete from ankle injury (Ozer et al., 2009). However, ankle taping may also change ankle kinematics and mechanism of neuromuscular function during exercise (Yoon et al., 2013). The purpose of this study is to investigate the change of muscle activation after taping during jumping and landing. Methods Seven male volunteers with aged 18-25 years were participated in this study. All subjects had no lower extremity musculoskeletal injuries history at least one year and had to test two conditions: with ankle taping and without taping. The ankle taping intervention adopted regular taping including "Figure Eight" and "Heel Lock" (Tregouet et al., 2013). Six different ways of jumping were tested including two countermovement drop jumps and two bounce drop jumps from 35 cm height platform and just in front of plate. Another two tests were forward jumping with distance of subject's half leg length and a leg length. The surface electromyography (TrignoTM, USA) was used to detect the muscles activation of anterior tibialis, biceps femoris, peroneus longus, rectus femoris, and gastrocnemius lateral. The "Wilcoxon signed-rank test" was used to examine the differences between taping and non-taping. Results The results showed that the significant differences were found at gastrocnemius lateral had less contraction after taping during drop jump from 35 cm height and forward jumping with subject's half leg length ($P < 0.05$). The other significant differences were found at biceps femoris also had less muscle activation after taping during countermovement jump just in front of the force plate and forward jumping with subject's leg length ($P < 0.05$). Discussion There were only two muscles that had less activation after taping. The ankle taping may provide more rigid and stable condition for landing and jumping, therefore the gastrocnemius did not need contract so much to keep joint stability. Since ankle could get more stable during landing, therefore, the subjects could jump easier and did not need much contract of the biceps femoris. Moreover, the subjects could have better proprioception after taping, therefore, the subjects may have better neuromuscular function and did not need much muscles contraction during motion especially in the drop jump. The results from this study may suggest the athletes to have ankle taping to reduce the muscle loading and prevent injury. However, the constraint of ankle joint during motion may need further investigation. References Ozer D., Senbursa G., Baltaci G., Hayran M., (2009), *Clin J Sport Med*, 19(4), 205-210. BIOMECHANICAL FACTOR OF THE AGE-SPECIFICITY IN THE INCIDENCE OF SEVER'S DISEASE

Hashizume, S.1,2, Iwanuma, S.2, Kanehisa, H.3, Torii, S.2, Kawakami, Y.2, Yanai, T.2

1: Juntendo University (Japan), 2: Waseda University (Japan), 3: National Institute of Fitness and Sports in KANOYA (Japan)

Introduction Sever's disease occurs most frequently in boys aged 10-13 (Micheli and Ireland 1987). The mechanism of Sever's disease has been proposed as follows; a large tensile force is applied repeatedly to hyaline cartilage at the immature attachment site of the Achilles tendon, and this induces repetitive microtrauma accompanied with inflammation. Although the presence of hyaline cartilage at the injured site partly accounts for the age-specificity, additional factors, particularly those that influence mechanically the magnitude of tensile stress at the site, may also account for the age-specificity. Therefore, we examined the age-related differences in the structural parameters of foot and ankle influencing the tensile stress at the attachment site of the Achilles tendon. Methods Sixteen boys aged 7-9 (low incidence group), 24 boys aged 10-13 (high incidence group) and 19 young adult males voluntarily participated. A magnetic resonance imaging system was used to record a series of right foot images. From these images, the cross-sectional area (CSA) of the attachment site of the Achilles tendon and the mechanical advantage, which is defined as the ratio of the Achilles tendon moment arm to the moment arm of the ground reaction force were determined as the structural parameters of foot and ankle. An index was calculated by using these structural parameters to represent the magnitude of the tensile stress at the Achilles tendon attachment site for a given intensity of physical activity. Results and Discussion The index of the tensile stress was significantly greater in boys aged 10-13 (16.8 N/mm²) than in those aged 7-9 (12.2 N/mm²) and was not different between boys aged 10-13 and young adult males (14.4 N/mm²). This indicates that the attachment site of the Achilles tendon is subject to a greater tensile stress for the high incidence group than the low incidence group for the given intensity of physical activity. The mechanical advantage was not different among the groups. The CSA of the Achilles tendon insertion was significantly greater in young adult males (117 mm²) than in boys groups and was not different between boys aged 7-9 (69 mm²) and 10-13 (78 mm²). Body mass was greater in older groups than in younger groups. These suggest that the onset of growth spurt for the CSA does not coincide with that for body mass, and this gap might result in the significantly large index for boys aged 10-13. The delayed onset of growth spurt for the CSA of the Achilles tendon insertion may be an additional biomechanical factor that accounts for the age-specificity in the incidence of Sever's disease. DOES THE KINESIO TAPING HELP TO RECOVER AFTER DELAYED ONSET MUSCLE SORENESS ON WRIST EXTENSOR MUSCLES?

Tsung Yeh, C., Ya Ting, H., Hwai Ting, L.

Kaohsiung Medical University

Introduction Kinesio taping has often applied in athletes before and after training. The Kinesio taping may increase local circulation, reduce local edema by decreasing exudative substance, improve circulation in facilitating the muscle, provide proper afferent input to the central nervous system, change range of motion of the affected tissues (Kase K et al., 2003) and relieve pain. The purpose of this study is to investigate whether the Kinesio taping could assist the joint in proprioception, muscle strength, and wrist extensor muscles control after

delayed onset muscle soreness (DOMS). Methods Three college subjects without musculoskeletal injury and weight training at least 6 months were recruited in the study. The dynamometer (Biodex, USA) was used to make subjects DOMS and measured the joint proprioception and it joint strength. The subjects was instructed doing eccentrically exercise of the wrist extensor muscles three sets, one set of 12 repetitions. The resistance was set as 70% of 1 RM. All subjects felt soreness after 24-48 hours to reach DOMS. Proprioception test was set at wrist extension 30 degrees, maximum extension muscle strength test, and muscle control test were examined before eccentric exercise, just after exercise and 24, 48, 96 hours after eccentric exercise. Muscle control test are including throwing disc to the target and holding a custom-made fishing rod with 1.5 kg ball to move to the goal with 50 cm distance. Results With the Kinesio tape, the muscle activations were smaller than the condition without taping in the muscle strength test, but the strength was higher. In throwing disc and fishing rod control test, subjects with Kinesio taping had lower distance error than without taping. But no significant difference was found in passive proprioception between these two conditions. Discussion One of the functions of Kinesio taping is enhancement of muscle performance by strengthening weakened muscles and controlling over-active muscles. The results of this study also had similar findings. One study found the subjects with Medial Elbow Epicondylar Tendinopathy improved the force proprioception after Kinesio taping (Chang HY et al., 2010). In our study, the kinesio taping also could help muscle control after Kinesio taping. The possible effects of Kinesio taping may be due to the skin and muscle proprioceptors stimulation to sense the alteration of message concerning changes in stretch, load, and pressure (Halseth et al., 2004). Kinesio taping can assist muscle strength and muscle control after DOMS. References Hufnagel AF, Forestier N. (2006), *Neurosci Lett*, 403, 109-113. THE EFFECTS OF KINESIO TAPING ON MUSCULAR ENDURANCE OF DEEP NECK FLEXORS FOR SUBJECTS WITH FORWARD HEAD POSTURE : A PILOT STUDY

Chia Ning, C., Yen Cheng, L., Lan Yuen, G.

Kaohsiung Medical University

INTRODUCTION: Kinesio taping (KT) has been theorized to be an effective treatment to restore muscle function and assist the postural alignment. Because of the change of life style, modern people usually have sedentary behavior. The poor muscular endurance may lead to the poor postures. There are few studies about the effect of kinesio tape on forward head posture (FHP) alignment and deep cervical flexors. METHODS: 5 subjects were recruited in this study. The subjects were two males (mean age 19.0 ± 1.4 years old) and three females (mean age 19.7 ± 2.0 years old) who agreed to participate in this study. Custom-designed neck strength measure instrument (ICC, intra-class correlation = 0.968~0.988) and postural assessment system (ICC= 0.94~0.95) were used to measure cranio-vertebral angle and muscular endurance respectively. KT was applied on levator scapulae and upper trapezius in traditional taping method and applied on C7 to T3 in placebo taping method. Subjects will have 3 times measurements which are before taping, after taping and after 3 days taping. Subjects were demand to maintain maximal voluntary contraction of craniocervical flexion till fatigue. We quantified muscular endurance by investigating muscle fatigue time which defined the time of the muscle moment drop to 50% of its peak value. All subjects have to be evaluated their cranio-vertebral angle which is the angle between tragus and C7 by the postural assessment system. RESULTS: The improvement of posture alignment percentage, placebo taping method was better than traditional taping method (before taping and after taping $7.03\% > 3.00\%$, before taping and after 3 days taping $16.37\% > 10.20\%$). The improvement of muscular endurance percentage, placebo taping method was better than traditional taping method (before taping and after taping $163.57s > 67.15s$, before taping and after 3 days taping $257.46s > 118.10s$). The difference between before taping and after taping and before taping and after 3 days taping have no significant effect ($p > 0.05$). DISCUSSION: In this research, We applied KT on the levator scapulae and upper trapezius to alter FHP and investigated the change on deep neck flexors muscular endurance. The results suggested that KT may be able to improve the FHP and then increase deep neck flexors muscular endurance (placebo > traditional taping methods). Our findings were similar to previous studies that indicated KT has positive effects to muscular performance and alignment. The results observed in this study may be explained by the fact that after correcting the sitting posture of subjects, KT was applied on C7-T3 spinal process. Because of the correcting the sitting posture of subjects, it generates a tension of KT that cause placebo method better than traditional method. REFERENCES: Garrett, T., J. Youdas, and T. EFFECTS OF ANKLE TAPING ON KNEE JOINT BIOMECHANICS DURING A CUTTING MANEUVER

Ting Yi, C., Pei Hsi, C., Hwai Ting, L.

Kaohsiung Medical University

Introduction Ankle sprain is a common injury during sports. Many athletes use prophylactic taping to prevent or reduce incidence of ankle sprain injuries. But taping may cause changes in lower limb biomechanics. The purpose of this research is to investigate that effect of prophylactic ankle taping on knee joint biomechanics. Methods Ten subjects with the average height of 159.8 ± 3.8 cm, average weight of 55.3 ± 8.8 Kg, and average age of 21 ± 2 years old participated in this study. All participants are healthy without previous musculoskeletal injuries. Cutting tasks were conducted under un-taped and taped conditions. Each subject was asked to perform a 90 degree cutting maneuver with their right leg. (Besier et al., 2001) The speed of tasks was 5 ± 0.5 m/s. Taping was executed by a single certified senior athletic trainer. In this study, Qualysis motion capture system was used to collect data. Data calculations were performed in visual 3D and statistic analyzed with SPSS (Version14). Statistic used Paired-T test and set the significance level at $p < 0.05$. Results The result of knee joint flexion of initial contact angle (IC) did not show significant difference between the taping and the un-taping group. The knee varus angle of the taping group at the beginning of contact was significantly higher ($p < 0.001$) than the un-taping group. Comparing with the un-taping group, the knee external rotation angle was significantly higher in the taping group ($p = 0.024$) at initial contact. The peak knee flexion angle and the peak knee varus angle did not show significant difference between the two groups. Nonetheless, the peak knee external rotation angle was significantly higher in the taping group ($p = 0.017$). Discussion The results of this study showed that ankle taping may change the knee joint biomechanics. (Santos et al., 2004). At initial contact, the knee varus and external rotation angle increased significantly. Furthermore, the peak knee external rotation angle also increased significantly. Increased varus knee angle may indicate that the knee joint is exposed to higher loading during the deceleration phase of cutting motion. Markolf et al. (Markolf et al., 1995) also pointed out that higher knee external rotation angle may increase the risk of ACL injury. Therefore, the effect of ankle taping on knee joint biomechanics should be carefully considered while choosing prophylactic ankle taping to reduce the risk of lower extremity injury. ANALYSIS OF SPINE MOVEMENT IN VOLLEYBALL SPIKE WITH RESPECT TO BACK PAIN

Fett, D.1, Felker, K.1, Heinrich, K.2, Funken, J.2, Brüggemann, G.P.2, Platen, P.1

1 Ruhr-University Bochum, 2 German Sport University Cologne

Introduction Low back pain (LBP) remains a major health problem not only in the general population but also in sports. It is reported by approximately 30% of athletes. In volleyball the lifetime incidence of LBP is 74%. Besides individual and psychological risk factors, physical load of athletes is important in the mechanism of long-term pain. During competitive sports the spine is charged by repetitive high mechanic efforts. Therefore, sports-related injuries and overuse in spine are a common consequence. Thus, the aim of this study was to evaluate specific movement patterns regarding the range of motion (ROM) of different parts of the spine for quantifying their risk-potential of back pain. **Methods** We measured ROM of the cervical, thoracic and lumbar spine of 4 elite volleyball players (2=m, 2=f) according to flexion, extension, lateral flexion and rotation during 8 spikes. The movements were recorded using 15 high-frequency cameras for capturing 70 light reflecting markers, which had been fixed on the players skin. Data analysis was conducted by using Vicon Nexus and were evaluated by assorting certain angles of risk according to the classification of DIN EN 1005-4 (red, yellow, green range, with red being associated with high risk). **Results** To achieve a maximum ball velocity the spine is in a strong curve tension combined with a strong rotation at the end of the backswing. During 29,1% of the movement the whole spine was in the red range (max. ROM: -16,3°; SD: 2,7), the thoracic spine spend 32,9% (max. ROM: -11,7°; SD: 2,3) and the cervical spine 78,8% (max. ROM: -46,8°; SD: 12,3) in this risk range (<0°). The lateral flexion of the spine remained in the green range during approximately the whole time. Only 2,2% was spend in the red range (<-20°; >20°) and furthermore 18,1% in the yellow range (-10° - -20°; 10°-20°). The results of the cervical lateral flexion showed similar low time sequences in the red range (11,8%) (<-10°; >10°), while during cervical rotation 30,4% was spend in the red range (<-45°; >45°). **Discussion** The analysis of spine movement during spikes in volleyball received specific movement patterns at increased risk for back pain because of hyperextension. By analyzing other volleyball specific movements similar outcomes were observed. This is in line with further investigations showing degenerative changes in the spine shape with respect to hyperlordosis. The study underlines the necessity of specific spine stabilizing training programs in addition to specific training units for the prevention of back pain in volleyball. **Acknowledgement** The study was supported by the Federal Institute for Sport Sci., Germany (IIA1-080102B/11-14).

ANALYSIS OF STATIC SPINE ANGLES IN DIFFERENT HANDLEBAR POSITIONS IN TRIATHLON WITH RESPECT TO BACK PAIN

Felker, K.1, Fett, D.1, Heinrich, K.2, Funken, J.2, Brüggemann, G.P.2, Platen, P.1

(1) Ruhr-University Bochum, (2) German Sport University Cologne

Introduction Back pain (BP) is reported by approximately 30% of athletes and lifetime incidence of BP in triathlon is 68%. The two main mechanisms of long-term pain include sports-related injuries and overuse. Several studies found a relationship between sagittal spinal angles and BP. In order to better understand underlying mechanism the purpose of the present investigation was to evaluate the range of motion (ROM) in different triathlon specific handlebar positions regarding different parts of the spine. **Methods** We analyzed the ROM of different parts of the spine in four competitive triathletes (m=2, f=2; 25,5±1,91 yrs., 174,38±6,94 cm, 64,25±4,11 kg) while sitting on the bike with three different handlebar positions (upper (UH), lateral (LH) and aerodynamic time trial handlebar (AH)). 15 high-frequency cameras captured the trajectories of 70 light reflecting markers which had been fixed on the subject's skin. Using the software Vicon Nexus seven angles were used to describe the ROM of the cervical, thoracic and lumbar spine with respect to flexion and extension. The data was evaluated by assorting certain angles of risk according to the classification of DIN EN 1005-4 (red, yellow and green range with red associated with high risk). **Results** The most important findings include the following: During the whole time of cycling, extension of the cervical spine remained in the red range (<0°) in all three positions (UH: -43,37° ±10,60°, LH: -44,34° ±9,44°, AH: -52,06° ±10,99°). Furthermore, flexion of the total spine and of the thoracic spine was in the yellow range (total spine: 20°-60°, thoracic spine: 20°-40°) in all subjects during all handlebar positions (total spine: UH: 43,94° ±5,93°, LH: 44,09° ±6,84°, AH: 49,04° ±6,65°; thoracic spine: UH: 30,39° ±4,75°, LH: 32,45° ±6,99°, AH: 34,95° ±2,26°). **Discussion** The different handlebar positions in triathlon during training and competition imply an increased risk for back pain mainly in the area of the cervical spine. This is in line with clinical findings of a nearly 50% lifetime incidence of neck pain in triathletes. The total stress of the spine is composed of the type of discipline, duration, intensity, and individual style of all training units and competition. Further factors, like vibration forces while cycling are of importance as well and should be considered in further research. The results of this investigation underline the necessity of specific spine stabilizing training programs in addition to the discipline specific training units. **Acknowledgement** The study was supported by the Federal Institute for Sport Science, Germany (IIA1-080102B/11-14).

ANALYSIS OF THE PSYCHOLOGICAL STATE OF RUNNERS IN THE SÃO PAULO INTERNATIONAL MARATHON

Sierra, W., Jones, J.M., Siegl, L.L., Azevedo, D.G., Leocadio, M.O.L.V., Benetti, M., Boaventura, M.F.C., Gorjão, R., Coneglian, V., Sierra, A.P.R.

Núcleo de Integração Humana

Introduction: In the last few years, we have observed a series of social and environmental changes that have resulted in physical activity being now considered a factor of prevention and treatment for several illnesses. With this, there was also a development of Sports Psychology with psychological evaluation methods allied to the practice of sports, which measure characteristics, attributes, and transitory

emotional states under controlled conditions, developing profiles and prognostic. Objectives: The objective of this study was to verify the state of anxiety and humor of marathoners participating in the São Paulo International Marathon, as well as to verify if there are changes in the humor of these runners in the post-marathon. Methodology: 74 male marathoners, aged 19 to 51 years old (34 ± 8.36). Who answered the CSAI2 and Brunel questionnaires before the race, and, the Brunel again after the race, both in Portuguese. Statistical analysis: For the statistical analysis, we established a score for each domain of the questionnaires. We used the T-Student Test to compare the pre and post race moments, and the Pearson correlation to check the relation between variables ($p < 0.05$). Results: Regarding the domains related to anxiety, we have found: 14.81 ± 4.54 ; 13.7 ± 3.53 ; 30.36 ± 4.42 , for cognitive anxiety, somatic anxiety and self-confidence, respectively. For the states of humor in the pre and post race, we found: tension 47.12 ± 7.97 and 41.33 ± 5.46 ($p < 0.01$); depression 46.68 ± 5.33 and 49.63 ± 9.23 ($p < 0.01$); anger 48.92 ± 8.66 and 51.25 ± 12.13 ($p > 0.05$); stamina 59.12 ± 7.17 and 48.92 ± 8.24 ($p < 0.01$); fatigue 43.26 ± 5.24 and 61.52 ± 13.99 ($p < 0.01$); confusion 44.62 ± 5.37 and 45.13 ± 5.66 ($p > 0.05$). We have found a moderate negative correlation of self-confidence with cognitive and somatic anxiety. Discussion: We were able to observe that, with regards to the pre-race, there was a reduction in the tension and stamina, and an increase in depression and fatigue. Our results are similar to the findings of Rohlf's et al (2008), which found in adults in competitive game situations an increase in depression, anger and fatigue, as well as a reduction of stamina. The low cognitive and somatic anxiety values negatively related to the high self-confidence score show that, because the athletes are self-confident about their training, their anxiety level was reduced. However, the increase in depression post-race may be related to the results of the marathon, mainly considering the high initial self-confidence level. The stamina and fatigue seem to be reflexes of the participation in the race and the tiredness that it produces.

WORKING MEMORY CAPACITY AS EXECUTIVE ATTENTION FOR PREDICTING WHO WILL 'CHOKES' UNDER PRESSURE

Wood, G.I, Vine, S.J.2, Wilson, M.R.2

1: Liverpool Hope University, UK 2: University of Exeter, UK

Attempts to explain the mechanisms behind pressure-induced performance failure implicate anxiety's effect on attentional control as a principle contributing factor (Wilson, 2008). Interestingly, recent research has suggested that individual differences in working memory capacity (WMC) reflect fundamental differences in an individual's ability to control their attention (Engle, 2002). In this study we explored the possibility that individual differences in WMC could predict those participants who would fail under pressure in a handgun shooting task. Methods: Twenty participants were assigned to two working memory capacity groups based on their OSPAN performance scores. Each group performed a Stroop handgun shooting task under practice conditions and then under counterbalanced conditions of low and high threat. The shooting task required participants to read a target word (word and ink either congruent or incongruent) in the centre of a projected display and then shoot to the corresponding coloured target positioned in the periphery. The time to fixate the correct target and the final fixation on the target prior to trigger pull (quiet-eye; Vickers 2007) were recorded using eye-tracking equipment. Performance was measured in terms of shooting accuracy and total shot time. Results: The low-WMC group experienced impaired visual search time to locate the target and increases in their total shot time when shooting with incongruent target words. Furthermore, the low-WMC group experienced significant reductions in shooting accuracy when anxious. Conversely, the high-WMC group experienced no significant differences in either attentional control or performance measures. No differences in QE durations were seen between groups or across threat conditions. Conclusion: Results support the suggestion that WMC is a good predictor of performance among individuals who find it difficult to maintain task goals in the face of interference and who also perform worse under pressure. However, the lack of convergence between changes in gaze and changes in performance may suggest possible additional effects of kinematic variables behind the anxiety-induced performance decrements observed. PRE-COMPETITION ANXIETY PROFILE OF NORWEGIAN EQUESTRIANS

Helle, I., Haugen, T., Johansen, B.T.

Universitet i agder

Introduction Athletes who have a high trait anxiety view more situations as more threatening than those with lower trait anxiety and so respond with a higher state anxiety. This is known as competitive trait anxiety (Martens et al 1990). This may lead to a problem in e.g. the communication between horse and rider, and it may affect the rider's performance (Visser et al 2007). The aim of this study is to track the pre-competition anxiety prior to an important competition in a group of Norwegian equestrians show jumpers. Methods 17 participants, age 10-45 (mean 19.5, SD=9.434) were chosen in this study. 48 hours before the competition they completed a 27-item questionnaire that measured subscales of cognitive and somatic anxiety, and self-confidence – CSAI-2 (Competitive State Anxiety Inventory-2) (Martens et al 1990). This procedure was repeated 24 hours, 2 hours, and 1 hour before starting the competition. Repeated measures Anova tests were performed in order to investigate potential changes in anxiety and self-confidence. Results The results showed a statistically significant increase in somatic anxiety level ($M_{48} = 10.9$, $SE_{48} = 0.75$) between 48 hours and 2 hours/1 hour before competition ($M_2 = 12.5$, $SE_2 = 1.04$; $M_1 = 12.7$, $SE_1 = 1.19$), but there was no significant difference in cognitive anxiety level. Moreover, there was a significant drop in the self-confidence between 24 hours ($M_{24} = 28.9$, $SE_{24} = 1.89$) and 2 hours/1 hour before competition ($M_2 = 27.4$, $SE_2 = 2.01$; $M_1 = 26.7$, $SE_1 = 1.99$). Discussion The results in this study revealed a significant increase in somatic anxiety level from 48 hours to hours/1 hour before competition. This was not the case for the cognitive anxiety level. This may indicate that even if you anticipate that you are tense in your body (somatic), you are not going to be tense in your brain (cognitive) as well. However, the significant drop in self-confidence among these equestrians, suggest that there is a certain relationship between the two of them. In general, no equestrians had very high cognitive or somatic anxiety level before competition. This may be explained by their competitive level (national top level) or that they simply are show jumpers and thereby used to demonstrate their skills in jumping over fences and walls (Fitzpatrick 2004). TRANSCENDENTAL MEDITATION EFFECTS IN THE SPORTS PERFORMANCE IN HIGH PERFORMANCE ATHLETES.

López Trejo, V., Murguía, G., Villalobos, S., De Santiago, M., Fritzler, W.

Universidad del Fútbol y Ciencias del Deporte

Introduction TM Transcendental meditation is a technique of Indian origin, who has amply demonstrated its health benefits, as it has been used successfully in preventing cardiovascular diseases and those resulting from stress. There is little evidence of its usefulness in the sport even though it has been applied to high performance athletes. This research aims to establish the effectiveness of Transcendental Meditation TM to evaluate a series of physiological, anthropometric, psychological, biochemical and physical in elite athletes of the Football University and Sports Science (UFD acronym in Spanish). **Methods:** This experimental research was using the TM technique in a group of players, high-performance, compared with a control group of similar characteristics training and competition, selected at random. The experimental group (EG) received an induction course to the art and technique practiced 2 times daily for 4 months, were measured for biochemical variables, psychological, electroencephalographic, physical, physiological and anthropometric at the beginning and end of study both groups. **Results.** A sample of student athletes of the Alto Rendimiento Tuzo including 15 athletes in the EG and 15 in the GC, the average age in both groups was 16.6 years and shared similar demographic characteristics. The most significant quantitative result was the reduction of anxiety in the GE as demonstrated statistical significance compared with the control group and between the first and second evaluation of group $P = 0.0000041$, the other variables showed no significant differences. With regard to qualitative variables 75% of students reported an overall improvement after meditating and 45% reported improvement in sport performance, which was not confirmed quantitatively. **Discussion.** This study demonstrated that TM does not improve athletic performance, and anthropometric variables, although it reduces stress and anxiety in athletes. Among the evaluated biochemical variables creatine phosphokinase is found that it decreased significantly in the experimental group which was reflected in the reduction of sports injuries. This can be an effective tool to improve pre-competitive conditions and if it becomes a daily practice, perhaps could contribute to the improvement of sports variables secondarily. **Bibliography.** Robert H. EMOTIONAL INTELLIGENCE, PERSONALITY TRAITS AND PSYCHOPHYSIOLOGICAL STRESS RESPONSES DURING ANTICIPATION OF PUBLIC SPEAKING TASK IN ELITE ATHLETES

Üngür, G., Bayazit, O., Tok, S., Bakır, M.

Dokuz Eylül University, School of Sport Sciences and Technology

Introduction Coping with stress is quite important for sporty performance in sport field that has intense competition. In this context, some individual traits may contribute to athletes. In recent years, it was seen that besides subjective methods objective physiologic parameters were examined in certain sport studies revealing significant findings (Shelly-Trembley 2006, Huang and Hung 2010, Laborde, Brüll, Weber and Anders 2011). Therefore, the aim of this study was to analyze the effect of emotional intelligence (EI) and personality traits on electrophysiological stress responses of elite athletes. **Method** Schutte Emotional Intelligence Scale and short form Five Factors Personality Inventory were completed by 54 elite athletes (32 male, 22 female). In order to trigger stress responses, participants were asked to prepare a speech to perform in front of small group introducing their own sport branches, and were given 5 minutes for preparation. In these laboratory processes, electrophysiological parameters which consist of electroencephalography (EEG), heart rate variability (HRV) and skin conductance response were recorded by a portable biopotential amplifier (Nexus 10 Mark II, Holland). **Results** In course of preparation for a speech, it was found that participants, who have high score on dimension of utilizations of emotions, have lower low frequency/high frequency (LF/HF) ratio, while participants, who have high conscientiousness trait, have lower skin conductivity. In addition, it was found that participants, who have high agreeableness trait, have lower heart rate. **Discussion** The present study provided evidence to suggest that personality traits together with EI may lead different psychophysiological response patterns under stress. According to research findings, it may be said that, people who have high level of ability for utilization of emotions, have lower stress responses. In another study, similarly, negative significant correlation was found between dimension of emotional control and LF/HF ratio (Laborde et al 2011). Since athletes, who have high conscientiousness trait, have lower skin conductivity before speech task, it may be said that athletes who have this personality trait have lower stress responses before performance. Moreover, it may be said that people who have high agreeableness trait stay calmer while preparing for a speech task. **References** Shelly-Trembley JF, Kline JP. (2006). A STUDY OF ASSOCIATION OF OBJECTIVELY MEASURED MODERATE TO VIGOROUS PHYSICAL ACTIVITY WITH JOB STRESS RESPONSE AND DEPRESSIVE SYMPTOMS IN JAPAN

Shi, M., Honda, T., Chen, T., Supartini, A., Kumagai, S.

Kyushu University

Introduction Moderate to vigorous physical activity (MVPA) was associated with a decreased risk of mental disorders, such as depression and anxiety (Dunn, et al., 2001). Additionally, previous studies have also found self-reported physical activity moderated the relationship between job stress and depressive symptoms (Kai, et al., 2009). However, studies investigated the associations of objectively measured MVPA with job stress and depressive symptoms are scarce. Therefore we examined whether accelerometer-derived MVPA level was associated with job stress response and depressive symptoms among workers in Japan. **Methods** We used data of 367 Japanese workers. MVPA was measured by tri-axis accelerometer for one week and classified into two types: locomotive and non-locomotive MVPA by validated algorithm (Oshima, et al., 2010). Job stress response (JSR) was measured by the Brief Job Stress Questionnaire. Depressive symptoms were measured by the Center for Epidemiologic Studies-Depression Scale. Associations between total MVPA, locomotive MVPA and non-locomotive MVPA and JSR were analyzed using linear regression analyses. Associations between the same activity indices and depressive symptoms were analyzed using logistic regression analyses. **Results** There was significant association between locomotive MVPA and JSR for adjusted analysis ($b = -0.074$, 95% CI: $-0.147 \sim -0.001$) but no significant association for the crude ($b = -0.060$, 95% CI: $-0.131 \sim 0.010$). There was no statistically significant association between total MVPA and JSR, resulting from all the crude ($b = -$

0.022, 95% CI: -0.069~0.026), and adjusted analysis ($b=-0.027$, 95% CI: -0.075~0.023), nor between non-locomotive MVPA and JSR for all the crude ($b=0.015$, 95% CI: -0.064~0.093), and adjusted analysis ($b=0.021$, 95% CI: -0.065~0.167). There was no statistically significant association between all activity indices and depressive symptoms. Discussion The result indicated that locomotive MVPA was associated with lower JSR in this study sample. A possible explanation for the lack of associations with depressive symptoms could be the different aspects of the points of emphasis between self-report and accelerometry (e.g., intensity, during work or leisure-time). Future study should combine objective and subjective measures to assess PA, so as to achieve a broad pattern of PA for identifying the effect of physical activity on depressive symptoms and stress. CHANGES IN THE ACUTE RECOVERY AND STRESS SCALE DURING A HIGH-INTENSIVE TRAINING PERIOD IN WELL-TRAINED CYCLISTS

Feistenauer, C.1, Hammes, D.1, Skorski, S.1, Schwindling, S.1, Kellmann, M.2, Meyer, T.1

1: *Institute of Sports and Preventive Medicine, University of Saarland (Saarbrücken, Germany).* 2: *Faculty of Sport Science, Ruhr-University Bochum (Bochum, Germany).*

Introduction Underperformance in sports is mainly caused by an imbalance of stress and recovery from training, competition, and life-style factors (Kellmann, 2010). To prevent underperformance it is necessary to monitor the acute recovery and stress state. For that purpose a new instrument was developed (Hitzschke et al., 2013), but has not been validated in an intensive micro cycle so far. The aim of the present study was to validate the Acute Recovery and Stress Scale (ARSS) during an intensive training and recovery period in well-trained cyclists. **Methods** 28 cyclists (5 ♀, 23 ♂, age: 29 ± 7 y) completed an 11-day training camp including performance tests at day 1, day 8 and day 11. Training days consisted of 2 cycling sessions per day (high-intensity-low-volume and low-intensity-high-volume training). Day 8 was followed by two days of recovery. Each morning the ARSS was filled in by all participants. Scales range between 0 (not at all) and 6 (absolutely). 32 adjectives, which express acute feelings, are separated into two categories with each including four scales assessing acute physical, mental, emotional and overall recovery and stress states (Hitzschke et al., 2013). **Results** At the latest on day 4 and culminating on day 8 of the training camp the subtests of the ARSS except Emotional Balance/Imbalance revealed significant differences as related to baseline measurement on day 1. Mean differences and standard error between day 1 and 8 in descending order were for stress scales Muscular Strain ($-3.10 \pm .37$ p < .01) Overall Strain ($-2.01 \pm .23$; p < .01), Lack of Activation ($-1.20 \pm .29$; p < .02) and Emotional Imbalance (n.s.), for recovery scales Physical Performance Capability ($1.55 \pm .30$; p < .01), Overall Recovery ($1.88 \pm .31$; p < .01), Mental Performance Capability ($1.21 \pm .30$; p < .03) and Emotional Balance (n.s.). During the two days of recovery all scales returned to baseline again. **Discussion** The results indicate that the ARSS is able to monitor acute physical, mental and overall stress and recovery sensitively during a high intense training period in trained cyclists. However, emotional factors did not change over the span of the study. This confirms findings from Koelling et al. (2013) whereby no emotional influences might be expected in training camps, if there is no pressure to perform. It is to be expected that emotional influences change over a prolonged intensive training period. To conclude, the ARSS is able to monitor stress and recovery factors in well trained cyclists. **References** Hitzschke, B., Koelling, S., Holst, T., Ferrauti, A., Meyer, T., Pfeiffer, M. & Kellmann, M. ANALYZING THE CORRELATION BETWEEN SELF-ESTEEM AND ATTITUDE OF 25 YEAR OLD AND YOUNGER PARTICIPANTS DOING EXERCISE

Bingol, E.1, Sahin, A.2, Erdogan, B.S.2, Aldemir, G.Y.3, Filiz, K.4, Eravsar, H.5

1:MSKU(Mugla,Turkey),2:MAEU(Burdur,Turkey),3:MUI(Istanbul,Turkey)4:GU(Ankara,Turkey),5:AU(Antalya,Turkey)

Introduction The purpose of this study was to analyze the correlation between self-esteem and attitude coming out in stressful situations. **Methods** Research groups included 200 participants doing exercise regularly for one year in private fitness centers in Antalya and Konya , 83 of whom were men and 117 of whom were women (age=21,49 + 1,659). Self esteem Scale developed by Arıca (1999) and Attitudes to Cope up with Stress Scale developed by Özbay (1993) were used to reach the purpose of this study. Significance level $P<0,05$ was obtained by using Kolmogorov-Smirnov test, t test, one way anova test to analyze and interpret the data and Tukey test to define the difference between groups. SPSS (Statistical package for social sciences) was used to find and examine the data. Result As a result meaningful and linear correlation between sub dimensions of the attitude to cope up with stress and active planning was obtained. Self of Sense ($r=497$), self-confidence ($r=577$), depressive emotion ($r=531$), self-sufficiency ($r=572$) achievement-performance ($r=476$) were concluded. $P<0.01$ **Discussion** It was concluded that young participants had different attitudes to cope up with stress because of the characteristics of their genders and these attitudes had intermediate and upper intermediate correlation with their self-esteem. It may be said that exercise is a helpful activity for the young people for developing the level to cope up with stress. According to Yeltepe and Yargıç, 2011, similar conclusions were obtained in the researches past. Reference Yeltepe, H., Yargıç, İ.L. (2011). THE COMPARISON OF PHYSICAL SELF-CONCEPT AMONG SEX & ACTIVE/INACTIVE STUDENTS

Fathirezaie, Z.1,3, Zamani Sani, S.H.1,3, Salehzade, K.2, Brand, S.3, Pühse, U.3, Gerber, M.3

1. *Institute of physical education & sport science, Shahid Beheshti University, Iran,* 2. *Institute of psychology,* 3. *Institute of exercise and health science,University of Basel. Switzerland*

Introduction This study investigated the comparison between physical self-concept at girls/boys and active/inactive students. **Methods** The study population of 490 people in two groups of students were classified as active ($n= 222$) or inactive ($n= 268$). Physical self-concept was assessed through the 70 item Physical Self-Description Questionnaire (PSDQ) (Marsh et al., 1994). Individual (230 boys & 260 girls) reply to PSDQ with 11 components of physical self-concept (physical activity, body fat, appearance, endurance, strength, esteem, coordination, flexibility, sports competence, Gen.physical self-concept, and health). For data analysis descriptive statistics and one way ANOVA,

MANOVA to examine the differences in the level of significance 0.05 was used. Results Results showed that there is a difference in global physical self-concept between active boys, inactive boys, active girls and inactive girls ($F(3,486) = 81.62, P < 0.0005$). The 11 subscales of the PSDQ were analyzed by a MANOVA with sex (girl/boy) as independent factors. Significant multivariate main effects were found for sex (Hotelling's Trace = 0.083, $F(11, 476) = 3.58, P < 0.05$). The significant multivariate main effect of sex can be attributed to three subscale. Inspection of the means reveals that boys scores higher on two subscales (endurance & sports competence) & girls scores higher on one subscale (flexibility). Significant multivariate main effects were found for active/inactive (Hotelling's Trace = 0.98, $F(11, 476) = 42.50, P < 0.05$). The significant multivariate main effect of active/inactive can be attributed to all subscales. Inspection of the means reveals that active students scores higher on all. Discussion Consistent with previous studies in other cultures (e.g., Caglar, 2009) and with the expectations of the present study, sex differences were obtained in physical self-concept with males consistently scoring higher than females on more subscales, expect flexibility & appearance. For example, males seem to have higher expectations for success in sports and physical activity because of the dominant male learning context in physical education. The gender stereotyping of physical abilities lead to the sex differences in participation motives, length of activity participation, and type of physical preference. Males are encouraged to participate in competitive sports to develop masculine aspects of their self-identity, but females are often discouraged from participating in competitive athletics out of fear of masculinizing their physiques, attitudes, and behaviors. Therefore females are less likely to participate in sports in which the body is employed as an instrument of strength. References Caglar, E. (2009). Similarities and differences in physical self concept of males and females during late adolescence and early adulthood. *Adolescence*, 44(174): 407-419.

EXPLORING THE IMPACT OF PRIMING ON CRICKET FIELDING PERFORMANCE

Ashford, K.J., Bansor, G.

Brunel University

Introduction Research has demonstrated that priming can induce behavioral or perceptual change in a variety of settings (e.g., Bargh et al., 1996; Hull et al., 2002; Nelson & Norton, 2005) although sport and more specifically, motor skill performance, remain relatively unexplored areas. Findings to date indicate performance enhancements following prime presentation (e.g., Ashford & Jackson, 2010; Friedman & Elliot, 2008) but further exploration is required, particularly in relation to more ecologically valid techniques. Thus, the aim of the study was to explore the efficacy of priming in promoting cricket fielding accuracy via the mediums of scrambled sentences and video. Methods Twenty-four skilled cricket players completed a fielding task under low- and high-pressure conditions. They were required to throw a cricket ball as accurately as possible at a circular target positioned 27.4m away; the target was 2m in diameter. Participants were randomly allocated to a control, scrambled sentence priming, video modelling with embedded primes, or video-modelling group. Priming tasks contained forty target words associated with autonomous skill execution. Results Repeated measures ANOVA results revealed a significant pressure x group interaction. In follow-up tests examining each group a significant decrease in accuracy was observed from the low- to high-pressure condition for the control group, while a significant increase was present for video priming. No differences were detected for scrambled sentence priming or video modelling. Discussion Priming and video modelling techniques enabled participants to maintain performance across conditions rather than enhancing performance as described in previous research (e.g., Ashford & Jackson, 2010; Boyer et al., 2009). Such results indicate that, particularly for the former, beneficial effects may not be as robust as initially suggested, however, when the two were combined an improvement in performance under pressure was evident. Many athletes view video footage prior to competition in order to evaluate an oppositions' style of play or tactics; Thus, incorporating priming stimuli in this medium may allow athletes to maintain the same pre-competition routine whilst benefiting from the effects of priming. Although these results are encouraging further research is required to clearly establish the applicability and robustness of this technique. References Ashford KJ, Jackson RC. LEPTIN RECEPTOR MOLECULAR VARIANTS ARE DIFFERENTLY REGULATED BY EXERCISE AND ENERGY DEFICIT IN HUMAN SKELETAL MUSCLE

Pérez Suárez, I., Calle Herrero, J., Ponce González, J.G., Losa Reyna, J., Santana, A., Holmberg, H.C., Calbet, J.A.L.

University of Las Palmas de Gran Canaria, MID Sweden University

Introduction Leptin signals in skeletal muscles through pathways which share some steps with the insulin and IGF1. We have recently shown that LEPR (OBR-170) is increased in the dominant arm of tennis players 1 and is reduced in deltoid and vastus lateralis (VL) of obese compared to control subjects 2. The aim of this study was to determine whether exercise up-regulates the protein abundance and phosphorylation status of the different molecular variations of the LEPR (OBR-170, 128, 98A or 98B) in human skeletal muscle. We hypothesized that exercise will up-regulate leptin signaling in skeletal muscle. Methods Fifteen overweight men underwent three experimental phases: pre-test (PRE); caloric restriction (3.2 Kcal/kg body Wt/d) + exercise (45min unilateral arm cranking/d + 8h walking/d) for 4 days (CRE); and control isoenergetic diet + reduced exercise for 3 days (CD). During CRE, the diet consisted solely of whey protein (PRO, n=8) or sucrose (SU, n=7) (0.8 g/kg body Wt/d). Muscle biopsies (135 biopsies in all) were obtained from the trained and untrained deltoid, and VL, after 12h fast at PRE, and end of CRE and CD. The molecular variants of LEPR (OBR-170, 128, 98A and 98B) were determined by western blot and LEPR mRNA by PCR. Results Serum leptin was reduced by ~60% following CRE and CD ($P < 0.05$). LEPRs were more abundant in arm than leg muscles. LEPR mRNA was increased in exercised muscles after CRE. OBR-170 was reduced after CRE and CD only in the control arm ($P < 0.05$). OBR-128 was increased after CD in exercised extremities ($P < 0.05$). OBR-98A was increased after CRE in trained arm, and after CD in legs ($P < 0.05$). However, OBR-98B was increased after CRE and CD in both arms and exercised extremities ($P < 0.05$), being these effects more pronounced in the PRO group ($P < 0.05$). After CD, LEPR mRNA returned to basal levels while LEPR expression was

increased in all muscles ($P < 0.05$). The fraction of LEPR activated (Tyr1141 phosphorylated) was reduced in arms but not in leg muscles. LEPR phosphorylation was correlated with JAK2 (upstream) and STAT3 (downstream) phosphorylation ($r = 0.67-0.89$, $P < 0.05$). Discussion Caloric restriction seems to reduce the abundance of LEPR, but this effect varies depending on specific molecular variants of the receptor. The reduction of LEPR is partly counteracted by exercise, likely contributing to increase muscle leptin sensitivity. Whey protein ingestion facilitates these effects. Resuming normal food ingestion after a period of severe energy deficit is accompanied by increased expression LEPR in skeletal muscle. INCREASING DIETARY PROTEIN INTAKE DOES NOT PRESERVE LEAN BODY MASS DURING CALORIC RESTRICTION IN OVERWEIGHT MIDDLE-AGED TO ELDERLY PEOPLE

Backx, E.I., Tieland, M.I., Borgonjen, K.I., Claessen, P.I., van Loon, L.I., de Groot, L.I.

1 Wageningen University, 2 Maastricht University

Background Weight loss is commonly accompanied by a decline in skeletal muscle mass. Although weight loss can have substantial health benefits in overweight and obese adults, the reduction in skeletal muscle mass may have adverse outcomes such as poor physical performance. A prospective study showed that elderly with the higher protein intake lost less lean body mass than elderly with the lowest intake of protein during three years of follow-up (Houston et al., 2008). Limited long-term intervention studies show that a high protein diet can preserve muscle mass during weight loss, although there are ample discrepant findings in the literature (Wycherley et al., 2012). Objective To investigate the impact of a high protein diet on lean body mass preservation during caloric restriction in overweight, middle-aged to elderly people Design Sixty-one overweight and obese men and women (63 ± 0.6 y) were randomly assigned to either a high protein diet (HP; 1.5 g/kg/d) or standard protein diet (SP; 0.8 g/kg/d) during 25% caloric restriction. During this 12 wk double-blind fully controlled dietary intervention trial, 90% of the diet was provided by the university and 10% could be selected from a short list of products. At baseline and after the intervention, body weight, lean body mass (DXA), leg strength (1RM) and physical performance (400m walk test, SPPB) were assessed. Statistical analyses were performed using ANCOVA with baseline measurements, gender and BMI as covariates. Results Body weight declined significantly by 9.0 ± 0.4 kg in both groups ($P < 0.01$) with no significant differences between the high protein and standard protein group (HP: 8.9 ± 0.5 vs SP: 9.1 ± 0.6 kg; $P = 0.584$). In accordance, lean body mass declined significantly by 1.9 ± 0.2 kg ($P < 0.01$) without a significant treatment effect of diet (HP 1.8 ± 0.4 vs SP 2.1 ± 0.3 kg; $P = 0.213$). Leg strength decreased significantly following caloric restriction (8.9 ± 1.8 kg; $P < 0.01$), with no differences between groups (HP 8.8 ± 2.6 kg vs SP 8.9 ± 2.6 kg, $P = 0.296$). In addition, 400m walking velocity increased significantly over time (from 1.45 ± 0.02 to 1.49 ± 0.03 m/s; $P < 0.01$), without a significant effect of diet ($P = 0.219$). There were no significant changes in SPPB score over time (0.13 ± 0.12 points in both groups; $P = 0.132$) or between groups ($P = 0.483$). Conclusion Increasing dietary protein intake does not preserve lean body mass or attenuate the loss of muscle strength following 12 weeks of caloric restriction. References Houston et al. (2008). EFFECTS OF NITRATE SUPPLEMENTATION ON AEROBIC PERFORMANCE IN SUBJECTS WITH DIFFERENT FITNESS LEVEL

Ramaglia, M., Bellistri, G., Annoni, S., Crociani, B., Rasica, L., Marzorati, M., Porcelli, S.

National Council of Research

Introduction Dietary supplementation with either sodium nitrate or nitrate-rich beetroot juice has been consistently shown to reduce the oxygen demand of submaximal exercise (1) and improve time to exhaustion during high-intensity exercise (3,5). However, the ergogenic effect of nitrate supplementation in well-trained endurance athletes remains uncertain (2,4). Aim of this study was to evaluate the effects of short-term nitrate [NO_3^-] supplementation on aerobic performance in subjects with different fitness level. Material and Methods Twenty-one subjects (22.7 ± 1.8 years, mean \pm SD) with different fitness level were involved in a randomized double-blind crossover study. Subjects were tested after 6 days of supplementation with either 0.5 l per day of nitrate-containing (about 5.0 mmol) water (NITR) or nitrate-free water (PLA). Participants performed an incremental running test in order to assess their peak oxygen uptake ($\dot{V}\text{O}_{2\text{peak}}$). Several repetitions of sub-maximal (about 60% $\dot{V}\text{O}_{2\text{peak}}$) constant load exercises on a motorized treadmill and a 3-km running time trial on the field were also performed. Results $\dot{V}\text{O}_{2\text{peak}}$ value ranged from 34 to 63 $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$. Plasma [NO_3^-] was 13.4 ± 5.7 μM and 83.5 ± 37.7 μM in PLA and NITR respectively. During constant-load exercise, $\dot{V}\text{O}_2$ at steady-state was significantly lower in NITR (1.90 ± 0.4 $\text{L}\cdot\text{min}^{-1}$) compared with PLA (2.05 ± 0.4 $\text{L}\cdot\text{min}^{-1}$). There was a significant negative correlation between the $\dot{V}\text{O}_{2\text{peak}}$ value and the change in [NO_3^-] following NITR ($R^2 = 0.71$, $p < 0.001$) and between the $\dot{V}\text{O}_{2\text{peak}}$ value and the change in $\dot{V}\text{O}_2$ at steady state ($R^2 = 0.69$, $p < 0.001$). As for 3-km Time Trial, no significant differences were observed between PLA (766.5 ± 140.8 sec) and NITR (766.4 ± 135.6 sec). However, if only subjects with a low fitness level (< 50 $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) were considered, the 3-km running performance significantly improved after NITR. Conclusion The results of the present study suggest that individual fitness level affects the ergogenic benefits induced by [NO_3^-] supplementation. Discrepancy results in literature may be explained by different source and/or duration of nitrate supplementation. Further studies are needed to clarify the molecular mechanism underlying this process. References 1. Bailey SJ, Winyard P, Vanhatalo A, et al. J Appl Physiol 2009 2. ASSOCIATION OF ACTN3, CNTF AND PTK2 WITH SKELETAL MUSCLE PHENOTYPES IN UNTRAINED MALES

Stebbing, G.K., Morse, C.I., Williams, A.G., Day, S.H.

Manchester Metropolitan University

Introduction The ability to perform physical activities requires muscle strength, which is known to vary inter-individually (Stebbing et al., 2013). The genetic contribution to this inter-individual variation is yet to be confirmed, despite a number of associations between single-nucleotide polymorphisms (SNPs) and skeletal muscle phenotypes, most notably with elite athlete status. We aimed to establish if SNPs in the ACTN3, CNTF and PTK2 genes were associated with maximal voluntary contraction (MVC) torque and specific force in untrained men. Method Vastus lateralis (VL) skeletal muscle phenotypes were measured in untrained Caucasian men ($n = 100$). Knee extension (KE) and flexion (KF) isometric MVC torque was measured in the right leg using isokinetic dynamometry, and VL muscle architecture, size and length were measured using B-mode ultrasonography. These data were used to calculate VL specific force. DNA was isolated from whole blood and participants were genotyped for ACTN3 R577X (rs1815739), CNTF G-6A (rs1800169) and PTK2 A/C (rs7843014) SNPs

using real-time PCR. Results Genotype frequencies were all in Hardy-Weinberg equilibrium. There were no differences in specific force between the genotypes of ACTN3, CNTF ($P \geq 0.074$) or PTK2 ($P = 0.051$) although this did approach significance. When combining PTK2 AC and CC genotypes, VL specific force was 7.5% higher for homozygous AA individuals (20.9 ± 2.9 N·cm⁻²) than C-allele carriers (19.4 ± 2.5 N·cm⁻²; $P = 0.008$). No differences between ACTN3, CNTF or PTK2 genotypes were observed for KE MVC ($P \geq 0.690$) or KF MVC ($P \geq 0.446$). Discussion The lack of association between isometric MVC and ACTN3, CNTF or PTK2 genotype is similar to previous reports in untrained men (Erskine et al., 2012; De Mars et al., 2007; McCauley et al., 2009), suggesting minimal importance of these particular polymorphisms on MVC in an untrained population. The greater muscle specific force observed in homozygous A-allele individuals compared to C-allele carriers of the PTK2 SNP is consistent with previous work from our lab and suggests that AA individuals are more effective at lateral force transmission through the impact of PTK2 on the expression of focal adhesion kinase (Erskine et al., 2012). Specific force is a true reflection of intrinsic muscle strength in athletes and in disease conditions, so PTK2 (rs7843014) should be investigated in relevant cohorts. DOSE-RESPONSE RELATIONSHIP OF ENDOGENOUS ERYTHROPOIETIN IN RESPONSE TO AN ACUTE HYPOXIC EXPOSURE

Turner, G.1,2, Ross, E.2, Richardson, A.1, Maxwell, N.1, Pringle, J.2

1: University of Brighton (Eastbourne, UK), 2: English Institute of Sport (Loughborough, UK)

Introduction Haematological adaptations resulting from altitude training camps or sleeping in hypoxia are well documented (Rasmussen et al, 2013). There is evidence to suggest there is a rapid decrease in endogenous erythropoietin (EPO) and total haemoglobin mass (tHbmass) on return to sea level from altitude (Garvican et al, 2012) – factors associated with a decline in endurance performance at that time (Wachsmuth et al, 2013). Intermittent hypoxic exposure on return from altitude may provide a stimulus to prevent this decrease in EPO and tHbmass, which may in turn attenuate a decrease in performance. Therefore, we sought to establish the dose-response relationship of endogenous EPO to differing levels of acute normobaric hypoxia, to ascertain its efficacy in raising EPO in the post-altitude period. Methods Eight physically active males (age 27 ± 4 yrs, body mass 77.5 ± 9.0 kg, height 179 ± 6 cm) attended the laboratory on four separate occasions, in a randomised order, and rested passively in a hypoxic chamber for 2 h whilst exposed to a simulated altitude of ~3,600 m (FiO₂: 0.135), ~4,200 m (FiO₂: 0.125), ~4,800 m (FiO₂: 0.115), and sea-level (FiO₂: 0.209). Venous blood samples were drawn immediately pre-exposure, then at 1 and 2 h during exposure and 2, 4 and 6 h post-exposure to assess changes in blood EPO concentration ([EPO]). Results Baseline [EPO] was averaged across all four trials for each participant to account for diurnal variations (5.9 ± 1.1 mU/mL). At 3,600 m, mean [EPO] increased to peak at 2 h post-exposure at 7.6 ± 1.5 mU/mL (20% increase; $P = 0.150$). At 4,200 m [EPO] increased to peak at 2 h post-exposure at 8.1 ± 1.5 mU/mL (43%; $P = 0.008$). At 4,800 m, mean [EPO] increased to peak at 2 h post-exposure at 8.9 ± 2.0 mU/mL (52%; $P = 0.001$). In all three conditions [EPO] remained elevated up to four hours post-exposure. There was a marked individual variability in [EPO] release at all altitudes, however, the variance across the group was smallest at 2 h post-exposure (cv in percent change from baseline) across all three altitudes. Discussion Intermittent normobaric hypoxic exposure elevates [EPO] in accordance to severity of altitude imposed, but with considerable inter-individual variance. This method could be used to alleviate the transient nadir seen in [EPO] in the days and weeks after chronic altitude exposure, which may in turn serve to maintain or preserve enhancements in tHbmass and exercise performance. DOPAMINE D1 RECEPTOR MEDIATES CAFFEINE-INFLUENCED EXERCISE PERFORMANCE, THERMOREGULATION AND BRAIN NEUROTRANSMISSION

Zheng, X.Y., Hasegawa, H.

Hiroshima University

Introduction Caffeine (CAF) is widely consumed to improve the exercise performance. Recently, we observed that CAF improved endurance exercise performance, and increased core body temperature (T_{core}) and extracellular dopamine (DA) release in the preoptic area and anterior hypothalamus (PO/AH) in exercising rats (Zheng and Hasegawa, 2012). However, in that study, it is difficult to conclude that CAF-improved exercise performance is due to central dopaminergic activation. To investigate the precise mechanism, clarifying whether the blockage of dopaminergic pathways prevent the ergogenic effect of CAF is needed. Moreover, the blockage of DA D1 receptor prevented CAF-induced hyperactivity and hyperthermia at rest (Vanattou-Saïfoudine et al., 2010). The purpose of this study was to examine the effect of a blockage of DA D1 receptor on CAF-induced changes of exercise performance, thermoregulation and neurotransmitters release in the PO/AH. Methods T_{core}, tail skin temperature (T_{tail}: an index of heat loss), and oxygen consumption (VO₂: an index of heat production) were measured. Brain microdialysis samples were collected every 10 min, and analyzed by HPLC for DA, noradrenaline (NA) and serotonin (5-HT). After 40 min of baseline collections, rats were intraperitoneally (i.p.) injected with either D1 antagonist (SCH: SCH23390, 1 mg/kg) or saline (SAL). 60 min before the start of exercise, rats were i.p. injected with either 10 mg/kg CAF or SAL. Rats ran until fatigue at a speed of 18 m/min, at a 5% grade, on the treadmill, at 23°C. Results The run time to fatigue (RTTF) in SAL was longer than that in SCH and SCH-CAF, but there was no difference of RTTF between SCH and SCH-CAF (SAL: 99.3 ± 25.4 min, SCH: 20.8 ± 20.0 min, SCH-CAF: 19.4 ± 15.1 min). SCH increased T_{core}, decreased T_{tail} and extracellular DA in the PO/AH. Pre-treatment with SCH inhibited CAF-increased T_{core}, T_{tail}, VO₂, and DA release. Neither CAF nor SCH affected NA and 5-HT in the PO/AH. Discussion Consistent with Balhazar et al. (2010), we found that SCH-impaired exercise capacity may be related to the blockage of DA release in the PO/AH-induced the decrease of the tolerance to heat storage. Increased DA in the PO/AH improved the exercise capacity through overriding the critical limiting T_{core}. In this study, SCH prevented CAF-increased DA, inhibited heat loss, increased T_{core}, decreased the tolerance to heat storage, induced fatigue, impaired the ergogenic effect of CAF. Our results indicate that central dopaminergic pathways play an important role in the ergogenic effect of CAF. References Balhazar CH et al. (2010). Pharmacol Rep 62, 54–61. DELAYED RESPIRATORY COMPENSATION ABOVE A GIVEN LACTATE THRESHOLD INDICATES IMPROVED 1000M RUNNING PERFORMANCE

Heyde, C.

Albert Ludwigs University Freiburg

Introduction: The anaerobic portion of total energy system contribution during middle-distance running has been estimated to relevant portions of about 34% and 26%, for 800m and 1500m performances respectively (Spencer et al. 2001). Thereby, the capacity of anaerobic glycolysis is impaired by exercise induced metabolic acidosis and relies on compensative buffer mechanisms (Parkhouse et al. 1984). It has been shown that the so-called relative functional capacity of buffering (relFB) at workloads within respiratory compensation (RCP) and the lactate threshold (LT) can be used to differentiate between anaerobic and aerobic trained athletes (Röcker et al. 1994). However, the potential of relFB to predict a real performance has never been elucidated. Therefore, the aim of this study was to examine whether delayed RCP above a given LT (via relFB) indicates improved 1000m running performance. **Methods:** Within 5 days, 50 male and 40 female healthy subjects (18-54 y, 157-197 cm, 49.1-93.2 kg) performed a standardized incremental test on treadmill and a competitive 1000m run on a 400m running track. Average running speed for the 1000m run (P_{1k}), peak oxygen uptake per kg body mass (VO_{2Peak}), speed at LT (P_{LT}) and RCP (P_{RCP}) were determined. As previously described (Röcker et al. 1994), relFB was calculated by the workload difference within P_{LT} and P_{RCP} in relation to P_{RCP} . Multiple linear regressions have been used to calculate the percent portions of explained variances provided by the predictors VO_{2Peak} , P_{LT} and relFB. **Results:** Means of P_{1k} , VO_{2Peak} , P_{LT} and P_{RCP} but not relFB ($P=.788$) differed significantly ($P<.0001$) between females and males. The coefficient of determination (R^2) for the final model was 0.818 ($P=.001$). VO_{2Peak} , P_{LT} and relFB, respectively provide portions of 41.64%, 16.75% and 23.41% partial explained variance. No significant differences were observed when comparing separate models for males and females. **Conclusion:** VO_{2Peak} and P_{LT} are the strongest predictors for an individual's best 1000m running performance. However, our study demonstrated that delayed respiratory compensation above a given LT indicates improved relFB and 1000m running performance. relFB in case of valid and reliable determination, implies practical relevance in sports with considerable anaerobic contribution. The relationship between in vivo buffering capacity and relFB, the reliable detection of RCP as well as longitudinal training studies should be focused in future observations. **References:** Parkhouse WS, McKenzie DC. *Med Sci Sports Exerc* 16: 328-338, 1984. WHOLE-BODY CRYOTHERAPY INTERCOOLING - PHYSIOLOGICAL REACTIONS AND EFFECTS ON RECOVERY OF RUNNING PERFORMANCE

Krueger, M.1,2, de Marees, M.1,2, Broich, H.3, Mester, J.1,2

German Sport University Cologne

INTRODUCTION: High-level individual- and team sport athletes carry out one or more training sessions with high intensities and volumes per day in addition to competition, defining acute recovery from high-intensity exercise as an important factor for success. Whole-body cryotherapy (WBC), i.e. the exposure to dry air of -110°C , is one new method discussed to enhance recovery from strenuous exercise. Since the effects of intercooling, induced by cold-water immersion on endurance performance appear to be inconsistent in literature and, to the best of our knowledge WBC has not been used as an intercooling method so far, the aims of the present study were 1) to investigate the effect of WBC-intercooling on acute recovery of endurance performance and 2) to discuss physiological differences potentially affecting acute recovery of endurance performance. **METHODS:** Ten healthy, endurance-trained male athletes (26.0 ± 2.2 yrs, 183.0 ± 3.3 cm, 76.8 ± 6.7 kg, 11.0 ± 1.8 % body fat; peak oxygen uptake: 58.6 ± 4.9 mL/kg/min) participated in two experimental trials in randomized order, separated by one week. Both times athletes performed 45 min of high intensity interval training (HIIT), followed by one hour of recovery that was either conducted with 3 min of WBC or without cooling (CON). In order to test performance, time to exhaustion (t_{lim}) was measured in a ramp test protocol before HIIT ($R1$) and after recovery ($R2$). Oxygen uptake, heart rate (HR), rating of perceived exertion (RPE) and the tissue saturation index (TSI) of the m. vastus lateralis, measured by near-infrared spectroscopy, were recorded during the ramp tests as well as body temperature (T_{body}) at different time points. **RESULTS:** T_{body} was significantly reduced after WBC (pre: 35.0 ± 0.3 ; post: 30.7 ± 0.6 $^{\circ}\text{C}$). The difference in t_{lim} between $R1$ and $R2$ was significantly lower after WBC compared to CON ($p = 0.01$; Cohen's d: 1.37). During submaximal steps of $R2$ HR (best $p < 0.01$) and RPE (best $p < 0.01$) showed significantly lower values after WBC and TSI was significantly higher at submaximal and maximal intensity (best $p < 0.01$). **CONCLUSION:** This study showed that WBC (3 min at -110°C) is able to improve acute recovery of short-term maximal endurance performance (15 min). This may be explained by a higher oxygenation of the m. vastus lateralis after WBC as an indication for higher blood volume and enhanced oxygen supply of the locomotive muscles. In addition the subjects rating of perceived exertion is reduced in submaximal intensities after WBC.

INFLUENCE OF POST-EXERCISE HYPOXIC EXPOSURE ON HEPcidIN RESPONSE IN ATHLETES

Badenhorst, C.E.1, Dawson, B.1, Goodman, C.2, Sim, M.1, Cox, G.R.3, Gore, C.J.3, Tjalsma, H.4, Swinkels, D.W.4, Peeling, P.1

Introduction. Exercise-induced iron deficiency is a common nutritional disorder diagnosed in endurance athletes. Current research suggests the high incidence may be due to post-exercise elevations in the iron regulatory hormone, hepcidin. A number of regulatory processes are suggested to influence hepcidin production in the body, with the inflammatory cytokine IL-6 proposed to increase its production, and hypoxia proposed to reduce its activity. As a result, the aim of this investigation was to assess the influence of simulated altitude exposure ($\sim 2900\text{m}$ above sea levels) for a 3 h recovery period following intense interval running on post-exercise inflammation, serum iron, ferritin, erythropoietin and hepcidin responses. **Methods.** In a repeated measures, cross-over design, ten trained male endurance athletes completed two 8×3 min interval running sessions at 85% of their maximal aerobic velocity, before completing either a hypoxic (HYP: $FO_2 \sim 0.1513$) or a normoxic (NORM: $FO_2 0.2093$) 3 h recovery period. Pre-, post-, and 3 h post-exercise blood was analysed for IL-6, serum iron, ferritin, erythropoietin and hepcidin. **Results.** Post-exercise IL-6 was significantly elevated ($p < 0.01$) compared to baseline, but was not different between conditions. Hepcidin levels were significantly elevated ($p < 0.01$) at 3 h post-exercise when compared to baseline for both conditions, but were significantly lower ($p < 0.05$) in the HYP trial. The relative change for hepcidin at 3 h post-exercise time was significantly different between the two conditions ($p = 0.02$). No significant differences existed for erythropoietin, serum iron or ferritin. **Discussion.** Post-exercise recovery conducted in a hypoxic environment successfully attenuated the commonly reported elevations

in hepcidin activity as compared to recovery in normoxic conditions. Since elevated hepcidin levels degrade and internalise the iron absorption channels in the gut, a hypoxic recovery may ultimately improve iron absorption from post-exercise meals; a postulation that requires further investigation. This study however, shows that hepcidin activity can be manipulated in the post-exercise period, and as such, strategies may be developed to control this hormone in an attempt to reduce the prevalence of iron deficiency in athletes.

PERFORMANCE IS ENHANCED AFTER 5 H RECOVERY FOLLOWING CARBOHYDRATE AND PROTEIN COMPARED WITH ISOCALORIC CARBOHYDRATE INGESTION

Dahl, M.A.1, Jensen, J.1, Skålhegg, B.S.2, Jeppesen, P.B.3, Overgaard, K.4

Introduction Elite athletes in endurance sports often perform more than one training session per day. Post-exercise nutritional intake may exert influences on glycogen repletion and short-term recovery. The aim of the present study was to compare the impact of a carbohydrate and protein diet (CHO+Pro) with an isocaloric carbohydrate diet (CHO) after an exhaustive exercise (EX) on glycogen synthesis and performance 5 h later. **Methods** Nine male subjects (mean±SEM, age: 26.7±1.7 yrs, VO₂peak: 58.1±2.2 ml/kg/min) volunteered for the study. Subjects arrived at 8.00 A.M. on experimental days, and performed EX biking at 70% of VO₂peak until exhaustion. With a double-blinded crossover design, either CHO+Pro (0.4 g Pro and 0.8 g CHO/kg/h) or CHO (1.2 g CHO/kg/h) was consumed the first 2 h. After 2 h, a standardized lunch was consumed and a standard recovery-drink was served after 4 h. After 5 h recovery, performance was tested by a time to exhaustion (TTE) test. Workload during TTE corresponded to 70% as during EX. Biopsies were harvested from v lateralis following EX, the 5 h recovery and after TTE. Performance was only assessed with 5 subjects. Results Fasted blood glucose and muscle glycogen were 4.9±0.1 mM and 535.7±30.3 mmol/kg dw, respectively. Subjects cycled for 107.0±5.6 and 101.1±9.0 min before the intervention with CHO and CHO+Pro, respectively (p>0.05). After EX, muscle glycogen was reduced to 152.1±30.7 and 109±31.9 mmol/kg dw in CHO and CHO+Pro, respectively (p>0.05). Blood glucose was 3.4±0.2 and 3.6±0.3 mM after EX in CHO and CHO+Pro, respectively (p>0.05). During recovery, muscle glycogen resynthesis was 41.3±5.8 and 46.8±23.9 mmol/kg dw/h in CHO and CHO+Pro, respectively (p>0.05). Blood glucose peaked at 7.4±0.3 mM in CHO+Pro, and at 9.1±0.4 mM CHO (p<0.01). Area under curve was significantly higher during recovery in CHO than CHO+Pro (p<0.05). After TTE, muscle glycogen was 145.5±34.7 and 158.2±40.2 mmol/kg dw in CHO and CHO+Pro, respectively (p>0.05). Nitrogen balance was -10.7±6.3 in CHO and 19.6±7.6 mg N/kg in CHO+Pro (p<0.05) TTE was improved after CHO+Pro (54.6±11.0 min) compared to CHO (46.1±9.8 min; n=5, p<0.01). **Discussion** Although AUC for glucose was higher in CHO compared to CHO+Pro, recovery of muscle glycogen was similar. Nitrogen balance was negative during CHO, and positive during CHO+Pro. Recovery of performance was greater in CHO+Pro than in CHO, but glycogen was reduced similarly. Contact mariusad@student.nih.no

EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON NEUROMUSCULAR FATIGUE

Abdelmoula, A., Baudry, S., Duchateau, J.

Université Libre de Bruxelles

Introduction Previous work reported that transcranial direct current stimulation (tDCS) applied over the motor cortex increased time to failure of a sustained submaximal isometric contraction performed with elbow flexors [35 % of maximal voluntary contraction (MVC)] repeated 60 min after a similar contraction (1). To further investigate tDCS effects on neuromuscular fatigue, and the influence of corticospinal projections onto spinal motor neurones, this study investigated the effect of tDCS on time to failure of elbow flexion and thumb abduction sustained contractions, and changes in corticospinal excitability for biceps brachii and abductor pollicis brevis muscle, respectively. **Methods** 14 subjects performed two isometric contractions (60 min apart) until failure at 35% of MVC torque in 4 separate sessions (2 sessions/muscle group). During one session, tDCS was applied over the motor cortex for 10 min at the end of the rest period whereas during the other session for the same muscle group, sham stimulation was applied. Surface electromyography (EMG) was recorded for biceps brachii and abductor pollicis brevis during elbow flexion and thumb abduction contractions, respectively. Before and after each fatiguing contraction, muscle torque was measured during MVC and motor evoked potentials (MEP) by transcranial magnetic stimulation were recorded during 35% MVC torque contractions. **Results** During sham sessions, the time to failure of the second contraction was briefer for elbow flexion and thumb abduction contractions (p<0.01). However, the time to failure of the second contraction (expressed as % of those of the first contraction) was greater after tDCS (94.5±6.7%) than sham (75.4±5.8%; p<0.01) session for elbow flexion but not thumb abduction contractions (tDCS: 86.6±3.8%; Sham: 83.9±3.6%; p=0.58). For both muscle groups, the decrease in MVC torque was not different between the two sustained contractions in both sessions. Similarly, changes in EMG activity and MEP amplitude did not differ between contractions and sessions (p>0.05). **Discussion** Time to failure of the second contraction is increased following tDCS for elbow flexion but not thumb abduction sustained contractions. However, this different effect of tDCS on time to failure between muscle groups is not related to specific modulation of EMG activity or MEP after tDCS, confirming previous work involving elbow flexors (2). The different effect of tDCS on time to failure between the two muscle groups might reflect a greater effect of tDCS for fatiguing contractions that involve synergistic and postural muscles although the underlying mechanisms remains unknown. FASCICLE BEHAVIORS DURING ISOMETRIC CONTRACTION DIFFER BETWEEN VASTUS LATERALIS AND VASTUS INTER-MEDIUS

Ando, R., Nosaka, K., Inami, T., Tomita, A., Watanabe, K., Blazeovich, A., Akima, H.

Nagoya University

Introduction Fascicle shortening behavior influences the mechanical properties of contracting muscles. With regard to the quadriceps femoris, fascicle shortening behavior in vastus lateralis (VL) during static and dynamic contractions has been previously examined, however fascicle behavior in vastus intermedius (VI), the second largest quadriceps component, has not been reported. According to one cadaveric study, optimal VL and VI sarcomere lengths occur at approximately 60° and 115° of knee flexion (0° is fully extended), respectively (Cutts 1988). Thus it is assumed that the functional role of these muscles is largely affected by knee joint angles. It is possible that fascicle shortening behavior is different between VL and VI, which is also knee joint angle-specific. This study therefore compared the fascicle shortening behaviors, i.e. fascicle length (FL) changes, in VL and VI during isometric contractions at 60° and 110°. **Methods** Eleven healthy men (27 ± 4 y, 175.6 ± 5.3 cm, 76.0 ± 12.1 kg) participated in the study. Longitudinal sonographic images of VL and VI were obtained at rest and during 50% of maximal voluntary isometric contraction at knee joint angles of 60° and 110° using extended field-of-view of ultrasound imaging. FLs of both muscles were measured from each image, and between-scan coefficient of variance (CV) for three images were calculated. FL change during the contraction from the resting length was determined from the following equation: FL change (%) = (resting FL – contracting FL) / resting FL × 100. **Results** Between-scan FL CVs at rest and during isometric contraction were 1.9% and 3.0% for VL, and 3.1% and 2.8% for VI, respectively. FL at rest was 105.6 ± 7.9 mm for VL and 100.8 ± 8.6 mm for VI at 60°, and 120.0 ± 10.5 mm for VL and 118.7 ± 7.6 mm for VI at 110°. The magnitude of decrease in FL was greater ($p < 0.001$) at 60° ($22.3 \pm 5.3\%$) compared with that at 110° ($9.6 \pm 4.7\%$) for VL, but was not different ($p = 0.22$) between 60° ($19.0 \pm 5.3\%$) and 110° ($16.4 \pm 4.5\%$) for VI. The FL decrease in VI was greater ($p < 0.01$) than that in VL at 110°. **Discussion** These results show that fascicle behavior during submaximal isometric contractions differs between VL and VI at a longer muscle length. FL change difference between synergists would induce different tendon and/or aponeurosis displacement, which could affect force transfer efficiency (Blazeovich et al., 2006). It appears that the relative contribution of VI for knee extension is greater when compared with VL at a longer muscle length. **References** Cutts. (1988) J Anat, 160, 79-88. Blazeovich et al. IS STRENGTH OF ANKLE MUSCLES RELATED TO POSTURAL INSTABILITY?

Cattagni, T., Scaglioni, G., Laroche, D., Van Hoecke, J., Gremeaux, V., Martin, A.

université de bourgogne

Introduction It is well known that the maximal capacity of torque production of ankle muscles has a negative linear correlation with the length of center of pressure (CoP) displacement (Billot et al. 2010). This relationship has never been investigated in elderly fallers. Thus the purpose of the present study was to analyse the relationship between maximal isometric torque (MIT) of ankle muscles and CoP displacement, in a population aged between 18 and 90 years old, including elderly fallers, then try to identify a threshold of torque under which balance control is compromised. **Methods** Plantar flexors (PF) and dorsal flexors (DF) MIT and CoP displacement were measured on 83 volunteers, including 21 healthy young adults (age: 24.1 ± 5.0), 11 healthy middle aged adults (age: 50.1 ± 4.7), 22 healthy elderly non-fallers (age: 74.5 ± 7.3) and 29 elderly fallers (age: 80.0 ± 6.7). The sum of PF and DF MIT was normalized to body weight (nMIT) whereas CoP displacement was normalized to body size (nCoP). The best association between nMIT and nCoP was determined by applying a linear regression analysis and a log-linear correlation test. Receiver operating characteristic (ROC) curve was used for the assessment of sensitivity and specificity of nMIT. The optimal cut-off, defined by the Youden index (sensitivity+specificity-1) and the area under the curve were calculated. An area under the curve of 1 indicates perfect discrimination between fallers and non-fallers, whereas a value of 0.5 indicates poor discrimination. **Results** The function that best described the relationship between nCoP and nMIT was log-linear ($r = 0.67$, $P < 0.01$) rather than linear ($r = 0.62$, $P < 0.01$). The area under the ROC curve was 0.95, indicating that nMIT is an appropriate measure to discriminate elderly fallers from non-fallers. The highest Youden index (0.79) was observed at $3.1 \text{ N} \cdot \text{m} \cdot \text{kg}^{-1}$. The sensitivity was 0.90, indicating that 90% of elderly fallers generated a torque $\leq 3.1 \text{ N} \cdot \text{m} \cdot \text{kg}^{-1}$ whereas the specificity was 0.89, indicating that 89% of non-fallers generated a torque $> 3.1 \text{ N} \cdot \text{m} \cdot \text{kg}^{-1}$. **Discussion** The significant relationship between MIT and CoP indicates that ankle muscle weakness contributes to the increase of postural instability and risk of falling. In particular 90% of fallers were detected under the critical threshold of $3.1 \text{ N} \cdot \text{m} \cdot \text{kg}^{-1}$, this means that under this level of muscle torque, postural stability is dramatically deteriorated and balance control is compromised. Therefore the measure of ankle torque production in clinical routine could be used to detect potential risks of falling. **Reference** Billot M, Simoneau EM, Van Hoecke J, and Martin A. EEG SPECTRAL PARAMETERS ASSOCIATED WITH CORTICAL CONTROL OF CONTINUOUS BALANCE TASKS

Hülsdünker, T.1, Mierau, A.1, Neeb, C.1, Kleinöder, H.2, Strüder, H.K.1

German Sport University Cologne

Introduction In addition to the well described positive effects of balance training on rehabilitation, there is growing evidence in the literature indicating balance training to effectively improve athletic performance in a variety of sports. Current research acknowledges that the cortex is crucially involved in balance control. However, previous studies mainly investigated cortical activity following transient disruptions of balance, while the cortical mechanisms underlying continuous balance control are largely unknown. Since balance training programs commonly consist of continuous tasks, the identification of cortical parameters involved in continuous balance control may have implications for training and rehabilitation purposes. **Methods** In this study 37 subjects were exposed to nine continuous balance tasks while standing in an upright position on a solid surface, or an oscillating platform. Task difficulty was varied by altering surface stability and base of support. Platform oscillations were measured as an indicator of balance performance. EEG was recorded from 32 scalp locations. Independent component analysis was used for artifact correction and Fourier transformation was performed to obtain spectral power values. Theta, alpha, beta and gamma frequency bands were analyzed in the frontal, central, parietal and occipital regions of the cortex. **Results** Repeated measurement analysis of variance revealed increased theta and gamma power when balance tasks became more difficult. This increase was most pronounced over the parietal cortex. Furthermore, frontal theta as well as contralateral centro-parietal gamma power positively correlated with platform oscillations during unipedal stance on a freely oscillating platform. Altering base of support had greater effects on theta and gamma power than altering surface stability while the alteration of both factors simultaneously induced the highest power values. However task difficulty had only minor effects on the alpha and beta power. **Discus-**

sion The results of the present study indicate that theta and gamma oscillations are involved in continuous balance control. More specifically, theta and gamma oscillations could act synergistically in forming a fronto-parietal network regulating error detection and processing. In this context frontal theta oscillations are suggested to detect balance disturbances while centro-parietal gamma oscillations control corrective limb movements to re-establish stability. Significance The results of this study provide new insights into the neurophysiology of continuous balance control. This knowledge can be used to optimize existing balance training protocols to enhance athletic performance, as well as to improve the outcome of rehabilitation programs following injury.

PRESYNAPTIC INHIBITION OF IA AFFERENTS DOES NOT VARY WITH SWAY POSITION AND DIRECTION DURING UPRIGHT STANDING

Johannsson, J., Duchateau, J., Baudry, S.

Université Libre de Bruxelles

Introduction The amplitude of the Hoffmann (H) reflex evoked in soleus during upright standing varies with the direction and to some extent with the position of the centre of pressure (CoP) (3). Such modulation has been attributed to Ia presynaptic inhibition although this assumption is challenged by recent work (1). This study investigated specifically the influence of body sway direction and CoP position on Ia presynaptic inhibition. Methods Eighteen subjects participated in this study. Surface electromyography (EMG) was recorded for soleus (SOL), gastrocnemius medialis (GM) and tibialis anterior (TA) muscles. H reflex (test H reflex) was evoked in soleus by tibial nerve stimulation. Ia presynaptic inhibition was assessed by two H-reflex conditioning methods: D1 inhibition (fibular nerve conditioning stimulation), and heteronymous facilitation (femoral nerve conditioning stimulation). Changes in conditioned H/test H (condH/testH) ratio reflects modulation in Ia presynaptic inhibition (2). Results The SOL EMG was greater during forward than backward sways ($p < 0.01$) and forward than backward CoP position ($p < 0.05$), whereas GM and TA EMG did not vary. The H-reflex amplitude was slightly greater during forward ($41.5 \pm 18.9\%$) than backward sway ($39.3 \pm 18.9\%$; $p < 0.001$) but did not vary with CoP position ($p = 0.19$). However, the H reflex/SOL EMG ratio did not vary with sway direction or CoP direction ($p > 0.05$). The condH/testH ratio varied neither with sway direction ($p > 0.84$) nor CoP position, ($p > 0.95$), for both D1 inhibition and heteronymous facilitation. Discussion The modulation of the H reflex with sway direction was not accompanied by similar changes in condH/testH ratio, suggesting that Ia presynaptic inhibition is not the primary mechanism involved in the observed H-reflex modulation. The greater SOL EMG activity during forward sways and unchanged H reflex/ EMG ratio, however, may indicate a reflex gain compensation mechanism in Ia afferent pathway, although further work is needed to clarify such point. NEUROMUSCULAR AND KINEMATIC ADAPTATION IN RESPONSE TO A PERTURBATION-BASED BALANCE TRAINING

Krause, A., Freyler, K., Gollhofer, A., Ritzmann, R.

University Freiburg

Introduction Slips and stumbles are one of the main causes of injuries in elderly. To obviate the risk of falling, training should focus on facilitating postural reactions to externally provoked instabilities (Granacher et al., 2012). In expansion to the well investigated sensorimotor training (SMT), there is still little evidence about a reactive balance training, which simulates slipping situations similar to those occurring in everyday life (PERT). The objective of this study was to evaluate the effect of PERT vs. SMT on postural stability and to gather knowledge about its influence on balance strategy and neuromuscular control. Methods 38 subjects were assigned to SMT (on instable surfaces) or PERT (unexpected translations of the support-surface in 8 directions on a swinging platform). Both trainings comprised 12 20-min sessions. Before and after 4 weeks of training, postural responses to posterior translations in monopodal stance were assessed: (i) Ankle, knee and hip joint kinematics were implemented as well as (ii) electromyographic (EMG) recordings of m. soleus (SOL), m. tibialis anterior (TIB), m. biceps femoris (BF) and m. rectus femoris (RF). EMG responses were divided into three reflex phases (short-latency-, SLR; middle-latency-, MLR; late-latency response, LLR). Results After 4 weeks of training stance regulation was modified as follows: (i) An increase in knee joint amplitude (PERT +17%; SMT +14% $P < 0.05$) was accompanied by a decrease in ankle joint velocity (PERT -10%; SMT -3% $P < 0.05$). Ankle joint amplitude and knee joint velocity remained unchanged. (ii) EMG data showed an increased activation of the thigh muscles BF (PERT SLR +196% MLR +151%; SMT SLR +45% MLR +42% $P < 0.05$) and RF (PERT SLR +60%; SMT SLR +46% $P < 0.05$). Shank muscles remained unchanged. Discussion The results indicate (i) an augmented knee joint excursion and reduced ankle joint velocity in response to unexpected posterior translation. Concomitantly, (ii) neuromuscular control was increasingly regulated through the thigh muscles particularly in early reflex phases. The shift from ankle to the knee joint may support a more effective 2-segment postural control strategy regulated by the distal limb segments (Hatzitaki et al., 2005). Importantly, these neuromuscular and functional adaptations were more pronounced in PERT compared to SMT. Thus, reactive balance training, even greater than SMT, improves postural responses to external disturbances and hence may reduce the incidence of falls in elderly people. NEUROMUSCULAR FATIGUE FOLLOWING MAXIMAL VOLUNTARY VERSUS IMAGINED CONTRACTIONS

ROZAND, V., LEBON, F., PAPAXANTHIS, C., LEPERS, R.

INSERM 1093

Introduction Motor imagery training can induce strength gains on upper and lower limbs (Yue & Cole, 1992; Ranganathan et al., 2004). However, the effects of motor imagery on muscle fatigue remain unknown. The aim of the present study was to investigate neuromuscular alterations following a mental-training session including maximal imagined contractions (MICs), a physical-training session including maximal voluntary contractions (MVCs), and a combined-training session including both MVCs and MICs. Methods Ten participants took part in this study. The mental-training session consisted in 80 MICs of the elbow flexors. The specific pattern used was 5-s of MIC and 10-s of rest. During the physical-training session, the participants followed the same pattern but MICs were replaced by MVCs. During the combined-training session, subjects followed the same pattern than during the physical-training session but 5-s MICs were performed during the 10-s rest periods. MVC torque was assessed 5 times over the course of the training, as well as 10 min after the end of the training in the three protocols. Central activation ratio (CARC) and corticospinal excitability (at rest and during MIC) were estimated using transcranial magnetic stimulation. Results Corticospinal excitability was always facilitated during MIC compared to rest, ensuring that the participants imagined the desired movement during the mental-training and the combined-training sessions. The physical training and the combined training induced both a •40 % drop of MVC torque and a •10 % drop of CARC, without significant difference between the

two sessions. On the contrary, the repetition of MICs did not reduce maximal force production capacity and did not alter CARc. Discussion The current study demonstrated that a single mental-training session did not induce any neuromuscular fatigue of the elbow flexors, contrary to actual contractions. In addition, the results showed that a combined-training session did not induce additional fatigue compared to physical training. Maximal muscle activation was not altered by the repetition of MICs in the mental-training session, and was not exacerbated in the combined-training session. This absence of neuromuscular changes following both mental- and combined-training sessions compared to the physical-training session could be due to the weaker activation of the cortical areas and corticospinal pathway during MI compared to actual movement. The data suggest that MI may be used to increase total workload during a strength training session, and thus to obtain higher strength gains without exacerbating neuromuscular fatigue. BRAIN ACTIVATION IS HIGHER FOR WIDE-PULSE, HIGH-FREQUENCY ELECTRICAL STIMULATION AND VOLUNTARY EXERCISE AS COMPARED TO CONVENTIONAL ELECTRICAL STIMULATION

Wegrzyk, J.1, Ranjeva, J.P.1, Confort Gouny, S.1, Fouré, A.1, Vilmen, C.1, Boudinet, H.1, Maffiuletti, N.A.2, Place, N.3, Benda-han, D.1, Gondin, J.1

1 Aix-Marseille Université; 2 Schultess Clinic; 3 UNIL

Introduction Neuromuscular electrical stimulation is widely used in training and rehabilitation in order to enhance and/or restore muscle mass and function. In contrast to voluntary contractions (VOL), conventional stimulation (CONV) that is characterized by narrow pulse durations and low stimulation frequencies, is limited due to a non-physiological motor recruitment order (1) leading to a rapid onset of fatigue (2). The use of wide pulses and high frequencies (WPHF) has been reported to involve a higher central contribution than CONV, thereby resembling the neuromuscular activation profile of VOL (3). We hypothesized that functional magnetic resonance imaging (fMRI) could reveal a higher involvement of the cerebral central motor system for VOL and WPHF as compared to CONV stimulation. Methods 8 healthy subjects (24 ± 3 yrs) performed CONV (25 Hz, 0.05 ms), WPHF (100 Hz, 1 ms) and VOL isometric contractions in a randomized order inside a 1.5T scanner. Each protocol consisted of 20 submaximal (10% MVC) intermittent plantar flexions (20s on/ 20s off ratio). Force was continuously recorded and self-reported pain was assessed using a visual analog scale. A single-shot gradient-echo EPI sequence was used to acquire fMRI data during the three exercise types using a block design paradigm. Subsequently, first level and second level analyses were performed to determine individual and group-wise activation patterns for each condition. Results Force time integral did not differ significantly between VOL (1762 ± 323 Ns), CONV (1834 ± 557 Ns), and WPHF (1490 ± 1655 Ns); pain ratings were low and unchanged for the three conditions. Within-group fMRI analyses showed significant brain activation in the lower limb somatosensory-motor network, the posterior cingulate, and the temporal lobe for each exercise condition contrasted with the resting period. Direct comparisons between conditions showed hyperactivation of prefrontal and premotor areas for WPHF and VOL relative to CONV. Discussion Our results confirm the hypothesis that the cerebral central motor system is more involved during WPHF and VOL as compared to CONV, especially in the executive and the control motor systems. Despite the fact that muscle contractions are artificially evoked, the brain activation pattern of WPHF stimulation resembles the physiological brain activation profile of VOL. This finding may be of particular high interest for rehabilitation purposes to maximize central effects when patients are not capable of performing voluntary contractions. ACTIVATING MUSCLES FROM PRE-ACTIVATION TO MVC

Penasso, H.

University of Graz

Using inverse dynamics the determination of muscle forces from in vivo tasks requires different mathematical formulations of the underlying structures. Commonly used models include at least a geometrical ratio (G) of external to internal (muscle-) values, force produced by a contractile element (CE), and an equation representing the neural stimulus as a function of time: $A(t)$ (Erdemir et al., 2007; Zajac et al., 1989). Siebert et al. (2007) derived $A(t)$ from the solution of a system of two ordinary differential equations (ODE), which they deduced from physiological and physical considerations. These are the change in the number of active fibers $dn(t)/dt = u(t)(n_{max} - n(t))$ and the excitation $du(t)/dt = U*(u_{max} - u(t))$, with the sum of fibers n_{max} , the maximum excitation u_{max} , and the constant excitation rate U . In order to solve the ODE's they assumed $n(0) = u(0) = 0$. However, for real experimental conditions with $n(0) > 0$ the corresponding pre-activation $A_{pre}[0,1]$ had to be calculated from the function $A(t)$ at time point t_{pre} . Values before t_{pre} were set constant to A_{pre} . Nevertheless, this implies that at t_{pre} the excitation of unused fibers is ongoing already ($u > 0$). Many movements (e.g. squat jumps) are started from constant pre-activation states where the recruitment of additional fibers will not start before an increased neural stimulus occurs. Therefore, we get two boundary conditions: $n(0) = A_{pre}$ and $u(0) = 0$ to solve the system of ODE's. As $A(t)$ is a ratio between 0 and 1, we set $n_{max} = 1$ (100%). This leads us to a smooth and more general activation-function with one calculated (A_{pre}) and two arbitrary parameters (u_{max} , U): $A(t) = (A_{pre} - 1) * \exp[-(u_{max} * (U * t + \exp[-U * t] - 1) / U) + 1]$, $t \geq 0$; $A(t) = A_{pre}$, $t < 0$. We perform the calculation of A_{pre} with $A_{pre} = F_{meas} / (G * f_{iso})$, where F_{meas} is the measured force and f_{iso} is the maximal isometric force of the CE. Thus, we propose an equation for activation dynamics, that should be non-linear parameter estimation agreement with measured force-time curves. As we perform non-linear parameter estimations to obtain individual neuro-mechanical muscle properties, a better goodness of fit is expected in general. NUTRITION AND VELOCITY MEASUREMENT IN SPANISH NATIONAL TEAM WHEELCHAIR BASKETBALL PLAYERS

Grams, L., Ferro, A., Villacieras, J., Pérez Tejero, J., Garrido, G.

Faculty of Physical Activity and Sport Sciences-INEF.

Introduction The Spanish Male National Team in Wheelchair Basketball shows high performance level. Hence, optimal nutrition are required to enhance their competitive performance, and specifically, to reach high speed. There are only a few studies available describing nutrition practice in wheelchair basketball (Goosey-Tolfrey et al. 2010) and neither the comparison of maximum velocities testing and nutrition parameters. First we have done a nutritional intervention and we found an improvement in diet composition (Grams et al, 2013).

Methods Diet intake and 20 m sprint test of 11 Spanish National Team Wheelchair Basketball players, aged 30.2 ± 6.0 yrs and weight 74.8 ± 14.9 kg were measured both in May and June 2013. Diet composition was estimated by a food weighing diary (Mettler-Toledo 1g accuracy) for a 3-day period. Dial Alce® was used to determine nutrient composition. Additionally all players took part in two 20 m sprint test and velocities were calculated in real time at 200 Hz by a laser system BioLaserSport® (Ferro, 2012; Ferro and Floria, 2010) using a sensor LDM301-Jenoptik laser-type-1 (2000 Hz). Average velocities (Vm), maximum velocities (Vmax) and relative maximum velocities (RVmax), over the sections (0-3, 3-5, 5-10, 10-15, 15-20 m) were analyzed. Results In the second test, players obtained better results with significant differences in Vm and Vmax in all sections ($P < 0.05$) except in 0-3 m. We found an improved diet quality and related results to Vmax15-20 (4.8 ± 0.32 m/s vs 5.2 ± 0.24 m/s; $P = 0.001$). A positive correlation ($P = 0.029$) between carbohydrate intake per Kg and Vmax15-20 was found. Conversely, results showed a negative correlation with the Vmax15-20 with higher intake of Kcal/kg ($P = -0.003$), which leads to a negative correlation to the diet quality index ($P = -0.012$). This could be explained by a higher saturated lipid intake ($P = 0.006$) and a lower polyunsaturated in the first evaluation ($P = 0.045$).

Discussion One of the reasons to explain a better velocity test in the second evaluation could be the improvement of diet composition together with specific velocity training. However further nutritional advice should focus on higher carbohydrate intake, which still not meet the ACSM recommendation, at the different meals and at the same time reducing portions of dairy and meat that contains more energy density. Key words: adapted basketball, diet composition, maximum velocity, laser system. References ACSM (2009). MSSE. 41 (3), 709-731. Goosey-Tolfrey L. (2010). APAQ.27, 47-59. Grams et al (2013). BODY COMPOSITION ASSESSMENT IN WHEELCHAIR ATHLETES

Cavedon, V.I., Milanese, C.I., Piscitelli, F.I., Zancanaro, C.I.

University of Verona

Introduction For wheelchair athletes (WA), reduced physical capacity in injured parts of the body would result in great alterations in their body composition (BC). The assessment of BC of WA turns out to be an important way of measuring the results of an athlete's training, as well as of achieving real improvements in performance and training quality. The aims of this study was first to evaluate 3-compartment BC characteristics of WA pre- and postseason and, second, to compare %FM estimated by skinfold thickness (SKF) measurement with %FM measured by dual energy X-ray absorptiometry (DXA) in WA. Methods Twenty-eight WA (age: 34.94 ± 8.20 ; BMI: 23.51 ± 4.06) underwent DXA analysis. Bone mineral content [BMC], bone mineral density [BMD], lean mass [LM], fat mass [FM], and %FM were assessed at the total body and at regional level. BMC and BMD of the lumbar spine (LS) in anteroposterior projection were also considered. %FM was calculated with the Durnin-Womersley equation from the value of four standard skinfolds, measured with a Holtain caliper. All measurements took place at the beginning of the competitive season. Twelve WA (aged 31.33 ± 10.07 [SD]y; BMI: 24.12 ± 4.15 [SD]) were also tested at post season. The Wilcoxon test was conducted to assess changes in BC parameters over the season. Pearson's product-moment correlation coefficient (ps), paired t-tests and a simple linear regression analysis were used to assess the relationships between SKF and DXA %FM. The level of significance was set at $P \leq 0.05$. Results Results showed a significant increase in total body BMC and BMD postseason ($+3.58\%$, $P = 0.002$; $+2.52\%$, $P = 0.004$, respectively). As shown by regional analysis, BMC was accrued at the pelvis ($+4.47$, $P = 0.05$) and at the LS ($+3.14$; $P = 0.015$). Moreover, at postseason BMC and BMD values were increased at the trunk ($+3.94$, $P = 0.028$; $+3.01$, $P = 0.008$, respectively). LM and FM did not change significantly over the season as well as %FM, but for the right arm (-2.95 , $P = 0.002$). A valid and complete set of DXA and SKF measurements was available for eighteen WA. The ps correlation was significant between SKF and DXA %FM (ps = 0.954, $P = 0.000$). On average DXA and SKF were statistically different ($P = 0.002$). SKF %FM was significantly lower than %FM measured with DXA scanning (-9.94%). Regression equation was: DXA %FM = $0.168 + 1.054(\text{SKF \%FM})$. Adjusted R² was 0.905.

Discussion Our findings suggest that sport training seems to be effective for WA to increase total body BMC and BMD in particular at the trunk site. Comparison between the SKF method and DXA in WA athletes shows a substantial underestimation of %FM performed with the four-skinfold method. These results indicate the need to use an ad hoc SKF analysis comprising the sublesional regions. Contact: valentina.cavedon@univr.it

COMPARISON OF CARDIAC ADAPTATION TO WORKLOADS ON A FOOTBALL TEAM AT THE BEGINNING AND END OF PRESEASON BY THE CHIGNON INDEX

Domínguez, I., López, V.

Universidad del Fútbol y Ciencias del Deporte

Introduction Training effects represent a series of adaptations to cardiovascular level. To analyze this adaptation, the Chignon Index, which determines the development of the heart muscle in relation to each training load and also provides the ability for the same, is employed. The aim of this study was to compare cardiac adaptation at the beginning and end of a season in a soccer team. Methods A prospective and longitudinal study, including players of the First Division soccer team of Pachuca (FCP) was performed. The independent variable was the preseason training conducted at an altitude of 1880 m above sea level for two weeks, the dependent variable was the

performance of an electrocardiogram to measure aerobic anaerobic index (Index Chignon) through interpretation that considers Levelled Systems 0.5 to 1 Predominantly Anaerobic and Aerobic greater than 1 Predominantly the lower values of 0.5, the electrocardiogram was obtained both at the beginning of the season and the end of it with the intention of assessing adaptation to loads during the preseason. Results Cardiological evaluation was performed on all athletes of the FCP (26 players) with a mean age of 23.8 \pm 5.3 years. The initial electrocardiogram interpretation showed that of all athletes evaluated 4 had aerobic anaerobic index with predominantly aerobic, 16 showed graded adaptation to physical load systems and 6 of them showed a tendency anaerobic. After the completion of the preseason where physical work load is focused on aerobic character, the second evaluation showed predominantly aerobic 5 players with 10 leveled systems and 11 players with anaerobic predominance. The findings showed that all 13 players had a normal ECG. The electrocardiogram showed 11 players with a, considered as normal, respiratory sinus arrhythmia, and finally two of them showed incomplete right bundle branch block of the bundle of His. Discussion According to the results, it was observed that despite having made physical loads during preseason predominantly aerobic, no statistical significance was made in the index Chignon with modification to the aerobic predominance. In contrast to the predominance, further changes were detected as anaerobic. So, we consider that the Chignon index, despite being used in various institutions, in this case did not prove to be a useful instrument to assess adaptation to physical load during the preseason. Chignon test is cheap but may never be as efficient as the echocardiogram. References Serratosa F, Boraita P (2000). Morphological characteristics of the athlete heart. EFFECTS OF A PROGRAM OF VIGOROUS TRAINING AND 8 WEEKS OF DETRAINING IN A GROUP OF OVER 65

Fois, F., Migliaccio, G.M., Melis, S., Siccu, M., Collu, G., Melis, F., Todde, F.

CONI - Italian Olympic Committee

Purpose: The aim of this study was to evaluate, through the Senior Fitness Test (SFT), the effect of 12 weeks training and 8 weeks detraining on motor abilities in a group of over 65 adults. Methods: Twenty healthy and sedentary people were recruited (12 men and 8 women, aged 69.60 \pm 3.99 years, weight 70.75 \pm 12.09 kg, height 161.33 \pm 6.95 cm) and tested at the beginning of the study (T0), after 12 weeks of exercise (T1) and after 8 weeks of inactivity (T2). The battery of the SFT aimed to evaluate the muscular strength, the flexibility, the agility and the aerobic capabilities by the following tests: Chair Stand, Arm Curl, 2-Minutes Step, Chair Sit-and-Reach, Back Scratch and 8-Foot Up-and-Go. The training span lasted for 12 weeks (36 sessions of 60 minutes/3 times a week) and included both aerobic and anaerobic exercises along with functional exercises using a platform (step) and small equipments (dumbbells, elastic bands...). According to the ACSM guidelines the activity ranged between 40% and 84% of the heart rate reserve (HRR) and it was monitored continuously by a heart rate monitor (Polar T31 Coded™) and a telemetry system (Hosand®). During the second part of the study the supervised workouts were interrupted. Results: The analysis of the data (1 way ANOVA for repeated measures) showed significant differences ($p < 0.05$) between T0 and T1 for arm curl, chair stand and chair sit n reach. This last test was the only one with a significant decrease between T1 and T2. Between T0 and T2 was found significance for the test arm curl, chair stand, 2' step and chair sit n reach. Conclusions: These data suggest that a 12 weeks training program produces substantial improvements in muscle strength and in mobility of the lower part of the body; in the no training phase the strength values were maintained, the mobility deteriorated and the resistance increased (compared to T0). We may assume that after the training time the subjects have changed their habits by keeping, even during the training cessation, one active lifestyle with all the benefits related to it. CHARACTERISTICS OF THE STEPS IN THE APPROACH PHASE OF THE LONG JUMP BETWEEN BLIND AND ELITE ATHLETES

Padulles, J.M.1, Torralba, M.A.2, Padulles, X.1, Olsson, H.J.2, García, A.1, De Fuentes, M.L.2, López, J.L.3, Theodorou, A.4

1: INEFC-UB (Barcelona, Spain), 2: UB (Barcelona, Spain), 3: GREAF-Uv (Vic, Spain), 4: UA (Athens, Greece)

Introduction. Athletics is one of the emblematic sporting disciplines for people with disabilities and the one that attracts the largest numbers of participants and the widest range of events. It develops an spatial-temporal physical skills, and is a key sport for blind people in these areas. The long jumper during the approach run has three primary tasks to perform: to develop a maximal manageable horizontal velocity that can be used effectively during the take-off; to adjust the position of the body during the final few steps to bring it in an optimal take-off position with minimum loss of horizontal speed and to precisely adjust step length so that foot placement at jump take-off is as close as possible to the distal edge of the jump table from which the jump is measured (Hay, 1986; Hay and Koh 1988; Theodorou et al. 2010). Purpose. The purpose of this study is to compare the running approach to the take-off in long jump male blind athletes, in the final of the Paralympic Games London 2012 with elite athletes and to identify the differences observed in F11 category. Methods. It was performed a kinematic analysis in a group of 11 athletes. The variables analysed in the last three strides (3L, 2L, 1L) of the approach run were: Stride velocity, SV (m/s); Stride frequency, SF (Hz); Stride length, SL (m); Stride time, ST (s). The best jump of each athlete was selected for further analysis. Data collection was performed using 4 high-speed cameras Casio Exilim F1 at a frequency of 300 Hz. The image analysis was performed with Dartfish Pro Suite 2010 software. The statistical analysis of the data was performed using PASW V.18.0.0 software. Results. 3 / 2 / 1 to last . SV(m/s); 8,25 \pm 0,41 / 8,34 \pm 0,38 / 8,43 \pm 0,33. SF(Hz); 3,93 \pm 0,37 / 4,00 \pm 0,32 / 4,53 \pm 0,34. SL(m); 2,11 \pm 0,24 / 2,28 \pm 0,28 / 2,12 \pm 0,14. ST(s); 0,25 \pm 0,02 / 0,25 \pm 0,02 / 0,22 \pm 0,01. Discussion. Horizontal velocity during the last three strides before take-off has been shown to have a high correlation with the official jump distance. When measuring Paralympic athletes, using the same biomechanical parameters used for measuring high-level athletes, a wide range of similarities in the patterns used and the correlation with jumping distances achieved can be found. EFFECTS OF DIFFERENT INTENSITIES OF ACUTE EXERCISE ON BLOOD GLUCOSE AND LIPID PROFILE OF INDIVIDUALS WITH SPINAL CORD INJURY

Alves, E.S.1, Santos, R.V.2, Ruiz, F.S.1, Lira, F.S.3, Lima, G.4, Schulze, T.1, Tufik, S.1, De Mello, M.T.1

1: UNIFESP (São Paulo, Brasil), 2: UNIFESP (Santos, Brasil), 3: UNESP (Presidente Prudente, Brasil), 4: CEPE (São Paulo, Brasil)

Introduction Spinal cord injury promotes changes in the autonomic nervous system (ANS) leading to hormonal and metabolic changes. Exercise is one of the main therapies for rehabilitation of individuals with spinal cord injury. Besides, acute physical exercise increases the metabolic demands of the muscle modulating blood glucose and lipid profile. Thus, the aim of this study was to evaluate the effects of different intensities of acute exercise on blood glucose and lipid profile of individuals with spinal cord injury. **Methods** Thirteen male volunteers underwent 2 groups: Group Control (C) (n=5), and spinal cord injury group (SCI) (n=8). The group C presented age $26 \pm (3.1)$ years; mean (SD), height $175.6 \pm (12.9)$ cm, weight $75.1 \pm (16.9)$ kg. The group SCI presented: age $29 \pm (6)$ years, height $170.8 \pm (7.7)$ cm, weight $59.2 \pm (6.2)$ kg. The subjects performed three sessions of exercise at different intensities: light, moderate and intense. Glucose, triglycerides, HDL-C, VLDL, LDL-C and total cholesterol were assessed on blood samples taken before, immediately and 30 minutes after exercise sessions. The analysis of variance (ANOVA) for repeated measures and Tukey's post hoc test was conducted for analysis. The significance level was $P < 0.05$. **Results** We observed a significant increase of glucose levels in group C after 30 minutes of moderate exercise compared to baseline (104 ± 20.3 vs. 83 ± 25.6 ; $p=0.035$). In turn, we observed a significant decrease on this parameter in SCI group after 30 minutes of light exercise (78 ± 7.7 vs. 94 ± 21.1 ; $p=0.039$). Regarding lipid profile, we observed an increase on triglycerides (150 ± 41.4 vs. 120 ± 29.1 ; $p=0.035$) and VLDL (24 ± 4.1 vs. 30 ± 8.2 ; $p=0.035$) parameters in SCI group at 30 minutes after the session of moderate exercise compared with values immediately after the exercise. **Discussion** A decrease in blood glucose after 30 minutes of light exercise can be explained by a lower activation of catecholamines by suppressing the release of glucose into the bloodstream (Leicht et al 2013). In turn, moderate intensity increased adrenergic activation may have led to an increase in triglycerides and VLDL after the exercise session. These results suggest that individuals with spinal cord injury have different metabolic responses to acute exercise compared to individuals without disabilities. **Financial Support:** FAPESP (2012/16086-9) and Associação Fundo de Incentivo à Psicofarmacologia (AFIP). **References** Leicht CA, Goosey-Tolfrey VL, Bishop NC. PROJECT 'TRAPIANTO...E ADESSO SPORT'. EFFECTS OF EXERCISE ON QUALITY OF LIFE OF SOLID ORGAN TRANSPLANT PATIENTS: PRELIMINARY RESULTS.

Peruzzo, M., Rica, E., Capone, S., Ermolao, A.

University of Padua

Introduction Different studies have suggested that physical activity can play an important role in improving quality of life in solid organ transplant recipients. However, the population investigated is still limited, while it is still not defined which specific domains can receive a greater benefit. The aim of the project "Trapianto... e adesso Sport" is to assess the effect of a mixed protocol (endurance and resistance training) on a sample of heart, liver and kidney transplant recipients recruited in different Italian Transplant Centers. **Methods** Subjects enrolled in the study have been assigned with non-randomized method at 2 cohorts: the Exercise Cohort (EF) including transplanted subjects receiving a physical exercise prescription to be carried out in a qualified gym, and the Control Cohort (CT), which includes transplant patients not receiving any exercise prescription. Each participant has been tested through 3 evaluations (baseline evaluation – T0, after 6 months – T6, and after 12 months – T12) at a Sport Medicine centre, where along with others functional tests, the Italian version of Short Form 36 Health Survey (SF-36) was administered. The survey consists of 36 questions that yields an 8-scale profile of functional health and well-being scores like Physical Functioning (PF), Role-Physical (RP), Role-Emotional (RE), Bodily Pain (BP), General Health (GH), Vitality (VT), Social Functioning (SF) and Mental Health (MH). **Results** Currently, 111 subjects have been enrolled in the study, 50 of them (liver and kidney transplants) have completed all 3 evaluations. EF subjects (n=32) have shown statistically significant improvements from baseline to T6 ($p < 0.05$) in the AF, RP and RE scale. Moreover, a significant improvement between data obtained from T0 to T12 in domains like AF, RP, BP, GH, SF and RE was observed. Analyzing the subgroup of patients evaluated in our Center (n=26), baseline results give us a picture of the general condition among heart, liver and kidney patients at the beginning of study. SF-36 scores at T0 show that liver transplant recipients suffer a more compromised health condition compared with heart or kidney receivers, which profiles are essentially overlapped. **Discussion** To summarize, the quality of life that the transplanted subjects present early after transplantation, often before they have been going a cycle of rehabilitation depends on the type of transplant, on immunosuppressive therapy side effects and on the pre-transplant clinical conditions. Furthermore, an adapted and personalized exercise program to these patients could improve their perception of different scales of the QOL, like we have just observed in our first results after 6 or 12 months of exercise program.

INVESTIGATING PHYSICAL ACTIVITY IN CHILDREN AND YOUNG PEOPLE WITH INTELLECTUAL DISABILITIES USING OBJECTIVE METHODS

Downs, S.J.1, Fairclough, S.J.1, Knowles, Z.R.1, Boddy, L.M.1

Liverpool John Moores University

1: The Physical Activity Exchange, Liverpool John Moores University (Liverpool, UK) **Introduction** The purpose of this study was to describe objectively measured habitual physical activity (PA) levels and sedentary behaviours of children and young people with intellectual disabilities (ID), within UK special educational needs (SEN) schools. This is the first study within the UK to use objective methods to examine PA levels and sedentary behaviour specifically in children and young people with ID. **Methods** Thirty nine 7-15 year old participants (6 girls) who had ID were involved in this study; participants were from 3 SEN schools (1 primary school and 2 secondary schools). PA was assessed over 7 days using accelerometers and stature, sitting stature and body mass were measured. Body mass index and somatic

maturation were calculated. Twenty six participants (6 girls) were included in the final analysis. Multivariate analysis of covariance (MANCOVA) was used to investigate differences in PA patterns and sedentary time by sex, and additionally by school year group (Primary vs High schools). Results Participants spent 43.22 min/day on average in moderate to vigorous physical activity (MVPA) and 508 min/day on average in sedentary activities, with 19.2% (n = 5) of participants meeting government PA guidelines of ≥ 60 min/day of MPVA. Male participants (44.67 min/day) engaged in more habitual MVPA than females (38.62 min/day), however no significant differences were observed ($p > 0.05$). Similarly, primary school participants (45.10 min/day) engaged in slightly more habitual MVPA than high school participants (42.16 min/day) ($p > 0.05$). Conclusion Children and young people with ID do not engage in sufficient health enhancing PA to achieve recommended guidelines. This study highlights the need to increase total PA and decrease sedentary behaviour in this population through appropriately designed PA interventions. Despite the small sample size, this study is the largest in Europe to date to specifically investigate PA in children and young people with ID. Contact S.J.Downs@2012.ljmu.ac.uk

GREAT STRENGTH GAIN WITHOUT PAIN FOLLOWING DOWNHILL WALKING TRAINING

Maeo, S., Yamamoto, M., Kanehisa, H.

National Institute of Fitness and Sports in Kanoya

Introduction Downhill walking can be considered an eccentric exercise modality for knee extensors. Although exercise-induced muscle damage (EIMD) often occurs after eccentric exercise, it has been suggested that such EIMD can be prevented by gradually increasing training volume through intervention (Flann et al. 2011). This study aimed to examine the changes in knee extensor strength, as well as markers of EIMD, induced by total volume-matched incremental (INC) or constant (CONS) duration downhill walking training. **Methods** A total of 32 healthy young males completed a 4-wk INC (n = 10) or CONS (n = 12) training program or served as a control group (n = 10). The INC and CONS groups conducted a downhill treadmill walking (load: 10% of body mass, gradient: 28%, velocity: 5 km/h) 1 session/week for 4 weeks. The total exercise duration over the training period was 160 min for both groups, but INC group gradually increased the exercise duration (from 10 to 30, 50, and 70 min) whereas the exercise duration per session for CONS group was 40 min for all 4 sessions. Before and after the intervention, muscle thickness of knee extensors and maximal knee extension torques in eccentric (-120, -60, -30 deg/s), isometric (0 deg/s), and concentric (30, 60, 120, 240 deg/s) conditions were measured. For INC and CONS groups, EIMD markers (muscle soreness, plasma creatine kinase activity, knee extension torque, and ROM of knee joint) were also measured before and up to 72 h following each session. **Results** After the intervention, control group did not show any changes in all variables. Both INC and CONS groups significantly increased maximal knee extension torques at all angular velocities without changes in muscle thickness. The relative gain in eccentric torques (INC: +18%, CONS: +24% on average) was significantly higher than those in isometric (+13%, +13%) and concentric (+8%, +12% on average) torques with no difference between groups. In CONS group, considerable changes in EIMD markers were found following the first session, but such changes were attenuated throughout the training period in INC group. **Discussion** Some studies on elderly adults reported that downhill walking training may be effective for improving the knee extensor strength (Isner-Horobeti et al. 2013). Flann et al. (2011) suggested that when the total training volume is the same, the strength gain after eccentric training would be similar despite the difference in training protocol. The current results support these findings and indicate that downhill walking training can increase the strength capability of knee extensors, specifically for eccentric strength, and that EIMD can be avoided by gradually increasing the training volume. **References** Isner-Horobeti et al. (2013) *Sports Med*, 43:483-512. Flann et al. (2011) *J Exp Biol*, 214:674679. Contact smaeko1985@gmail.com

THE POTENTIAL CONTRIBUTION OF ACTIVE VIDEO GAMING IN INCREASING ADHERENCE TO PHYSICAL ACTIVITY GUIDELINES

Mackintosh, K., Standage, M.

Swansea University

Research suggests that active video gaming can increase energy expenditure (EE) and heart rate (HR) and thus potentially increase Physical Activity Levels (PAL), but little is known about the influence of single- or multi-player interactions. The aim of the present study was to further examine EE and HR elicited during active video gaming, both in a 1- and 2-player situation, to ascertain if active games can meet the EE associated with current physical activity (PA) guidelines. In addition, to further elucidate the potential modulating effect, positive and negative affect, subjective vitality and intrinsic motivation were assessed. Thirty-six (19 male) participants (21.7 ± 3.8 years; 69.3 ± 13.5 kg; 1.72 ± 0.08 m) wore an Actiheart® unit for seven full days, prior to performing both conditions in a randomised order, each involving 30 min of 'Wii Boxing'. Significant increases from baseline for HR and EE were found in both conditions, with HR and EE being similar between conditions ($P > .05$). Energy expenditure was significantly higher in both conditions for males (4.9 ± 2.0 and 5.0 ± 2.1 METs; 1- and 2-player respectively) than females (3.5 ± 1.5 and 3.2 ± 1.4 METs; 1- and 2-player respectively). Further, males experienced higher pressure/tension in both conditions, and negative affect in a 1-player situation ($P < .01$). The findings provide further evidence for the role active video gaming may play in enhancing daily energy expenditure and potentially enable adults to meet current physical activity guidelines and gain associated health benefits.

GENDER DIFFERENCES IN ISOLATED UPPER-BODY POLING AMONG PERFORMANCE-MATCHED CROSS-COUNTRY SKIERS

Myhre, K.1, Welde, B.1, Hegge, A.M.2, Sandbakk, Ø.2

1: Nord-Trøndelag University College (Levanger, Norway), 2: NTNU (Trondheim, Norway)

Introduction Although male and female elite skiers possess the same professionalism and general training patterns, it has recently been shown that gender differences increase as the contribution from poling increases. To gain further understanding about this phenomenon, the present study compared sprint and endurance performance, energetic capacities, efficiency during isolated upper-body poling, as well as body composition or training in male and female performance-matched cross-country skiers. **Methods** Eight male cross-country skiers (age 20 ± 3 yrs, body mass 77.1 ± 7.0 kg, $\text{VO}_{2\text{max}}$ 73.1 ± 5.4 mL·min⁻¹ kg⁻¹, FIS 103±22) and nine female cross-country skiers (age 22 ± 2 yrs, body mass 63.5 ± 5.2 kg, $\text{VO}_{2\text{max}}$ 64.5 ± 4.2 mL·min⁻¹ kg⁻¹, FIS 103±24) completed three 4-min submaximal stages, a 3-min performance test and a 30-sec Wingate sprint test on a modified Concept2 SkiErg. Ventilatory variables were assessed by open-circuit indirect calorimetry. Work rate and cycle rate were measured with the ergometers internal software, as validated with force and velocity measurements. Body composition was measured using dual-energy X-ray absorptiometry. Training data from the last six months before testing were quantified based on training diaries. **Results** There were no differences in submaximal metabolic rate-work rate regression

lines between genders (all $P < 0.001$). On the 3-min test, males achieved 95% higher work rate and 59% higher $\text{VO}_{2\text{peak}}$ ($\text{L} \cdot \text{min}^{-1}$) (both $P < 0.001$). On the 30-sec test, males performed 114% higher work rate ($P < 0.001$). Gender differences in work rate increased as intensity increased ($P < 0.05$). Males had 35% and 59% higher absolute lean mass in trunk and arms (both $P < 0.001$), and higher distribution of body mass localized in the upper body (61% vs 57%; $P < 0.001$). Total training hours did not differ between genders, but males logged 113% more upper-body strength training and 35% more time in the classical technique than females (both $P < 0.05$). Conclusions The differences in upper-body performance between men and women increased with increasing intensity, with the differences being significantly higher than what could be explained by diversity in aerobic energy delivery. The relationship between metabolic rate and work rate did not differ between genders, but the effect of intensity indicates that anaerobic capacity differentiates genders in upper-body exercise. This is further supported by the greater work per cycle and higher distribution of lean mass in the upper limbs among male skiers. Interestingly, training data indicated more upper-body strength and endurance training in males which might be an underlying reason for the relatively large differences in upper-body capacities. EFFECTS OF NONSPECIFIC ENDURANCE TRAINING ON SPECIFIC PERFORMANCE IN INLINE SPEEDSKATING

Hildebrand, C., Abel, T., Hesse, C., Claßen, S., Strüder, H.K.

German Sports University

Introduction: To be competitive and successful, inline speedskaters require a mix of swiftness and power combined with a high aerobic and anaerobic capacity. Thus, a highly developed aerobic performance level enables the athletes to sustain a high average of speed ($40 \text{ km} \cdot \text{h}^{-1}$), as well as ensuring a fast recovery between the tactically high intensive efforts of attacks (Thomas et al. 2004). Since the right period to develop this ability is in winter, a sport-specific training is weather-related not possible. Hence, we investigated the influence of a nonspecific training (cycling, running) on inline speedskaters' sport specific endurance performance. **Methods:** 14 high level inline speedskaters (7 male, 7 female, 24 ± 8 years, 175.4 ± 9.7 , 67.5 ± 11.2 kg, body fat: 15.3 ± 2.2 %) were randomized divided in two groups (running, cycling) and trained at 60% of $\text{VO}_{2\text{max}}$ over 7 weeks with 2 sessions per week (81-90 min) each on treadmill or cycle ergometer respectively. Before and after the training intervention all subjects performed an incremental exhaustive specific and nonspecific (cycling or running) test. In addition to blood lactate (LA) and glucose (BGL) concentration (mmol/l), oxygen uptake (VO_2 , absolute [$\text{l} \cdot \text{min}^{-1}$] and relative [$\text{ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$]), ventilation (VE [$\text{l} \cdot \text{min}^{-1}$]), ventilatory equivalent (VE/ VO_2 [$\text{l} \cdot \text{min}^{-1}$]) respiratory quotient (RQ) and heart rate (HR [$\text{b} \cdot \text{min}^{-1}$]) were measured or calculated through a portable spirometry system to determine the exercise effects. **Results:** Body fat was reduced significantly in both groups (cycling: $p=0.021$, running: $p=0.004$). On sub-maximal efforts all measured parameters were significantly ($p \leq 0.02$) improved from pre to post without any group effect. Similar results occurred in maximum values for VO_2 , RQ and VE/ VO_2 ($p=0.01$) at the same exercise intensity. The cycle exercise resulted in significant decreases in maximum HR ($p=0.021$) and BGL ($p=0.004$) during inline speedskating. The corresponding effect sizes are $d=0.95$ and $r=0.72$ respectively. **Conclusion:** The results indicate that nonspecific training at 60% of $\text{VO}_{2\text{max}}$ effects inline speedskaters' endurance performance positively. Although most of the analyzed parameters did not differ significantly after the different types of training, the cycling-specific effect on maximum HR and BGL should be considered for optimal fundamental endurance training. These results coincide with the assumption that cycling imitates superiorly the inline speedskating movement pattern than running (Martinez et al. 1993). **References:** Thomas C, Sirvent P, Perrey S, Raynaud E, Mercier J. ENHANCING PERFORMANCE IN ELITE WATER POLO PLAYERS: DRY-LAND TRAINING, IN-WATER TRAINING, AND COMBINED TRAINING

Ramos Veliz, R., Suarez Arrones, L., Requena, B., Saez de Villareal, E.

UNIVERSITY OF PABLO DE OLAVIDE

Objective: This study compares the effect of three different training stimuli on strength and other qualities critical to water polo (WP) performance. **Design:** Thirty elite WP players were randomly assigned to three experimental groups: combined training (dry-land and in-water strength training, CG), in-water specific strength (WSG), and plyometric (PG). Participants performed strength and plyometric training three days a week for a total of 6 weeks. WP training was conducted five days per week. **Method:** 10m-T-Agility Test, 20-m maximal sprint swim, maximal dynamic strength (1RM, bench press (BP) and full squat (FS)), in-water vertical jump, countermovement jump (CMJ) and throwing velocity (ThV) were measured. **Results:** Pre-training results showed no significant differences among the groups in any of the variables tested. After six weeks significant improvements ($p \leq 0.05$) were found in PG group in CMJ (6.1%); in CG and WSG groups in-water vertical jump (4.4%) and (5.1%), respectively. Maximal dynamic strength 1RM FS significantly increased in all groups (ICG (14.20%), WSG (11.55%), and PG (14.59%)), but in 1RM BP increased only in the CG and PG groups (12.65%) (7.67%) respectively. ThV significantly increased in all groups (ICG (17.57%), WSG (12.80%), and PG (11.43%)) and in Agility test only CG group (7.37%) significantly decreased. **Conclusions:** A combined training approach using dry-land and in-water specific strength exercises results in a improvement in maximal strength, in-water vertical jump, throwing and agility performance and the resemblance between movement patterns and the specificity of strength exercises common to the training and testing methods also contributes to greater performance improvement.

EFFECT OF A MULTIMODAL PROGRAM ON BODY COMPOSITION AND CARBOHYDRATE METABOLISM DURING PREGNANCY

Ferrari, N.1, Bauer, C.2, Brockmeier, K.3, Strueder, H.K.2, Graf, C.2

UK Cologne

1: UK Cologne, Cologne Centre for Prevention in Childhood and Youth/ Heart Center (Cologne, Germany), 2: DSHS Institute of Movement and Neuroscience (Cologne, Germany), 3: UK Cologne, Heart Center (Cologne, Germany) **Introduction** Sedentary behavior and high caloric diet during pregnancy seem to have negative influences on mother and child, e.g. risk for gestational diabetes mellitus or obesity. Excessive maternal weight gain during pregnancy is linked to obesity in early childhood. In terms of perinatal programming health promotion strategies are increasingly important to prevent weight gain during pregnancy. However, studies to improve physical activity during pregnancy report inconsistent results on maternal body composition and risk of gestational diabetes. Therefore, the aim of the present study was to examine the effect of a multimodal program on maternal body composition, carbohydrate metabolism (T0: 16 weeks vs. T1: 36 weeks of gestation) and birth weight. **Methods** 36 women with a mean age of 32.7 ± 4.0 years, mean pregnancy week of 15.2 ± 2.9 weeks and a pre-pregnancy body mass index of $22.9 \pm 3.2 \text{ kg/m}^2$ were randomized to either an intervention

group (IG, n=20) or a control group (CG, n=16). The intervention consisted of 60 min supervised endurance training, 60 min strength training for at least twice per week for a minimum of 16 weeks and nutrition counseling four times during the program. Venous blood samples (3x6 ml) were taken of all participants after an overnight fast (>10h at T0 and T1). Fasting glucose as well as human plasma insulin concentrations were measured and HOMA-IR was calculated. Skinfold thickness was measured using a Harpenden skinfold caliper at three points (Jackson et al. 1980). Results There was no difference in fasting glucose level, insulin concentration or HOMA-IR between both groups. Baseline percent (%) body fat was higher in the IG comparing the CG (26.8 +/- 7.6 % body fat vs. 21.9 +/- 5.1 % body fat; p=0.047). After the intervention IG showed reduced % body fat (-7.2 +/- 5.7) whereas in CG % body fat was increased (3.9 +/- 3.4; p<=0.001). There was a significant interaction between IG/CG, difference % body fat and birth weight (p<=0.001); a higher reduction in % body fat during pregnancy was significantly correlated with lower birth weight (r= -0.483, p=0.005) and infants weight at 4 weeks (r=-0.533; p=0.005). Discussion A multimodal program during pregnancy can contribute to a significant reduction of % body fat during pregnancy. Reduction in body fat during pregnancy is associated with lower birth weight and infants weight in the first month. No effect was found on carbohydrate metabolism. IMPROVING CARDIORESPIRATORY FITNESS BY INDOOR-CYCLING DOES NOT CHANGE SELF-REPORTED OR MEASURED DAILY PHYSICAL ACTIVITY – PRELIMINARY RESULTS

Brandes, M., Ginsel, S.

University Oldenburg

Introduction Several health benefits are related to cardiorespiratory fitness (CRF) (Garber et al., 2011). As CRF is linked to daily physical activity (PA) (Hainer et al., 2009), health interventions often promote daily PA to improve CRF. Potentially, a systematic enhancement of the physiological capabilities could improve the response to promotions of daily physical activity. Thus, we investigate if a systematic training of CRF will increase daily PA. Methods 79 participants (n=33 in control group (CG; 9 females, age 46 ± 9 years, BMI 27.4 ± 3.7); n=46 in intervention group (IG; 6 females, age 44 ± 9 years, BMI 28.2 ± 4.1)) performed a maximal incremental bicycle ergometer test. Maximum workload, maximum oxygen uptake (VO2max) and workload at a heart frequency of 150 beats/min (PWC150) were measured. All participants filled in the International Physical Activity Questionnaire (IPAQ) and were equipped with a pedometer for 14 days (StepWatch, Orthocare Innovations, USA). The same protocol was repeated after four months. In-between, the IG performed an indoor-cycling training twice a week for 14 weeks, the CG did not receive any intervention. Results In the IG, significant changes (p<.001) were obtained for increase in maximum workload (204.3 vs. 242.4 W), VO2max (33.0 vs. 36.0 ml/min/kg) and PWC150 (153.6 vs. 184.5 W). No significant changes were found for the number of daily steps (12.120 vs. 12.280 steps/day) and IPAQ score (4128 vs. 4247 MET-minutes/week). In the CG, VO2max decreased significantly (36.9 vs. 35.1 ml/min/kg). No significant changes were found for maximum workload (219.5 vs. 218.2 W), PWC150 (161.5 vs. 161.8 W), number of daily steps (12.760 vs. 12.396 steps/day) and IPAQ (3942 vs. 3493 MET-minutes/week). Discussion Although the training intervention significantly improved CRF at maximal (VO2max) and submaximal (PWC150) conditions similar to previous studies (Bianco et al., 2010), the advanced physiological capabilities are not transferred automatically into more daily physical activity, similar to previous studies (Orron et al., 2012). Consequently, health-related interventions targeting CRF by indoor-cycling should include theoretical and practical guidelines for improving daily physical activity to sustain the effects of the intervention. ON THE ORIGINS OF ORGANIZED SPORTS MEDICINE IN SWITZERLAND

Colombani, P.C., Gojanovic, B.

Federal Office of Sport

Introduction Germany is often considered the country of origin of organized sports medicine (Arndt, 2012). The German «Reich Committee for the Scientific Research of Sports and Physical Exercises» was indeed founded in 1912, but it was pretty much inactive. A real constitution of the committee never occurred, no board was ever instituted and two main tasks were never carried out: the creation of a sports medicine journal and the organization of a yearly sports medicine conference (Court, 2008). Relevant activities can only be attributed to the «German Association of Physicians for the Promotion of Physical Exercise» that was founded in 1924. Organized sports medicine in Switzerland In Switzerland, the «Committee for the Organization of the Sports Medical Service» was created on February 11, 1923, as one of the committees of the «Swiss National Association for Physical Exercises» (SLL), which was founded 10 months earlier (SLL, 1923). The «Sports Medical Service» was organized and made Switzerland, according to its first president, the Swiss pioneer in sports medicine Wilhelm Knoll, the second country with an organized sports medicine. Knoll, however, declared that Norway and not Germany was the first country with a nationally organized sports medicine (Knoll, 1948). This means that Knoll did not consider the German Reich Committee of 1912 to be an organized sports medicine. Unfortunately, no information about the Norwegian organization, which apparently was founded around 1900, has been uncovered so far. The «Sports Medical Service» consisted of two sports physicians, an athlete, eight heads of regional sports medical services and 60 physicians ultimately working with the athletes (Knoll, 1925). Its tasks were the «hygiene of school and adolescent youth, so that they are better prepared for sports, monitoring and examination of young athletes, research of long-term damages caused by sports, research of sports types, sports injuries and the creation of a sports medical library». Switzerland can thus be considered as one of the pioneer countries in sports medicine. References Arndt, KH (2012). *Dtsch Z Sportmed*, 63, 93. Court, J (2008). 1.3. MO-BN12 BM Muscle Function

NONLINEAR ANKLE MOMENT SUMMATION OF RAT TRICEPS SURAE MUSCLES

Tijs, C.1, van Dieën, J.H.1,2, Baan, G.C.1, Maas, H.1

VU University Amsterdam

1.VU University, Faculty of Human Movement Sciences (Amsterdam, The Netherlands) 2.King Abdulaziz University (Jeddah, Saudi Arabia)

Introduction Triceps surae muscles play an important role during tasks such as cycling, running and jumping. Therefore, it is important to understand the mechanical effects that these muscles have. Soleus (SO), lateral and medial gastrocnemius (GA) muscles are mechanically connected to each other via the common Achilles tendon and via epimuscular connective tissues. This suggests that these muscles are not independent actuators and, hence, joint moments exerted by these muscles individually may not sum linearly. The aim of the present study was to assess ankle moment summation of triceps surae muscles for a range of ankle angles in the rat. **Methods** Sagittal plane ankle angle was varied stepwise from 150 deg. to 70 deg., while the knee angle was kept constant at 90 deg. At each ankle angle, SO and GA muscles were first excited separately followed by excitation of both muscles simultaneously (GA+SO). Nonlinear ankle moment summation was assessed by subtracting the ankle moments exerted by SO and GA individually from the ankle moments exerted during GA+SO excitation. **Results** During excitation of GA+SO simultaneously, active plantarflexion moment was significantly lower (on average by $-2.7 \pm 3.4\%$, $p < 0.001$) than the mathematical sum of the active plantarflexion moment exerted by SO and GA individually. SO muscle contraction resulted in significantly less Achilles tendon lengthening than during contraction of GA ($p = 0.018$) and GA+SO ($p = 0.013$). For ankle angles between 130 deg. and 70 deg., length changes of the Achilles tendon due to SO contraction were minimal (0.00 ± 0.18 mm), while the Achilles tendon was lengthened 0.17 ± 0.14 mm and 0.15 ± 0.13 mm in response to GA and GA+SO contraction, respectively. **Discussion** The nonlinear summation found in this study can be caused by stretch of common elastic components, such as the Achilles tendon (Sandercock, 2000). GA muscle contraction resulted most likely in lower lengths of SO muscle belly due to higher lengths of the Achilles tendon. Therefore, SO force production during individual SO excitation would be different from SO force production when GA was activated simultaneously. Other mechanisms can also cause nonlinear moment summation: (i) An increase in Achilles tendon moment arm in response to GA contraction (Maganaris et al., 1998); and (ii) Effects of epimuscular myofascial force transmission (Maas and Sandercock, 2010). We hypothesize that the limited nonlinearity ($< 3\%$) reflects a limited net effect of opposite effects of these mechanisms on the ankle moment. Introduction The measurement of net joint moment at different angular velocity reveals important relationships for the dynamic strength capabilities in skeletal muscles (Winters, 1990; Zatsiorsky and Prilutsky, 2012). The aims of this study were: - to obtain the torque-velocity relationships of the elbow flexors and extensors of concentric contractions in females; and - to compare polynomial equations from 1st to 4th order and thus determine the optimal fitting function. **Methods** Ten healthy women (22.0 ± 1.8 y) were unilaterally tested by isokinetic dynamometer (Biodex System 4) at velocities of 30o, 75o, 120o, 150o and 210o/s for elbow flexors and extensors, and velocity of 0o/s at 90o-135o or 45o-90o, respectively. The normalized data for the peak torque were plotted against velocities, fitted by polynomial functions (from 1st to 4th order) and Akaike Information Criterion (AIC) was computed (OriginPro 8). The optimal curves were examined for ability to predict velocities, higher than the tested ones. **Results** The peak torque (mean \pm SD, Nm) of extensors (32 ± 5) and flexors (30 ± 6) at velocity of 0o/s, was reduced to 49 ± 3 and 59 ± 3 % respectively at velocity of 210o/s. The optimal fitting of torque-velocity data was modeled with 4th order polynomial for the flexors (AIC = 346.5) and 2nd order polynomial for the extensors (AIC=265.4). However, a non-physiological curvature was obtained when extrapolating the models to higher velocities with the optimal coefficients. **Discussion** The values for peak-torque of flexors and extensors are similar to those of Pinter et al. (2010). The difference established for the optimal fitting function between muscle groups are in accordance with Frey-Law et al. (2012). Although, the optimal equations fit the data well, the fitting with polynomials did not allow to predict the physiologically-consistent behavior at higher or maximal velocities. It remains to be established whether other class functions may provide a better mean for prediction of the velocity. **References** Frey-Law LA, Laake A, Avin KG, Heitsman J, Marler T, Abdel-Malek K (2012). THE ROLE OF EMG ACTIVITY AND ELASTIC ENERGY REUSE IN THE KNEE EXTENSOR MUSCLES DURING CONCENTRIC CONTRACTIONS

Hegyi, A.1, Bartha, K.1, Péter, A.1, Cronin, N.2, Tihanyi, J.1

Semmelweis University, Faculty of Physical Education and Sport Sciences

1Department of Biomechanics, Kinesiology and Informatics, Faculty of Physical Education and Sport Sciences, Semmelweis University (Budapest, Hungary) 2Department of Biology of Physical Activity, University of Jyväskylä (Jyväskylä, Finland) **Introduction** Pre-activity prior to the shortening of muscle has a significant role in the enhanced performance of concentric contractions (McBride, 2008). Elastic energy reuse in the musculotendinous system is also documented to be one of the main contributors to the higher work output (Wilson & Flanagan, 2008). However, it is not clear which factor is more important regarding positive dynamic work. We aimed to define the role of EMG

activity and elastic energy storage during pre-tension of the knee extensor muscles on the mechanical characteristics of muscle shortening. Methods 20 young (20.75 ± 1.2 yrs) subjects volunteered for this study. Maximal voluntary isometric contraction (MVC) of the knee extensor muscles was measured at the optimal angle for each subject. After that they performed concentric contractions with different pre-tension levels from an individually optimized angle to full extension. The shortening phase of every contraction had to be performed as fast as possible. The pre-tension levels were set at 20, 40, 60, 80 and 100% of the MVC and had to be reached in two different ways: as quickly as possible (F) and with no time constraint (S). Torque, knee angle and angular velocity were measured by Multicont II dynamometer. EMG activity was also recorded from the vastus lateralis and - medialis muscles in each task. Results The positive mechanical work in the first 10 degrees of shortening was significantly higher in F than in S when the pre-tension was 20, 40 and 60% ($p < 0.05$). Between 15-35 degrees after the release the differences in work output were not significant anymore ($p > 0.05$). Similar results were observed in the EMG activity during these periods. Moreover, the EMG activity was significantly higher before the release in F compared to S at 20-80% pre-tensions ($p < 0.05$). However, mechanical work increased linearly as a function of the pre-tension level during F and S ($R > 0.9$, $p < 0.05$). Discussion The effect of activity level and elastic energy reuse of the muscle could be separated via this method. It seems that the explosive execution of pre-tension causes significantly higher EMG activity before shortening. This primarily affects the early phase of muscle shortening and has significance at lower pre-tension levels. However, elastic energy can increase the positive work significantly via the higher pre-tension level, which provides more elastic energy storage. References McBride JM, McCaulley GO, Cormie, P. RELIABILITY OF HUMAN VASTUS LATERALIS FASCICLE LENGTH MEASUREMENTS USING A SEMI-AUTOMATIC TRACKING ALGORITHM APPLIED TO ULTRASOUND IMAGES

Marzilger, R.1, Panteli, C.2, Karamperis, A.3, Bohm, S.1, Mersmann, F.1, Arampatzis, A.1

Humboldt Universität zu Berlin

1: HU (Berlin, Germany), 2: APTH (Thessaloniki, Greece), 3: UT (Trikala, Greece) Introduction Vastus lateralis (VL) fascicle length measurements are often applied in exercise interventions to investigate muscle adaptation, however the reported reliability of these measurements is low (Mairet et al., 2006) to moderate (Raj et al., 2012). The reasons for those findings could be the used ultrasound probe length (incomplete fascicle depiction) or the manual analysis of the fascicles in ultrasound images by different observers. Therefore, the purpose of the present investigation was to assess the reliability of a semi-automatic tracking algorithm (STA) measuring the VL fascicle length based on ultrasound images obtained with a 10 cm probe. Methods The VL fascicle length was examined in inactive state from 17 participants (27.9 ± 4.3 y, 177.4 ± 8 cm, 71.8 ± 8.2 kg) using an ultrasound device (Esaote). Five trials of the VL muscle structure were captured on 2 different days (3-4 days' rest), while the participants were sitting in a dynamometer (Biodex) and their knee joint was passively moved from 0° - 100° with $10^\circ/s$. The fascicle length was calculated with a STA over the entire range of motion. Fascicle segments between the deeper and upper aponeuroses were identified in an initial video frame and fascicle length was determined in a linear manner between the aponeurosis. The algorithm analyzed the changes of brightness contours in consecutive frames and recalculated the fascicle length. Intra-class-correlation (ICC), root-mean-square differences (RMS) and a t-test were used to examine the reliability of the fascicle length at every 10° knee angle. The Spearman-Brown prophecy formula (SB) was used to estimate the required trials to achieve a reliability of 0.95. Results The ICC values for the trials of day 1, day 2 and both days were in average 0.84, 0.83 and 0.78, respectively. The RMS between days was in average 12.5 mm. There were no statistically significant differences ($p > 0.05$) in the fascicle length values between days. According to SB, five to six trials are necessary to achieve a reliability of 0.95. Discussion The findings indicate a rather moderate reliability of VL fascicle length measurements based on ultrasound images. Therefore, it is crucial to average 5 – 6 trials to achieve a high reliability of the VL fascicle length measurement. We conclude that the developed STA can be reliable used for the assessment of VL fascicle length if at least 5 trials are considered. References Mairet S, Maisetti O, Portero P. (2006). INFLUENCE OF CAFFEINE ON PARTICULAR NEUROMUSCULAR PROPERTIES - A PILOT STUDY

Höher, P., Penasso, H., Thaller, S.

Institute of Sport Science

Introduction Several studies discussed the beneficial effects of caffeine on endurance, but there is a lack of information on the positive effects during short-time muscle activation. Therefore, the purpose of our study was to investigate the influence of caffeine on the force-velocity relation (FV) of the muscle as well as on the activation dynamics in short-time movements. Methods In a single-blind, crossover, randomized counterbalanced study design, 12 male subjects (25.5 ± 2.5 yr, 1.80 ± 0.05 m, 76.42 ± 6.27 kg) performed several leg extension movements with maximum voluntary contraction on an inclined leg press. The trials were conducted with preceding administration of caffeine containing coffee (CAF) and decaffeinated coffee (DECAF). 45 minutes prior to exercise each subject got 4-5 mg CAF or DECAF/kg body weight. Subsequently they performed dynamic leg extension movements with different loads and isometric movements with fixed skid of the leg press. In accordance with the wash-out phase, > 1 week, the subjects ingested the opposite substance (CAF or DECAF) and passed the test protocol a second time. By using nonlinear parameter identification, neuromuscular properties - for getting FV of the muscle - were determined from a model of the movements (Siebert et al., 2007). Results In the CAF compared to the DECAF conditions an increase of the maximum isometric force ($20.3 \pm 12.1\%$, $p = 0.0008$) and of the maximum power output ($22.8 \pm 19.4\%$, $p = 0.01$) of the knee extensors could be observed, whereas in the activation of the muscle no effect could be measured. The FV of all subjects showed increased forces below optimal velocity. At higher velocities a decrease of force was observed for one third. Discussion Hodgson et al. (2013) found no differences between caffeine and coffee on muscle force. According to Park et al. (2008), the preceding administration of caffeine leads to higher maximal voluntary isometric force during muscle contraction. The particular impact of caffeine and the individual initial neuromuscular properties could explain the widely varied influence on the FV. The initial state reflects the fiber distribution and the efficiency of the muscle. Therefore, a follow-up study to investigate the dependence of caffeine induced effects on the initial state of the muscle and to establish a mathematical model has already started. SENSITIVITY OF THE FORCE-VELOCITY RELATIONSHIP OF LEG EXTENSORS OBTAINED FROM LOADED AND UNLOADED VERTICAL JUMPS

Jaric, S.

University of Delaware

SENSITIVITY OF THE FORCE-VELOCITY RELATIONSHIP OF LEG EXTENSORS OBTAINED FROM LOADED AND UNLOADED VERTICAL JUMPS Introduction Recent research suggests that maximum performance multi-joint movements could reveal a fairly strong, linear force-velocity (F-V) relationship (Bobbert, 2012; Samozino et al. 2012; Yamauchi et al. 2009) instead of the classical hyperbolic one (Hill, 1938). The aims of the present study were to assess the pattern of F-V relationship and its sensitivity across different F and V variables and different types of vertical jumps performed by two distinctive subject groups. Methods Twelve sedentary men and 12 strength-trained men performed maximum vertical jumps with and without arm swing that were either loaded or unloaded by constant external forces of up to 30% of their body weight. Both the maximum and averaged F and V data were recorded. The regression parameters of a linear F-V model [i.e., F- (F0) and V-intercepts (V0) and the calculated maximum power P (Pmax)] were further analyzed. Results The observed F-V relationships proved to be strong and approximately linear across the jump and variable types and in both the sedentary and strength-trained subjects (median correlation coefficients ranged .82-.94 and .75-.96 respectively). Both F0 and Pmax revealed markedly higher values in strength-trained than in sedentary subjects (all $p < .01$) and for maximum than for averaged values of F and V (all $p < .01$). However, the differences in V0 across the variables and jumps, as well as the differences in all parameters between the two jump types remained small and partly insignificant. Discussion The results suggest that the F-V relationships of leg muscles can be modeled by a linear regression even when both positive and negative external loads are applied to obtain different F and V data. The model proved to be not only sensitive to detect the population-specific differences, but also applicable to both the jumps performed with and without arm swing, as well as when either averaged or maximum values of F and V are used. Based on both previous (Yamauchi et al. 2009; Nikolaidis 2012; Samozino et al. 2012) and present findings, we conclude that the assessment of the linear F-V relationship obtained from the loaded vertical jumps could be developed into a standard method for testing the force, velocity and power generating capacity of leg extensors. HARDNESS COMPARISON OF TISSUE-MIMICKING MATERIALS MEASURED USING DIFFERENT TYPES OF MUSCLE-HARDNESS METERS

Murayama, M.1, Nagaoka, M.K.1, Uchiyama, T.1, Yoneda, T.2

(1: Keio Univ., 2: Juntendo Univ. (Japan))

Purpose: Changes in muscle hardness could be caused by changes in muscle tension and/or volume from intense exercise. There are many commercial muscle hardness meters, and a hand-held type that uses indentation is commonly applied. However, these devices have inconsistent parameters, including the units used for measurement and the amount of indentation applied. Most hand-held devices utilize a small amount of indentation. The purpose of this study was to compare the measurements taken with a muscle hardness meter with a large indentation and hand-held-type muscle hardness meters. **Methods:** A large-indentation-type muscle hardness meter, TK-HS100 (TK) (Tokushu-keisoku, Japan; indentation: 20 mm), was used as the basis for the comparison. The following hand-held-type muscle hardness meters were also used: PEK-1 (PK) (IMOTO MACHINERY, Japan; indentation: 10 mm max), NEUTONE TDM-Z1 (NT) (TRY-ALL, Japan; indentation: 3 mm), and M123KNT-5 (MK) (Shiro sangyo, Japan; indentation: 5 mm). Commercially produced tissue-mimicking materials, so called "phantoms" (OST, Japan), were used for the experiments. The Young's moduli of the phantoms were 15 (Y15), 30 (Y30), and 50 kPa (Y50). To simulate the human body, Y15 (thickness: 5 mm) was placed on top of Y30 or Y50 (thickness: 50 mm). Thus, Y15 was used to simulate subcutaneous tissue (soft), whereas the bottom phantom simulated muscle (hard). Additional phantoms covered in pig leather were also prepared. The hardness values of the one- and two-layer phantoms (Y15, Y30, Y50, Y15 + Y30, and Y15 + Y50) and the leather covered phantoms (L + Y15 + Y30 and L + Y15 + Y50) were measured using four different muscle hardness meters. In the two-layer and covered phantoms, the hardness measurements targeted the bottom phantom used to simulate the muscle. **Results and Discussion:** In the two-layer phantoms, the hardness value measured by the TK device was nearly equal to the Young's modulus of the target phantom: Y30 or Y50. However, with the MK hand-held device, the hardness value was closer to that of Y15 than to that of Y30 or Y50. Furthermore, the readings obtained with the PK and NT devices were quite different from the hardness values of the phantoms. With the covered phantoms, the hardness values were higher than those obtained for the two-layer phantoms. The hardness measured by TK were overestimated compared with the target phantoms. It seemed that the leather covering increased the tension and resisted the indentation, even though the phantom was a relatively soft material. Nevertheless, PK, NT, and MK underestimated the hardness values. These findings showed that the hand-held devices could not detect the hardness of the bottom-layer phantom because of the small amount of indentation. Contact: murayama@z3.keio.jp

GASTROCNEMII STRUCTURE AND SPECIFIC TENSION IN CLAUDICANTS WITH PERIPHERAL ARTERIAL DISEASE

O'Brien, T.D.1,2, King, S.L.1,3, Vanicek, N.3

1: Liverpool John Moores University, UK 2: Bangor University, UK 3: University of Hull, UK

Introduction Peripheral arterial disease (PAD) is a chronic, atherosclerotic disease and often presents with intermittent claudication (IC): muscle pain brought on by muscular activity due to reduced oxygen supply and metabolite removal. PAD-IC most commonly affects the lower limbs in the elderly, limiting mobility and physical activity. The combination of disease and disuse likely impacts on muscle size, structure and quality (specific tension; ST). These musculoskeletal characteristics are important determinants of muscle strength and physical function, both of which are known to be reduced in PAD-IC (McDermott et al., 2008). The aims of this study were to determine whether the 1) size and structure, and 2) specific tension of the gastrocnemii muscles were altered with PAD-IC. **Methods** The muscle (ML), tendon (TL) and fascicle (FL) lengths and pennation (θ) were measured at rest and during isometric MVC at optimum ML in the lateral (GL) and medial gastrocnemius (GM) of 10 controls, 7 uni-lateral and 6 bi-lateral claudicants, using ultrasonography. Volume and physiological cross sectional area (PCSA) were calculated for a combined gastrocnemii group (GS). Joint MVCs were corrected for voluntary and antagonist activation and moment arm length, and were normalised to GS PCSA to calculate ST for the combined muscle group. Between-group differences were analysed using an ANOVA. Pearson's correlations were used to determine associations between disease severity, assessed using ankle:brachial pressure index, and musculoskeletal parameters. **Results** No significant differences were found

between groups for any structural or functional variable. With increasing disease severity, TL decreased ($R=0.59$, $p=0.02$) and GL and GM FL relative to TL increased ($R=-0.70$, $p<0.001$). Trends towards reduced GS PCSA ($R=0.50$, $p=0.06$) and GL θ ($R=0.35$, $p=0.16$) were evident. No relationship existed between disease severity and plantarflexion MVC ($p=0.74$) or GS ST ($p=0.85$). Discussion Increasing severity of PAD-IC resulted in altered muscle-tendon structure; muscle and fibre length increased and tendon length reduced. Such adaptations may reduce the energy cost of active length changes, thereby attenuating the functional losses in an ischemic environment. The apparent lack of between-group differences in gastrocnemii structure may be due to a masking effect caused by the range of disease severity. In addition, the lack of an association between disease severity and ST suggests intrinsic muscle "quality" is preserved despite clear clinical progressions in disease. Therefore the "quality" of the muscle should not be a limiting factor in the strength, function and response to training of claudicants. References McDermott et al. (2008) J Am Ger Soc, 56, 724-9

INDIVIDUAL DIFFERENCES IN MUSCLE ACTIVATION DURING ISOKINETIC MOVEMENTS WITH DIFFERENT LOADS

Thaller, S., Höher, P., Penasso, H.

University of Graz

Introduction For many studies of the effects of physical exercise in training processes or therapy it is necessary to exert an utmost similar stress to the muscle. Often this stress is quantified by the load or, already individualized, by a certain percentage of the isometric force fiso. Previous studies (e.g., Penasso et al. 2013) showed that even in normalized movements there are large differences in the power and force production and thus in the muscle stress. Aim of this study is to access the individual differences in the activation of the knee extensor muscles for isokinetic knee extension movements due to individual force-velocity relations FV. We investigated movements with loads normalized to fiso and to the relation between the optimum force fopt (e.g., the force at maximum power output) and fiso. Method The individual FV of the knee extensors of 7 male subjects (24 ± 1.8 yrs, 180 ± 0.6 m, 75 ± 7.6 kg) were determined according to Siebert et al. (2007). Using these data we simulated isokinetic movements with external velocities EV 0.6 m/s and 1 m/s on a vertical leg press with loads normalized to a) 70% fiso, and b) 150% fopt. We calculated the muscle force via the force on the leg press and the individual geometrical relations, e.g., leg lengths, knee angle, pinnation points. By comparing this muscle force with the force of MVC-activated muscles due to FV we determined the percentage of activation of the involved muscles as a function of time, A(t). For accessing individual differences in the activation we calculated the maximum activation MA, the integrated activation $IA = \int A(t)dt$, and the average activation AA, defined as IA divided by the total time of the movement. Results fopt varied between 30% and 40 % of fiso ($35.9\% \pm 3.48\%$). For all subjects, A(t) decreased after a short acceleration phase, and increased for contraction velocities larger than vopt. A(t) ranges between 21% and 100%. For EV 0.6m/s the values for MA, IA, and AA were a) $76\% \pm 14\%$, $13\% \pm 10\%$ s, $49\% \pm 7\%$, and b) $80\% \pm 13\%$, $13\% \pm 10\%$ s, $52\% \pm 7.3\%$. For 1m/s we got a) $91\% \pm 5\%$, $13\% \pm 10\%$ s, $62\% \pm 7\%$, and b) $95\% \pm 7\%$, $19\% \pm 6\%$ s, $66\% \pm 9\%$. Discussion The fraction fopt/fiso in the muscle describes the shape of the FV and therefore the efficiency, and is related to the fibre distribution. Thus, vopt plays an important role in A(t). Despite the differences in vopt and fopt/fiso, normalizing the load to fopt does not lead to less variation of the activation for both EV. For getting comparable percentages of activation it is therefore necessary to take the whole information of FV into account via individualized modelling. BODY ADIPOSITY INDEX IS NOT RELATED TO BLOOD PRESSURE IN NORMOTENSIVE BRAZILIAN MEN AND WOMEN

Dutra, M., Martins, K., Xavier, E., Jacó, B., Gomes, R., Reis, D., Santos, D., Santos, E., Souza, A., Cêzar, D., Barreira, D., Araújo, P.

Technical School of Health of Planaltina

Introduction Recently, Bergman et al. (2011) suggested a new body adiposity index (BAI) calculated from measurements of the hip circumference and height. This index showed a significant correlation with body fat measurement by dual-energy X-ray absorptiometry in both African-Americans and Mexican Americans. However, it remained to be seen whether the BAI is equally useful in predicting health outcomes. Therefore, the aim of this study was to analyze correlations among anthropometric indexes and systolic (SBP)/diastolic (DBP) blood pressure. Methods Two hundred and seventeen men and women (42.2 ± 10.4 years) from the community of Planaltina (Federal District, Brazil) participated in the study. Anthropometric measures analyzed were weight, height, Body Mass Index (BMI), BAI, Waist Circumference (WC) and Waist-to-hip ratio (WhR). SBP and DBP were measured through auscultatory method. Spearman test was conducted to analyze correlations. Results Mean values for BMI, BAI, WC and WhR were, respectively, 27.0 ± 4.4 kg/m²; $29.8 \pm 5.1\%$; 87.7 ± 12.3 cm and 0.87 ± 0.08 . SBP and DBP (mmHg) mean values were, respectively, 119.7 ± 14.7 and 78.0 ± 10.4 . Correlation coefficients (all $p<0.01$) for BMI with SBP and DBP were, respectively, 0.35 and 0.39. For WC with SBP and DBP were, respectively, 0.37 and 0.42. For WhR with SBP and DBP were, respectively, 0.33 and 0.32. BAI did not correlate to blood pressure. Discussion Although Bergman et al. (2011) found that BAI is a good predictor of adiposity, the results of this study suggest that BAI may be less useful than BMI, WC and WhR to assess cardiovascular risk. Previous work has shown similar results (Snijder et al. 2012). The absence of correlation found between BAI and blood pressure could be because the BAI formula calculates the index of adiposity based on hip circumference alone, which represents subcutaneous fat. On the other hand, central obesity (WC) seems to be the main focus of the association of anthropometric measures and cardiovascular risk (Lima et al. 2012). Since only tape measurement is required, WC may be even better than BMI or BAI, when a simple and practical indicator of cardiovascular health risk is required. DOES THE TIME OF THE DAY OF FOOD INTAKE INFLUENCE BODY COMPOSITION IN TRIATHLETES?

Ghiani, G.1, Tocco, F.1, Marongiu, E.1, Sanna, I.1, Pusceddu, M.1, Loi, A.1, Pinna, V.1, Lantini, T.1, Angioni, G.1, Concu, A.1, Crisafulli, A.1

University of Cagliari 1: Department of Medical Sciences, Sport Physiology Lab., University of Cagliari (Italy)

Introduction It is well known that athletic performance and recovery are both enhanced by optimal nutrition. It is also known that breakfast is the most important meal of the day, and that the time of the day influences overall daily food intake in humans (De Castro 2004). Despite this fact, Italian breakfast is usually quantitatively poor, providing less than 20% of the total intake. Moreover, breakfast skipping is highly prevalent in Europe (Rampersaud et al. 2005). The aim of this study was to counsel a proper diet and a rich breakfast, providing 30% of daily needs, in a group of recreational male Ironman and to check whether this had an impact on their Fat Mass (FM), as Ironman athletes take advantage from low body fat (Knechtle et al. 2011). **Methods** Six recreational male Ironman triathletes, who were in the preparing season and trained for about 20 hours per week, participated in the study. To assess their energy expenditure, each of them wore Sensewear Armband (SWA) for 48 hours (Casiraghi et al. 2013). They also attended an interview about their usual diet. Then, they were given a proper diet, both in terms of calories and nutrients. The given diet provided 30% of total daily intake at breakfast, that was different from their usual one, which provided less than 20%. For each subject FM was detected three times by mean of plicometry before starting the diet and every three months (Durnin and Womersley, 1974). **Results** Data collected from SWA emphasized that their energy requirements were very high (average 3200 ± 484 Kcal/day), because of a high physical activity level (average value 1.85 ± 0.22). After starting the diet the participants reported a better feeling of wellness and energy, and modified their body composition reducing their FM significantly (FM T0 11.47 ± 2.36 Kg, FM T3 8.95 ± 2.21 Kg, FM T6 9.47 ± 2.54 Kg, $p < 0.05$), but preserving their free fat mass. **Discussion** Taking into account that Ironman training highly recruits the energetic sources of athletes, it is possible to speculate that this richer breakfast had influenced their body composition changes. Further investigations are needed to better clarify this point. **References** De Castro JM. (2004). J Nutr, 134(1), 104-11. Rampersaud GC, Pereira MA, Girard BL, Adams J, Metz J. (2005). BODY COMPOSITION CHANGES AND ENERGY COST OF RUNNING IN AMATEUR ATHLETES

Tocco, F.1, Ghiani, G.1, Marongiu, E.1, Sanna, I.1, Melis, F.1, Angioni, G.1, Lantini, T.1, Pinna, V.1, Migliaccio, G.M.2, Loi, A.1, Pusceddu, M.1, Concu, A.1, Crisafulli, A.1

1: Department of Medical Sciences, Sport Physiology Lab., University of Cagliari (Italy), 2: Italian Regional Olympic Committee, Sardinia, Italy

Introduction It is well known that distance runners (DR) with the lowest body mass (BM) generally achieve the best results. This is probably due to the fact that generating force to support BM is the primary determinant of the metabolic cost of running (Cr). Moreover, a low percentage of fat mass (FM) characterizes DR and plays a pivotal role on their performances. Considering that the knowledge of relationships between body composition (BC) and Cr is scarce, we tested the hypothesis that Cr could decrease by modifying BC with a combined protocol of specific diet and training. **Methods** 47 normal-weight subjects were enrolled. They were divided in three groups: the first group attended a dietary protocol (A), the second a running program (B) and the last one, both (C). A personalized diet was provided to groups A and C (15% from proteins, 55% from carbohydrates and 30% from fats) and the groups B and C performed a running program of about 30-40 km per week. Athletes underwent to anthropometric measurements (Durnin and Womersley, 1974) and an exercise test at the beginning of the study (T0) and on the 3rd (T3) and 6th (T6) month after T0, in way to assess BC and Cr changes. Cr was assessed by means of O₂ uptake (VO₂) measured during a run at 10 km•h⁻¹ on the treadmill. **Results** Preliminary data (35 out of 47 subjects) show that the mean Cr values of 3 groups were modified from 1.06 ± 0.06 to 1.02 ± 0.14 Kcal•kg⁻¹•km⁻¹ for A ($p > 0.05$ T0 vs. T6), from 1.03 ± 0.09 to 0.94 ± 0.08 Kcal•kg⁻¹•km⁻¹ for B ($p < 0.01$ T0 vs. T6) and from 1.04 ± 0.09 to 0.95 ± 0.11 Kcal•kg⁻¹•km⁻¹ for C ($p < 0.05$ T0 vs. T6). The mean FM values were reduced from 13.3 ± 4.8 to 11.42 ± 4.7 kg for A ($p > 0.05$ T0 vs. T6), from 12.25 ± 3.4 to 11.36 ± 2.6 kg for B ($p < 0.01$ T0 vs. T6) and from 11.64 ± 4.05 to 9.65 ± 3.47 kg for C ($p < 0.001$ T0 vs. T6). **Discussion** Only B and C groups showed Cr and FM values significantly diminished from T0 to T6. Moreover, diet seems to have any effect on Cr since no difference was found between B and C groups. Taking into account that the current data are not definitive, they suggest that Cr was probably due to specific adjustments induced by running only. A recent research (Taboga et al., 2012) shows that, in obese subjects, the Cr seems to be independent with respect to BM increments, probably because elastic tissue can adapt maintaining its ability to store elastic energy. **References** Durnin JV, Womersley J. ERRORS IN THE ESTIMATION OF BODY COMPOSITION INDUCED BY HYPOHYDRATION

Rodriguez, N., Galloway, S.D.R.

University of Stirling

INTRODUCTION Dual energy X-ray absorptiometry (DXA) is a popular tool to determine body composition (BC) in athletes, and is increasingly used for whole body and segmental analysis of lean mass or fat mass gain/loss in response to exercise or nutritional interventions. Previous studies with athletes have assessed the effect of daily activities, exercise and meal intake on DXA estimates of BC in athletes (Nana et al., 2011, 2013). The aim of the present study was to assess the effect of exercise-heat stress induced hypohydration (HYP, > 2% of body mass (BM) loss) vs. maintenance of euhydration (EUH) on DXA estimates of BC, sum of skinfolds (SF), and impedance (IMP) measurement in athletes. **METHODS** Competitive athletes (23 males and 15 females) recorded morning nude BM for 7 days prior to the first main trial. Measurements on the first trial day were conducted in an overnight fasted and EUH condition (2hrs after ingestion of 500ml water), and then again after a period of exercise-heat stress aimed at inducing HYP of $\geq 2\%$ of the initial BM. During a second trial day, we repeated the first trial day but fluid and electrolyte losses and estimated energy/glycogen usage were replaced during the exercise period using a carbohydrate-electrolyte sports drink (Gatorade) to maintain BM in a EUH state. **RESULTS** A reduction in total BM (1.6 ± 0.4 kg; $2.3 \pm 0.4\%$ HYP) and total lean mass (1.3 ± 0.4 kg), mainly from a reduction in trunk lean mass (1.1 ± 0.5 kg), was observed using DXA when participants were HYP. Fat percent increased ($0.3 \pm 0.3\%$), however, total fat mass did not change (0.1 ± 0.2 kg). SF and IMP dropped on the HYP trial (losses of $1.5 \pm 2.9\%$ and $1.6 \pm 3\%$ respectively). When athletes replaced fluid losses during the exercise-heat stress, DXA estimates of BC and SF did not change from pre to post exercise. However, IMP demonstrated a reduction from pre to post exercise on

the EUH trial. **DISCUSSION** With exercise-heat stress induced HYP we observed a considerable significant reduction in total tissue and lean mass determined by DXA reflecting the sweat loss. Changes in BC by region revealed the main loss with HYP was localised to the trunk lean mass. Losses in SF and IMP with HYP incorrectly suggest fat mass loss. When EUH was maintained there were no significant changes in BM, DXA estimates, or sum of SF values pre to post exercise, but IMP still declined. Use of DXA for lean mass assessment must scan athletes in a EUH state. This is particularly important when considering changes with nutritional or exercise interventions. **REFERENCES** Nana, A., Slater, G. R., Hopkins, W. G., & Burke, L. M. NUTRITIONAL KNOWLEDGE AND ATTITUDES TOWARDS HEALTHY EATING OF COLLEGE –GOING MALE ATHLETES OF HARYANA STATE.

Rathee, B.

Maharishi Dayanand University Rohtak

Introduction: Haryana is one of state in India where sports is taken on war footing. Haryana has produced significant numbers of international players in wrestling, boxing and athletics. Sports performance is largely depend upon good nutrition. Many studies quote that athlete have very limited knowledge of nutrition and athlete do not use their knowledge in making proper food choices. Keeping in view of this the study based food nutrition has been carried on M.D.University sports students. **Method:** A well structured questionnaire design to assess nutritional knowledge and attitude of male athlete of various athletic events. The questionnaire was developed using carefully selected questions from questionnaires created by Barr (1986) and warblow et al.(1978) Reliability ($r=0.82$) and construct validity have been determined for the questionnaire by Barr(1986) Few questions were modified to assess the components of nutritional knowledge and attitude of the Haryana male athlete that were not addressed by the either questionnaire. A sample of 50 male athletes of various athletic events was selected on the basis of random sampling. The said well structured questionnaire was administered personally by the researcher. **Results:** The mean score of nutritional knowledge test was 42.83/85(50.38 correct) while incorrect and uncertain responses accounted for majority of answers, the lowest correct response were recorded for fat, energy and weight management (30.4, 35.6 and 32.2 respectively) the attitude towards gaining nutrition information was quite positive(94.5%) but a massive impact of family food habits was observed. This study suggests that athlete lack knowledge of nutrition, healthy food choices, and components of balance diet and role of nutrition on physical performance. **Discussion:** - Majority of the athlete under study were belonging to rural area. The academic levels of the subjects were poor and they believe more in traditional food that is rich in fat and sugar. Lack of education and interest in food science create hindrances in understanding the value of nutrition in sports. **References:** Vinti Davar 2012, nutritional knowledge and attitude towards healthy eating of college going women Hockey players *Journal of Human ecology* 37(2): 119-124(2012) Barr SI 1986, Nutritional knowledge and selected nutritional practices of female recreational athletes. *Journal of nutritional education*,18: 167-174 Barr SI 1987 Nutritional Knowledge of female varsity athletes and university students. *Journal of American Dietician Association*,87: 1660-1664

EXPLORING GENERAL AND SPORTS NUTRITION AND FOOD KNOWLEDGE IN ELITE MALE AUSTRALIAN ATHLETES

Belski, R., Devlin, B.

La Trobe University

Introduction: It is important for athletes to understand basic nutrition information and have a sound understanding of their energy and nutrient needs. This is particularly relevant with the recent controversy regarding Australian Rules Football (AFL) and supplementation/doping in the media. Minimal research has investigated the nutrition knowledge of elite athletes with no published research exploring the nutrition knowledge of AFL players. **Objective:** To gain insight into the current level of nutrition knowledge, both general and sports nutrition, in elite male AFL players. **Methods:** Forty six elite male AFL athletes (age 23.46 ± 2.75 years) participated in the study. Nutrition knowledge was measured using a questionnaire adapted from two previously validated tools. It contained 123 questions relating to five areas of nutrition knowledge: dietary recommendations, sources of nutrients, choosing everyday foods, alcohol and sports nutrition. **Results:** The total nutrition knowledge score was 74.37 ± 10.92 (60.46%). The athletes demonstrated good knowledge of broad nutrition messages including recommendations to increase intake of fruit and vegetables and decrease intake of fat. Confusion was evident regarding more specific recommendations. For example, the athletes are aware of what foods contain fat and that fat intake should predominately be made up of unsaturated fat, yet less than 25% correctly identified what foods contained the different types of fats. Despite being able to recognise foods containing carbohydrates, there was a lack of awareness of the amount of carbohydrate foods that should be consumed to meet requirements of an athlete. **Conclusions:** Overall results of nutrition knowledge of AFL players are similar to other published research, however there is a lack of awareness of key areas of nutrition that need to be addressed. Being aware of the level of nutrition knowledge in athletes will allow for sports dietitians to more efficiently improve knowledge with the hope of influencing intake and behaviour.

ANALYSIS OF BODY COMPOSITION AND SOMATOTYPE HIGH PERFORMANCE TO PLAYERS OF FOOTBALL CLUB PACHUCA

Lopez Roldan, A., Villalobos Vallejo, S., Delgado Cardenas, J.

Universidad del Futbol Y Ciencias Del Deporte

Introduction. Many sports have achieved a position within the global elite, through studies of the functional and morphological characteristics of biometric athletes such as body composition and somatotype each specialty or sports mode, either individually or collectively have a well defined specific kineanthropometric pattern. As he helped fend of this study to analyze young footballers Pachuca football team, in order to generate tools that will help us standardize ideality for their sport, achieving improve athletic performance. **Methods.** Descriptive, prospective and cross-sectional study. A total of 28 first team players football club pachuca was evaluated. ISAK the anthropometric method, full to assess each player profile was used. The assessment data were collected in payroll anthropometric data capture. Subsequently the data were processed and analyzed in the anthropometric software BodyMetrix®. Thus, the results of body composition in kilograms, percentage obtained the graphic representation in somatochart somatotype and quantitative component values were also obtained: endomorph, and ectomorphy mesomorphy. **Results.** It was found that the players have a percentage of 46.60 % of muscle mass, Fat mass of 24.60%, 11.40% residual mass, bone mass of 7.60% and 5.60% mass skin. Possess a dominant mesomorph somatotype balanced. Obtaining a endomorphy 2.69, Mesomorphy 4.60, ectomorphy 2.75. **Discussion.** The results of this study adhere a recent study by J. L. Arcodia (2010) determined the current Argentine footballer somatotype of 2.3-4.8-2.2 values being even more

similar to the diagnosed Players Club Pachuca, It was considered that the quantification of aspects of morphological and dietary constitution may lead to a better understanding of the relationship between the constitution and athletic performance, but we must emphasize that functional assessments should incorporate as physical capacities, which in conjunction with determining somatotype could ensure more accurate information on the morphological and functional status of the athlete, and identify their characteristics and consistent with the requirements of the sport (suitable somatotype), where the requirements for football involve a combination of gross motor skills and thin. The results are reference to find ideality in body composition and somatotype in high performance athletes with the firm intention of improving their performance and competitiveness. PREVALENCE OF RISK AND RISK FACTORS OF EATING DISORDERS AMONG MALE ADOLESCENT ATHLETES AND UN-TRAINED CONTROLS

Pustivšek, S., Hadžić, V.I, Dervišević, E.I

University of Ljubljana, Faculty of Sport

Introduction Eating disorders (ED) are serious and increasingly common condition among adolescent athletes and their untrained age-matched counterparts. Therefore, the purpose of this study was to examine risk factors and prevalence of risk for ED among adolescent male athletes and age-matched controls. **Methods** Athletes were representing 22 different sports (n = 228; controls n = 123), separated in to 3 different groups by dominant metabolic process. All participants were age 15-17 on the time of measuring. SCOFF questionnaire was used to determine risk for ED. Body composition was measured with InBody230. **Results** The highest percentage of risk for disordered eating (37.2 %) was found in aerobic group. 19.2 % of anaerobic athletes have already tried to lose weight more than three times. An improvement of sport results was the most common reason for dieting at athletes (19.6 – 44.2 %), and better self-esteem at controls (41.5 %). A higher number of controls compared with the athletes were defined as underweight according to BMI for age percentiles criteria. **Risk factors** for ED were different among groups. **Discussion** The higher prevalence of risk for ED in aerobic sports could due to the fact that extra body weight can limit performance. In contrast, a lack of difference in frequency of disordered eating was observed between anaerobic, aerobic-anaerobic and control group. This confirms findings of some studies on high school athletes which report no greater risk for the development of an ED than controls (1–3). Young athletes are perfectionists and extremely performance oriented and because of this they could be at increased risk for development of an ED (4). Recent study has already shown that adolescent athletes have better attitude to breakfast than controls (5). Our results showed that athletes in aerobic group have the best eating habits, according to breakfast and number of meals, compared with other athletes and controls. Releasing first meal of a day is for them the strongest factor which can increase risk for disordered eating (p = 0.028). Breakfast has been included as a risk factor for the first time and results has shown that it is the most important predictor in the aerobic group (p = 0.028). Trainers are still the main reason for dieting in adolescent athletes. **References** Fulkerson, J. A., Keel, P. K., Leon, G. R. & Dorr, T. (1999). *Int J Eat Disord* 26, 73–79. EFFECTS OF SPONTANEOUS PHYSICAL ACTIVITY AND FOOD CALORIE ON COGNITIVE FUNCTIONS OF THE RAT

Felszeghy, K.I, Pósa, A.2, Varga, D.2, Varga, C.2, Nyakas, C.I, Radák, Z.I

1: Semmelweis University ; 2: University of Szeged

Introduction It has been well established that both physical activity and calorie restriction elicit improving effect on learning and memory functions. On the other hand, high triglyceride content of the diet, as well as, inactive living style has several adverse physiological effects and negatively influences cognition. In the recent study rats were used to examine the impact of regular voluntary physical exercise on the cognitive performance of the animals. Moreover, the effect of the diet calorie content on the learning capacity was estimated by a well evaluated spatial learning task, the Morris water maze. **Methods** Adult male Wistar rats were separated into inactive and running groups. Inactive animals were placed by three into normal cages, while running animals were placed separately into cages containing running wheel that can be used voluntarily. Both groups were distributed further into three diet groups as follows: standard food consumed ad libitum as “control group”; calorie restriction consumed 25g standard food per animal as “calorie restriction group”, high triglyceride containing diet consumed 60% standard food and 40% grease as “high triglyceride group”. Following 12 weeks of treatments animals were tested in Morris water maze for spatial learning ability. **Results** A significant interaction was found between diet and physical activity concerning their effect on learning performance. Spontaneous running activity improved working memory (short-term memory) but weakened reference memory (long-term memory) of the control rats receiving standard food. Physical activity impaired the performance in calorie-restricted group. A considerable enhancement of working memory occurred following calorie restriction in inactive animals. Regular running activity improved working memory in animals received high triglyceride containing food leaving unaltered the reference memory function. **Discussion** Our results indicate that in inactive animals calorie restriction can enhance cognitive capacity, but induces impairment if a regular physical activity is present. High calorie intake strongly weakens cognitive performance in inactive animals, but results in less impairment together with regular running. Moreover, we can conclude that short-term memory is more sensitive to the alteration either in physical activity state or in diet than long-term memory. Contact kfelsz2008@gmail.com

THE QUIET EYE AND TASKS DEMANDS: DO TOUGHER SHOTS NEED A QUIETER EYE?

Walters-Symons, R., Wilson, M.R., Klostermann, A., Vine, S.J.

University of Exeter

The Quiet Eye (QE; Vickers 1996) has been shown to underpin successful performance, differentiating both expertise (inter-individual) and proficiency (intra-individual), with experts and successful attempts characterised by longer QE durations. The QE is proposed to reflect the time needed to organise and fine tune the parameters of movement (e.g. force and direction). In order to examine this prediction and build upon previous research we experimentally manipulated the difficulty of a golf putting task; we hypothesised that if the QE is related to motor programming then a more difficult task should be associated with longer QE durations. 33 golfers (M age= 21.16, SD= 3.98) with an average handicap of 6.5 (SD= 6.02) performed putts in 4 conditions of increasing difficulty. We manipulated the length of the golf putt (short-4ft, long-8ft) and the contact point of the putter head (large-1.7cm, small-0.5cm,) giving increasingly difficult putting conditions of short-large [1], short-small [2], long-large [3] and long-small [4]. We measured performance (radial error from hole in cm) and QE (in ms) for 10 putts in each condition. A repeated measures ANOVA was performed on the performance and QE data. The performance data suggest that we were successful in increasing the difficulty of the task ($F(3,93) = 26.46, p = .000$), with the best performance in condition [1] (8.57cm), followed by [2] (9.10cm) followed by [3] (16.11cm) and finally the worst performance was in condition [4] (23.40cm). The QE data suggest that, in keeping with our hypothesis, the QE was lengthened as task difficulty increased ($F(3,87) = 11.91, p = .043$). The QE was shortest in condition [1] (1787.85ms) and increased to condition [2] (1939.78ms) and condition [3] (2076.51ms), with the longest QE in condition [4] (2164.08ms). More detailed analysis of the QE reveal that it was the proportion of the QE that occurred before movement initiation (pre-QE) which increased with shot difficulty, rather than the proportion that occurred during the swing (Online-QE; see Vine et al., 2013). Results support the notion that more complex tasks are associated with a longer QE duration, specifically participants appear to spend longer fixating the target prior to movement. This likely reflects the time needed to process visual information gathered in a pre-performance routine, to inhibit external distraction, and to pre-programme the increasingly difficult parameters of the movement. INTERPERSONAL MECHANISMS EXPLAINING THE TRANSFER OF WELL- AND ILL-BEING IN COACH-ATHLETE DYADS

Stebbing, J., Taylor, I.M., Spray, C.M.

Middlesex University

Introduction. Recent cross-sectional research has indicated that coaches' psychological health may influence their interpersonal behaviour (Stebbing, et al., 2012) and considerable evidence exists to support the associations of such behaviour and athletes' psychological health (Bartholomew, et al., 2012). Indirect evidence from alternative contexts also alludes to a reciprocal process, whereby athletes' functioning and well-being may influence coach interpersonal behaviours (Taylor, et al., 2008), which, in turn, affects coaches' own psychological health (Deci, et al., 2006). Taken together, this research implies a transfer of well- and ill-being from coach to athlete (and vice versa) through interpersonal exchanges, yet this line of enquiry has yet to be addressed. **Method.** In a time-lagged design, 82 coach-athlete dyads from one of nine individual sports completed self-report measures of positive and negative affect before and after a single training session, and measures of perceived in-session coach autonomy supportive and controlling behaviours. **Results.** Structural equation modelling supported two actor-partner interdependence models, in which coaches' positive (negative) affect at the beginning of the session predicted athletes' perceptions of their coaches' autonomy supportive (controlling) behaviours during the session. In turn, these behavioural styles predicted athletes' positive (negative) affect at the end of the session, after controlling for athletes' pre-session levels. The transfer of positive and negative affect from athlete to coach was not fully supported by the data. Nonetheless, coaches' perceptions of their own autonomy supportive (controlling) behaviours were associated with their post-session positive (negative) affect after controlling for initial levels. **Discussion.** Evidence is provided for the transfer of positive and negative affect from coaches to athletes through interpersonal exchanges, but not vice versa. The key implication of the present research is to ensure that coaches are supported so that they can experience positive affect (and limited negative affect), in order to facilitate adaptive sport environments and the subsequent well-being of themselves and their athletes. **References.** Bartholomew, KJ, Ntoumanis, N, Ryan, RM, Bosch, JA, & Thøgersen-Ntoumani, C. THE RELATIONSHIP BETWEEN PLAYER OFF-FIELD LIFE AND ON-FIELD ENGAGEMENT

Pink, M., Saunders, J., Styne, J.

Australian Catholic University

Introduction There has been much anecdotal support from athletes and coaches in various professional sports indicating that engaging in interests outside of sport (i.e., maintaining a work life balance) in a supportive environment is beneficial for player engagement and performance. There has however been little quantitative evidence to either support or reject these links. The aim of the present study was to investigate professional AFL players' engagement in off-field activities, the support they receive to do so, perceptions of the adequacy of their free time, and how these variables might predict on-field engagement. **Methods** 430 professional Australian Rules football (AFL) players (M age = 22.93 years, SD = 3.35) were recruited for the study. Players completed a survey instrument which included the Athlete Engagement Questionnaire (AEQ; Lonsdale et al., 2007), The Athletic Identity Measurement Scale-7 (AIMS-7; Brewer et al., 2001), and

items developed concerning players' perceptions of club support for off-field life and the adequacy of their free time. In addition estimated time spent in social, recreational, and family based activities were recorded. Multiple hierarchical regression was used to identify those variables best able to predict athletic engagement. Results Players' perceptions of club support for off-field life, the adequacy of their free time, and time spent engaging in social activities predicted 13% ($P = < .05$) of the variance in players' athletic engagement scores after controlling for the strength of athletic identity and team success at the time of data collection. Discussion This study provides some initial evidence that clubs' support for players' off-field lives and the adequacy of players' free time are associated with professional AFL players' quality of on-field engagement. These results add some support to the argument for a beneficial link between the work life balance experienced by professional athletes and their on-field effort and performances. Players' perceptions of being supported in their off-field life and the adequacy of their free time were stronger predictors than simply the amount of time spent in non-football related activities. Although limited by its reliance on self-reported measures and the inability of cross-sectional analyses to show cause and effect relationships, the present study provides support for the notion that AFL clubs looking for a competitive advantage would be wise to continue to strengthen their support for players' off-field lives as part of a prudent high performance strategy. CHANGES IN PSYCHOSOCIAL STRESS AND RECOVERY AND INJURY OCCURRENCE: A ONE-YEAR PROSPECTIVE STUDY

van der Does, H., Brink, M.S., Lemmink, K.A.P.M.

Hanze University of Applied Sciences

Introduction Indoor team sport players have a high injury risk (Theisen et al., 2012). It is assumed that psychosocial stress and recovery have an impact on this risk (Jung, 2000). The aim of this study is to investigate if changes in psychosocial stress and recovery during the course of a season are related to injury occurrence. Methods During the 2011-2012 competitive season 66 male and female indoor team sport players (age: 22.2 ± 3.4 yr, length: 189.2 ± 10.7 cm, weight: 82.9 ± 13.0 kg) participated in this study. To assess psychosocial stress and recovery the players completed the Dutch version of the RESTQ-Sport (Nederhof et al., 2008) every three weeks. Difference scores were calculated for each three-week period for the 19 subscales of the RESTQ-Sport. Injuries were registered during the course of the season by the medical staff of the team according to the FIFA registration system (Fuller et al., 2006). Comparisons were made between injured and non-injured players for the mean difference (Mdiff) scores on the 19 subscales of psychosocial stress and recovery. The mean difference was taken over the two 3 week periods before the injury for the injured players and the mean difference over the remaining periods was taken for the non-injured players. Results Fifty-three injuries (80%) were reported, resulting in an average of 15.6 days of medical attention and 16.7 days of time loss. A significant ($p < 0.05$) larger decrease in perceived "fitness/being in shape" was found for injured players (Mdiff = -0.203, SD = 0.78) over the 3 weeks before the injury compared to the non-injured group (Mdiff = 0.003, SD = 0.73). The other 18 subscales showed no difference between injured and non-injured players. Discussion Three weeks before the occurrence of an injury, players perceive a decreased fitness and felt less in shape. It seems that players already felt discomfort but still participated in sport until they were forced to quit. As a result, injuries may become more severe and lead to more time loss. The RESTQ-Sport seems a useful tool to track changes in stress and recovery and detect players at risk, which makes it possible to prevent them from becoming injured. INFLUENCE OF "ACOUSTIC AND VISUAL PACESETTERS" ON PERFORMANCE

Lecce, D.1, Cortis, C.1, Sanuheza Alfaro, S.P.1, Fattorini, L.2, Pasquali, M.2, Rodio, A.1

1 University of Cassino and Lazio Meridionale; 2 Sapienza University of Rome

Introduction: Appropriate acoustic stimuli may induce ergogenic effects or decrease the perception of fatigue during exercise (1). Before the exercise, the listening music can be used to improve performance modifying the motivational state (2). Furthermore, it has been demonstrated that music tempo matching with the exercise cadence can induce an auditory-motor synchronization that optimize exercise efficiency (3). Besides acoustic, the visual stimuli have been also proven capable to improve the tolerance of high intensity exercise (4). The aim of this study was to assess the influence of acoustic and visual pacesetters synchronized with exercise cadence with regard to energy expenditure. Methods: Seven healthy male subjects (age: $30 (\pm 3.74)$ yrs; height: $177 (\pm 6.63)$ cm; weight: $79.29 (\pm 7.63)$ kg) were enrolled and underwent to a 30 minutes exercise at constant speed on a cycloergometer at a workload intensity corresponding to 70% of the ventilatory threshold. Energy expenditure was evaluated in 3 experimental conditions: ASEPTIC (AS), no stimulus; ACUSTIC (AC), sound at 120 beat per min; and VISUAL (VS), image sequence at 120 frames per min. In all trials, $\dot{V}O_2$ was measured breath by breath by means a metabolimeter (K4b2, Cosmed, Rome, Italy). Results: The total oxygen consumptions ($\dot{E}E_{tot}$) calculated as $\dot{V}O_2 \times 20.1$, scaled by body mass, were: $569 (\pm 108.9)$ ml/kg, $532 (\pm 97.6)$; $521 (\pm 110.8)$ ml/kg; $526 (\pm 97.9)$ ml/kg in AS, AC, VS respectively. Statistical analysis showed that $\dot{E}E_{tot}$ in AC and VS were different by AC. In particular 93.70% (± 3.83) and 92.64% (± 4.02) were the percentage of $\dot{E}E_{tot}$ in AC and VS when compared with AS. Discussion: The effect of acoustic or visual pacesetters on $\dot{E}E_{tot}$ in a speed constant cycling exercise at submaximal workload was evaluated in comparison with a same exercise without stimuli. In particular, it was obtained that the subject's engage decrease when a rhythmic stimulus, acoustic or visual, is present. The results of this study could be used for the development of new training modalities and tool. Reference: 1) CI Karageorghis et al. ASSESSING BIOLOGICAL MATURITY IN YOUTH FOOTBALL - PSYCHOMETRIC PROPERTIES OF THE MATURITY OFFSET-PROTOCOL

Votteler, A., Höner, O., Murr, D.

University of Tübingen

Introduction Performance advantages of relatively older and biologically more mature players hinder fair and efficient talent selection and development (Votteler et al., 2013). Since coaches' rating of biological maturity is imprecise, more objective and reliable methods are necessary. The assessment of skeletal maturity is too costly for large samples in nationwide talent development programs. Therefore, measuring age at peak height velocity (PHV) with the maturity-offset-protocol (Mirwald et al., 2002) appears to be a useful alternative. This study evaluates the method's psychometric properties and its utility for coaches in a football talent development program. Methods On two occasions (average timespan 5 months), the PHV of 415 selected players from the age groups U11 to U14 was calculated with the maturity offset-protocol. Additionally, biological maturity was subjectively rated by players' coaches. Test-retest-reliability was analysed with Pearson correlation. Absolute stability was analysed with a repeated measures ANOVA and Blend-Altman plots. Validity was examined with Spearman rank correlations between absolute maturity-offset (years from PHV) and growth velocity of height, as well as between PHV and coaches' ratings. The distribution of PHV-categories (early mature, normal, late mature) was evaluated with regard to the utility of the maturity-offset-protocol for coaches. Results The test-retest-reliability of PHV was high ($r=.95^{**}$). Differences in PHV between age groups ($\eta^2=.27^{**}$) and measurement points ($\eta^2=.24^{**}$), as well as a 0.1 year mean difference in the Blend-Altman plot, proved limited absolute stability. Moderate correlations between maturity-offset and height growth velocity ($r=-.40^{**}$) as well as between PHV and coaches' rating ($r=.44^{**}$) indicated only acceptable validity. A small variation of PHV ($SD=.52$) led to a narrow distribution of PHV-categories with only 2.7% of players being categorised as early or late maturing. Discussion The maturity offset-protocol provides a simple method of acceptable validity for the diagnostics of biological maturity in talent development programs. Due to the low absolute stability of PHV (Malina et al., 2013), and a narrow distribution of PHV-categories in homogeneous samples of selected players, the utility for coaches is low. Consequently, the more reliable methods of skeletal maturity should be used for smaller samples. In large samples, coaches should be better educated concerning the subjective diagnostics of biological maturity. References Malina, R, Koziet, SM. (2013). *J Sport Sci*, in press. WHAT IS THE TEMPORAL BODY?

Hogenova, A.

Charles University

Science describes the spatial body very accurately. It takes time into consideration but it is Aristotelian time, successively, moving forward and divided into the past, present and future. However, it is far more important to understand temporality in relation to the body. What is temporality? As this publication repeatedly explains, temporality is the present, containing a substantial history, which lays out the future in connection with a searing present. The body is temporal, i.e. it has a substantial history (die Gewesenheit), which with the present lays out our future. At first glance, this is an exaggeration. In the body we carry our past yields in the forms of protention and noesis like a filter through which our future opens up to us. In other words, it would not be an entire coincidence if we fell off a cliff which we often climb because we are climbers, as it is something predisposed in our desire to climb the cliff and reach the optimal life position, it belongs to us. Just as we carry this falling off the cliff within us, we also carry the seeds of future illnesses. They are not due to causes that have arisen in the present. Long ago we were destined to get these illnesses. Our body in connection with the soul is predisposed to disease. Why? Because the layout of a situation is predetermined in our essential orientation. EXTERNAL FOCUS OF ATTENTION ENHANCES MOVEMENT AUTOMATIZATION

Kal, E.1,2, Van der Kamp, J.2,3, Houdijk, H.1,2

1. Heliomare R&D, Wijk aan Zee, The Netherlands 2. Research Institute MOVE, FBW-VU, Amsterdam, The Netherlands 3. Institute of Human Performance, University of Hong Kong, Hong Kong

Introduction Ample evidence shows that focusing attention on movement effects (i.e. external focus) results in superior motor performance compared to focusing on movement execution itself (i.e. internal focus; Wulf, 2013). The underlying mechanism remains unclear, however. A possible explanation is provided by the constrained action hypothesis. This holds that an external focus enhances automatic motor control, whereas an internal focus induces conscious control of movement. Automatically controlled movements are more robust to dual-task interference, are executed more fluently and with higher regularity, and require less EMG activity compared to consciously controlled ones. A similar pattern of results should therefore be observable for movements performed with an external compared to an internal focus. This study set out to test these predictions. Methods Thirty healthy adults (25 ± 7 years) performed a cyclic one-leg extension-flexion task at a comfortable pace for one minute. Four trials were performed with each leg; 1 single and 1 dual-task trial with an internal focus, and 1 single and 1 dual-task trial with an external focus. Attentional focus was manipulated via instructions. The cognitive dual-task was a letter fluency task. Movement automatization was assessed by measuring dual-task costs (DTCs), EMG activity, movement fluency (dimensionless jerk), and movement regularity (sample entropy). Lower DTCs and EMG activity, and higher movement fluency and regularity indicated more automatized movements. Results An external focus led to significantly better motor performance (i.e., shorter movement duration), lower cognitive DTCs and more fluent and regular movement execution than an internal focus. No differences were found in EMG activity. Discussion An external focus of attention resulted in superior motor performance and enhanced movement automatization compared to an internal focus, thus providing strong evidence for the constrained action hypothesis. Overloading working memory by attempting to consciously control movements is often considered to underlie choking under pressure. In this light, providing learners with internally referenced instructions and feedback may both result in suboptimal skill acquisition as well as an increased risk of skill breakdown in high-pressure and dual-task situations. MO-SH13 Psychological Interventions

INVESTIGATE THE EFFECTS OF IMAGERY PRACTICE TO SKILLS DEVELOPMENT FOR THE BRANCH OF VOLLEYBALL PLAYERS

Elçi, G., Ağbuğa, B.

Institute of Health Sciences

Elçi, G.1, Ağbuğa, B.2 1: Bartın University, (Bartın, Türkiye), 2: Pamukkale University, (Denizli, Türkiye) Introduction Affecting the development of physical performance are many psychological skills. One of them is the ability of the imagination (Konter, 2006). Imagination of the most well-known use of the area is the development of sports skills and to learn. In the mind of the athlete's specific sport skills development is important for the application several times (Vealey and Walter, 1993). The aim of this study is to determine the effects of eight weeks imagery practice to skills development for 15-18 years volleyball players. Methods Sixty six athletes (age=16.27±0.90) participated in Bartın City. Athletes are grouped into four different groups according to their age of sport. Groups are scattered into "Control Group (n = 16)", "Imagery Group (n = 17)", "Training Group (n = 16)" and "Imagery & Training Group (n = 17)". Prepared by the researchers, "The Observation Table of Tennis Serve" is used as a data collection tool. Pattern of the study is pre-test – post-test control group. The athletes, before the starting eight weeks imagery practice, recorded their tennis serve videos, and three different volleyball trainers were watched scoring in the range of "1" to "5" points. At the end of the eight week imagery practice, post-test was recorded and watched for scoring by the same trainers. Descriptive statistics, the One-Way Analysis of Variance and the ANOVA of Repeated Measures tests were performed for data analysis. Results According to research results, significant differences weren't found between pre-test and post-test measurements. In addition, there was a significant difference between pre-test and post-tests without looking groups separation. As a result, practice of imagery provided a development for the age of between 15-18, however it is not significantly meaningful when it compares with other practices. Discussion Service skills in volleyball competitions to win an important technique in many studies that have been mentioned (Marcelino et al., 2005). Tennis service of the development of skills, examination and imaging studies did not show any difference compared to other applications. As a result of this study is similar to the implemented of the imaging studies to become a skill and gain in performance that can be achieved tangible success that you should take the time considered (Hall, 2001). IMPLICIT THEORIES OF MENTAL TOUGHNESS AMONG ADOLESCENT NETBALLERS

Daniel Gucciardi, F., Jackson, B., Hodge, K., David Anthony, R.

School of Physiotherapy and Exercise Science, Curtin University

The scientific study of mental toughness has occurred primarily within sport contexts (for reviews, see Gucciardi & Gordon, 2011), and has developed as a result of mental toughness being one of the most commonly applied but least understood terms among key stakeholders such as coaches and athletes. Recognizing that life experiences (i.e., nurture) alongside biological factors (i.e., nature) are necessary to help shape one's development (Gottesman & Hanson, 2005), researchers have attempted to better understand how mental toughness is developed via retrospective interviews with elite performers or support staff (e.g., coaches, sport psychologists) who have worked with these individuals (for a review, see Connaughton, Thelwell, & Hanton, 2011). In this research, however, it is typically assumed that these individuals believe mental toughness can be developed or changed, or a sampling bias may exist whereby only those people who consider mental toughness to be malleable were purposefully sampled to provide their views. Thus, a substantively important yet untested assumption is whether all people subscribe to the viewpoint that mental toughness is open to development and change. Drawing from an implicit theory framework (Dweck & Leggett, 1988; Dweck, 1999), the purposes of this study were to examine whether adolescent netballers (N=230; M = 14.98 years; SD = 1.51) believe mental toughness is immutable (i.e., entity/fixed) or changeable (i.e., incremental/growth), and if these beliefs are differentially related to key indicators of psychological well-being. Participants completed a hardcopy survey containing measures of implicit theories of mental toughness, self-efficacy, hope, optimism, resilience, and thriving. Results revealed that netballers either believe mental toughness is open to change and development, or are ambivalent as to its malleability. Netballers who subscribed to the view that mental toughness is malleable reported higher levels of self-efficacy, hope, optimism, resilience, and thriving. The current study, therefore, offers two important contributions to the study of mental toughness. First, these findings showed that it might be erroneous to assume that all people subscribe to the viewpoint that mental toughness is open to development. Second, people's lay beliefs about the malleability of mental toughness have important implications for cognitive (e.g., thoughts about one's available resources to deal with situational demands) and motivational (e.g., avoidance or approach) that have been reported as important correlates in previous research (e.g., Connaughton et al., 2011).

ALTITUDE ON RECOVERY OF ELITE SWIMMERS: EXAMINING THE EFFICACY OF THE LAKE LOUISE ALTITUDE MOUNTAIN SICKNESS QUESTIONNAIRE.

Patrick, T.

Aspetar Orthopaedic & Sports Medicine Hospital

Altitude training has become a normal means of enhancing athletic performance (Millet, Roels, Schmitt, Woorons, & Richalet, 2010). Of considerable importance is the attainment of a sufficient dose in order to achieve the desired increases in haematological and ventilatory capacity (Millet et al., 2010). Given the recommended length and nature of exposure required, it is expected that some athletes will experience impairments to wellness and sleep patterns (Buchheit et al., 2013; Sargent et al., 2013). While several methods have been reported regarding the assessment and monitoring of the various recovery parameters (e.g. Buchheit et al., 2013; Sargent et al., 2013); the use of

the Lake Louise Mountain Altitude Sickness Questionnaire (AMS) has been well established as a simple and reliable method for assessing Altitude Mountain Sickness (AMS) (Savoirey et al., 1995). Given that there is no available reliability data for the Lake Louise AMS Questionnaire, an important area of investigation is to determine whether the variation of scores on the Lake Louise AMS Questionnaire corresponded to additional sleep information that was collected concurrently as part of the daily monitoring protocol. Methods Phase One of this study involved the participation of 3 elite swimmers participating in an 18 day altitude exposure. The Lake Louise AMS Questionnaire was administered at the same time daily after awakening and the Zeo Sleep Monitoring System was used by all participants with the data recorded every morning. Results and Discussion Using visual inspection of the available Lake Louise AMS Questionnaire yielded several differences demonstrating that the questionnaire was not as sensitive a mechanism as the sleep monitoring device data in detecting changes to sleep quality and impairment. Given the importance of sleep to overall recovery, this is of considerable importance when informing decisions related to the altitude setting to be implemented as part of the hypoxic protocol and also in tailoring the training loads that are prescribed during the altitude training camp.

VALIDATION OF THE BRAZILIAN VERSION OF THE SPORT-MULTIDIMENSIONAL PERFECTIONISM SCALE 2

Nascimento Junior, J.R.A., Vissoci, J.R.N., Vieira, L.F.

Maringá State University

Introduction Studies have showed that perfectionism level of an athlete may be considered a key factor on the sports career, given that it is defined as the establishment of high performance patterns by the athlete and be accompanied for a tendency of extremely critic assessment regarding to individual or team behavior in the sporting context (FROST et al., 1990; FLETT; HEWITT, 2005). In this perspective, validation studies about the perfectionism characteristics of athletes are very important to the scientific context. Therefore, this study aimed to validate the Sport-Multidimensional Perfectionism Scale-2 (SMPS-2) to the Brazilian context. Methods Participants included seven professionals (four translators and three doctors in Sport Psychology) and 395 athletes of different types of collective and individual sports of the state of Paraná, Brazil. Data analysis was conducted through coefficient of content validity (CCV) confirmatory factor analysis (CFA), Cronbach's alpha (α), composite reliability (CR) and the intraclass correlation coefficient (ICC) ($p < 0,05$). Results The results showed that the Portuguese version contains clear and relevant questions (CCV > 0,80). The scale has good internal consistency ($\alpha > 0,70$ e CR > 0,70) and test-retest reliability (ICC > 0,75). A confirmatory factor analysis showed that nine items didn't show acceptable individual reliability, and thus were excluded. The final (modified) SMPS-2 model with 33 items showed satisfactory fit indexes ($\chi^2 = 931,89$, $df = 475$, $p \leq 0,001$; $\chi^2/df = 1,97$, GFI = 0,90, AGFI = 0,89, CFI = 0,91, TLI = 0,91, RMSEA = 0,05) and the multi-group analysis showed the invariance between men and women ($\chi^2_{dif}(27) = 24,637$; $p = 0,595$). Discussion This is the first Brazilian study of validation of perfectionism scale. This version showed good results at the content analysis, reliability and factor validity and test-retest reliability (BLUNCH, 2008; MARÔCO, 2010), showing that Brazilian version of the SMPS-2b proved to be valid to assess the perfectionism traits in sporting context. However, it is important to highlight that the scale was reduced to 33 items, respecting the criteria of individual reliability and adjustment (KLINE, 2012). References Blunch N. (2008). COMPARISON OF PROGRESSIVE MUSCULAR RELAXATION AND INTERVENTION WITH BIOFEEDBACK TO DECREASE ANXIETY IN FOOTBALL

Acuña, M.

University of Football and Sport Sciences

COMPARISON OF PROGRESSIVE MUSCULAR RELAXATION AND INTERVENTION WITH BIOFEEDBACK TO DECREASE ANXIETY IN FOOTBALL Introduction It can be said that there are thousands of specific stress sources; definitely research reflected both in important events (a penalty kick) as in everyday situations (pass the ball a teammate, the wrong move resulted in a goal) game cause stress and affect athlete's emotional state. Physiological aspects such as rapid heart rate, sweating, nervous gestures besides the impact on optimizing the execution of the movement and thus its performance. In this work we decrease the anxiety of football players with "Light and sound System" of Biofeedback techniques. Methods If we add to this the factor of 'situational stress' which are a general sources of stress, there is such importance placed on an event or competition and immediately (match of a final or a game of decline) after uncertainty arises effect surrounding the outcome of the event. The objective of this research is through mental training will be a reduction of anxiety in soccer player. In this research, we first delineate the anxiety that players applying the meter SAS-2 Sport Anxiety Scale, then the player will have a technique based on Psychological Biofeedback Mind Training. Results Subject 1 decrease his anxiety level in 37%. Subject 2 decrease their anxiety level in 40%. 2 subjects doesn't have a decrease but neither a increment of anxiety. 4 subjects decrease their anxiety around 50% and the others have a decrease around 20%. Discussion One can see that there is a significant reduction in anxiety with Light and Sound System Biofeedback Technique that Progressive Muscular Relaxation of Jacobson, these differences are mainly influenced by personal and environmental factors in the RPM, availability to work as distracting factors that occur during the intervention. With the Light and Sound System with the influence of these factors is avoided as once placed the instrument, it works directly with the central nervous system of subjects and no active participation is required of these. Taking into account that the results with the Light and Sound System decreased more than Progressive Muscular Relaxation, this is a effective tool in the mental and emotional control in sports. References Buceta, J.M (1996) Sports Lessons and Sports Psychology: Prevention and Retrieval. Budzynski, T.(2011) The Clinical Guide to Sound and Light System. Guzmán (2007). INCIDENCE OF EATING DISORDERS IN FEMALE TEAM AND AESTHETIC SPORTS

Molnár, A., Tóth, K., Boros, K., Boros, E., Balogh, L.

University of Szeged

Introduction: Nowadays the several types of eating disorders (ED) provoke frequent problems all over the world. Many publications suggest the connection between ED and sport (Sundgot-Borgen, 1994). Beside the classic EDs such as anorexia nervosa and bulimia nervosa, anorexia athletica can also occur in the period of active sport activities. As far as the connection of ED and sport is concerned, we

should mention the female athlete triad. It means the combined occurrence of disordered eating, secondary amenorrhea and bone mineral disorders (Torstveit, 2005). In the present study the occurrence of ED was examined among physically inactive women (C), female team sport (TS) players and aesthetic sport (AS) competitors (n=154). Methods: Female handball players (n=72), gymnasts (n=42), fitness competitors (n=40) and physically inactive women (n=96) participated in the examination. The possible occurrence of ED was investigated by EDI (Garner, 1983) and SCOFF (Morgat, 1999) questionnaires. Statistical analysis: Mann-Whitney U-test. Results: The first three subscales of EDI are capable to detect ED. The 'Drive for Thinness' (C: 2.615 ± 0.39 S.E.M.; TS: 3.375 ± 0.5 ; AS: $4.43 \pm 0.35^{***}$) and the scores of 'Bulimia' were significantly higher among AS competitors (C: 0.44 ± 0.13 ; TS: 0.82 ± 0.29 ; AS: $4.49 \pm 0.37^{***}$). There was no significant difference between the 'Body Dissatisfaction' of any participants (C: 6.31 ± 0.64 ; TS: 6.54 ± 0.72 ; AS: 5.6 ± 0.44). Although there were a few participants in every group whose scores reached the critical limit, but none of them passed it in all the previously mentioned three subscales. Consequently, we could not detect ED among the participants by EDI. The next five subscales of EDI measure psychopathology commonly associated with, but not unique to, ED. 'Ineffectiveness', 'Interpersonal Distrust' and 'Interceptive Awareness' were significantly higher among AS competitors. We could not observe any significant difference between the 'Perfectionism' or 'Maturity Fears' of any participants. The SCOFF test reveals that significantly more AS competitors (40.24%^{***}) show the signs of ED than TS players (8.33%) or C (9.375%). Discussion: According to the EDI results, despite the fact that we did not detect ED, the higher subscales' scores of AS competitors suggest that they are more disposed to have ED. The SCOFF results seem to prove this statement. The shortness and simplicity of SCOFF test can explain the contradiction between EDI and SCOFF results. References: Sundgot-Borgen J. MOTOR SKILLS ASSESSMENT TO PREDICT TABLE TENNIS PERFORMANCE? – A LONGITUDINAL STUDY

Faber, I.R.1, Oosterveld, F.G.J.1, Elferink Gemser, M.T.2, Nijhuis van der Sanden, M.W.G.3

1. Saxion University of Applied Sciences; 2. HAN /University Medical Centre Groningen; 3. Radboud University Medical Centre

Introduction Talent development programs in table tennis are used to help young children, who have been identified as high potentials, to develop into elite players. Selecting young players for these programs remains extremely difficult, because of the unpredictability of long-term success. A motor skills assessment (MSA) could be helpful in talent development by estimating essential perceptuo-motor skills of young players, which are considered requisite to develop excellent technical and tactical qualities (Vandorpe et al. 2012). The Netherlands Table Tennis Association uses a MSA in their talent development program. This MSA has proven reproducibility and good prospects for validity (Faber 2013a, 2013b). However, the predictive value is still unknown. This study aimed to investigate the predictive value of the MSA for table tennis competition outcomes in a longitudinal design. **Methods** In total, 39 young table tennis competitive players (7-11 years) were tested using the MSA. The MSA consists of eight test items measuring table tennis specific skills under varying conditions: sprint, agility, vertical jump, speed while dribbling, aiming at target, ball skills, throwing a ball and eye-hand coordination (Faber 2013a, 2013b). Competition results were monitored 2.5 years (five consecutive competition periods of 6 months). An Generalized Estimating Equations analysis was conducted to explore univariate and multivariate models for the MSA items to predict longitudinal competition results. Test age, sex and training experience were investigated as covariates. **Results** All MSA test items but one (agility), test age, and training experience were significant predictors of competition outcome in univariate models ($p < 0.001$). The best fitting model included the test items: sprint, throwing a ball, and eye-hand coordination. These test items explained 46% of the variance of the longitudinal competition results. Test age was included as covariate. **Discussion** The results confirm that assessing perceptuo-motor skills is meaningful in a talent development program. The test items included in the best fitting model cover essential performance characteristics: speed, agility, anticipation and ball control. However, it must be emphasized that for a fair prediction of successful performance, multidimensional performance characteristics should be taken into account (Elferink-Gemser et al. 2011). **References** Elferink-Gemser et al. SECULAR TRENDS OF PHYSICAL FITNESS IN 11 TO 14 YEAR OLD AUSTRIAN YOUTH SKI RACERS: A COMPARISON BETWEEN 2005-2008 AND 2009-2013 TIME PERIODS

Raschner, C., Müller, L., Patterson, C., Hildebrandt, C.

University Innsbruck

Introduction There is evidence that physical fitness of children has declined across age groups during the last decades (Albon et al., 2010). Limited scientific information is available concerning secular trends of junior athletes and no research has assessed physical fitness of youth ski racers over time. Therefore the aim of this study was to compare fitness data of competitive youth ski racers from 2005-2009 (group 1) with those of 2010-2013 (group 2). **Methods** Due to cooperation with provincial ski teams and secondary ski boarding schools 11-14 year old female (F) and male (M) ski racers annually underwent the same anthropometric measurements (height and weight) and fitness tests (Coopertest, isometric leg strength, agility test, counter movement jump and drop jump) (Raschner et al., 2012). Group 1 included 703 children (F=244, M=459), group 2 679 children (F=171, M=508). Differences between group 1 and 2 of 11, 12, 13 and 14 year old ski racers were calculated separately with the Student's T-test or Mann-Whitney U-test. Statistical significance was set at $p < 0.05$. **Results** A significant increase from group 1 to group 2 in height and weight was found only in 11 and 12 year old M ski racers. Agility performance was statistically better in group 2 within 12 and 13 year old M and 11 year old F children. F and M ski racers of group 2 had a significantly lower isometric leg extension strength compared to children of group 1 (F: 12 and 14 year olds, M: 11-14 year olds). Reactive strength results were statistically better in group 1 within 12-14 year old M children. No significant differences were found in endurance and counter movement jump performance between ski racers of group 1 and 2. **Discussion** Reduced fitness in competitive 11-14 year old ski racers was not found in all variables. The most significant decreases were observed in leg strength performance. This

could be partially explained by the upcoming problem of overuse injuries in teenager alpine ski racers (Hildebrandt and Raschner, 2013). The focus in children's strength training for this age group has shifted from increasing loads to weight lifting technique. Additionally ski equipment changes and inconsistent race slope conditions have led coaches to train agility more with these young athletes. Ski racing demands a multitude of physical abilities, thus endurance and power training were emphasized similarly in group 1 and 2. References Albon HM, Hamlin MJ, Ross JJ. POTENTIAL OF PERFORMANCE TRACKING IN MALE EXPERT SHOT-PUTTERS FOR BENCHMARKS IN JUNIORS

Wulff, J., Hoffmann, A.

Institute for Applied Trainings Science

Introduction In order to especially promote the junior athletes with the greatest probability to win medals in Olympic Games or World Championships sport associations and coaches are much interested in evaluating the athletic potential of the individual athlete based on performance benchmarks. The expertise approach of talent research focuses retrospectively on the development and practice of experts compared to less successful athletes (Ericsson, Krampe, & Tesch-Römer, 1993). The purpose of this study was to quantify the performance level and the annual increase of male expert shot-putters at various points in time in order to set benchmarks for junior athletes. **Methods** Time series consisted of sequences of season's best results and the competition performance of all male shot-putters who have been competing in Senior World Championships and/or Olympic Games since 1999. Using one-way ANOVA group differences in performance and annual improvement between medalists (rank 1-3), finalists (rank 4-12) and participants (rank >12) were analyzed at different ages. Elite athletes who were not successful or did not compete in junior age were not included in the analysis. Therefore group differences were also calculated for lead variables in the years in advance of the main competition. **Results** Beginning at an age of 22 or 5 years before the competition medalists, finalists and participants differ significantly in throwing distance and the differences becomes even greater in higher ages. The absolute and relative annual improvement is higher in medalists (0.25 ± 0.10 m) than in finalists (0.20 ± 0.12 m) and participants (0.15 ± 0.10 m). Medalists are able to set seasonal bests significantly closer to the major competition. The difference between performance in the major competition and the seasonal best is significantly higher in finalists and participants. **Discussion** Male shot-putters do not develop their athletic performance linearly depending in line with their chronological age. Some top-athletes as D. Armstrong or R. Hoffa reached the top-level first in adult years. Performance in junior competitions is not an appropriate indicator for talent potential. Our results show that the time lag in advance to major events and the corresponding improvement of performance values serve much better for benchmarking for junior athletes. Further research, including the level of performance determinants as physical, technical and psychological abilities, is necessary to evaluate the potential and the progress of junior athletes and to give practical advice to the coaches of young elite athletes. **References** Ericsson, K. A., Krampe, R. T., & Tesch-Römer, C. (1993). The Role of Deliberate Practice in the Acquisition of Expert Performance. *Psychological Review*, 100(3), 363-406.

THE INFLUENCE OF DIGIT RATIO AND ACHIEVEMENT MOTIVATION ON ENDURANCE PERFORMANCE IN HANDBALL TALENTS.

Tirp, J.1, Büsch, D.2, Strauß, B.3, Baker, J.4, Pabst, J.2, Kungl, A.M.4, Schorer, J.1

1: University of Oldenburg, 2: Institute for Applied Training Science, Leipzig 3: University of Münster, 4: York University Toronto

Introduction The influence of nature and nurture on sporting peak performance has been widely discussed (Baker & Davids, 2007). A potential biomarker that seems to influence sporting performance, especially in endurance activities, is the ratio between the second and the fourth digit (2D:4D digit ratio) (Hönekopp & Schuster, 2010). Interestingly, endurance is also a highly trainable capability, requiring sustained motivation over an extensive period. The aim of this study was to investigate whether endurance performance in handball talents is determined more by digit ratio or achievement motivation. **Methods** 220 boys (M age = 15.1 years) and 176 girls (M age = 14.1 years) from a national talent selection camp were examined for this study. Endurance performance was measured using a shuttle run test and digit ratio was determined using digital photographs. Athletes' also completed the Achievement Motivation Scale (AMS). **Results** For boys there was a significant correlation between shuttle run test and digit ratio, $r = -.14$, $p = .04$. The correlation between shuttle run test and AMS also reached significance, $r = -.20$, $p < .01$, but the association between digit ratio and AMS was not significant, $r = -.01$, $p = .89$. For girls the correlation between shuttle run test and AMS just failed significance, $r = -.15$, $p = .06$. The correlations between shuttle run test and digit ratio, $r = -.07$, $p = .39$, and digit ratio and AMS, $r = -.12$, $p = .12$ were non-significant. **Conclusion** Our results suggest endurance performance is not strongly associated with digit ratio or achievement motivation in handball talents. While our results indicated significance in males the explained variance was below five percent. Hönekopp and Schuster (2010) showed strong correlations between endurance performance and digit ratio and it is possible our results may be best explained with the homogeneity of the group (cf. Lidor et al., 2005). A deeper insight might be gained from investigating this question in more heterogeneous groups. **References** Baker, J., & Davids, K. TALENT IDENTIFICATION OF YOUNG PLAYERS IN A PROFESSIONAL SOCCER CLUB

Gil, S.M.1, Zabala Lili, J.1, Bidaurrezaga Letona, I.1, Badiola, A.1, Santos Concejero, J.1, Lekue, J.A.2, Granados, C.1

1 Department of Physical Education and Sport, University of the Basque Country (UPV/EHU). 2 Athletic Club de Bilbao

Introduction Selecting the most talented young players is essential for high-level soccer clubs (1). Thus, the aim of the study was to analyse the talent identification process of soccer players selected to be incorporated to the youngest team of a professional club. **Methods** The selection was performed by the technical staff of the Athletic Club of Bilbao through the observation of players (aged 9-10 years) during training sessions and matches. This process had two phases: firstly, identification (pre-selection) of the best players of the county (54 outfield players, OFs, and 10 goalkeepers) and a final selection (17 OFs and 4 goalkeepers). Also, these groups were compared to 34 age-matched non-(pre)selected players of an open soccer camp (Camp). Pre-selected and Camp players underwent anthropometric, maturity and performance (30-m sprint, 30-m+10cones, Yo-Yo IR level1, CMJ, hand-dynamometry) measurements at the beginning of the study. Statistical comparisons, using student's t or U-Mann-Whitney's tests, were made once the final selection was performed. **Results** Pre-selected OFs were older (9.83 ± 0.27 vs. 9.63 ± 0.29 years, $p < 0.05$) and leaner (sum of skinfolds: 48.86 ± 15.50 vs. 66.16 ± 29.75 mm,

$p < 0.05$) than Camp players. Besides, they performed better in velocity (4.96 ± 0.21 vs. 5.53 ± 0.30 s, $p < 0.001$), agility (5.81 ± 0.28 vs. 6.38 ± 0.32 s, $p < 0.001$), endurance (617.95 ± 233.24 vs. 463.52 ± 223.27 m, $p < 0.01$) and CMJ (29.07 ± 3.27 vs. 26.87 ± 3.07 cm, $p < 0.01$). OFs who were finally selected were older (9.95 ± 0.29 vs. 9.78 ± 0.25 years, $p < 0.05$) and displayed better agility (5.68 ± 0.27 vs. 5.86 ± 0.27 s, $p < 0.05$) and endurance (725.71 ± 226.73 vs. 574.85 ± 224.62 m, $p < 0.05$) than the non-finally-selected OFs. Regarding goalkeepers, they were taller, heavier and had more body fat than OFs; also, they performed worse in the physical tests ($p < 0.05$). Finally selected goalkeepers were older, taller, had a taller predicted height, advanced maturity and performed better in the hand dynamometry and jump tests ($p < 0.05$) than the non-finally-selected. Discussion Thus, the technical staff selected OFs with a particular anthropometry and the best performance, particularly agility and endurance, while goalkeepers had a different profile. Moreover, chronological age had an important role in the whole selection process (2). References 1 Williams & Reilly (2000). Talent identification and development in soccer. ANALYSIS OF THE STANDARD OF PERFORMANCE IN YOUNG MALE AND FEMALE TRIATHLETES

Peter, P.1, Marque, F.1, Oberhoffer, R.1, Schönfelder, M.2

1: Technische Universität München (Munich, Germany), 2: Research Institute of Molecular Sport and Rehabilitation Medicine (Salzburg, Austria)

Introduction Triathlon has a short history, but result lists show that the quantity of young participants in triathlon competitions is growing from year to year. Scientifically gained data of young triathletes, however, is practically lacking. Thus, the aim of the present study was to develop a standardized and triathlon specific test battery for annual talent scouting of the Bavarian triathlon association to gain performance reference data to screen and standardize performance of young male and female triathletes. Methods A triathlon-specific test battery has been applied as a standardized test procedure in several talent scouting workshops to gain long-term data from young triathletes. The present test battery contained anthropometric measurements, sub-distance tests in swimming and running, a critical-power-test on cycle ergometer, basic sport-motoric tests and a questionnaire measuring the performance motivation. Additionally, training and competition data of the young athletes have been collected. In sum, 185 male and 131 female Bavarian triathletes at the age of 10 to 19 years took part in the talent detection workshops from 2009 to 2013. Results Mean swim performance over 400m ranged from 0.87 ± 0.08 m/s to 1.09 ± 0.22 m/s (10 to 19 years). Mean running performance over 1000m ranged from 4.3 ± 0.3 m/s to 5.3 ± 0.5 m/s (10 to 19 years). Successful triathletes showed better abilities in sub-distance performance in swimming and running and spend more hours for training than their coeval counterparts. The physique of squad triathletes seems to be more ectomorphic, thus taller and thinner than the shape of non-squad athletes. Results of a correlation analysis showed positive correlations of limb length and swimming and running performances. Significant correlations ($p < 0.05$) have been found for running performance and reactive jump abilities. Discussion The gained performance data gives meaningful indications for the performance abilities of young, new blood triathletes and set complex standards for their future training goals. The results for anthropometric and performance data showed similar results to data from adult triathletes (Sleivert and Rowlands, 1996; Landers et al. 2000). Sub-distance performances were analyzed before by Moeller et al. (2008) in young elite athletes with assimilable results. In sum, using the present reference data will improve talent scouting in future showing a more differentiated shape of young triathletes. References Sleivert G, Rowlands D. (1996). THE EFFICACY OF USING ESTABLISHED PHYSICAL TESTING AND A NOVEL MOVEMENT COORDINATION TEST BATTERY FOR TALENT IDENTIFICATION INTO A SELECTIVE ENTRY SCHOOL-BASED SPORTS ACADEMY.

Berry, J.1, Vallance, B.2, Clark, D.2

1: Victoria University, 2: Maribyrnong Sports Academy

Introduction Physiological and anthropometric testing has provided the metrics most widely adopted to inform the talent identification process (Vaeyens, Lenoir, Williams, & Philippaerts, 2008). Currently, there is a lack of research to inform this important process at younger age levels for entry into talented athlete pathways. A relatively new movement coordination test battery has been proposed as a useful talent identification tool in younger athletes. The KörperKoordinations Test Für Kinder (KTK) is a non-sport specific battery that includes tasks of balancing, hopping, and jumping (Vandorpe et al, 2012). The use of established physical test protocols along with the addition of the novel KTK movement coordination test may provide a more robust information set to guide the talent identification process. The use of performance metrics to aid the selection process is relatively new at the academy and selection has relied primarily on the 'coaches eye' in the past. The purpose of this study was to 1) investigate if the physical test battery can systematically identify those prospective student-athletes that are subsequently selected into the sports academy, and 2) investigate if a general test of movement coordination (KTK) can systematically identify those prospective student-athletes also. Methods Participants were 102 male (11-12yrs) prospective student-athletes with 37 of those subsequently identified as talented and offered a place at the academy. The physical test battery consisted of height and weight, vertical jump, and a 20m speed. The movement coordination test battery consisted of four discrete tasks that were timed and/or scored. The tasks are 1) walking backwards on a balance beam (x3 widths), 2) single leg hopping over foam blocks progressing in height with each successful attempt, 3) sideways jumping over a centre divider, and 4) manipulation of two small support platforms to move across the floor. Results ANOVA revealed a significant main effect for group with 20m speed, hopping for height, sideways jumping, and platforms superior for the academy group. Positive or neutral data trends were exhibited across the remaining variables for height, weight, vertical jump, and balance. Discussion The results indicate 20m speed and the inclusion of a general test of movement coordination appears to be a useful addition to a talent identification test battery for Sport Academy selection at the primary-to-secondary school transition point. EFFECT OF MONTH AND YEAR OF BIRTH ON PLAYING TIME DURING INTERNATIONAL HANDBALL COMPETITIONS, WITH RESPECT TO PLAYING POSITION.

Karcher, C., Ahmaidi, S., Buchheit, M.

Université Jules Vernes, Amiens

Introduction A clear relative age effect (RAE) has been reported in handball, based on players birth distribution both within (month of birth) and between (odd vs. even year of birth) competitive seasons (1,2,3). Moreover, this RAE effect was playing position-dependent (1,2,3). However, classical RAE analyses (i.e., players distribution within a team roster) don't consider the actual playing time during competitions, which may have actually more impact on matches performance. The objective of the present study was to examine the between- and within-year RAE on playing time during international competitions with respect to playing positions. **Methods** Team compositions (477 players) of the quarter finalists of 2013 World championship, 2012 Olympic tournament and 2014 European championship were analyzed. Month and year of birth were collected in the starting list of each team for center, left and right backs, left and right wings, goalkeepers and pivots. Players were categorized into birth quartile (Q1 Jan-Mar; Q2 Apr-Jun; Q3 Jul-Sep; and Q4 Oct-Dec) and as odd/even year. Playing times were retrieved from official statistics. Data were analyzed for practical significance using magnitude-based inferences (4). **Results** There were no clear difference in playing time between players born in odd ($44 \pm 22\%$) and even years when all players were pooled together, as well as for left wings ($51 \pm 27\%$), center backs ($47 \pm 18\%$), goalkeepers ($47 \pm 26\%$) and pivots ($38 \pm 20\%$). Backs (right: $40 \pm 23\%$, left: $40 \pm 22\%$) and right wings ($43 \pm 21\%$) born during even years played possibly slightly more than their younger counter parts. Pivots ($44.3 \pm 23.3\%$), left ($66.4 \pm 20.2\%$) and right ($52.6 \pm 19\%$) wings born in Q3 were likely-to almost-likely to play slightly-to-largely more than player born in the other quarters. Goalkeepers ($59 \pm 28\%$), left ($43 \pm 21\%$) and center ($51 \pm 14\%$) backs born in Q4 played likely-to very likely substantially more than their older counter parts. Right backs ($52 \pm 24\%$) born in Q1 played likely substantially more than their younger counterparts. **Discussion** Despite the strong RAE observed in male elite international handball which promotes players born earlier during even years (3), playing times were only slightly affected by players' year and month of birth, and for some playing positions only. We found however an unexpected trend for a reversed monthly-related RAE on playing time (i.e., $Q3 > Q1$). **Reference** 1. Schorer J et al, Scand J Med Sci Sports 2009; 19: 720-730. 2. NATIONAL AND STATE REPRESENTATIVE YOUTH ATHLETES EXHIBIT POSITIVE DIFFERENCES ON A PHYSICAL TEST BATTERY WITHIN A SCHOOL-BASED SPORTS ACADEMY.

Vallance, B.1, Berry, J.2, Carroll, R.1

1: Maribyrnong Sports Academy, 2: Victoria University.

Introduction Reporting of physical test scores and anthropometric measures is common in sports research with examples in Australian football and Rugby League (Veal, Pearce & Carlson, 2010; Gabbett, 2002). However, there is little research available that looks across multiple sports and talent levels in an effort to inform coaches and sport scientists of both emerging and benchmark performance levels. Profiling elite level youth athletes can assist the formulation of age-appropriate performance benchmarks that can be subsequently used for coaching or talent identification purposes (Cullen et al., 2013). The purpose of this study was to establish if national and state level student-athletes across a range of sports exhibit distinct fitness and anthropometric profiles compared to the wider sports academy cohort. **Methods** Participants included 153 male (13-16yrs) and 108 female (13-16years) student-athletes in total with 30 male and 41 female athletes subsequently identified as either a national and/or state representative for their sport. Twenty-seven sports were represented in this sample. The test battery consisted of height and weight, vertical jump, 20m speed test, and the Yo-Yo Intermittent Recovery Test Level 1 (YYIRT1). Data was collected as part of routine testing during the athlete development program at the sports academy. Results Separate ANOVA's were conducted to negate any gender influence. In the male data, there was a significant main effect for group with bodyweight higher for the representative group. Positive trends were exhibited across the remaining variables for height, vertical jump, 20m Speed, and YYIRT1. There was no significant main-effect for group in the female data although positive trends were exhibited across all variables for height, weight, vertical jump, 20m Speed, and YYIRT1. **Discussion** The results indicate national and state representative athletes exhibit positive differences on physical test battery scores compared to the wider sports academy cohort. While these differences were not pronounced, with the exception of bodyweight, they were consistent across all tests and across gender. Conversely, the results highlight the academy athletes as a whole are relatively homogenous in relation to the physical test battery scores. This is to be somewhat expected as athletes apply to the academy via a talent identification process and all participate in the athlete development program which includes physical preparation. Future research should explore the technical and tactical areas of performance to maximise any benchmarking exercise. This study provides a framework for coaches and sport scientists to develop age-appropriate performance benchmarks. **References** Cullen B, Clegg C, Kelly D, Hughes S, Daly P, Moyna N. (2013). MO-BN13 Motor Control Learning 3

OBSERVATION OF A FASTER PERFORMANCE DURING MAXIMAL ARM CRANKING INCREASES CADENCE AND SPEED BY 3.6%

Wrightson, J.1, Smeeton, N.J.1, Ross, E.Z.1,2

University of Brighton, UK1, English Institute of Sport, UK2

The study of action observation on movement has almost exclusively focused on understanding motor control processes. Seldom has performance been studied. We examined the effects of artificially increasing cadence of an observed model on maximal performance.

Power (W), speed (m/s) and cadence (RPM) were measured in 11 participants whilst they performed an arm crank exercise maximally for nine minutes. During this performance they observed another person performing the same action at a cadence equal to their previous performance on a 10 km arm crank time trial (MAX condition), 15% above (MAX+15 condition) and 15% below (MAX-15 condition) this performance. The model's cadence changed to one of these three conditions every 3 minutes during the nine minute test. Participants were naive to this manipulation. This test was repeated in different orders of manipulated cadence to control for the influence of block order on the test. Results averaged across the two tests showed significant differences in power ($p < 0.05$), cadence ($p < 0.01$) and speed ($p < 0.01$) across the MAX, MAX+15 and MAX-15 conditions. Increases in cadence and speed were found in the MAX+15 compared to the MAX and MAX-15 conditions ($p < 0.01$). Cadence increased by 3.6% (± 3.0) and 4.8% (± 3.9) from the MAX+15 compared to the MAX and MAX-15 conditions respectively, whilst speed increased by 3.6% (± 3.0) and 4.7% (± 3.8) for the same comparisons conditions. However, there was only a tendency for power to be higher in the MAX+15 condition compared to the other two conditions ($p < .1$) although this variable had larger, but more variable, percentage changes 8.0% (± 8.3) and 9.1% (± 9.5) respectively. These results show action observation can affect maximal exercise performance and can provide a means for performance enhancement.

THE EFFECT OF REAL TIME FEEDBACK ON VELOCITY FLUCTUATIONS IN STEADY STATE ROWING

Lintmeijer, L.L., Hofmijster, M.J., Soest, A.J.

Vrije Universiteit Amsterdam

Introduction Rowing performance depends on maximization of mechanical power delivered by the rower(s) and minimization of power losses (1). Fluctuations in boat velocity result in a power loss due to boat drag that is higher than the corresponding power loss ($P_{\text{drag_mean}}$) that would occur if boat velocity would be constant at its average value. For skilled athletes, it is important to get reliable feedback in order to improve performance, especially when the variability in results is small (e.g. 2). Traditional feedback methods lack the accuracy to differentiate between small variations in effects, such as power loss due to velocity fluctuations. Therefore, we developed an innovative tool to provide real-time visual and auditory feedback about this power loss, and we performed preliminary experiments to evaluate the efficacy of this feedback. **Methods** An algorithm was developed to estimate boat velocity in real time from combined accelerometer data (100Hz) and GPS data (10Hz). Power loss due to fluctuations in boat velocity, averaged over each full rowing cycle, was transformed into a single numeric parameter indicating the actual average power loss to boat drag, relative to $P_{\text{drag_mean}}$. This parameter was fed back visually in real time to single scull rowers, using an android smartphone for both data processing and feedback. In addition, auditory feedback was generated using pitch mapping of the instantaneous power loss due to velocity fluctuations around the mean velocity. **Results** Preliminary results suggest that access to real-time visual or visual+auditory feedback over the course of four training sessions leads to improved awareness of velocity fluctuations and a slight decrease in the associated power loss due to velocity fluctuations. Currently, we are performing a study in which the efficacy of this feedback system is compared to the efficacy of traditional feedback by a rowing coach, while controlling for stroke rate and average boat velocity. **Discussion** It must be noted that optimal rowing performance is achieved when the trade-off between power generated by the rower and power loss is optimal. This implies that minimization of power loss due to velocity fluctuations is unlikely to contribute to rowing performance in itself. Indeed, the current study is the first of a series of studies in which feedback tools will be developed and evaluated for all relevant terms in the power equation for steady state rowing, ultimately supporting elite rowers to converge to the optimal trade-off between all relevant power terms. **References** (1) Hofmijster, M.J., Van Soest, A.J., & De Koning, J.J. THE SIMON PARADIGM IN A THROWING TASK: THE QUIET EYE INHIBITS INTERFERENCES

Klostermann, A., Bachmann, F., Hossner, E.J.

University of Bern

Introduction For the explanation of the well-documented efficiency of long final fixations for superior motor performance, among others, it is hypothesised that the so-called Quiet Eye (QE) inhibits interfering movement variants in movement preparation and execution (Klostermann, 2013). For an experimental test of this hypothesis, interferences were experimentally manipulated by applying the Simon paradigm (e.g., Lu & Proctor, 1995) in a throwing task. **Methods** In a within-subject design, 16 participants threw balls at two targets displayed either to the left or to the right at a screen. In each trial, the respective target position was instructed via headphones by high- vs. low-pitched tones that were either presented to the left or the right ear (stimulus-response congruence was counterbalanced). Consequently, half of the trials had congruent and half of the trials incongruent stimulus and response locations. As dependent variables QE onset and offset – i.e. the first fixation on the target after stimulus onset relative to movement initiation – as well as the radial error were calculated. Furthermore, efficiency of QE was assessed by running intra-individual correlations between the QE measures and the radial error. All variables were analysed by 2 (congruence) \times 2 (target position) ANOVAs with repeated measures. Further, the relevance of QE efficiency was determined by simple t-tests with zero correlation as test value. Two participants had to be removed due to technical problems with the eye tracker. **Results** The Simon manipulation was successful as revealed by a later movement initiation, $F(1,13) = 12.42$, $p < .01$, $f = 0.98$, and inferior performance, $F(1,13) = 4.71$, $p < .05$, $f = 0.61$, in incongruent when being compared to congruent trials. Beyond, both for QE onset and QE offset neither significant main effects nor interactions were revealed (all $ps > .12$). Finally, only for QE offset a significant main effect for congruency appeared, $F(1,13) = 5.91$, $p < .05$, $f = 0.67$, with lower and from zero differing, $t(13) = 2.84$, $p < .05$, $d = 0.79$, negative correlations for incongruent vs. congruent trials. **Discussion** Since incongruences between stimulus and response location affected the throwing movement negatively the lab-based Simon effect could be extended to gross motor skills. Additionally, as expected, only for incongruent trials the efficiency of the QE was revealed with later QE offsets enhancing performance. This finding suggests that interferences caused by the stimulus-response incongruence evoked a functionality of the QE strengthening the suggestion of an inhibition mechanism for the explanation of the QE phenomenon (Klostermann, 2013). **References** Lu C-H, Proctor, RW (1995). *Psychon B Rev*, 2, 174-207. OPTIMAL USE OF VISUAL INFORMATION IN ADOLESCENTS WITH DEVELOPMENTAL COORDINATION DISORDER

de Oliveira, R.F.1, Billington, J.2, Wann, J.P.3

1: *LSBU*, 2: *U Leeds*, 3: *RHUL (UK)*

Introduction Recent reports offer contrasting views on whether or not the use of online visual control is impaired in individuals with developmental coordination disorder (DCD). However, the type of task used may be confounding interpretations. In sequential pointing or double-step reaching, where individuals with DCD show poor performance, they acquire one target before movement initiation and then need to integrate the online information with that movement preparation (Wilmot et al. 2006). In perturbation studies there is either an unexpected target change requiring immediate correction to the ongoing movement (Hyde and Wilson 2011), or a rotation of the visual feedback requiring adaptation of movement over trials (Kagerer et al. 2006). Thus online control was not examined; the type of control required for ongoing actions where neither the final target nor the path are visible, and where reaction time does not play a key role. **Methods** Participants were 22 adolescents (12 males and 10 females; $M = 19$ years, $SD = 3$). Half were diagnosed with DCD using the Movement Assessment Battery for Children (DCD group; $n = 11$) and half reported typical development (TD group; $n = 11$). We used performance on a steering/tracking task as a measure of information processing and examined the use of advance visual information in 5 conditions of advance visual information: 125, 250, 500, 750, 1000 ms. Results With increased duration of advance visual information, the TD group showed a pattern of linear improvement. For the DCD group, however, the pattern was best described by a U-curve where optimal performance occurred with about 750 ms of advance information. **Discussion** The results suggest that the DCD group has an underlying preference for immediate online processing of visual information. They do not show a generalised deficit in visuomotor control, instead they show a pattern where their use of visual information is more temporally constrained than TD controls. The exact timing for optimal online control may depend crucially on the task, but too much advance information is detrimental to the performance of the DCD group. These results are in accordance with previous findings in DCD and typical populations (de Oliveira and Wann, 2010; Raab et al., 2013) regarding the integration of information at different timescales. **References** de Oliveira RF, Wann JP (2010) *Exp Brain Res* 250(3):387-94 Hyde CE, Wilson PH (2011) *Brain Cogn* 75(3):232-41 Kagerer FA, Contreras-Vidal JL, Bo J, Clark JE (2006) *Hum Mov Sci* 25(4-5):622-33 Raab M, de Oliveira RF, Schorer J, Hegele M. VISUAL SEARCH STRATEGIES IN SOCCER PLAYERS EXECUTING A POWER VS. PLACEMENT PENALTY KICK

Timmis, M., Turner, K., Van Paridon, K.

Anglia Ruskin University

Introduction- The visual search strategies employed by soccer players when executing the penalty kick has received widespread research interest. Consistent differences have been highlighted in visual search strategies between elite and sub elite soccer players and the strategies adopted between penalty kickers. When taking a soccer penalty kick, players can execute either a placement or power shot. To date, there is no research investigating the visual search strategies of soccer players when executing a power or placement penalty kick. This was the focus of the present study. **Methods-** 12 amateur footballers took 2 power and placement penalty kicks, indoors, according to The Football Association (F.A.) guidelines for indoor football. A goalkeeper stood in the centre of a goal measuring 3.66m wide by 1.83m high. A football was placed 6 metres from the centre of the goal. The power penalty required players to kick the football with maximum power whilst ensuring a goal was scored. The placement penalty required players to kick the football accurately to a corner of the goal. Eye movements of the penalty kicker were recorded using SMI Eye tracking glasses. Peak horizontal velocity of the football when being kicked and end location of the football were also recorded. **Results-** The football was kicked significantly harder and more centrally in the power compared to the placement penalty ($p < .001$ and $p = .018$ respectively). In the power penalty, the relative fixation length was significantly longer on the ball ($p = .049$) and goalkeeper ($p = .042$), but shorter on the goal ($p = .037$) compared to the placement penalty. There were significantly more fixations on the goalkeeper ($p = .036$) but less on the goal ($p = .044$) in the power compared to placement penalty. Average fixation length was significantly shorter on the goal in the power compared to placement shot ($p = .011$). There was no significant difference in total trial length between conditions or in the number of penalties scored ($p > .05$). **Discussion/conclusion-** Results highlight differences in visual search strategies when executing placement and power penalty kicks. Players in the power shot fixated and kicked more centrally to the goal. In the placement shot, fixations and kicks were directed more towards the periphery of the goal. These findings add further support to the tight coupling between gaze and visuomotor control of aiming, and the importance of the visual system in guiding output from the motor system (Land, 2009; Wood and Wilson, 2010). **References-** Land MF (2009). *Vis Neurosci*, 26:51-62. RELATIONSHIP BETWEEN MOTOR DEVELOPMENT, WEIGHT STATUS AND MOTOR COORDINATION PROFICIENCY

Issartel, J., Gaul, D., Cody, D.

Dublin City University

Introduction The main objective of this study is to investigate the effect of weight status on children's ability to coordinate and control their movements. It is believed that increased weight might affect children's ability to coordinate movements accurately compared to their normal weighted peers. If this is the case, the decreased perceptual-motor function might impede performance of everyday life activities (D'Hondt et al., 2009) as well as their willingness to participate in physical activity (Bouffard, 1996; Cairney et al., 2005). This could offer new insight into why obese and overweight children have difficulty in engaging in physical activity thus increasing the likelihood of becoming obese in adulthood. At the same time this could explain inter-individual differences observed in the motor development of children and adolescents. **Methods** This study assessed both the motor developmental level of 60 children aged between 6 and 12 years old. Two tests were used. The first one assessed the fine motor skills ability using the validated Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2). The second test was measuring the level of motor coordination using a custom pendulum device allowing a characterisation of the role of vision and audition in a synchronisation task. **Results** The performance in the synchronisation and the fine motor skills task increase significantly with age. Obese children tend to perform at a lower level than their peers for the same age and those for both the synchronisation task and the fine motor skills. The main differences occur in the audio task with a significant lower level of performance of the obese cohort compared to the normal weight children. **Discussion** As expected the level of performance increased with age but the weight status seems to play an important role in the motor performance. These results indicate that the obese cohort is falling behind their peers for the same age in term of motor development. The level of performance for 1) the fine motor skills and 2) the synchronisation task indicate a lack of sensory integration. This sensory motor deficiency offers a new angle to which we can view the

relationship between weight status, motor development and then the physical activity levels giving greater insights into how we could tackle this problem in the future. References Bouffard, M., 1996. INTERACTING CONSTRAINTS SHAPE EMERGENT DECISION-MAKING OF REFEREES

Renshaw, I., Russell, S.

Queensland University of Technology

Although much media attention is paid to officiating errors in high level sport, interesting questions such as 'how do the decisions of officials influence the outcome of a match?' and 'how and why do referees make the decisions they do?' still need answering. Previous research into referees' decision-making in football have assessed referee's accuracy by providing 'snap-shots' of decisions that have occurred during matches, with elite panels required to determine (i) if the referee in the match made the right decision or (ii) what they believe the correct call to be (without knowing the referee's decision). This study aimed to add to existing theoretical understandings of referee's decision-making by conceptualising the experiential knowledge of referees and asking them what factors influenced their decision-making in games. Using an ecological scale of analysis, a constructivist grounded theory approach was adopted to explore the functional relationship that exists between the referee and their environment. The participant cohort comprised 7 A-League referees (aged 23 to 35) and 8 local Brisbane league referees (aged 20 to 50), spanning the highest to lowest levels of competition in men's football in Australia. All referees were interviewed by the second author. In contrast to much of the previous research, results showed that referee's decision making was emergent and influenced by the interaction between individual, task and environmental constraints surrounding their performance. Irrespective of referee standard, all referees underpinned their decision-making processes by reference to a set of 'mental' individual constraints, which can be described as the 'four pillars'. These were conceptual notions of: safety, fairness, accuracy and entertainment. A fifth pillar 'consistency' referred to the referee's 'contextual sensitivity' and represents the referee's understanding of how they were able to successfully develop the four pillars over the course of a match. From a complex systems standpoint, decisions are therefore a system micro-component, constraining the action possibilities of players throughout the match. Decisions in this light act as boundaries for allowable dynamical behaviour and provide information about the nature of interactions between sub-systems (e.g. between players) throughout the game. Future research should explore how cultural constraints shape refereeing decisions.

PROCESSING CONDITIONS DURING PRACTICE AND OPTIMISING SKILL ACQUISITION

Uji, M., Bennett, S.J., Hayes, S.J., Ford, P.R.

Liverpool John Moores University

Introduction Expert performance in sport requires perceptual, cognitive, and motor skill, including visual scanning, decision making, and movement execution (Williams et al., 2011). In contrast to the large body of work examining the practice conditions leading to the acquisition of motor skill, there is limited research exploring the combined acquisition of perceptual, cognitive, and motor skill. The aim of this study was to examine the practice conditions required to cause the acquisition of these components of performance. Methods Participants were required to perform a novel computer-based task in a pre-acquisition-post-test design. The task involved moving a cursor across a computer screen to a target whilst avoiding a field of moving objects, which if touched ended the trial. Successful performance on the task requires acquired perceptual, cognitive and motor skill. Participants were allocated to three groups that differed with regards to the type of processing required during acquisition. In the acquisition phase, the first group practised the same task, and thus had the opportunity to acquire perceptual, cognitive and motor processing (PCM: n=13). The other two groups practised a variation of the task that required perceptual and motor processing (PM: n=13), or motor processing only (M: n=13). The frequency of successful trials in which the target was reached, visual search patterns, and the amount of explicit knowledge were recorded. Pre- to post-test data were submitted to 3 Groups x 2 Test ANOVA. Results There were no between-group differences in the pre-test. In the post-test, PCM group reached the target in significantly ($P < .05$) more trials compared to PM and M group (PCM = 5 trials; PM = 2 trials; M = 3 trials). PCM group had more efficient visual search patterns compared to M group, but not PM group. Finally, PCM group acquired significantly ($P < .05$) more explicit rules indicating a greater degree of cognitive knowledge (PCM = 4 rules; PM = 2 rules; M = 3 rules). Discussion Perceptual, cognitive and motor skill was acquired under specific practice conditions that contained those same processes. Conversely, skill acquisition in the PM and M groups was attenuated by manipulating the availability of perceptual information, and hence the requirement to engage in task-specific decision making activities. In addition, differences between the PCM and PM groups emphasise the importance of cognitive processing because both groups had similar visual search patterns. These combined effects indicate optimal practice in sport needs to contain the same perceptual, cognitive, and motor processing conditions as those found in the competition format of the sport. 15:00 - 16:00**Mini-Orals****MO-PM37 TT Overhead Sports****THE PHYSIOLOGICAL PROFILE OF MALE TEAM HANDBALL PLAYERS: WHAT DOES IT TAKE TO PLAY AT THE ELITE LEVEL?**

Michalsik, L.B.1,3, Madsen, K.2, Aagaard, P.3

1Aarhus University, Aarhus, Denmark 2University of Gothenburg, Gothenburg, Sweden 3University of Southern Denmark, Odense, Denmark

Aim To determine the physiological profile of male elite team handball (TH) players. **Methods** Male elite TH field players were evaluated during tournament match-play over a six season time span using physiological measurements and by subsequent physical testing. In addition, acute fatigue development in response to simulated TH match-play was determined for maximal isometric strength (MVC) and rate of force development (RFD) with synchronous electromyography (EMG) recording, while maximal vertical jump parameters were assessed using force plate analysis. **Results** Mean age and adult elite playing experience were 26.2 ± 3.1 years (group means \pm SD) and 7.1 ± 3.7 years. Wing players (84.5 ± 5.8 kg, 184.9 ± 5.7 cm) were less heavy and smaller ($p < 0.001$) than backcourt players (94.7 ± 7.1 kg, 191.9 ± 5.4 cm) and pivots (99.4 ± 6.2 kg, 194.8 ± 3.6 cm). Mean heart rate and relative workload during match-play ($n=41$) were 163 ± 5 beats \cdot min $^{-1}$ and 70.9 ± 6.0 % of $VO_{2\text{-max}}$. Relative workload was lower ($p < 0.01$) in the second half vs. the first (66.3 ± 5.9 % vs. 75.4 ± 5.6 % of $VO_{2\text{-max}}$). Post-match blood lactate concentration and fluid loss was 4.8 ± 1.9 mM (range: 2.8-10.8 mM) and 0.81 ± 0.41 l pr. match. Mean $VO_{2\text{-max}}$ was 5.18 ± 0.66 l $O_2 \cdot$ min $^{-1}$ corresponding to 57.0 ± 4.1 ml $O_2 \cdot$ min $^{-1} \cdot$ kg $^{-1}$. Total running distance in the Yo-Yo intermittent recovery test (level 2) was 895 ± 184 m (range: 520-1360 m), which was greater in wing players (975 ± 123 m) than backcourt players (897 ± 108 m) and pivots (827 ± 264 m) ($p < 0.05$). Fastest 30-m sprint time was 4.09 ± 0.12 s (range: 3.87-4.28 s). The repeated sprint test (7 x 30-m) yielded a mean fatigue index of -8.1 ± 2.7 %. Maximal "Jump and Reach" height was 0.71 ± 0.08 m (range: 0.61-0.86 m). Maximal ball throwing speed was observed using the set shot with 3-steps run-up (92.8 ± 5.3 km \cdot h $^{-1}$, range: 75.8-108.2 km \cdot h $^{-1}$). Decreases in quadriceps and hamstrings MVC ($\sim 10\%$) and RFD ($\sim 16-21\%$) were observed following simulated TH match-play ($p < 0.05$, $n=10$). Post-match maximal jump height (CMJ) was reduced (5.2%, $p < 0.01$), as was also CMJ RFD ($\sim 30\%$, $p < 0.05$). **Conclusions** Modern male elite TH imposes moderate-to-high demands on the aerobic energy system and high demands on the anaerobic energy systems during certain periods of the match. Physical profiles differed between playing positions, with wing players covering a greater total distance in the Yo-Yo test and showing superior jumping performance and repeated sprint capacity than backcourt players and pivots. In addition, wing players were lighter, smaller, younger and less experienced on adult elite level compared to all other playing positions. Indications of temporary fatigue and a subsequent decline in performance were observed, since the relative workload decreased both in the first and in the second half of the match. Further, maximal (MVC) and rapid muscle force characteristics (RFD, impulse) were acutely affected concurrently with marked reductions in muscle EMG following simulated TH match-play, which may potentially lead to impaired functional performance.

THE RELATIONSHIP BETWEEN GENERAL AND GAME BASED PERFORMANCE IN TEAM-HANDBALL

Wagner, H., Pfusterschmied, J., Orwat, M., von Duvillard, S.P., Müller, E.

University of Salzburg

Introduction Team-handball is a fast pace game of defensive and offensive actions including specific movements of passing and throwing a ball, jumping, blocking, tackling, fast accelerations and change of directions. However, team-handball performance is mostly measured using standardized endurance, strength and agility tests (Gorostiaga et al., 2005) that do not reflect actual performance in team-handball. Consequently, the aim of the study was to measure and compare general and game based performance in team-handball. **Methods** 15 experienced team-handball players performed a game based performance test (GBPT) (Wagner et al., 2014), an incremental treadmill-running test, a 30m sprinting test, lower and upper body strength test, and a counter movement jump (CMJ) test. We measured peak oxygen uptake ($VO_{2\text{peak}}$), utilizing portable metabolic system (Cosmed K4B2), blood lactate concentration (BLC $_{\text{peak}}$) (EKF, Biosen C), heart rate (Polar, Kempele, Finland), sprinting time, and offensive and defensive time actions (Inmotion LPM-system, Abatec, Austria), ball velocity and jump height during a jump throw (PeakMotus, Vicon Peak, UK), isometric leg force and shoulder and trunk rotation torque (ISOMED, D&R Ferstl, Germany), as well as jump height in the CMJ (AMTI, Watertown, USA). Relationship between general and game based performance was determined utilizing Pearson Product-Moment correlation. **Results** We found correlation ($r > .55$, $P < .05$) between sprinting times in the general and GBPT as well as offensive time actions in the GBPT, between shoulder and trunk rotation torque, and between jump height in the CMJ and general sprinting time ($r < -.55$). Team-handball players with greater body mass reached a lower $VO_{2\text{peak}}$ in the GBPT, a greater starting time (0-15m) in the general sprint test and a lower jump height in the CMJ. Surprisingly, we also found correlation between the jump height in the CMJ and jump throw and the $VO_{2\text{peak}}$ in the GBPT and no correlation between the $VO_{2\text{peak}}$ in the GBPT and the incremental treadmill-running test. **Discussion** In conclusion, we found that standardized tests measuring general performance of endurance, strength and agility are only marginally suitable to determine specific team-handball performance in experienced team-handball players. Whereas, sprinting tests and a counter movement jump test were appropriate to determine team-handball game based agility and speed no relationship between general endurance and strength, or team-handball game based performance was found. **References** Wagner H, Orwat M, Pfusterschmied J, Hinz M, Bacharach D, von Duvillard SP, Müller E. (2014). J Strength Cond Res, (submitted) Gorostiaga EM, Granados C, Ibanez J, Izquierdo M. (2005). Int J Sports Med, 3, 225-232. Contact herbert.wagner@sbg.ac.at

MEAN POWER AND VELOCITY IN ACCELERATION PHASE OF TRUNK ROTATION IN ATHLETES WITH DIFFERENT EXPLOSIVE FORCE PRODUCTION CAPACITY

Zemková, E.1, Jeleň, M.1, Ollé, G.2, Chren, M.1, Olej, P.1, Štefanovský, M.1, Zapletalová, L.1, Žiška, J.3, Hamar, D.1

1: Faculty of Physical Education and Sport, Comenius University, 2: Faculty of Civil Engineering, Slovak University of Technology, 3: Faculty of Mechanical Engineering, Slovak University of Technology

Introduction Previous study showed that mean velocity in acceleration phase of trunk rotation is a sensitive parameter able to identify within and between groups differences [2]. However, effective execution of movement requires also strength and power of trunk muscles. These muscles (erector spinae, abdominal oblique, and rectus abdominis) are mainly active during the acceleration phase of trunk rotation (e.g., the golf swing) [1]. Considering the power in acceleration phase as a parameter of functional assessment of trunk muscles, its ability to distinguish athletes with different demands on explosive force production capacity was estimated. **Methods** Altogether 92 athletes (age 23.4 ± 4.1 y, height 178.1 ± 8.4 cm, weight 85.6 ± 15.7 kg) of karate, ice-hockey, tennis, golf, ballroom dancing, rock & roll dancing, judo, wrestling, canoeing, rowing, weightlifting, and bodybuilding performed 5 rotations of the trunk to each side in a seated position with barbell of 20 kg placed on the shoulders. The FitRO Torso Dynamometer was used to monitor basic biomechanical parameters involved in exercise. Mean velocity and mean power in acceleration phase of trunk rotation were analysed. **Results** Mean power was significantly higher in tennis players than golfers (176.3 ± 28.2 vs. 121.2 ± 24.9 W, $p = .028$). However, mean velocity did not differ significantly between these groups (162.7 ± 20.1 vs. 157.4 ± 19.8 °/s, $p = .454$). Significantly higher values in rock & roll dancers than ballroom dancers were found in both mean power (194.2 ± 35.8 vs. 108.4 ± 21.7 W, $p = .001$) and mean velocity (189.1 ± 24.5 vs. 141.0 ± 17.5 °/s, $p = .009$). Mean power was also significantly higher in judoists than wrestlers (234.1 ± 42.3 vs. 200.2 ± 39.0 W, $p = .047$). However, there were no significant differences in mean velocity between these groups (184.3 ± 23.8 vs. 179.0 ± 22.0 °/s, $p = .457$). Comparison of individuals showed higher values of mean velocity and mean power in ice-hockey player than karate competitor (13.1 vs. 15.6 %), in canoeist than rower (26.7 vs. 31.9 %), and in weightlifter than bodybuilder (36.5 vs. 44.1 %). **Discussion** More pronounced group and individual differences in mean power than in mean velocity in acceleration phase of trunk rotation were found. These differences may be attributed to specificity of training involving trunk movements of different velocities under different load conditions. **References** 1. Watkins RG et al. (1996). *Am J Sport Med*, 24(4), 535-8. 2. Zemková E et al. (2013). *Eur J Sports Med*, 1(1), 216. Contact zemkova@fsport.uniba.sk

THE INFLUENCE OF THE BALL SPEED AND BALL PLACEMENT TO THE MOVEMENT TIME OF THE FOREHAND STROKES IN TENNIS

Wang, Y.C., Liu, Y.T.

National Taiwan Normal University

Introduction The forehand stroke is not only a basic skill in tennis but also the most frequently used skill in tennis games. From the constraints perspective (Newell, 1986), the performance of the tennis forehand stroke is the result of the interactions among the organismic, environmental, and task constraints. The approaching ball speed and the landing location of the ball are two of the task constraints that influence the performance of the forehand stroke. The purpose of the study was to examine the effects of the ball speed and ball placement to the movement time of the tennis forehand strokes. **Methods** Seven male division 1 college tennis players participated in the study. Two conditions of ball speed (fast and slow) and 2 conditions of ball placement (service line, baseline) were manipulated. Continuous rallies were performed during each condition where the participants returned the balls from behind the baseline. A high speed camera (300 fps, Casio) was used to videotape the rallies from the right side of the participants. The ball speed and the movement time of the forehand strokes were derived from the Kwan 3D digitizing system. The 2 way repeated measure ANOVA was used for data analysis. **Results** The ball placement close to the baseline resulted in a significantly shorter movement time of the forehand strokes than those of the balls placed close to the service line, $F(1,6) = 38.15$, $p = .001$. The interaction between the ball placement and ball speed also showed significant effect, $F(1, 6) = 6.32$, $p = .046$. Simple main effect analyses showed that, for the slow speed condition, the difference of the movement time between the 2 placement conditions was greater, compared to that of the fast speed condition. No ball speed effect was significant. **Discussion** The results of the study show that the movement time of the forehand strokes is influenced by the interaction of ball speed and location, and the ball location seems to have greater impact than the ball speed. Future studies will continue to examine the task constraints to other performance measures of forehand strokes during the natural tennis rally situation. **Reference** Newell, K. M. (1986). Constraints on the development of coordination. In M.G. Wade & H.T.A. Whiting (Eds.), *Motor skill acquisition in 50 children: Aspects of coordination and control*, 341-360. RELATIONSHIP BETWEEN RANGE OF MOTION TESTS WITH THROWING KINEMATICS AND THROWING PERFORMANCE IN ELITE HANDBALL PLAYERS.

Tillaar, R.

University College of Nord Trøndelag

Introduction A lot of handball players experiences shoulder pain during their handball carrier (Haslan et al., 2008). In baseball altered shoulder mobility (increased external rotation) is found to stress the glenohumeral structures of the shoulder and thereby the disposition to shoulder pain and shoulder injuries (Werner et al., 2001; Miyashita et al., 2008a+b). However, in these studies passive range of motion (ROM) tests are conducted and not the actual range of motion during throwing. The question rises if the measured ROM of the shoulder also influences the real throwing kinematics in handball. Therefore, the aim of this study was to investigate relationships between the active and passive ROM of the glenohumeral external rotation angle with the maximal external rotation angle and throwing performance during two windup techniques in elite handball players. **Methods** Twenty-two elite handball players participated in the study in which the maximal ball release velocity and maximal external rotation angle during maximal standing throws with a whip-like and circular windup (van den Tillaar et al., 2013) were measured together with the maximal active and passive glenohumeral ROM of the external rotation angle lying supine on a bench (Miyashita et al., 2008a). **Results** Significantly higher maximal external rotation angles (132°) were found during the throws with the whip like windup than at all other measurements (125°) together with a significantly lower external rotation angle during the active glenohumeral external rotation angles (105°). No significant correlations were found between the glenohumeral ROM of the external rotation with the maximal ball release velocity and the maximal external rotation angles measured during the two types of throws ($r \leq 0.29$; $p \geq 0.183$). **Discussion** Differences in the ROM of external rotation angles can be explained by the use of active and passive structures in the shoulder during the different tests and the two throwing techniques. That no significant correlations were found between the ROM test with the throwing kinematics and performance indicates that the ROM tests on healthy elite handball throw-

ers cannot help us to identify potential fast throwers or recognize potential injuries combined with changed kinematics (Werner et al., 2001; Miyashita et al., 2008b). DETERMINANTS OF SPORTS RESULT IN KAYAKING ON THE EXAMPLE OF JUNIOR ATHLETES

Rynkiewicz, M., Rynkiewicz, T., Żurek, P.

PW Znak - Test Mateusz Rynkiewicz & University School of Physical Education in Poznan - Faculty in Gorzów Wlkp.

The aim of this study was to identify the determinants of sports results in kayaking. We conducted the complex examination of condition and coordination motor skills of kayakers, and determined their relationship to the results of specialist tests. Moreover, we tried to define the level of motor skills which is typical for Polish junior kayakers and compare our findings to the results reported by other authors. The study included 18 kayakers at mean age of 16.2 years. The following tests were conducted: 2000 m and 1000 m paddling in a kayak, maximum power test during kayak ergometer paddling, VO₂ max and power developed during kayak ergometer paddling at intensity corresponding to ventilator threshold (VT), body composition, 1500 m track running, measurements of strength endurance and power developed during series of six repetitions bench press and bench pull. Also the levels of dynamic and static balance were determined. Statistically significant relationship was documented between paddling speed and power developed at a threshold intensity (VT), the velocity of barbell movement during bench press and bench pull, and the level of static balance. Moreover, a strong correlation was observed between maximum power during kayak ergometer paddling and the kayak paddling speed. According to these findings, kayakers should show high level of power at VT intensity and maximum power determined during kayak ergometer paddling. Moreover, they should be characterized by high velocity of barbell movement during bench press and bench pull, and high level of static balance. The results of this study enabled us to determine the typical level of preparation of Polish junior kayakers. Body structure and capacity of examined kayakers did not differ markedly from relevant values reported by other authors.

THE ROLE OF PELVIS AND THORAX ROTATION VELOCITY IN BASEBALL PITCHING.

van der Graaff, E., Hoozemans, M.J.M., Hoezen, M., Nijhoff, M., Veeger, H.E.J.

Vrije Universiteit

Introduction Maximizing throwing velocity is one of the main goals in baseball pitching. It is suggested that pelvic kinematics play an important role in achieving high throwing velocities, specifically in the initiation thorax rotation. The objective of the present study was to study the role of thorax and pelvis rotation velocities during baseball pitching. Methods During the preseason (T1), 3d kinematic analyses of body segments during throws of pitchers of the Dutch AAA team (n=8, age = 16,1 ± 0,7, height = 181,7 ± 7,9, weight = 76,9 ± 8,1) in our movement laboratory were performed. This was repeated 3 months later (T2). The thorax segment was defined using reflective markers attached to the skin at C7 and T10 at the dorsal side of the body and the processus xiphoideus and incisura jugularis at the ventral side of the body. The pelvis was defined using markers attached to the skin at the SIPS and SIAS on the right and left side. Segment angular velocities were directly calculated from the rotation matrices following Zatsiorski (1998). Separation is the time delay between the peak rotation velocity of the pelvis and thorax. Results At T2, thorax peak rotation velocity (T1: 1008 SD 50 °/s, T2: 1044 SD 32 °/s, p=0,00), pelvis peak rotation velocity (T1: 648 SD 76 °/s, T2: 684 SD 104 °/s, p=0,03) as well as throwing velocity, expressed here as peak velocity of DIP-III, (T1: 67 SD 3 mph, T2: 71 SD 3 mph, p=0,00) were significantly higher compared to T1. When looking at the differences between T1 and T2, we could not show a significant association between changes in throwing speed velocity and changes in thorax - or pelvis peak rotation velocity. However, the change in time delay between the peak rotation velocities of the pelvis and thorax between T1 and T2 appeared to be significantly and positively associated with the change in throwing velocity (Pearson's r=0.66). Conclusion High thorax and pelvis rotations may be an indicator for high throwing velocities in baseball pitching. In addition, timing of these rotations (i.e. "separation") appears to be important for acquiring high throwing velocities. Separation between thorax and pelvis peak rotation deserves to be focused on in scientific research as well as in training practice in developing high throwing velocities. A next step might be to calculate the effect of separation differences on segmental power flow. References Zatsiorski, V.M. (1998). Kinematics of Human Motion. ACHILLES TENDINOPATHY REQUIRES DIFFERENT MANAGEMENT IN REACTIVE VS DEGENERATIVE STAGE: A RANDOMIZED TRIAL OF 2 PHYSICAL THERAPIES ASSOCIATED TO A DIETARY SUPPLEMENT CONTAINING MUCOPOLISACCHARIDES

Balius, R., Álvarez, G., Baró, F., Jiménez, F., Pedret, C., Pujol, M., López, D., Martínez, D., Ramírez, P., Martínez Puig, D.
Bioiberica S.A.

Question: What is the therapeutic benefit of a supplement containing mucopolisaccharides in patients with Achilled tendinopathy when added to an eccentric exercise program? Is the same protocol useful for all stages of disease? Design: Prospective controlled study. Participants: 59 patients were randomly assigned to 1 of 3 treatment groups, and classified according to the disease stage: reactive vs degenerative tendinopathy. Intervention: Treatment groups were eccentric training (EC), EC + a dietary supplement containing Mucopolisaccharides, type I Collagen and Vitamin C (EC+MCV), and passive stretching program + MCV (PS+MCV). Outcome measures: Patients were evaluated at baseline, 6 and 12 weeks with VISA-A for function, visual analog scale (VAS) for pain, and ultrasound characterization for the evolution of tendon structure. Results: A significant improvement in VISA-A score, pain at rest and pain during activity were detect-

ed in all 3 treatment groups at 6 and 12 weeks follow-up, when compared to baseline. In patients with reactive tendinopathy the reduction on pain at rest was greater in the groups supplemented with MCV than in the EC group ($P < 0.05$). In patients with degenerative tendinopathy, a significant reduction of the bilateral thickness and neovascularization degree of the affected tendon, were detected in the PS+MCV group. Conclusion: MCV seems to be safe and effective for management of tendinopathies, providing some additional benefit to the physical therapy. This is especially evident in early stages of the disease, when the tendon doesn't present severe matrix and vascular changes. Trial registration: NCT01691716.

CHANGES IN LOWER EXTREMITY MUSCLE MASS AND MUSCLE STRENGTH AFTER WEIGHT LOSS IN OBESE MEN

Kim, B., Tsujimoto, T., So, R., Tanaka, K.

University of Tsukuba

Introduction To reduce the risk of developing musculoskeletal pain or osteoarthritis, it is important for obese men to maintain in muscle mass and muscle strength after weight loss. The purpose of this study was to investigate changes in lower extremity muscle mass and muscle strength resulting from combination of caloric restriction and exercise. **Methods** Sixty Japanese men (BMI 29.1 ± 2.2 kg/m², 49.5 ± 9.2 yr) concurrently attended a 12-wk diet class 1 d/wk and a 12-wk exercise class 3 d/wk. Body weight, body composition by dual-energy X-ray absorptiometry and isokinetic knee extensor strength at angular velocity of 60°/s and 180°/s by dynamometry (Biodex System 3: Biodex Medical Systems, Shirley, NY) were assessed before and after the 12-wk period. Leg muscle mass were calculated using leg lean mass, excluding leg bone mass. We adopted the peak torque, the amount of work and the average power in isokinetic assessment to evaluate maximal muscle strength, muscle endurance and muscle power. **Results** Average body weight following the 12-week intervention declined -12.1 ± 4.0 kg ($P < 0.01$). The weight loss consisted of -6.6 ± 2.1 kg ($P < 0.01$) in whole body fat mass and -5.1 ± 2.3 kg ($P < 0.01$) in whole body lean mass. And, -1.6 ± 2.3 kg ($P < 0.01$) in the reduced whole body lean mass was leg muscle mass. maximal muscle strength (-11.9 ± 23.9 at 60°/s, -6.9 ± 14.8 at 180°/s) and muscle endurance (-24.5 ± 68.4 at 60°/s, -71.2 ± 189.5 at 180°/s) were significantly declined whereas, muscle power (-1.9 ± 15.4 at 60°/s, -3.4 ± 28.5 at 180°/s) was statistically unchanged. In addition, body mass-normalized muscle mass strength ($+17.2 \pm 27.7$ at 60°/s, $+12.1 \pm 16.2$ at 180°/s) was significantly increased. **Discussion** Weight loss program in this study led to loss of leg muscle mass, maximal muscle strength and muscle endurance, whereas normalized muscle strength were increased and muscle power was unchanged, statistically. While loss of muscle mass could be a concern, increased relative muscle strength and unchanged muscle power are beneficial for obese men. Because, unchanged muscle power and increase in relative muscle strength suggest that physical function is ameliorated. **Conclusion** After weight loss program in this study, leg muscle mass, maximal muscle strength and muscle endurance were significantly decreased. However, muscle power was unchanged and normalized muscle strength was significantly increased. **References** 1. Andersen et al.(2003).Obesity research. 11(10), 1159-1162 2. Vincent et al.(2010). BACK TO SPORTS AFTER ANTERIOR CRUCIAL LIGAMENT RECONSTRUCTION WITH DYNAMIC INTRALIGAMENTARY STABILIZATION TECHNIQUE

Bieri, K.1,2, Müller, T.1, Ahmad, S.2, Kohl, S.2

University Hospital of Bern, Switzerland

Objective: Dynamic intra-ligamentary stabilization (DIS) has been developed as a new technique for the treatment of acute ACL ruptures. The DIS device combines an internal dynamic screw-spring mechanism with a thin polyethylene thread to provide continuous stability of the knee joint during the self-healing period [1]. Compared to conventional reconstructive techniques, where the injured ligament is replaced with a graft, the DIS technique challenges the rehabilitation settings with a new clinical situation, where the ACL is preserved. The single-leg hop test battery is a valid and reliable functional measurement tool after ACL reconstruction and is generally accepted as one of the most important tests regarding re-engagement in sporting activities [2, 3]. Test performance is expressed as a percentage of test performance to the healthy limb ("limb symmetry index"). To pass the "back to sports" criterion, a normal hop symmetry index (index values $\geq 85\%$) is required [4]. The intention of this study was to investigate hop test performance 6 months after DIS surgery for ACL rupture. **Material and Methods:** 23 (16 m, 7 w) recreational athletes were included following ACL reconstruction with the DIS surgical technique (mean age 25 ± 10). The subjects performed standardized hop tests during routine control 23 ± 2 weeks postoperatively [2]. **Results:** All patients performed the hop tests as described. The mean limb symmetry index of $93 \pm 9\%$ was above the "back to sports" criterion. **Conclusion:** The goal of ACL surgery and rehabilitation is to reach the best functional level for patients in a short period of time. Today's gold-standard in the treatment of ACL ruptures using autologous materials, has several well-known disadvantages such as donor-site morbidity, loss of proprioception and persisting strength deficit. These pitfalls can be limiting for sports performance. In this study, recreational athletes who received ACL repair using the DIS technique did not show any deficits in hop test performance 6 months postoperatively. These findings indicate that preserving the still vital ACL may be a good option for a safe return to previous activity level in an appropriate period of time. **References:** 1. THE PLANTARIS TENDON AND THE PERITENDINOUS CONNECTIVE TISSUE IN MIDPORTION ACHILLES TENDINOPATHY – STUDY ON INNERVATION AND SIGNALING SUBSTANCES

Spang, C., Alfredson, H., Forgren, S.

Umea University

Introduction Midportion Achilles tendinopathy is a painful condition of the Achilles tendon, which is mainly seen as a consequence of high and wrong loading history (Cook & Purdam, 2009). Around 7-9% of athletes performing high frequency of running and jumping suffer from this condition (Alfredson, 2003). The mechanisms are still not fully understood and rehabilitation remains challenging. Recent studies have shown that a subgroup of patients exhibits a thickened plantaris tendon coalescing with the Achilles tendon and that its release together with a scraping of the peritendinous connective tissue leads to good outcome (Alfredson, 2011). Morphological examinations

have further approved that this thickened plantaris tendon shows tendinosis-like morphological features similar to the Achilles (Spang et al., 2013). This study wanted to further characterize the plantaris tendon and the peritendinous connective tissue with focus on innervation patterns. Methods The plantaris tendon and the adjacent peritendinous connective tissue of 9 patients (8 men with a mean age of 41,2 years and 1 women with an age of 58) and one healthy individual (women, 27 years) were evaluated immunohistochemically for expression of neuronal marker (PGP 9.5) and components of glutamate (VGluT2 and NMDA1) and substance P (SP and NK-1 R) signaling pathways. Results The peritendinous connective tissue but not the plantaris tendon exhibited occasional expression of PGP 9.5. Several of these neuronal structures further showed expression of NMDA1, SP and NK-1. Fibroblasts in the peritendinous connective tissue and tenocytes in the plantaris tendon showed immunoreactions for SP (weak), NK1 R, NMDA1 and VGluT2. Discussion This study shows that the plantaris tendon seems to have no neuronal innervation. Thus, the peritendinous connective tissue, containing sensory nerve fibers (expression of SP, NK-1 R and NMDA1) might be the source of pain. The plantaris tendon might however contribute via compressive load on the Achilles tendon (Cook & Purdam, 2011). Based on the biochemical hypothesis (Danielson, 2009), the fibroblasts in the peritendinous connective tissue or the tenocytes in the plantaris tendon might be a source of nociceptive substances as they can release glutamate and SP. However, further studies are needed to fully understand tendon pain and to fully define the role of the plantaris and the peritendinous connective tissue in Achilles tendinopathy. THE ACUTE EFFECTS OF SELF-MYOFASCIAL RELEASE WITH FOAM ROLLING ON FLEXIBILITY AND MUSCLE STRENGTH IN THE LOWER EXTREMITY

Su, H., Yu, T.C., Chu, I.H.

KAOHSIUNG MEDICAL UNIVERSITY

Introduction A warm up is a generally accepted and recommended method to reduce the susceptibility of musculoskeletal injury. It increases connective tissue extensibility, which may improve flexibility and function, while possibly improves muscular performance. Self-induced myofascial release (SMR) is a manual-therapy technique developed to help reduce restrictive barriers or fibrous adhesions seen between layers of fascial tissue (MacDonald et al., 2013). During SMR, subjects use their body weight on a myofascial foam roller to exert pressure on opposing soft tissues (Healey et al., 2014). Foam rolling is proposed to improve muscular function, performance, and joint ROM (MacDonald et al., 2013). Yet, whether a foam rolling protocol can be used as a warm up to improve one's flexibility and muscle strength is unknown. The purpose of this study was to compare the acute effects of static stretching, dynamic stretching, and foam rolling warm-up protocols on flexibility and muscle strength in the lower extremity in healthy college students. Methods Thirty participants (mean age 21.4±1 yr, 15 males and 15 females) completed four test sessions on nonconsecutive days within 2 weeks. In each session, participants first completed baseline measures of flexibility (sit and reach test) and peak strength of hamstrings. Next, participants performed 5 minutes of light aerobic cycling followed by 12 minutes of one of the four conditions (i.e., rest, static stretching, dynamic stretching, and foam rolling) randomized for that session. The three warm-up protocols were performed on the following four muscle groups: 1) quadriceps, 2) hamstrings, 3) tibialis anterior, and 4) gastrocnemius. Posttest measures were performed immediately after the intervention. Repeated Measures Analysis of Variance and post hoc comparisons were conducted to compare the effects of different protocols on flexibility and strength. Results The scores (cm) of sit-and-reach test improved significantly more in the foam rolling conditions (3.69±2.5°) as compared to that in the rest condition (-0.77±5.7°, p=0.004), static stretching condition (2.13±2.3°, p=0.052) and dynamic stretching (0.68±2.1°, p<0.001). For muscle strength, the isokinetic knee flexor muscle strength showed no changes in all four conditions. Discussion The results provide supporting evidence for the potential benefits of employing a foam rolling protocol as a warm-up exercise to increase the lower extremities flexibility and without hampering muscle strength production in young healthy adults. LOWER LIMB ELECTROMYOGRAPHIC ACTIVITY DURING CYCLE ERGOMETER, ELLIPTICAL CROSS-TRAINER AND TREADMILL EXERCISE

O'Donovan, J.I, Fleming, N.2, Donne, B.1

1:Human Performance Laboratory, Trinity College Dublin, Ireland, 2:Kinesiology Department, Indiana State University, USA.

Introduction Lower limb injuries commonly occur in sports. A frequent dilemma athletes and coaches face is trying to maintain fitness during the rehabilitation phase, and, to date, various non-impact methods have been used; namely, cycling and cross-training. While both modalities, like running, involve cyclical patterns, it is likely that neuromuscular movement patterns vary significantly. How much patterns differ is important, to ensure that running motor patterns and efficiency are maintained. Methods Competitive male athletes (n=12, mean ± SD; 27±5 yr, mass 77±8 kg, BMI 23.4±2.1 kg.m-2), completed randomised incremental tests to exhaustion on treadmill, cycle ergometer and elliptical cross-trainer, separated by ~48 h. An additional EMG testing session at two sub-maximal loads (low- and moderate-intensity; namely, 60 and 80% VO2R) was performed. Participants exercised for 5-min epochs, followed by a 10-min rest, at both intensities on each ergometer. Surface EMG (ME 6000, Mega, Kuopio, Finland) was recorded in the final minute of each 5-min epoch from gluteus maximus (GM, n=8), vastus lateralis (VL, n=11), semitendinosus (ST, n=12) and gastrocnemius (GA, n=11). Synchronous video kinematic data identified discrete cycle onsets, rmsEMG data were amplitude normalised relative to the maximal activity recorded in any trial, averaged over 10 consecutive cycles and analysed using a two-way repeated measures ANOVA, P<0.05 inferred statistical significance. Results Post-hoc analysis revealed that mean ± SEM activity in GA was significantly greater on treadmill vs. cross-trainer at 60 and 80%VO2R (13.8±1.7 vs. 6.2±0.9 % and 16.2±1.8 vs. 8.2±1.2 %, P<0.001) and on cycle ergometer vs. cross-trainer at 80%VO2R (13.1±1.8 vs. 8.2±1.2 %, P<0.05). Mean ST activity was significantly higher on treadmill vs. cycle ergometer and elliptical cross-trainer at both 60%VO2R (14.9±2.0 vs. 10.3±1.8 and 10.5±2.1 %, P<0.05) and 80%VO2R (16.9±2.3 vs. 11.1±2.2 and 11.5±2.5 %, P<0.01). Assessing intensity effects, normalised EMG data were significantly (P<0.05) greater that at 80 vs. 60%VO2R; on treadmill in GA, GM and ST, on cross-trainer in GM and VL, and on cycle ergometer in GA and VL. Discussion Overall, EMG activity in VL and GM were comparable across investigated modalities. However, the elliptical cross-trainer did not reflect treadmill or cycle ergometer EMG activity in GA or ST. These are important muscles in running biomechanics. Therefore, over reliance on cross-trainers, for a prolonged time period during a rehabilitation phase, could potentially lead to significant deconditioning of GA and ST and possibly neuromuscular functioning, thereby pre-disposing an athlete to further injury upon return to sport.

COCHRANE REVIEW: INTERVENTIONS FOR PREVENTING ANKLE LIGAMENT INJURIES

Janssen, K.W., van der Wees, P.J., Rowe, B.H., de Bie, R., van Mechelen, W., Verhagen, E.A.L.M.

EMGO+ VUmc Amsterdam

Introduction Ankle ligament injury is the most prevalent and universal sports injury. Prevention of ankle injuries could preserve health in people who participate in high-risk sports and those who have suffered a previous ankle ligament injury. The aim of this review was to assess the effects of interventions for preventing ankle ligament injuries and re-injuries. **Methods** Randomised controlled trials evaluating interventions for preventing ankle ligament injuries were eligible. Primary outcomes were: incidence of ankle ligament injury; severity of ligament injuries to the ankle; and patient-assessed ankle function. We searched the Specialised Register, CENTRAL, MEDLINE, EMBASE, SPORTDiscus, and CINAHL. Risk of bias of all included studies was independently assessed by two review authors. Where appropriate, the results of comparable studies were pooled using the fixed-effect model. **Results** A total of 38 trials concerning interventions for preventing acute ankle ligament injuries were included. Although the interventions were heterogeneous, and outcomes varied, the data from 27 trials could be pooled for the primary outcome 'incidence of ankle ligament injury'. The available data allowed sub-grouping for 'total ankle sprains', 'new ankle sprains' and 'recurrent ankle sprains'. Most participants were high school athletes, recreational athletes (age mainly 18 to 35 years) or military recruits. The interventions tested by the included trials fell into five main preventive strategies: foot-wear, taping, bracing, neuromuscular training, and multifaceted exercise programs. The quality of the evidence included in this review was moderate. **Discussion** In interpreting the results of this review, one should be aware of the variation in the participants, as the included trials mainly concerned recreational athletes, although a minority also concerned military recruits, elite and high school athletes. Therefore the evidence in this review is only applicable to active populations. **Conclusion** - there is no evidence for the use of high-top shoes; - there is limited evidence of low quality for a combination of high-top shoes and taping. - there is limited evidence of low quality for taping. - there is evidence of moderate quality for bracing preventing 'total ankle sprains', 'new ankle sprains' and 'recurrent ankle sprains'. - there is evidence of moderate quality for neuromuscular training preventing 'recurrent ankle sprains'; - there is very limited evidence of moderate quality for neuromuscular training preventing 'total ankle sprains'; - there is evidence of moderate quality for neuromuscular training preventing 'new ankle sprains'. - there is evidence of high quality for multifaceted exercise programs for preventing 'total ankle sprains'; - there is no evidence for multifaceted exercise programs for preventing 'new ankle sprains' and 'recurrent ankle sprains'. - there is very limited evidence of low quality for bracing over neuromuscular training in preventing 'total ankle sprains'.

SINGLE-LEG LANDING STABILIZATION TIMES IN SUBJECTS WITH FUNCTIONALLY UNSTABLE ANKLES

Kunugi, S.

university of tsukuba

Introduction Ankle sprains are the most common injury in physically active people and account for approximately 15% of all injuries in collegiate athletics. Ankle instability may exist following recovery, and individuals who continue to participate in activity may report of "giving way" at their ankles. These individuals have a pathology known as functional ankle instability (FAI). Cumberland Ankle Instability Tool (CAIT) is a valid and reliable tool to measure of functional ankle instability (Claire et al. 2006). Time to stabilization (TTS) have been used to evaluate the stability of subjects with FAI (Scott E Ross et al. 2005). The purpose of our study was to examine TTS differences between subjects with FAI and Stable ankles that divided with CAIT. **Methods** Fourteen Subjects with FAI (mean age 19.50 ± 1.00 years, CAIT score mean 30.00 ± 0.00) and 13 subjects with stable ankle (mean age 19.080 ± 0.45 years CAIT score mean 15.75 ± 5.50) were participated to this study. Subjects were tested 2 Single-Leg-Landing Stabilization Times. Anterior-posterior (A/P) and medial-lateral (M/L) time to stabilization was calculated for A/P and M/L components of the ground reaction force. Non-paired Test was used to compare different TTS/A/P Results There was significant difference for TTS M/L between FAI (mean 38.50 ± 20.71 ms) and stable ankle groups (mean 20.30 ± 2.79 ms). There was no significant difference for TTS A/P between FAI (mean 321.25 ± 121.04 ms) and stable ankle groups (mean 233.00 ± 46.82 ms). **Discussion** The subjects with FAI took longer to stabilize in the front and sagittal planes of motion compared with the stable ankle group. However, there was no significant difference for TTS P/L between FAI and stable ankle group. FAI have poor dynamic stability. **References** Claire E. Hiller, MAppSc, Kathryn M. Refshauge, Antia C. ELECTROMYOGRAPHIC ACTIVITY OF ANKLE MUSCLES DURING LATERAL HOPPING.

Masunari, A.

Ibaraki Prefectural University of Health Sciences.

Introduction An ankle sprain is the most frequent injury in the field of sports. Functional ankle instability (FAI) often results from ankle sprains. FAI is reduced the sports performance, especially, lateral movement performance. However, the ankle muscles activity of the athletes with FAI during lateral movement is not clear. Therefore, the aim of this study was to analyze the electromyographic activity of the muscles surrounding the ankle joint during lateral hopping. **Methods** Six male college football players with AI of the ankle joint and 6 non-FAI control players volunteered to participate in this study. We measured surface electromyography (EMG) of the tibialis anterior, tibialis posterior, peroneus longus, peroneus brevis, gastrocnemius lateralis and soleus muscle in all subjects during a lateral hopping task. And root mean square (RMS) was calculated from the electromyographic signal at each muscles for the period 200ms pre and post-initial contact(IC) and 400ms post-IC. **Results** The athletes with FAI showed a significant increase in pre-IC soleus RMS ($p < 0.05$). As for the other muscles, there were no significances. **Discussion** The athletes with FAI showed the different muscle activation pattern compared to the control group. This difference in movement may cause recurrent sprain **References** Yoshida M, Taniguchi K, Katayose M. (2011). J Strength Cond Res., 25(8), 2255-64 E. Delahunt, K. Monaghan, B. Caulfield. (2007). ISOKINETIC KNEE EVALUATION IN REHABILITATION CONTROL, CASE REPORT.

Piqueras, C., Mur, M.P., Sanchez, V.M.

BA4SYS

Introduction: A 38-year-old male runner presented to consultation with a 4-month history of right knee pain. He said the pain started suddenly. He began using ice compresses and ibuprofen, which offered minimal relief. The pain became so burdensome that he was unable to walk more than 2 blocks without having severe throbbing right knee pain, which he rated as 8 on a 0-to-10 pain intensity rating

scale. He denied any recent injuries, trauma, or contact with sick people. The patient's history was not significant. His right knee was oedema and muscle atrophy. The objective is rehabilitation treatment fitted to biomechanical test results, undergo several tests, our protocol and hard conditions with low velocities, Methods Rehabilitation exercises The patient performed different kind of intensities in several exercises: leg press, bench press, bent-over rows, exercise standing one foot instability, aerobic training jumping. In December, he ran slightly. Intensity was increasing as far as patient felt less pain and more stability, in average 5% per week. Evaluation Isokinetic: Patient was testing every month aprox. He performances extension flexion in isokinetic dynamometer mode Con/Con 60°/seg and 180°/seg. Peak torque and H/Q ratio was registered. We measured strength at low velocities, 30°, 75° and 90° with the aim to verify how response in hard conditions. Gait: In a platform force, gait analysis was obtained at comfortable velocity for the patient. We focused in ground reaction force during initial contact, stance, pre-swing and swing phases. Results We checked in April as compared to May and June, we objectified an improvement in the functional capacity. In August, we had some pain troubles so we had to change rehabilitation treatment, We obtained a decreased in strength and abnormalities in gait analysis. After adjusting treatment on December the evaluation is satisfactory, improvement strength, the performance, and being in percentile 90 of our data base. Isokinetic test at low velocities shows an improvement in force. Knee has the ability to develop strength. Gait analysis, we found some asymmetries during initial stance antero-posterior force. The patient refers don't feel pain during walking, even when he run slightly. Discussion Isocinetic assessment is useful in rehabilitation treatment, helpful to adjust endurance, strength, intensity. Training in instability conditions stimulates neuromuscular mechanism and the result is an improvement in strength and ability, coordination. . The objective is improve neuromuscular control, strength, power, ability, velocity and proprioception. In hard conditions, low velocities, the knee develops high strength, getting better. Asimetries in gait anlysis shows the knee is not as functional as the no involved knee, being necessary continue with the rehabilitation treatment. The stablitation and absortion forces during initial contact, is not being as well as it could develop.

HEMODYNAMIC RESPONSE TO MUSCLE METABOREFLEX ACTIVATION IN ELDERLY SUBJECTS

Crisafulli, A., Roberto, S., Marongiu, E., Marcelli, M., Loi, A., Mulliri, G., Concu, A., Milia, R.
university of Cagliari

Introduction Activation of the muscle metaboreflex leads to increase in mean blood pressure (MBP) due to increase in both systemic vascular resistance (SVR) and cardiac output (CO) (Crisafulli et al. 2003). However, in the human setting, this response has been studied mainly in young, healthy subjects (YS), while healthy elderly individuals (EI) have never been investigated. The aim of the present study was to test the hemodynamic response to metaboreflex activation in healthy EI older than 65 yrs. We hypothesized that they showed a reduced CO increment as compared to YS because of their reduced capacity to increase cardiac performance, pre-load, and consequently SV. **Methods** Fourteen healthy EI (8 females and 6 males, age 69.8 ± 3.5 yrs) were enrolled and randomly assigned to the following study protocol: 1) post-exercise muscle ischemia (PEMI) session, to study the metaboreflex, and 2) control exercise recovery (CER) session. Central hemodynamics were evaluated by means of impedance cardiography and echocardiography. Their response was compared to that of a control group of YS ($n = 14$, age 25.65 ± 8 yrs). **Results** The main findings were that there was not difference in the hemodynamic response to metaboreflex between groups. In detail, CO exhibited a similar increase with respect to the CER test during the metaboreflex activation (419.7 ± 413 vs. 724.7 ± 591.9 l·min⁻¹ for the EI and the YS group respectively). Similarly, SVR and MBP responses were not different between groups (135.2 ± 538.8 vs. 88.6 ± 296.5 dyne·sec·cm⁻⁵ and 12.6 ± 10.3 vs. 10 ± 7.6 mmHg for the EI and YS group respectively). **Conclusion** Our results indicate that hemodynamic response to metaboreflex activation is similar between elderly and young healthy individuals and that the cardiovascular control system maintains the capacity to adjust hemodynamic variables even in late stage of the lifespan. Crisafulli A et al. Muscle metaboreflex-induced increases in stroke volume. *Med Sci Sports Exerc* 2003; 35: 221-228.

CENTRAL HEMODYNAMIC CHARACTERISTICS OF CROSS-COUNTRY SKIERS 15-17 YEARS OLD

Alimpieva, O., Shishkina, A.
Ural Federal University

Introduction Nowadays every second is very important in high performance sport. Equipment of leading countries is the same therefore the most important part of win is training and abilities of athletes. In cross-country skiing key ability is endurance which is considerably defined by hemodynamic characteristics. **Methods** Thirteen well-trained skiers (men) were included in the study. The subjects' age was from 15 to 17. Each subject was well rested before testing and had not performed hard physical work during the previous 24 hours. In our investigation we used hemodynamic monitor of anesthesiologist and chosen the most important indicators such as heart rate, stroke volume, ejection fraction, cardiac output, stroke index, cardiac index, end-diastolic volume, end-diastolic index, index of left ventricle work and stroke index of left ventricle work. In measurement all athletes were at rest in the supine position. We used «STATISTICA 10» for statistical analysis. **Results** We described norms (mean \pm standard deviation) for each indicator in our group. Then we held correlation analysis between indicators and performance according to rating of skiers in Sverdlovsk-region (Russia). Statistical analysis showed significant correlation between athletes' performances and stroke volume ($r = -0.77$; 122 ± 22 ml), cardiac output ($r = -0.61$; 6.8 ± 1.6 l), end-diastolic volume ($r = -0.76$; 193 ± 34 ml), stroke index ($r = -0.82$; 69 ± 1 ml/m²), heart index ($r = -0.65$; 3.9 ± 0.9 l/m²), end-diastolic index ($r = -0.81$; 110 ± 17 ml/m²) and stroke index of left ventricle work ($r = -0.62$; 74 ± 14). No correlation between performance and heart rate (57 ± 8 beats/min), ejection fraction ($63 \pm 2\%$) and index of left ventricle work (4.2 ± 1.0). **Discussion** In our study the most of indicators are important for win in cross-country skiing. Such indicators as stroke volume, cardiac output and diastolic volume showed athlete's conditions and they might be predictors of competition results. But these indicators don't take into account body size of athlete therefore and different indices (stroke index, heart index, end-diastolic index and stroke index of left ventricle work) are calculated with previous indicators value and body surface area in some cases can be truer. Such indicators as heart rate, ejection fraction and index of left ventricle work don't have correlation with performance however they show a heart work quality and can be good indicators of overexertion.

EFFECT OF DIFFERENT SIMULATED ALTITUDES ON REPEAT SPRINT PERFORMANCE IN TEAM SPORT ATHLETES

Goods, P.1, Dawson, B.1, Landers, G.1, Gore, C.2,3, Peeling, P.1

1:School of Sport Science, Exercise & Health, The University of Western Australia, Crawley, Western Australia; 2: Australian Institute of Sport, Canberra, Australia; 3: Exercise Physiology Laboratory, F

Purpose: This study aimed to assess the impact of three simulated altitude exposure heights on repeat sprint performance in team sport athletes. **Methods:** Ten trained male team sport athletes completed three sets of repeated sprints (9 x 4 s separated by varying recovery jogging times and 3 min rest between sets) on a non-motorised treadmill (Woodway Force 3.0) at sea-level or at simulated altitudes of 2000, 3000 and 4000 m. Participants completed four trials in a random order over 4 weeks, with total work (J), mean power output (MPO), peak power output (PPO), blood lactate concentration (BLA) and oxygen saturation (SaO₂) recorded after each set. **Results:** Each increase in simulated altitude corresponded with a significant decrease in SaO₂. Total work across all sets was highest at sea-level and correspondingly lower at each successive altitude ($p < 0.05$; sea level 158914 ± 13094 J > 2000 m 149046 ± 10124 J > 3000 m 141126 ± 11083 J > 4000 m 127466 ± 8519 J). In the first set, MPO was lower at 4000 m only, but for subsequent sets 2 & 3, decreases in MPO were observed at all altitudes ($p < 0.05$; sea-level > 2000 m > 3000 m > 4000 m). Sea-level PPO was maintained in all sets except for set 3 at 4000 m ($p < 0.05$, 4000 m 1661 ± 520 W < sea level 2135 ± 365 W and 2000 m 2125 ± 376 W). Blood lactate levels at 4000 m were significantly greater ($p < 0.05$) than at sea-level after all sets, whereas BLA at 3000 m was only elevated compared to sea-level in the final 2 sets, and at 2000 m BLA was unchanged compared to sea-level. **Conclusions:** These results suggest that when completing intermittent hypoxic training, higher may not be better, since a simulated altitude of 4000 m may potentially blunt absolute training quality. Therefore, it is recommended that a moderate simulated altitude (2000-3000 m) be employed when implementing intermittent hypoxic repeat sprint training for team sport athletes to maintain training output while adding a hypoxic stimulus. However, the possibility of the increased metabolic cost at 4000 m having some positive outcome on performance cannot be discounted and should be further investigated in a training study.

THE EFFECT OF ISCHEMIC PRECONDITIONING ON REPEATED SPRINT CYCLING PERFORMANCE

Patterson, S.D., Glaister, M., Bezodis, N.E., Pattison, J.R.

St Marys University

INTRODUCTION Ischemic preconditioning (IPC) of skeletal muscle consists of brief periods of ischemia and reperfusion, which has been demonstrated to improve both sprint (Jean-St-Michel et al. 2011) and endurance performance (de Groot et al. 2010). The possible interaction between different types of exercise suggests that team sport athletes may benefit from IPC due to the repeated transitions from periods of low to high intensity metabolic work. The aim of the study was to investigate the effect of IPC on repeated sprint cycling performance. **METHODS** Fourteen healthy males (mean \pm SD; age 22.9 ± 3.7 years, height 1.80 ± 0.07 m, mass 77.3 ± 9.2 kg), recreationally active in various repeated sprint sports, were recruited to take part in a single blind, crossover design study. Following two familiarisation trials, participants underwent both an IPC and placebo (PLA) treatment involving four bouts of 5-minute bilateral cuff inflation of the lower limbs at 220 mmHg or 20 mmHg respectively. Following treatment, participants performed the repeated sprint ability (RSA) protocol, consisting of 12 x 6-s cycle sprints with 30-s passive recovery between each sprint. Respiratory gas exchange was measured throughout both trials. Ratings of perceived exertion (RPE, 6 – 20 Borg's scale) and blood lactate were recorded at rest and following sprints 4, 8 and 12. Peak power output (PPO) was determined for each sprint and fatigue index was calculated across all 12 sprints using the equation from Glaister et al. (2008): Fatigue Index (%) = $100 - [(\text{sum of power during each sprint} / \text{ideal power output}) \times 100]$. **RESULTS** Paired sample T-tests demonstrated PPO was significantly elevated following IPC (1630 ± 192 W) compared to the PLA condition (1594 ± 208 W). There was no difference between conditions for fatigue index (IPC: $14.7 \pm 5.9\%$ v PLA: $13.2 \pm 5.6\%$) or oxygen uptake (IPC: 2.69 ± 0.36 L.min⁻¹ v PLA: 2.58 ± 0.34 L.min⁻¹). Repeated measures ANOVA revealed no differences between IPC and PLA conditions for blood lactate or RPE. **DISCUSSION** These data indicate that IPC leads to an increase in PPO during sprint cycling. Further research should investigate the mechanisms behind the increase in PPO associated with the application of IPC prior to exercise. **REFERENCES** de Groot et al. INFLUENCE OF EXERCISE INTENSITY ON POSTEXERCISE MUSCLE PERFUSION

Stöcker, F., von Oldershausen, C., Schulz, T., Oberhoffer, R.

Technische Universität München

Introduction In current literature, there is evidence for the particular importance of local muscle perfusion or blood flow as a trigger for aerobic adaptations (Laaksonen et al. 2013). Especially training protocols like aerobic interval training consisting of repetitive series of high intensity followed by low intensity intervals seem suitable to gain an enhanced local muscle perfusion (Fu et al., 2011) and positive adaptations on the aerobic system (Talanian et al. 2006). It is supposed that high interval acts as a trigger for adaptations in the low interval (Buchheit et al. 2013). There is knowledge about acute effects of exercise on local muscle perfusion (Calbet et al. 2012) but a more detailed view on the impact of different exercise intensities is still missing. This study aims to examine to quantify postexercise muscle perfusion in relation to exercise intensity. **Methods** 17 men ($\text{VO}_{2\text{peak}} 50.2 \pm 5.9 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$) participated in the study. The experimental session consisted of six bouts of cycling exercise (Lode Excalibur, Groningen, NL) at exercise intensities corresponding to 40, 50, 60, 70, 80 and 90% $\text{VO}_{2\text{peak}}$ in random order, separated by 5min passive recovery. Prior to this a warm up (1min at 60% followed by 3min at 80% $\text{VO}_{2\text{peak}}$) was conducted. Muscle perfusion was measured noninvasively with a continuous wave near-infrared-spectroscopy (NIRS) device (portamon, Artinis, Zetten, NL), placed on the vastus lateralis muscle. Postexercise peak values of total haemoglobin (Peak40-90) were quantified in relation to the baseline values obtained during the last 30sec of the previous recovery period (BASE40-90). A repeated-measures-design ANOVA was used to compare the effects of the various intensities. **Results** Peak40-90 were all significantly higher than the corresponding baseline values. ANOVA reported significant differences between the different exercise intensities. Post hoc tests showed significant higher values for Peak80 and Peak90 in comparison to Peak40-70. **Discussion** These results suggest that all examined exercise intensities are sufficient to induce a postexercise local hyperemia. Intensities at 80-90% $\text{VO}_{2\text{peak}}$ induced a significantly higher hyperemia than intensities at 40-70% $\text{VO}_{2\text{peak}}$. Therefore, interval-training-protocols should be designed with exercise intensi-

ties of 80% VO₂peak or above to enhance local haemodynamics most effectively. References Buchheit M, & Laursen P (2013). Sports Med, 43(5), 313–338 Calbet J & Lundby C (2012). HYPOTENSION AFTER ENDURANCE EXERCISE AT ALTITUDE

Saito, Y., Nakamura, M., Eguchi, K., Kushibe, S., Ajisaka, R., Otsuki, T.

Kanazawa Seiryō University

It is well known that the mortality from coronary heart disease decline from the lowest to the highest altitude. Endurance exercise at altitude has chronic effect on improving vascular endothelial function (1) and decreasing baseline blood pressure (2). In addition, the recent study reported that endurance exercise has acute effect on vascular endothelial function (3). These studies suggested that acute hypotension after endurance exercise might be greater at altitude than at sea level. The purpose of this study was to investigate the hypotension after endurance exercise at altitude. Eight male college runners (20.0±0.3 years) were studied. Blood pressure (BP), heart rate and cardiac output were determined before and at 15, 30, and 60 minutes after a graded running to exhaustion under hypobaric hypoxia condition (HH trial, 586mmHg) and normobaric normoxia condition (NN trial, 760mmHg). In addition, to compare the results under the same absolute exercise intensity, we, under NN condition, investigated these parameters after the exercise of the same period as the exercise time of HH trial (NNsubmax trial, 760mmHg). Exercise time, peak running speed, peak oxygen uptake, and peak heart rate demonstrated significantly lower values in the HH trial than in the NN trial ($p<0.05$). However, no differences were observed in these parameters between the HH and NNsubmax trials. BP and total peripheral resistance (TPR) were reduced after the exercise from baseline ($p<0.05$), although the degree of changes were not different between the HH and NN trials. On the other hand, the trial×time interaction in systolic blood pressure (SBP) was observed between the HH and NNsubmax trials ($p<0.05$). These results showed that SBP tended to be lower in the HH than in the NNsubmax trial. Also, TPR showed lower value in the HH trial than in the NNsubmax trial ($p<0.05$). We conclude the magnitude of hypotension after endurance exercise might be greater at altitude than at sea level. 【Reference】 1)Bailey DM, Davies B and Baker J. MO-PM40 HF Ageing

THE AGE-RELATED CHANGES ON MUSCLE STRENGTH AND CARDIORESPIRATORY FITNESS. FROM SEPTUAGENARIAN TO NONAGENARIANS.

Costa, N.M.C.1, Rodrigues, L.P.1,2, Fernandes, F.1, Rodrigues, T.M.1, Silva, B.1, Simões, M.1, Bezerra, P.1,2

1:Viana do Castelo Polytechnic Institute (IPVC), 2:Research Center in Sports Sciences, Health Sciences and Human Development (CIDESD)

Introduction Aging has been associated with decline in physical fitness status including decreasing in muscle strength and cardiorespiratory fitness. Whether age-related changes in physical fitness are due to impairment either of muscle strength or cardiorespiratory capacity it's not well known. The aim of this study was to investigate the decline on both muscle strength and cardiorespiratory capacity according to age and sex. Methods One thousand and sixty participants (723 female and 337 male) with 70 years and more (septuagenarian, 74.2±2.8yrs; octogenarian, 83.5±2.6yrs; nonagenarian, 92.1±1.7yrs; $p<0.05$) were recruited from Viana do Castelo region. The subjects were tested on Handgrip Test (right hand, HandTr, and left hand, HandTL) and Static Knee Extension Test at 90 degree (right leg, KneeT) to access muscle strength. Cardiorespiratory fitness was measured through the Six Minutes Walking Test (6MW). ANOVA was performed, with post-hoc Bonferroni test when needed, to detect group differences. Linear Regression, specifically the slope (m), was used to evaluate the level of decline along age in muscle strength and cardiorespiratory fitness. Significance was set at $p<0.05$. The Human Research Ethics Committee of the IPVC approved the testing procedures and the written informed consent was obtained from the subjects. Results Males showed significant higher scores than females in all tests ($p<0.001$). Also, it was found significant decline between age groups within the different genders, with a $p<0.05$. Therefore, men had higher scores than women and less decline over time in all the tests: HandTr ($m=-0.33$ /yrs, $R^2=0.11$), HandTL ($m=-0.35$ /yrs, $R^2=0.12$), KneeT ($m=-0.37$ /yrs, $R^2=0.13$) and 6MW ($m=-0.40$ /yrs, $R^2=0.16$). Whereas, women had overall lower scores and greater decline: HandTr ($m=-0.44$ /yrs, $R^2=0.19$), HandTL ($m=-0.42$ /yrs, $R^2=0.17$), KneeT ($m=-0.38$ /yrs, $R^2=0.15$) and 6MW ($m=-0.52$ /yrs, $R^2=0.27$). Discussion In all tests men showed higher scores and lower decline, lower slopes, over time in muscle strength and cardiorespiratory capacity. These data may provide evidence that men have a lower rate of functionality loss than women. In both men and women the decline is different in the cardiorespiratory capacity (6MW) than muscle strength (HandT and KneeT), possibly indicating a greater dependence between cardiorespiratory capacity and age.

THE RELATIONSHIP BETWEEN WAIST CIRCUMFERENCE AND PHYSICAL FITNESS STATUS AS HEALTH PREDICTORS ACROSS ELDERLY LIFESPAN

Silva, B.1, Rodrigues, L.P.1,2, Fernandes, F.1, Rodrigues, T.M.1, Costa, N.M.C.1, Simões, M.1, Bezerra, P.1,2

1-Viana do Castelo Polytechnic Institute; 2-Research Centre in Sports Sciences, Health Sciences and Human Development (CIDESD)

Introduction Both waist circumference (WC) and waist to hip ratio (WHR) have been suggested to be good predictors of health risk. Likewise, physical parameters such as muscle strength and cardiorespiratory capacity have been found to be key health components. Whether age-related values of WC and WHR and physical status are associated to health risks it is not well established. This study aims

to investigate the relationship between waist and hip measures and physical fitness status on septuagenarian to nonagenarian, male and female. Methods One thousand and fifty participants aged 70 years and more (septuagenarian (70's) 74.2 ± 2.8 yrs; octogenarian (80's) 83.5 ± 2.6 yrs; nonagenarian (90's) 92.1 ± 1.7 yrs; $p < 0.05$) recruited from Viana do Castelo, northern Portugal. Subjects were classified according to WC and WHR as low/high risk for health, and tested on Handgrip Test (HandT) in Kg, Isometric Knee Extension Test (IKE) in Kg and 6 Minutes Walking Test (6MW) in meters. The two health risk identification conditions (WC or WHR), where compared on their ability to discriminate physical status using ANOVAs. Post-hoc Bonferroni tests were used when appropriate. Significance was set at $p < 0.05$. The Human Research Ethics Committee of the IPVC approved testing procedures. Results Fifty nine percent of the participants were allocated on similar health group of risk on WC and WHR. When using WHR as health risk predictor no significant difference was found between groups on any of the physical fitness tests. On the other side, significant differences were found between WC groups for HandT (low-risk, 26.7 ± 9.3 , high-risk, 24.2 ± 7.8 , $p < 0.05$), IKE (low-risk, 31.1 ± 14.9 , high-risk, 26.7 ± 13.4 , $p < 0.05$) and 6MW (low-risk, 369.7 ± 132.7 , high-risk, 323.3 ± 130.7 , $p < 0.05$). Physical fitness tests were also found to be different between gender (6MW, 319.6 ± 131.7 , 379.9 ± 128.4 ; HandT, 21.9 ± 5.9 , 31.9 ± 8.7 ; IKE, 22.7 ± 9.4 , 40.1 ± 15.0 ; $p < 0.05$, female and male respectively), and 70's (6MW, 392.1 ± 118.3 ; HandT, 27.4 ± 8.3 ; IKE, 31.9 ± 14.6) and both 80's (6MW, 277.4 ± 123.1 ; HandT, 22.6 ± 7.4 ; IKE, 24.0 ± 12.1 , $p < 0.05$) and 90's (6MW, 246.9 ± 107.2 ; HandT, 20.4 ± 8.6 ; IKE, 21.6 ± 9.5 , $p < 0.05$). Discussion Waist circumference seems to be better than waist to hip ratio to predict health status in the elderly. Waist circumference low-risk group shows higher physical fitness status than their counterparts of the high-risk group, independent of age or sex. Males and 70's showed better physical fitness than women and 80's or 90's, respectively. However, no significant differences were found between 80's and 90's. Contact: silvabruno@esdl.ipvc.pt

DIFFERENCES IN FIRE FIGHTER FITNESS AND PERFORMANCE RELATED TO AGE

Williford, H., Esco, M., Reilly, E., Witte, E., Walker, A.

Auburn University Montgomery

Introduction: The assessment of health and performance are important considerations when evaluating fire fighters. Job performance is often evaluated by a simulated job performance task (FFJPT). The purpose of the FFJPT was to quantify if the fire fighter meets the appropriate physical fitness and job related skills. In addition, as fire fighters age there are concerns regarding health, physical fitness, and job performance. The scientific literature indicates that men in general lose 40% of their muscle mass with a 30% decrease in strength by age 70 (Rogers & Evans, 1993). Maximal oxygen uptake decreases approximately 9% per decade for sedentary men (Elia, 1991). Methods: Three-hundred and ninety-seven male fire fighters were evaluated with the following mean \pm SD values: age 34.9 ± 8.6 yrs, height 1.80 ± 0.07 m, weight 88.18 ± 11.58 kg. All fire fighters performed a fitness test consisting of a 1.5 mile run, maximal sit-ups, and push-ups. Each fire fighter performed a maximal FFJPT, wearing turnout gear and self-contained breathing apparatus (SCBA). The FFJPT consisted of stair climb, hoist, forcible entry, hose drag, and dummy drag. The fitness and performance values were evaluated in increments of 10 years from age 19 to 59. A one way ANOVA was performed to evaluate differences in fitness and performance variables by decade with Bonferroni post hoc follow-up analyses. Results: The mean \pm SD values were: 1.5 mile run time 11.67 ± 1.76 min, push-ups 55 ± 18 , and sit-ups 47 ± 10 . The mean \pm SD FFJPT time was 4.33 ± 1.21 min. Results indicated that there were significant differences in fitness and performance based on age groups. From the 19 to 29 (age group) to the 50 to 59 (age group), push-ups decreased 35%, sit-ups 21%, 1.5 mile run 16%, and FFJPT 65%. Conclusions: This investigation found that fire fighters experience age related changes in fitness and performance. The largest percentage decrease was in the job task analysis skill. From the youngest to the oldest age group, job performance decreased 65%. Age related changes also occurred in muscular strength/endurance and cardiovascular fitness. Further analysis found that all fire fighters were able to perform the job tasks in the required minimal times; however it is important that fire departments address age related changes in fitness and performance.

PHYSICAL FUNCTION IN JAPANESE COMMUNITY-DWELLING OLDER ADULTS LIVING IN A RURAL REGION AND THE BUILT ENVIRONMENT USING GEOGRAPHIC INFORMATION SYSTEMS

Soma, Y.

University of Tsukuba

Introduction Neighborhood built environments may influence older adults' functional health and physical activity (Baulfor and Kaplan, 2002; Cauwenberg et al., 2011). Therefore, determining the impact of built environments on older adults' physical function may improve the effectiveness of city planning for preventive care management. The aim of this study was to explore the relationship between built environments and physical function. Methods Study participants were 591 older adults (men = 282, women = 309) living in Kasama city, a Japanese rural region. We evaluated physical function with the following tests: grip strength (GS), 5-m walking test at comfortable speed (WT), functional reach (FR), and Timed up and go (TUG). Using geographic information systems, we measured residential density (RD), number of local destinations (LD) and land slope (LS) of the participant's neighborhoods. The degree of each built environment variable was classified as low, medium or high. We used an analysis of covariance to study the association between physical performance and built environment in men and women. Results After adjusting for potential confounders, we found RD was associated with WT in men (low density-4.0 sec, medium-3.7 sec, and high-3.7 sec, trend P value < 0.05) and women (low density-3.9 sec, medium-3.7 sec, high-3.4 sec, trend P value < 0.05). In women, GS and TUG were associated with RD and LD, and TUG and WT with LS (trend P value < 0.05). While in men, only WT was associated with LD (trend P value < 0.05). Discussion The present study revealed the independent relationship between objective measures of neighborhood built environments and physical function in older adults. Baulfor and Kaplan, (2002) reported that subjective measures of neighborhood environment related to loss of physical function in older adults. In this study, both men and women living in an area of high residential density had superior walking ability. This is probably because high residential density tends to be designed for pedestrians to travel comfortably, which may influence their walking ability. Additionally, our results suggest that neighborhood environments are more likely to affect women's physical function than men's, perhaps due to different destinations and a preference for transportation mode. HEALTH AND BEHAVIORAL CHARACTERISTICS AS PREDICTORS FOR THE CONTINUITY OF PARTICIPATION IN PHYSICAL FITNESS CHECKUPS AMONG COMMUNITY-LIVING OLDER PEOPLE IN JAPAN

Kozakai, R., Ueda, T., Ide, K., Oda, S., Honda, R., Aiuchi, T.

Hokusho University

Introduction Health and physical fitness checkups are useful for prevention of chronic diseases and functional decline, as well as promoting the awareness of their health condition among older people. However, regular participants in health and physical fitness checkups are limited in the community. The purpose of the present study was to determine the predictors for continuity of participation in physical fitness checkups in community-living older people in a 1-year follow-up study. **Methods** The subjects were 384 people aged 60 years and over, who participated in the physical fitness checkups organized by local municipalities and Hokusho University in 2012. Individual attributes, health condition, lifestyle, Tokyo Metropolitan Institute of Gerontology Index of Competence (TMIG Index of Competence), social activities and exercise experience were checked by questionnaire. Body size and grip strength were measured using standard techniques. The follow-up checkup was conducted one year later. The measurements were compared between dropouts and participants in the follow-up. Multiple logistic regression models with participation in the follow-up as outcomes were used to estimate the association of baseline characteristics. **Results** The number of dropouts and participants in the follow-up was 206 (53.6%) and 178 (46.4 %), respectively. Age, sex, intellectual activity score in TMIG Index of Competence, work status, smoking habits, frequency of going outdoors and regular exercise were significantly different between dropouts and participants in the follow-up. In the unadjusted logistic regression model, smoking habits and frequency of going outdoors were significantly associated with participation in the follow-up. After controlling for all potential confounders, people who go outdoors every other day were significantly more likely to participate in the follow-up (OR 2.99, 95%CI 1.37-6.56). Using the forward selection model, the association was still significant (OR 2.72, 95%CI 1.27-5.84). **Discussion** In our exploratory analysis of health and behavioral factors for continuity of the physical fitness checkup, people who go outdoors every other day had about 3-fold higher rate of participation in the checkup. Other factors did not predict participation in the follow-up. Frequency of going outdoors is taken as a definition of houseboundness, which has been a serious geriatric concern. Our results suggest that frequent going outdoors could be an effective target for preventing health and functional decline among community-living older people. Contact kozakai@hokusho-u.ac.jp

SOCIO-DEMOGRAPHIC AND ENVIRONMENTAL CORRELATES INFLUENCING ELDERLY'S PHYSICAL ACTIVITY. A REPRESENTATIVE COMMUNITY STUDY

Aspvik, N.

Norwegian University of Science and Technology

Introduction Regular, moderate-intensity physical activity is seen to have a key role in the promotion of good health and the prevention of disease. For older adults, being regularly active has been associated with better physical and psychological health and functional capacity (Booth 2000). The aim of this study was to assess elderly's physical activity level (PA) and the role of socio demographic- and environmental factors. **Methods** The participants is a representative sample of elderly's (70-77) living in the city of Trondheim, Norway (N= 895). The ActiGraph accelerometer GT3X was used to obtain objective assessment of physical activity. Data were considered valid if it was at least 4 d of at least 600 min•d⁻¹ (Hansen, 2012). Based on the national physical activity recommendation in Norway (30min of MVPA per day), PA was measured as minutes in moderate to vigorous physical activity (MVPA). Determinants of PA were collected through questionnaire. Data were subjected to a binary logistic regression analysis using SPSS. **Results** Totally, 55.9 % of the participant (males: 57.5 %; females: 54.6 %) met the national recommendation. The independent variables chosen in this model explains 12.5 % of the variance in MVPA. Elderly's level of education (OR: 1.422*), being physical active at the age of 40 (1.568*), and physical- (.903*) and social (1.161*) environment all had a positive significant effect on the MVPA. Gender and physical demanding work didn't have a significant effect. **Discussion** Finding a positive correlation between educational level and PA, supports Lim et.al (2004), while being in contrast to the findings in Papadopoulou et.al (2003). The positive correlation between being active at 40 and 70-77 indicates that you establish some lifelong PA habits in adult age. Further, the results suggest that facilitating both elderly's social- and physical environment are important to stimulate physical activity. This supports the findings in Booth et al. (2000). **References** Booth M., Owen N., Bauman A., Clavisi O., Leslie E. (2000). THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH AND PHYSICAL ACTIVITY QUESTIONNAIRES FOR THE ELDERLY – AN ANALYSIS OF CONTENT

Lange, M., Eckert, K., Baumgärtel, S.

Faculty of Sport Science, University of Leipzig

Introduction Physical activity questionnaires (PAQ) have been widely accepted and extensively used to determine physical activity (PA) levels in individuals. Most of these questionnaires mainly focus on quantity of PA (energy expenditure). Looking at elderly persons not only quantity of PA is of interest, but also the quality. Functional activities such as home or lifestyle chores, contribute to a person's quality of life essentially. The aim of the study was to identify PAQ for the elderly, link their items to the ICF, analyze their contents and discuss the findings with regard to purpose. **Methods** Through a literature review using three databases (Pubmed, EBSCO Host, SPOMED) we included n=22 English PAQ which are applicable to older adults (60+ years) and have been sufficiently validated. Two independent professionals linked each item (N=555) to the ICF using established linking rules (Cieza et al., 2005). Kappa statistics have been calculated to determine context fit. **Results & Discussion** 555 items have been linked to 834 ICF concepts and 74 different ICF categories. A total of 41 items were classified as "non definable". The linked items represent categories predominantly in the ICF component activities and participation (96%) with a high variability of ICF domains between instruments. Out of the 834 identified concepts 27% of concepts were sports-related activities and 22% mobility related. Only 4% of the concepts inquire information on household tasks. Overall low-intense, functional activities are emphasized differently and are in most cases underrepresented. The estimated κ coefficients ranged from 0.45 and 0.99 for n=20 questionnaires. Two questionnaires showed unacceptable κ coefficient values (0.04 and 0.1). **Discussion** The results indicate that there is

a strong inconsistency in the understandings of measuring PA in older people with PAQ in general, but especially with regard to low-intensive, functional activities. Further research should focus (1) on a unique conceptual understanding of physical activity with regard to the physical activity behavior of elderly and should also focus (2) on developing a questionnaire for the elderly that gathers functional aspects of PA next to energy-related outcomes more explicitly. EVALUATION OF ANTHROPOMETRIC CHARACTERISTICS OF FEMALE IN DIFFERENT AGE GROUPS IN LATVIA

Plavina, L., Karklina, H.

National Defence Academy of Latvia, Riga Stradins University

Introduction Anthropometric characteristics form the basis for physical activities and health-related behavior, which is important for everyone in order to preserve physical and mental health (Jannsen et al, 2005; Contramestre et al, 2007[1,2]). The target of this work is to analyze and compare anthropometric characteristics of female in Latvia from childhood to adult life. **Material and methods** In order to reach defined target, we examined female aged 4 to 55 (N 979). We took the main anthropometric parameters such as height, body mass, and body circumstances (chest, upper arm). In addition, we determined anthropometric indices and coefficients. **Results** The body mass index is the major characteristic of the respondents which describes physical condition and nutrition level in any age group under discussion. In the 1st childhood group the average body mass index was 15.6 ± 0.8 . The value of BMI increased up to 17.6 ± 0.2 in the 2nd childhood group. In the next age group the height and body mass parameters increased further, and BMI average data of adolescent group reached 18.3 ± 0.4 . In the youth age group data of BMI were 21.9 ± 0.3 . The height and body mass parameters increased in the next age group (adults) - the BMI average data were 21.9 ± 0.2 in the 1st adult age group and 23.9 ± 1.1 in the 2nd adult age group, respectively. The body mass is the most yielding characteristic. The body mass average data in the 1st childhood group was 21.9 ± 3.7 kg. The body mass parameters increased over 63 % in the next age group (2nd childhood group) - 35.9 ± 0.6 kg, accordingly. The body mass data in the adolescent group were 42.4 ± 1.0 kg (over 18%). In the youth age group the body mass parameters were 62.6 ± 1.1 kg, however for adults the average body mass data were 63.1 ± 1.0 kg in the 1st adult age group and 68.2 ± 2.1 kg in the 2nd adult age group. The height parameters in the group of 1st childhood were 118.1 ± 1.0 cm. The height parameters increased over 20% in the age group of 2nd childhood - 142.6 ± 0.6 cm, respectively. The height parameters in the adolescent age group were 151.0 ± 0.7 cm. In the youth age group the height parameters were 169.2 ± 0.7 cm, whereas in the 2nd adult age group the height parameters were 169.2 ± 0.7 cm. **Conclusion** Anthropometric parameters of are very variable. Body compositions of female the most accorded to the standard data. Levels of BMI exceeded the standard data only for a small number of examined persons. **References** 1. THE EFFECTS OF SWIMMING ON THE BLOOD PRESSURE OF MIDDLE-AGED HYPERTENSIVE INDIVIDUALS

Silva, J.E.1,2, Teixeira, A.2, Rama, L.2

1. Prefeitura Municipal de Juiz de Fora-MG-Brasil 2. University of Coimbra

INTRODUCTION: Physical Activity (FA) is a non-pharmacological way to prevention and treatment of hypertension (HPT). Swimming, as a type of FA has also been recommended for the treatment and prevention of HPT, (ACSM, 1993; Pescatello, et al. 2004; AHA, 2002; Tanaka, 2009). **OBJECTIVES:** The aim of this study was to analyze the effects of regular swimming on blood pressure of middle-aged hypertensive individuals. **METHODS:** Eighteen volunteers were studied, being 9 males (48.77 ± 4.2 years old; 82.74 ± 1.4 kg) and 9 females (44.0 ± 6.36 years old; 60.82 ± 9.9 kg). The subjects have engaged into a regular swimming programme, consisting of three weekly fifty-minutes for 12 weeks. A Student's t-test was used to determine statistical significance ($p < 0.05$) and the differences before and after the 12-weeks regular swimming. **RESULTS:** At the end of the intervention the subjects presented significant statistical differences for the analyzed variables. There was an important reduction of Systolic Blood Pressure (SBP) for both sexes, (Males) from $141.54.0 \pm 4.32$ to $134.02.0 \pm 6.18$ mmHg and (females) from 137.31 ± 15.04 to 131.41 ± 14.50 mmHg. **DISCUSSION** Although some studies (ACSM, 1993; Pescatello, et al. 2004) recommend swimming as a form of physical activity to prevent and treat hypertension, few studies involving human beings have verified the relationship between swimming and hypertension. After the intervention there were decreases of 5.3 % (Male) and 4.5 % (female) for SBP between the measurements. The latest studies aimed at verifying the effects of swimming on hypertension in humans reported results similar to those found in our study (Tanaka et al. 1997; Silva, 2006). This allow us to conclude that a regular swimming program leads to a significant decrease in the Systolic blood pressure (SBP) of hypertensive adults. **REFERENCES** AMERICAN COLLEGE OF SPORTS MEDICINE. SHEFFIELD HALLAM STAFF WELLNESS SERVICE: FOUR YEAR FOLLOW-UP OF THE IMPACT ON HEALTH INDICATORS

Carter, A., Scaife, R., Kesterton, S., Humphreys, L., Breckon, J., Till, S., Flint, S.W., Maynard, I., Copeland, R.

Sheffield Hallam University

Introduction Alongside the increasing prevalence of chronic health conditions such as cardiovascular disease and obesity, has been greater intervention efforts. Due to the large proportion of time spent in the workplace (Office for National Statistics, 2011) and in many instances a likelihood of physical inactivity, poor nutrition and increased stress, this setting has increasingly been used for intervention efforts (e.g., Pronk & Kottke, 2009; The Black Report, 2008). Thus the aim of this study was to examine the impact of the Sheffield Hallam University Staff Wellness Service on health indicators over four years. Method The Sheffield Hallam Staff Wellness Service was advertised via email and newsletter across the university to employees. Overall 2651 employees of the university have attended the wellness service of which 427 respondents (male = 162, female = 265) have attended for four years. All 427 attended and consented to participate in the service. On attending the service, participants were assessed on health screen measures (BMI, blood pressure, cholesterol, high density lipoproteins and % body fat) at baseline and every year for four years. They also received lifestyle advice to improve and in some cases maintain their current health status and motivational interviewing to elicit behaviour change in working towards agreed lifestyle modification. Results Whilst trends suggest that the service had a beneficial impact on participants' health indicators (e.g., systolic blood pressure is on the cusp of significance), only diastolic blood pressure significantly improved from baseline to follow-up. Repeated measures ANOVA revealed that diastolic blood pressure was lower in all four follow-up assessments in comparison to the baseline measurement ($P < .05$). There was no significant difference for the other measurements across the five time points. An interaction effect was evident between cholesterol and participant sex, where males cholesterol decreased whilst females cholesterol increased ($P < .05$). Discussion In alignment with previous research (e.g., Pronk & Kottke, 2009) the findings of the current study suggest that the Sheffield Hallam Staff Wellness Service has been beneficial in improving health indicators over four years. The service is continuing to be offered to staff and as more participants complete follow up health screening at the service, a more informed judgement can be made regarding its effectiveness in improving health indicators. As Addley et al. (2014) suggests Interventions to improve employee wellbeing should incorporate physical activity; nutrition and mental health are these are often impacted by the workplace. WALK@WORKSPAIN: PREDICTORS OF SITTING TIME REDUCTIONS IN OFFICE EMPLOYEES

Bort Roig, J.I, Puig Ribera, A.I, Martori, J.C.I, Gilson, N.D.2

1. Universitat de Vic (Barcelona) 2. The University of Queensland (Australia)

Introduction: Sedentary office workers sit for around 9-11 hours a day (Tudor-Locke et al., 2011) and prolonged periods of sitting have been associated with an increased risk of all-cause mortality (Chau et al., 2013). This study investigated the predictors of reducing sitting time after enrolling in a web-based "sit less and move more at work" program. Methods: Predictors of reducing sitting time were identified from a quasi-experimental study (Walk@WorkSpain Project) with intervention group employees ($n=129$; 67% women). Following demographic, physical and behavioural baseline measures, the intervention consisted of a (i) ramping phase to progressively increase baseline counts to 10,000 steps/day through active work tasks, and short/long walking routes at work and; (ii) maintenance phase to sustain the increased volume of step counts through researcher support. Employees self-reported sitting time throughout the intervention. A logistic regression model examined relationships between baseline measures and change in sitting time post intervention. Results: Sixty percent of employees reduced their daily sitting time after completing the intervention. The strongest predictor of sitting time reduction was high waist circumference ($OR=1.02$, 95%CI: 1.00-1.05). Employees who reported more hours/ day sitting at baseline were more likely to change than those who sat less ($OR=1.00$, 95%CI: 1.00-1.00). Women were less likely to reduce sitting time after intervention than men ($OR=0.36$, 95%CI: 0.18-0.69). This model correctly classified 66% of intervention group employees. Discussion: High waist circumference, long periods of sitting time and sex predicted sitting time reductions in this Spanish sample of office employees. The findings provide insights into the characteristics of employees for whom Walk@WorkSpain may be most effective. References: Tudor-Locke C, Leonardi C, Johnson WD, Katzmarzyk PT. (2011). HEALTHY WORKFORCE PROJECT: FEASIBILITY AND USE OF A SIT-STAND WORKSTATION FOR REDUCING WORKPLACE SITTING TIME

Graves, L.E.F., Murphy, R., Shepherd, S., Hopkins, N.D.

Liverpool John Moores University

Introduction Excessive sitting time is a risk factor for cardiovascular disease and premature mortality independent of physical inactivity. Workplace interventions that reduce sitting time without interfering with work-related performance can inform work practices and organisational policy for occupational health. This study evaluated the feasibility and use of a sit-stand workstation for reducing workplace sitting time. Methods 26 of 47 eligible asymptomatic employees from one University in the North West of England were randomly allocated to an intervention group that received a sit-stand workstation (WorkFit-A, Ergotron Ltd) for 8 weeks. Time spent sitting, standing and walking during work hours was assessed at weeks 0, 4 and 8 via ecological momentary assessment diaries. Feasibility was assessed at 8 weeks via questionnaire. Repeated measures ANOVA assessed changes in sitting, standing and walking time over 8 weeks. Results At baseline, sitting time occupied 81% (mean 382.5 SD (56.7) min/d) of the working day. Compared to baseline, sitting time was lower at week 4 (295.0 (93.4) min/d, $p=0.001$) and week 8 (319.7 (101.0) min/d, $p=0.066$). Feasibility data suggest participants found the workstations easy and comfortable to use in front of colleagues. The workstation interfered with daily work-related tasks for 28% of participants. 66% of participants would use the workstation at work if offered to them by their employer. Discussion The sit-stand workstations trialled in this study reduced workplace sitting time by ~60 min/d after 8 weeks. Though feasible to use, the workstation interfered with work-related tasks for a minority of workers. Trials are warranted to determine the longer-term acceptance of sit-stand workstations and effect on work-related performance. Such trials should evaluate any associated benefits for physical, mental and social health, as well as additional organisation performance indicators such as cost-effectiveness. HEALTH PROMOTION IN DUTCH AND GERMAN SMALL AND MIDDLE SIZE COMPANIES-CRITICAL FACTORS FOR SUCCESSFULLY IMPROVING PHYSICAL ACTIVITY LEVELS

Wollesen, B., Piper, J., Fendel, R., Hartwig, C., Mattes, K.

University of Hamburg

Introduction In 2010 the EU-project "Fit for Business" started in Germany and the Netherlands to provide health promotion concepts and interventions to small and middle size companies. Employees of both countries have to deal with work related problems like sedentary work style or musculoskeletal disorders. In addition physical factors like pressure of time or pressure to perform are common distresses for work incapacity. The projects strategy included company specific health analysis to confirm goal orientated health interventions. This study compared the German (G) and the Dutch (D) data for infrastructure and activity levels. Moreover the critical factors of success to improve physical activity levels for both countries were analyzed. **Methods** 41 companies (N=4137; G n=2471, D n=1466) were examined with standardized questionnaires asking for infrastructure for health promotion, workload, physical complaints (Caffier et al., 1999), physical and mental wellbeing (SF-12), resources and health related behavior as well as wishes and obstructions for health promotion. Statistical pre-post analysis included Chi²-tests and multivariate tests. **Results** The comparison of both countries revealed significant higher work related physical and mental stresses for the Dutch employees; However, the German workers showed more physical complaints (e.g. pressure of time $p=.000$, $\chi^2=143.58$, $C=.247$; neck disorders $p=.000$, $\chi^2=197.86$, $C=.279$). Overall there were company specific activity based health conditions. The Netherlands provided a better infrastructure for health promotion. However the workers of both countries had comparable physical activity levels at the beginning of the project but only the German workers improved their activity levels significantly. **Discussion** Data analysis clarified the requirement for country, company and setting specific interventions. We suppose a relationship between the country and company specific infrastructure for health promotion and resulting workloads and physical complaints. However these factors did not explain the employees different motivation to join the project interventions to get more physical active. One explanation might be that the Dutch workers are more active during their working day whereas the Germans had more sedentary jobs with resulting physical complaints. In addition it has to be discussed if the project strategy which was realized in the same way for both countries should have been modified in order to the country-specific conditions. **Literature** Caffier, G., Steinberg, U. & Liebers F. EFFECTS OF TWO WEEKS OF STATIN TREATMENT ON MITOCHONDRIAL RESPIRATION IN HEALTHY MIDDLE-AGED MALES

Larsen, S., Helge, J.W., Dela, F.

University of Copenhagen

Introduction: Statins are widely used in the treatment of hypercholesterolemia. Recently it has been reported that the beneficial adaptations in regard to exercise training are blunted when exercise is combined with statin treatment (simvastatin). Mitochondrial respiratory capacity is suggested to be one of the most predictive physiological variables of endurance performance. It has been reported that mitochondrial respiratory capacity is impaired in patients treated with simvastatin (cross-sectional study). It has never been investigated in humans if different statins have an effect on mitochondrial respiratory capacity. Therefore, the present study was conducted to test if simvastatin and pravastatin have similar effects in regard to maximal mitochondrial respiratory capacity. We hypothesized that simvastatin would have a negative effect and that pravastatin would have no effect on maximal mitochondrial respiratory capacity. **Methods:** Twenty healthy middle-aged men were randomized to either two weeks of simvastatin (80 mg/day) or pravastatin (40 mg/day). A biopsy from vastus lateralis was obtained before and after the two weeks. Maximal mitochondrial respiratory capacity was determined using high-resolution respirometry (Oxygraph-2k, Innsbruck, Austria). Maximal oxygen uptake and hand-grip strength **Results:** Age, weight, body mass index and fat percentage were similar at baseline between the two groups, and did not change following the two weeks of treatment. Maximal oxygen uptake was similar between the groups at baseline and was not affected by the treatment. Maximal mitochondrial respiratory capacity was different ($P<0.05$) at baseline between the simvastatin and pravastatin treated subjects (67 ± 5 vs. 58 ± 4 pmol/mg/sec, respectively). The simvastatin treated subjects showed a reduced ($P<0.05$) maximal mitochondrial respiratory capacity (67 ± 5 vs. 63 ± 3 pmol/mg/sec, respectively), whereas no difference was seen in the pravastatin treated group (58 ± 4 vs. 58 ± 5 pmol/mg/sec, respectively). Hand-grip strength was reduced in the whole group after two weeks of treatment (51 ± 1 vs. 50 ± 2 kg), this was not significant within each group. **Discussion:** Two weeks of simvastatin treatment impair mitochondrial respiratory capacity, whereas pravastatin treatment does not have this deleterious effect. This difference could be due to the lipophilicity of the statin, and highlights the importance of controlling for the statin used. The present finding could be a possible explanation for the blunted effect when exercise is combined with statin treatment. This of course needs to be investigated further.

EFFECT OF CENTRAL ARTERIAL STIFFNESS ON ACUTE STRETCHING EXERCISE IN YOUNG MEN.

Yamato, Y.

Ritsumeikan University

BACKGROUND: Chronic aerobic exercise training induces the reduction of arterial stiffness. Additionally, arterial compliance increases after a single bout of aerobic exercise. The cross-sectional study was observed that arterial stiffness was higher in the poor-flexibility compared with the high-flexibility middle-aged and older subjects (Yamamoto et al, 2009). Recent studies reported that chronic stretching exercise increased carotid artery compliance or decreased blood pressure, but did not reduce central arterial stiffness in middle-aged and older adults (Cortez-Cooper et al. 2008, Wong A and Figueroa A, 2013). However, the effect of central arterial stiffness on acute stretching exercise remains unclear. **PURPOSE:** The purpose of this study was to clarify whether the central arterial stiffness reduces after a single bout of stretching exercise in the healthy young subjects. **METHODS:** Sixteen healthy young men (21 ± 2 years, 173 ± 4 cm, 63 ± 8 kg) performed stretching exercise or resting in randomized crossover study. Subjects were performed ten static stretching exercises (3 repetitions of 30 seconds with a 10-second passive recovery) in whole body (trunk, upper limb, and lower limb) for 40 min, while the resting performed only the same postural change as the stretching exercises for 40 min. Carotid-femoral pulse wave velocity (cfPWV), as an index of central arterial stiffness, systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), respiratory rate (RR) were measured before and immediately after stretching exercise and after 15, 30, and 60 min. **RESULTS:** cfPWV was decreased immediately after and after 15min the acute stretching exercise compared with before stretching exercise. However, in the resting control condition, cfPWV did not change. The decremental area under the curve of cfPWV for 0-60 min after the acute stretching exercise was greater than

that after the resting control condition ($P < 0.05$). SBP, DBP, HR, and RR did not change after the acute stretching exercise or the resting control condition. **CONCLUSION:** These results suggest that the acute stretching exercise may induce decrease in central arterial stiffness in healthy young men. CHANGES IN BLOOD LIPID AND MOOD STATE AND THEIR ASSOCIATION WITH TRAINING LOAD DURING MILITARY BASIC TRAINING PERIOD

Tanskanen, M., Remsu, T., Kyröläinen, H.

University of Jyväskylä

INTRODUCTION High blood LDL and low HDL levels are risk factors for cardiovascular disease. However, higher HDL levels (1) have been shown to be associated with worse total mood state. Even though military training has favourable effects on blood lipids (2), military environment might induce negative changes in mood state for young conscripts. The purpose of this study was to evaluate 1) changes in blood lipids and mood state during military basic training period (BT), 2) relationships between blood lipids and mood states and 3) effect of individual training load on changes in blood lipids. **METHODS** Fifty-two voluntary male conscripts (age 19.5 ± 0.3 years) participated in this eight weeks study. All measurements and queries were performed in the beginning, middle and at the end of BT. Venous blood samples were collected after overnight fast for total cholesterol, LDL-cholesterol, HDL-cholesterol and triglycerides. Mood states were assessed with the shortened version of POMS (Profile of Mood States). Heart rate data was used to calculate the individual training load (TRIMP, training impact) during BT. For statistical purposes, conscript were divided into tertiles based on TRIMP: >299 (TRIMP low), 298-236 (TRIMP moderate) and <235 (TRIMP high). **RESULTS** There were no statistically significant changes in blood lipids during BT. Significant decreases in POMS fatigue ($p < 0.05$), tension ($p < 0.01$) and confusion ($p < 0.001$) occurred over the first weeks of BT. Mainly worsened blood lipid values were associated with worsened mood and vice versa. However, higher levels of HDL-cholesterol were associated with greater tension and fatigue ($r = 0.30$, $p < 0.05$). Also decreased LDL-cholesterol levels were associated with greater confusion ($r = 0.30$, $p < 0.05$) during the last weeks of BT. Total cholesterol was higher among conscripts in the low TRIMP group, compared to the moderate ($p < 0.001$) and high ($p < 0.05$) TRIMP groups. **DISCUSSION** In conclusion, initially good blood lipids did not change during BT. However, favourable changes in HDL-cholesterol during BT increased tension and fatigue, which confirm the earlier findings. In contrast, favourable LDL-cholesterol changes was associated with higher confusion at the end of BT. The results further revealed that the higher the training load the better was the blood lipids profile. Thus, by increasing training load recommended blood lipid values can be achieved that may lead simultaneously to increased tension, confusion and fatigue. **REFERENCES** 1) Lieberman HR et al. *Health psychology*, 31:210-216, 2012. 2) Cederberg H et al. *Atherosclerosis* 216, 489-495, 2011.

SOCIAL ENTREPRENEURSHIP WITHIN THE SWEDISH SPORT MOVEMENT

Schenker, K.

Linnaeus University

Introduction The aim is to analyse the relationship between social entrepreneurship and sport. There is a growing convergence regarding the definition of social entrepreneurship, however. There is a need for clarity regarding underlying assumptions such as when social entrepreneurial activity arises and where social entrepreneurial activity occurs. To contextualize, this article takes its starting point in a social innovation entitled 'The Lift for Sport', initiated by the Swedish state. The Swedish state encourages sport for social change through financial resources, and the Sport Movement is expected to offer activities that promote health and development on equal terms. In addition to the ordinary funding of the Sport Movement, the Swedish government has since 2003 supported the Sport Movement with extra grants – with specified demands on the outcomes. **Methods** Qualitative data has mainly been collected through interviews of representatives from the Sport Movement. The empirical material is related to two special sport federations and eight sport clubs during 2009–2011. The data comprises 21 interviews, site visits to the sport clubs, document analysis of applications for project funding, the reports describing the activities, quantitative data regarding the number of participants, and activities and official media presentations. The interviews were semi-structured and most of them lasted no less than one hour. To convey the phenomena in a political and societal context, a theoretical framework concerning social orders, governing, the autonomy of organizations, and social entrepreneurship has been outlined. **Results** The two Sport Federations have existed for a long time, they are stable, and their corporate values are rather well defined. Because of the large number of members and activities, the federations are funded on a regular basis by the state. Entrepreneurial activities aiming for social change were not identified at the federation level, even if the federations expressed social missions. In four of the eight clubs that were part of the study, social entrepreneurial activities were identified. In the Lift for Sport, the sport organizations gained opportunities to realize their ideas. In some projects, entrepreneurs worked to break patterns and were not afraid to cross borders between social sectors, which resulted in a diffusion of social orders. **Discussion** The analysis shows that social entrepreneurship in sport needs to be understood in a political context. One possible suggestion is that the equation of social entrepreneurship is dependent on the autonomy of the organization in relation to governing aspects in the society, the organization's core values, and its innovation capacity in the form of entrepreneurs and ideas.

ORGANIZATIONAL CULTURE AND LEADERSHIP BEHAVIOUR AMONG PROFESSIONAL AND AMATEUR BASKETBALL AND FOOTBALL ORGANIZATIONS

Balogh, L., Gura, N., Mohacsi, L., Molnár, A.

University of Szeged, Faculty of Juhász Gyula Pedagogy

Background: The purpose of this study was to examine the complex phenomena of organizational culture (OC) and how it is affected by leadership behaviour in professional and amateur sport. Examining OC has become more and more popular in many fields of study among researchers and the fact that it is intertwined with leadership behaviour is unquestionable and has been proved in many studies before. Every organization has its norms, dynamics and rules which define its members' behaviour and attitude (Balogh, 2009). Schein (1992) defined OC as a "pattern of shared basic assumptions that the group learned as it solved its problems of external and internal integration". Still, we have tried to understand a piece of this elaborate phenomena. We hypothesize that amateur organizations have more familiar and less competitive inner environment than professional teams have. Based on this, we suggest that coaches of amateur teams are more supportive and rewarding and less autocratic than leaders of professional teams. We reckon teams that have stronger OC will more likely be effective than teams that don't feel that type of commitment. **Methods:** Two amateur and two professional basketball and football teams were examined. Cross-sectional analysis was conducted among athletes and their coaches (N=60). Leadership behaviour of coaches was measured with Chelladurai Multidimensional Model of Leadership (1980). Organizational-diagnostic multidimensional questionnaire was used to investigate the attitudes of organizations by Cameron and Quinn (2011). Each coach and player was asked, as a measurement of personal and organizational effectiveness. **Results:** We found significant correspondences ($p > 0,05$) of leadership behaviours in Training and Instruction, Democratic Behaviour, Social Support and Rewarding Behaviour categories between the four teams. The investigation of OC with the multidimensional model by Quinn indicated that clan culture dominates generally in the teams. According to the results, the feeling of effectiveness is just as low in the amateur football team as in the professional teams. **Conclusion:** Our hypotheses were verified and disproved at the same time. OC is affected by the behaviour of the leader. Nevertheless, not only amateur organizations but professionals find their organization a familiar place to be. These results indicate that to have a strong OC, teams should create familiar environment that they can build upon later. **References:** Balogh, László (2009): A szervezet-fejlesztés lehetőségei a sportszervezetekben – szervezeti kultúra diagnosztika (sportszervezetek szervezeti kultúrája és szervezeti bizalom-mintázata).
