Introduction Children's sprinter's running is different from the adults' primarily because of the difference in motoric abilities, morphological characteristics, physiological and biochemical characteristics and psychological and sociological characteristics. This research's aim has been to examine the anthropometric characteristics influence on the kinematic parameters of children's sprinter's running. **Methods** The sample of variables consists of variables which determine the anthropometric characteristics (14 anthropometric variables) and 32 kinematic parameters of sprinter's running. The kinematic parameters of sprinter's running in its maximal speed phase have been gathered by applying the Optojump technology (Microgate, Italy) and the sprinter's running times have been measured at each five metres on a 50 metres lap. **Results** The results obtained from the multiple regression analysis between the group of anthropometric characteristics and results in the 50 metres lap running have shown that the percentage of boys' fatty tissue has been isolated as a statistically significant variable, while among girls the same variable is on the edge of statistical significance. In the boys' factor structure of anthropometric characteristics two factors have been isolated, while there were three of them among girls. The first factor found with boys and girls is the body voluminosity factor, the second factor found among boys is the longitudinal dimensionality factor, while the second factor found among girls is the factor of fatty tissue quantity. The third factor found among girls is the longitudinal dimensionality factor. **Discussion** A negative connection to a higher percentage of fat or a higher quantity of subcutaneous fatty tissue with boys and girls has been determined for most of the variables. Boys with a lower quantity of subcutaneous fatty tissue achieve better results in the 50 metres running, have a shorter contact length, a longer duration of flight and a longer step length compared to boys with higher quantities of subcutaneous fatty tissue. Boys having better corporal muscular mass achieve a shorter contact length, a longer duration of flight and a longer step length. Girls with a lower quantity of subcutaneous fatty tissue achieve better results in the 50 metres running, have a shorter contact length and a longer step length. **References** Babić, V., Harasin, D., Dizdžar, D. EFFECT OF MOUNTAIN BIKE WHEEL DIAMETER AND SUSPENSION ON VIBRATION AMPLITUDES AT VARIOUS FREQUENCIES

Levy, M.1, Alumbaugh, B.2, Phillips, S.E.S.2, Smith, G.3, Smith, G.A.2

1: University of Minnesota Duluth; 2: Colorado Mesa University, Grand Junction, CO; 3: Colorado School of Mines, Golden, CO

Introduction Equipment innovations in mountain biking have touched nearly all components of a cycle including the wheels where larger diameters are now commonly used. Systematic comparison of riding kinematics for different wheel dimensions has not been investigated. This study's purpose was to compare 26 and 29 inch wheel vibration amplitudes at various frequencies on a standardized track with rigid and suspension fork conditions. **Methods** A standardized indoor track of 10 m length was built using plywood and wooden strips of various heights (1 to 7 cm). This provided a repeatable surface similar in roughness to a natural surface trail. Fork and handlebar accelerations were measured at 1500 Hz using PCB 356A32 accelerometers and wireless transmission to a nearby computer. Two front wheels of 26 and 29 inch diameter were matched in most characteristics (rim, tubeless tire, pressure) but differed in mass by 100 g (7% greater for the 29 inch wheel). The same hardtail carbon frame (Niner Air 9 with 29 inch rear wheel) was used for all testing. Rigid (R) and suspension (S) front forks (White Brothers Rocksolid; Rockshox Reba, respectively) were tested with each wheel condition. A single rider performed 10 trials with speeds between 2 and 8 m/s for each wheel/fork condition. Each trial traversed the measurement track passively without lifting or pedaling. Fourier analysis was used to calculate amplitude coefficients for each trial within a frequency range of 0 to 100 Hz. Fork amplitudes were compared for the R and S condition. Comparisons of amplitudes for each wheel size at each frequency level were made using t-tests, for each suspension condition. **Results** The largest fork amplitudes occurred between 7.5 and 12.5 Hz. The R condition produced amplitudes of 0.282 and 0.293 g (26- and 29-in wheel, respectively). In the S condition, amplitudes were significantly larger: 0.478 g for 26-in and 0.538 g for 29-in wheel. Wheel comparisons were significant for the S condition in the range of 20 to 40 Hz ($p < .05$). No significant comparison was found in the same range for the R condition. Fork amplitudes were consistently larger in the S condition for both wheels. **Discussion** Fork amplitudes revealed small measurable differences between wheels in the range of 20 to 40 Hz in the S condition. However, this observation was not repeated in the R condition, even if the trend was similar with smaller amplitudes. Fork amplitude does not appear to differentiate well between these two wheel sizes, but can be a sensitive variable when comparing suspension conditions. Other tracks built to produce higher vibration frequencies may yield different conclusions. Contact mlevy@d.umn.edu

AN INITIAL INVESTIGATION OF KNEE-ALIGNMENT CORRELATES WITH JAPANESE UNIVERSITY STUDENT SAMPLE

Sogabe, A., Iwasaki, S., Yoshimoto, T., Katsukura, Y.

Konan University, University of Kansas

PURPOSE: The purpose of this study was to examine possible knee alignment (KA) correlates using the variables: current condition of BMI and results of physical ability test (PAT). Previous studies indicate that possible risk factors for knee osteoarthritis are knee mal-alignment over time, frequency of participation in load-bearing sports, and over-weight. However, little KA-related research focuses on Japanese university student sample. Thus, this initial investigation hypothesizes KA associations with current conditions of BMI and PAT with a Japanese university student sample. Additionally, this study plays a role for upcoming longitudinal design research in order to examine development of knee alignment. **METHODS:** Japanese university students' (N = 236: Male = 116, 18.2 \pm 0.6 years & Female = 120, 18.2 \pm 0.5 years) KAs were measured as either Intercondylars (genu varum: bowleg) or Intermalleolars (genu valgum: knock-knee) distance in centimeters. KA, BMI, and physical ability test (PAT): 20m shuttle run and 50m sprint, were used for the computation of descriptive statistics and Pearson product-moment correlation coefficients. **RESULTS:** Descriptive statistics provided mean scores (M) and standard deviations (SD) for male (KA: M=2.43 and SD=3.09; BMI: M=21.62 and SD=3.33; 20m shuttle: M=88.13 and SD=25.67; 50m sprint: M=7.03 and SD=0.53) and female (KA: M=0.94 and SD=2.94; BMI: M=20.50 and SD=2.43; 20m shuttle: M=46.28 and SD=12.93; 50m sprint: M=8.98 and SD=0.73). Pearson product-moment correlation revealed three significant correlation coefficients of knee-alignment with: 1). BMI ($r = -.52$), 2). 20m shuttle run ($r = .19$), and 3). 50-m sprint ($r = -.31$) with the male sample. On the other hand, result with the female sample demonstrated a significant correlation coefficient between knee-alignment and BMI ($r = -.28$). * p values are less than 0.05. **CONCLUSIONS:** Results indicated that Japanese university students' KAs were significantly and negatively associated with their current conditions of BMI for both genders, which means the higher BMI score individual has, higher the tendency of having knock-knee (genu valgum). On the other hand, we observed significant links between KA and PAT (both scores of 20m shuttle run and 50m sprint) only with the male sample. Future longitudinal research should keep track of developmental individuals' KA, frequency and type of participation in high-intensity sports, BMI, and other body composition.

VIABILITY OF FINITE ELEMENT ANALYSIS FOR GLENOHUMERAL CONTACT ANALYSIS IN ELITE OVERHEAD ATHLETES

Goebel, R.1, Patel, N.2,3, Haghpahanah, B.2,3, Vaziri, A.3, Nazarian, A.2

1 Qatar University, 2 Harvard Medical School, Boston, USA; 3 Northeastern University, Boston, USA

Introduction: Athletes who conduct repeated shoulder motions, (e.g. Handball-, Baseball players), are prone to shoulder joint injuries (1). In these athletes, muscle and capsular tightness has been implicated in subacromial impingement and humeral shift (2). The primary purpose of this thesis is to gain deeper insight into biomechanics of the athletes shoulder through a description of a proof of concept study performed by pairing experimental and computational analysis to examine the effects of posterior-superior capsular tightness on humeral shift on the glenoid during abduction, based on a search to analyze the viability of using finite element (FE) analysis. **Method:** Capsular plication was analyzed to demonstrate the capabilities of FE analysis. 5 frozen left shoulders from males aged 61 \pm 5, were thawed and mounted onto a unique fixture capable of moving the cadaver in 7 degrees of freedom. Tests were conducted by pivoting the joint 60° to 100° in abduction. Reaction forces at the glenohumeral joint were measured, and reflective markers recorded the kinematic data to track the center of rotation of the glenohumeral joint. The FE model was generated using patient specific computed tomography scans. **Results:** Data shows that plication of the shoulder results in tensile forces in superior-inferior (y-axis) direction compared to compressive force in a normal shoulder. It will also lead to a decrease in tensile force in medial-lateral (z-axis) direction. Loads in the y-axis were different between the two conditions (baseline and plicated) for all arm positions (60°-100°, $P < 0.001$). Plication resulted in an increase in compression at load cell in sup-inf. plane throughout abduction. Loads in the z-axis were different between the two conditions (baseline and plicated) for three arm positions (70°-90° and $P < 0.001$). Plication resulted in an increased compression at load cell in med-lat. plane throughout abduction. An insignificant difference in contact area between the two states as sampled occurred. Thus, the plicate state is generating more pressure across the glenoid rather than shifting the humeral head to alleviate the stress accumulation.

Conclusion: This study proves the viability in using FE analysis to understand specific and unseen interactions within the glenohumeral joint. A similar method can be utilized to provide pathological understanding, and treatment, to elite overhead athletes with the purpose to reduce shoulder joint injuries. Literature: (1) Namdari S, et al. BIOMECHANICAL MOVEMENT ANALYSIS DURING TECHNIQUE TRAINING WITH USE AUTONOMOUS SENSOR SYSTEM

Nowoisky, H.1, Beissner, S.2

1: Olympic Service Center (Hannover, Germany), 2: University of Applied Sciences and Arts (Hannover, Germany)

Introduction In numerous of movement tests and sport relevant exercise tests is necessary to identify the actual state of power and explosive strength abilities for exacting special movement techniques. For detailed movement analysis were used a new miniaturized electronic measurement device, called „Autonomous Sensor System“. The developed sensor system can be applied, e.g., to joint cuffs and other parts of the human body without affecting a person's movement and posture. The measuring sensor system consist of following components: three-axis-inertial sensor and three-axis gyroskop, magnet field sensor, microcontroller board and radio module, automatically registration of signal courses (e.g. curves acceleration, velocity, distance, angle), mathematical processing of the signal courses (e.g. facts of single parameters in three-axis vectors and appropriate parameters of time until the reading of the maximal factors). The signal rate was 100 Hz. **Methods** Ten highly skilled athletes (16 till 21 years old) in four different sports and two strength exercises were measured by using sensor system while performing simple exercises. Following events and exercises were choice: Straight punch in Boxing, sensor fixed at arm and punch equipment, up and town phase in bench press, sensor fixed at barbel, up and town phase in bench pull, sensor fixed at barbel, tractive power of the arm in Judo, sensor fixed at tractive arm and pulley machine, shot put, sensor were fixed at throw arm. Three-axis kinematic and dynamic curves were recorded during three exercise repetitions in all sports and tests. The experimental set-up and mathematical processing of the signal courses allowed the recording of three-axis parameters with the special software. **Results** Measured signals were typical for tested techniques. Example shot put: In shot put are important parameters start velocity of the shot after relies the hand and shot put angle. Velocities of 7.8, 8.7 and 9.1 m/s, shot put angles of 38.1, 37.8 and 40 degree, fly distance shot of 16.2, 17.3 and 16.8 m. Example boxing: The body mass of athlete, 67 kg, 16 years old. Maximum of velocities, 5.2, 5.7 and 5.9 m/s, maximum of accelerations, 57, 61 and 54 m/s². **Discussion** It were showed the easy and fast use in sport practice. No complicated calibration process necessary. The biofeedback devise allow to inform about important and effective criteria which can intensify the capacity of athletes in different exercises. So it provides the parameter for the best performance of technique. In spite of existing individual technical variants, the special exercises can be considered an essential movement sequence which plays an important part in coaching both young athletes and elite athletes. This measurement sensor system objectifies and controls the generation of initial parameter in the different technique and exercise. This sensor system is small, flexible and not expensive. THE RELATIONSHIP BETWEEN TRICEPS SURAE LENGTH AND ITS INDIVIDUAL MUSCLE RECRUITMENT DURING A SQUATTING EXERCISE

Lauber, B.1,2, Farris, D.J.1, Lichtwark, G.A.1, Cresswell, A.G.1

1 The University of Queensland, 2 University Freiburg

The force producing capacity of a muscle is linked among other things to its length. During tasks such as squatting, lower limb joint rotations produce continuous changes in muscle length which requires the central nervous system to not only accurately monitor muscle length, but provide the appropriate timing and level of activation. Previous studies of triceps surae recruitment during a combined task of active isometric plantar flexion with passive knee flexion have shown a switch in recruitment from medial gastrocnemius (MG) to soleus (SOL) as changes in MG and SOL fascicle length were decoupled from each other (1,2). Whether the same pattern of MG deactivation and SOL activation occur during a similar but more functional exercise task like squatting is currently unknown. Therefore, the aim of this study was to investigate the relationship between MG and SOL muscle lengths and their respective recruitment and de-recruitment patterns when performing a squatting exercise. We hypothesised that muscles at longer lengths would be preferentially recruited to produce the required plantar flexion torque. Eight healthy subjects stood on two force platforms (one for each leg) and performed a squatting exercise with an additional mass of 20% bodyweight across their shoulders. Squats were performed from upright standing to 60° of knee flexion. Only the middle 40° of downward knee motion was analysed. Intramuscular electromyography was recorded from MG, lateral gastrocnemius (LG) and SOL. 3D motion analysis (200Hz) provided relevant joint kinematics and ultrasound images were simultaneously recorded at 80 Hz to measure muscle fascicle lengths of MG, LG, SOL. The results showed that MG activity decreased by $31 \pm 20\%$ over 40° of knee flexion which was accompanied by a shortening of its fascicles by 1.3 mm. SOL activity also decreased by a similar amount ($31 \pm 17\%$) over the same range of motion, however its fascicles lengthened by 1.7 mm. LG activity remained unchanged over the 40° range of measurement. The changes in MG and SOL activation were accompanied by a $40 \pm 5\%$ decrease in ankle torque and a $45 \pm 4\%$ increase in knee torque. The increase in fascicle length of SOL likely resulted in an advantageous shift in its length tension relationship allowing SOL to compensate for the decreased contribution of MG despite its lower level of activation. The current result further highlight the complex neural control of mono and bi-articular muscles in everyday tasks. **References** 1 Kenney & Cresswell 2001 EBR. 2 Lauber et al. 2013 (submitted)

THE EFFECT OF HAMSTRING STRETCHING ON MUSCLE HARDNESS AND ISOKINETIC MUSCLE PERFORMANCE

Kato, E., Takahashi, H.

Japan Institute of Sports Sciences

Introduction Stretching is commonly performed to increase flexibility or to prevent injury (Gajdosik 2001). However, some previous studies reported that stretching diminished muscle performance after stretching, especially in single joint movements (Avela et al. 2004; Fowles et al. 2000). In these cases, most of the stretching protocols used were completely different from those used by athletes. The present study aimed to clarify the effects and the time course of moderate hamstring stretching on the hardness and strength of the knee flexor muscles. **Methods** Thirteen healthy adults (age range 19-38 years, 9 males and 4 females) participated in this experiment. All subjects underwent three phases of 2-minute static stretching of the hamstring. Muscle hardness of the long head of the biceps femoris (BF) muscle and strength of isokinetic knee flexion torque (180°/s) were determined before and after stretching. Hardness of the long head of the BF was measured by using shear wave ultrasound elastography images. To follow the time course of the stretching effects, we de-

terminated the isokinetic torque of the knee flexors before, immediately after, and every 10 minutes after stretching. The muscle hardness of the BF was measured between each stretching session (first-second and second-third) as well as before, immediately after, and every 5 minutes after stretching. All measurements were performed until 30 minutes after stretching. Results After the first stretching, muscle hardness decreased significantly ($P<0.01$); after both the second and third stretching, muscle hardness decreased significantly compared with before stretching ($P<0.001$). Muscle hardness remained significantly reduced until 25 minutes after the stretching, after which it reverted to the initial level ($P=0.159$). This occurred 30 minutes after stretching. However, the knee flexion torque did not show any change at any time. Discussion Some previous studies reported that higher muscle hardness can cause muscle cramps, spasms, and damage (Fischer 1987; Murayama et al. 2000). As seen in this experiment, moderate stretching (~ 2 minutes) decreased the muscle hardness of the BF without a decline in the knee flexion torque. These findings suggest that moderate stretching is useful as a warm-up manoeuvre. References Avela J, Finni T, Liikavainio T, Niemela E, Komi PV (2004). DEFORMATION OF FOOT SHAPE AFTER A 35 KM ROAD RUN

Fukano, M., Matsuda, S., Iso, S.

Waseda University

Introduction The human foot acts as an interface between the human body and the ground, and the shape of the foot is of research interest for its role in lower extremity pathology, such as plantar fasciitis, metatarsal stress fractures, and medial tibial stress syndromes. Previous studies have reported that long-term postural modifications occur in the foot with aging. However, little information is available on the acute effect of a single long distance running on the shape of the foot. Such information is of great importance for running footwear development, as a proper fit is essential to achieve high-level performance and for injury prevention, including blisters and/or subungual hematoma. **PURPOSE:** The purpose of this study was to assess foot shape changes in experienced runners after a single long distance running. **Methods** Thirteen male collegiate runners (26 foot) participated in this study (age, 20.2 ± 3.0 y. o.; height, 171.3 ± 3.6 cm; weight, 54.5 ± 3.1 kg). Approval was obtained from the institutional review board, and informed consent was obtained from all subjects. A foot scanner was used to determine the three-dimensional foot shape with the subjects standing in an upright bipedal position before and after a 35 km (about 2 hours) road run on their right and left foot. Anatomical landmarks of the foot were identified and marked prior to scanning before running and these marks were retained for the scanning session after running. Foot length, ball girth, ball width, navicular height, dorsal height, hind foot angle, foot volume, and cross-sectional shapes were obtained from the scanning data. A paired t-test was performed to determine the differences between the variables before and after the 35 km run. Significance was set at $p<0.05$. **Results** The foot length, ball girth, and ball width were comparable before and after the 35 km run. The navicular height (pre, 39.0 ± 6.1 mm: post, 37.1 ± 5.5 mm), dorsal height (pre, 59.2 ± 3.6 mm: post, 57.8 ± 3.8 mm), and foot volume (pre, 839.5 ± 64.8 mm³: post, 824.8 ± 65.8 mm³) were significantly lower after running compared to those before running. The hind foot angle tended to be larger after running compared to that before running. **Discussion** The findings of the present study suggest that foot shape is altered by single long distance running. These results suggested that footwear fit and/or comfort can be worsened while long distance running because athletes tight shoe laces based on their pre-running foot shape before running. Thus, foot shape changes might be a factor of blisters and/or subungual hematoma during long distance running.

DOES THE ACTN3 GENOTYPE POLYMORPHISM UNDERLAY MUSCULAR STRENGTH IN YOUNG ICE HOCKEY PLAYERS?

Buśko, K.1,2, Orysiak, J.1, Michalski, R.1, Mazur Różycka, J.1, Gajewski, J.1, Lach, P.1

1: Institute of Sport (Warsaw, Poland) , 2: Kazimierz Wielki University (Bydgoszcz, Poland)

Introduction Ice hockey is a sport commonly considered as a power oriented discipline. It combines dynamic movements with aggressive play (Flik 2007). Not much is written about muscle strength of hockey players. Investigating muscle strength and its relationship with ACTN3 polymorphism can provide a valuable information. The aim of the study was to find out if this relation (if any) distinguishes somehow hockey players among athletes performing other sports. **Methods** Thirty four ice hockey and sixty five control athletes took part in the experiment. Descriptive statistics of the both groups is as follows: body height (179.3 ± 4.8 and 182.7 ± 7.9 cm), body mass (75.8 ± 7.2 and 79.2 ± 8.3 kg) and age (17.4 ± 0.9 and 17.5 ± 1.9 years) respectively for ice hockey players and athletes performing various sports. The R577X polymorphism of ACTN3 gene was determined using polymerase chain reaction (Mills 2001). Genomic DNA was extracted from peripheral blood leucocytes using Blood Mini kit (A&A Biotechnology, Poland). Maximal joint torques were measured for flexion and extension in the following joints: elbow, shoulder, hip, knee and for a trunk. Measurements were taken under static conditions using specially designed torque meters. **Results** The number of particular genotype carriers was as follows: 17 individuals with RX genotype, 14 with RR genotype and 3 persons with XX genotype in ice hockey group; 32 individuals with RX, 23 with RR and 10 persons with XX genotype in control group. Chi square test didn't reveal any differences in genotype/group proportions ($\chi^2 = 0.93$; $df = 2$). Ice hockey players had significantly stronger flexors and extensors in both knees and extensors of both hip joints. No interaction between group factor and genotype factor was found. Within both groups, genotype didn't differentiate observed variables. **Discussion** The results show that hockey players are stronger than other athletes. However, this might be due to a specific training that puts pressure on developing muscle strength. An essential conclusion regards to the fact that ACTN3 polymorphism does not differentiate athletes in relation to muscle strength and ice hockey players are not an exception. It is not in accordance to papers focusing on relation between physical features and ACTN3 polymorphism. In our opinion, determining this particular gene variant is not a sufficient method for selecting promising players. **Acknowledgements** The study was supported by the Fund for the Development of Physical Culture. KINEMATIC ASSESSMENT OF THE ART OF BALLET: BODY POSITIONING, BALANCE AND BASE OF SUPPORT IN THREE ESTABLISHED BALLET POSITIONS PERFORMED BY PROFESSIONAL BALLERINAS WITH VARIOUS SKILL LEVELS.

Green, A., Kerr, S., Dafkin, C., Olivier, B., McKinnon, W.

University of the Witwatersrand

Introduction: Ballet is a performance art that requires great skill and balance to perform. Limited literature is available documenting the balancing abilities of skilled ballerinas. Balance is particularly important to female ballet dancers as they are required to dance en pointe, minimizing their base of support (BoS). The aim of this study was to determine whether there were differences in balance control (centre of mass (COM) movement and COM height), as well as the area of the base of support (BoS) and skill (as defined by variables conventionally used to assess ideal execution of ballet positions) between groups of professional ballerinas with different levels of accomplishment. **Methods:** Twenty one professional female ballerinas classed as Graduate dancers (≤ 1 year academy dancing experience; $n = 7$), Corps de Ballet dancers (1 to 2 years academy dancing experience; $n = 7$) and Soloists (more than 2 years academy dancing experience; $n = 7$) participated in this study. All ballerinas performed three unassisted, standard ballet positions en pointe (retire, arabesque and penche) held for at least 3 seconds. Retro reflective markers were attached to specific anatomic landmarks and tracked by a 12 camera system. The Base of Support (BoS) was calculated using a pressure platform. **Results:** No significant difference in balance control (COM movement or COM height difference) was detected between the three skill groups. BoS, was significantly larger in the Corps de Ballet dancers compared to Soloist ($F = 4.822$, $p = 0.011$). The Soloists also showed significantly greater leg separation angles during penche when compared to Graduate dancers ($F = 5.557$, $p = 0.027$). Mean BoS surface area for retire was significantly greater than both arabesque and penche ($F = 6.745$, $p = 0.002$). **Discussion:** The major findings of the current study are that Soloists use a smaller BoS than the less accomplished Corps de Ballet dancers in all three positions tested (retire, arabesque and penche). It was also found that soloists have greater leg separation angles during a penche. In our study it was also notable that soloists were significantly older than the other two groups (Graduates and Corps de Ballet), therefore confirming work Schmit et al (2005) and Sarabon (2010) who found that experienced dancers exhibit better balancing skills, specifically during challenging balance conditions. A smaller BoS is believed to contribute to better proficiency and skill in ballerinas. The results from our study support the notion that skill difference exist even within professional ballerinas regarding flexibility, strength and joint motions. **References:** Sarabon N. (2010). THE SYSTEM FOR THE MARTIAL ARTS TRAINING ANALYSIS

Lach, P., Lach, P., Busko, K., Staniak, Z., Mazur Różycka, J., Gajewski, J., Michalski, R.

Institute of Sport

THE SYSTEM FOR THE MARTIAL ARTS TRAINING ANALYSIS **Introduction** One of the methods of assessing the physical fitness, strength and athletes' speed in combat sports is the analysis of combat simulation. The purpose of this study was designing a method and tools for measuring punching force using accelerometers. The essence of the project was to build a simple, versatile boxing training simulator that allows measuring a blowing and kicking force as well as reaction time of athletes. **Methods** The new system was designed to measure and analyze the mechanical characteristics of punching and kicking with upper and lower limbs in a boxing bag. System consists of a punching bag with embedded accelerometers, four signal lights attached to it and software. The punching bag is 170 cm high and weights 41 kg. The bag hangs vertically on the winch. It's mounted on the ropes that stabilize the device. Winch allows adjusting the suspension height of the bag. Acceleration transducers are placed inside the bag, which allow calculation of dynamics during punching the bag. The system runs with software that integrates all the parts and it allows controlling data acquisition and processing. The software calculates the strength of the blow, the point of a force application and its direction, energy of a hit and time reaction, defined as the time between the light signal and registering a punch. The force of a blow is calculated using the acceleration data. **Results** of testing the system The system was tested and results show that the average, relative error of force calculation amounts to 3%. The error of acceleration measures is less than 1%. The average, relative error of calculation the punching place on the boxing bag is 2%. **Conclusion** With using this boxing simulator, the intensity of training can be controlled more precisely, due to the possibility of setting e.g. time intervals between consecutive blows or sequence of delivered punches. The versatility of the software makes the system a good tool for practical application in training martial arts. **Acknowledgements** The study was supported by Ministry of Science and Higher Education - grant No. R RSA1 000951 in 2012-2015. SENSITIVITY OF A BALANCE TEST PREDOMINANT ACTIVITY OF THE LUMBO-PELVIC REGION OF THE BODY

Panjan, A.1, Sarabon, N.1,2

1: S2P, Laboratory for Motor Control and Motor Behaviour (Ljubljana, Slovenia), 2: UP, Science and Research Centre, Institute for Kinesiology Research (Koper, Slovenia)

Introduction In order to objectively evaluate balance abilities of the trunk, specific balance tests, which accentuate the role of the lumbo-pelvic region, should be used. The aim of this study was to assess the sensitivity of body sway while sitting on an unstable surface by comparing: (1) specifically trained subjects (wild water kayakers) and controls and (2) among three age groups of subjects from general population. **Methods** First part of the study included 16 kayakers and 16 healthy controls, while 36 healthy subjects from general population (12 in each group) were included in the age related part of the study. The three age groups contained subjects of age 12, age 22-27 and age 56-76, respectively. The body sway was assessed while the subject was sitting on a wobble board (Van Daele et al., 2009) with hands across the chest and eyes open. A force plate was used to measure the centre-of-pressure movement during the task. Independent samples t-test was used to assess differences between kayakers and controls, while analysis of variance test with post-hoc t-tests was used to tests differences among the three age groups. The level of statistical significance was at $p < 0.05$. **Results** Statistically significant differences ($p < 0.05$) were found between kayakers and controls for majority of the parameters (centre-of-pressure velocity, amplitude and frequency). Similarly, the differences among the three age groups were observed for majority of body sway parameters. **Discussion** Results of this study are supportive about the development and aging related changes in the control of functional stability of the lumbo-pelvic region. Moreover, the results confirm our hypothesis about the trainability of the lumbo-pelvic stability through specific training such as kayaking. **References** Van Daele U, Huyvaert S, Hagman F, Duquet W, Van Gheluwe B, Vaes P (2007). VALIDATION OF INSTANTANEOUS VELOCITY IN ELITE FREESTYLE SWIMMER USING A SINGLE ACCELEROMETER

Lussier, B., Charbonneau, M., Billaut, F.

Institut national du sport du Québec

Introduction Methods currently available to analyse speed variability in swimming rely on a few strokes sampled from the middle of each lap or on an average score of the laps (1). These methods only provide a performance snapshot, and offer limited information as to the evolution of instantaneous speed or other technical information during a swim. Here, we used an accelerometer to calculate swimmer's speed, and validated this speed in comparison with 5-meters splits during an entire 100-m freestyle swimming performance. **Methods** The acceleration signal was recorded at 100Hz (Nanotrack, Catapult) from an elite sprint swimmer during an all-out, 100-m swim. The signal was band-pass filtered to remove signal noise and gravity. Acceleration signal was then integrated twice to obtain time series positions, and positions were down-sampled to obtain 5-meters split. To validate this method, time splits were obtained every 5 meters from an overhang and two underwater cameras (60Hz). For these two methods, speed was obtained by a derivative of the time splits, and the error was quantified by calculation of the root mean square error (RMSE), coefficient of determination (r^2), maximum error and ratio (maximum speed of the accelerometer divided by maximum speed derived from time splits). **Results** The error between the two methods during the entire 100-m swim was as follows: RMSE was 0.1 m/s, r^2 was 0.99, maximum error was 0.3 m/s and ratio 0.88. Mean speed for the entire race with the accelerometer (1.75 m/s) was very close to that estimated from video-based time splits (1.77 m/s). **Discussion** The error in instantaneous velocity between the single accelerometer and the gold standard video-based time splits method was minor. The speed integrated from an accelerometer is therefore considered accurate during an entire race including dive, dolphin kicks, swim and turn. While the gold standard, video-based method is time consuming, the accelerometer-derived speed calculations can be made instantly, which greatly enhances coach's feedback to athletes. Further, the easy-to-use accelerometer is very small and allows the swimmer to swim freely compared with other methods (2). **References** 1. Schnitzler et al., *Int J Sports Med* 2010; 31(12): 875-881. 2. Villas-Boas et al., 29th ISBS Porto (Portugal), 2011; 85-89.

RELATIONSHIP BETWEEN MUSCLE SIZES AND MUSCLE MECHANICAL WORK DURING VERTICAL JUMPING

Suzuki, Y., Enomoto, Y., Murata, M., Takenaka, S., Takizawa, M.

University of Tsukuba

Introduction There are two primary functions of skeletal muscles in vertical jumping, one is to generate mechanical energy, and the other is to transfer and redistribute energy among body segments. The ability of a muscle to generate mechanical energy depends on its size, such as physiological cross-sectional area (PCSA) and fiber length, due to the force-length and force-velocity relationships (Burkholder et al., 1994). Therefore, it is inferred that the function of a muscle is affected by the size of muscle. The purpose of this study was to clarify the relationship between muscle sizes and mechanical work done by muscles during vertical jumping, using a musculoskeletal simulation technique. **Methods** For simulations of the jump motion we used a forward dynamic model of the musculoskeletal system consisting of four rigid segments (feet, shanks, thighs and a head-arms-trunk segment) actuated by 9 muscle-tendon complexes (gluteus maximus, iliopsoas, rectus femoris, vasti, biceps femoris (short head), hamstring, gastrocnemius, soleus, tibialis anterior) (Fujii & Moriwaki, 1992). We decided the masses, PCSAs, fiber lengths, and pennation angles of each muscle based on literatures (Fujii & Moriwaki, 1992; Ward et al., 2009). Activation dynamics of muscle were modeled with implementations of Hatze (1981) and Bobbert & van Zandwijk (1999). Stimulation of each muscle was increased toward its maximum of 1.0, and subsequently decreased toward its minimum of 0. The object function for motion optimization was set as a height of the center of mass at the apex of the jump. The stimulation onset and offset times of each muscle were optimized by use of a genetic algorithm. **Results and Discussion** There were significant positive correlations between mechanical work done by the muscles and muscles' mass and PCSA, but fiber length was not correlated with muscles' work. Although most of mechanical energy was generated by the relatively large muscles with large PCSA around the hip or knee joints, the ankle joint generated mechanical energy as much as the hip and knee joints. These results imply that the function of the relatively large muscles was to generate mechanical energy, but the small muscles may play a role to transfer and redistribute mechanical energy of body segments in vertical jumping. **References** Burkholder T.J., Fingado B., Baron S., and Lieber R.L. COMPARISON OF ENDURANCE PERFORMANCE, SPATIOTEMPORAL STRIDE PARAMETERS AND GROUND REACTION FORCES IN RUNNERS WEARING TRADITIONAL AND MINIMALISTIC RUNNING SHOES

Lichtenstein, E., Donath, L., Roth, R., Oeri, A., Faude, O.

University of Basel

Comparison of endurance performance, spatiotemporal stride parameters and ground reaction forces in runners wearing traditional and minimalistic running shoes **Introduction** Differences in spatiotemporal parameters as well as ground reaction forces (GRF) have been reported when comparing shod and barefoot running. It is also discussed whether barefoot running reduces injury rates (Murphy et al., 2013). Recent trends in shoe development therefore attempt to mimic the barefoot condition. It is speculated that running with so called minimalistic shoes (MS) also differs in above mentioned parameters and might influence performance when compared to running with traditional shoes (TS, Perl et al., 2012). Thus, we aimed to analyse spatiotemporal parameters, GRF and performance parameters while running in a new MS as compared to TS. **Methods** Thirteen recreational runners (10 women, 3 men, 24 (SD 1.2) y, 1.68 (0.07) m, 62.8 (6.0) kg, training volume >30 km/week) participated in this randomized crossover-study. Participants were tested once with their TS and once with a MS (On Cloudsurfer, On AG, Zürich, Switzerland). Test order was randomized with a 6-week wash-out period in between and a 2-week run-in period (to familiarize runners with MS) prior to the MS test. For each participant, the lactate threshold was determined for either condition during an incremental running test on a treadmill. On a second test day spatiotemporal stride parameters and ground reaction forces were recorded at 80% IAT (10.0 ± 0.5 km/h, not different between conditions) and 95% IAT (11.8 ± 0.6 km/h) on a treadmill. On the same day, a 4 km all-out test was performed on an outdoor athletic track. **Results** We found a likely higher peak vertical GRF during push-off (+5.7% [90% CI 1.3; 10.4], effect size (d)=0.5) at 95% IAT and a small possibly positive difference at 80% IAT (+2.2% [-3.5; 8.3], d=0.19). For spatiotemporal stride parameters and acceptance loads differences between conditions were possibly to likely trivial (d<0.14). Similarly, all performance parameters showed possibly to likely trivial effects (d<0.16). Only maximal blood lactate concentrations were very likely higher in the MS condition (+1.7 mmol/l [0.7; 2.8], d=1.0). **Discussion** Running with the analysed MS did not lead to rele-

vant changes in stride parameters or acceptance loads. This can be explained by the design of the shoe as the heel area has cushioning similar to TS. Increased peak vertical GRF can be attributed to the compressed, and then locked cushioning during push-off. This stronger push-off did not lead to altered performance as it was probably too small. We gratefully acknowledge the On AG (Zürich, Switzerland) for providing the MS.

EFFECT OF MOVING WITH VOICE DURING STANDING MOVEMENT FROM CHAIR IN HEALTHY ELDERLY PEOPLE

Tanimoto, M., Arakawa, H.

Kinki University

Introduction Vocalization, which frequently occurs during sports activities, may also naturally accompany vigorous movement in everyday situations such as standing up, climbing stairs, or lifting luggage. In Japan, words such as “Yo” or “Yoisho” are used in vocalization during daily physical activities. These words are used especially frequently by middle-aged and elderly people. The purpose of this study is to investigate the effect of vocalization using the word “Yo” during standing movement from chair, and clarify whether vocalization improves movement in elderly people. **Method** Fifteen healthy elderly men and women (71.1±2.5 years old: average ± SD) performed standing movement from chair at voluntary speed and maximum speed with and without vigorous vocalization using the word “Yo.” Motion capture kinematics and kinetics analysis and electromyography (EMG) analysis were performed to evaluate standing-up movement. Speed of standing up, floor reaction force, lower limb joints angle velocity, joints torque, EMG from vastus lateralis (VL) and biceps femoris (BF), and timing of vocalization (the phase at which subjects say “Yo” during movement), were measured. **Result** Peak floor reaction force in movement with vocalization was significantly higher than in movement without vocalization both at voluntary and maximum speed (1.24±0.06 vs 1.17±0.05 at voluntary speed, 1.38±0.08 vs 1.33±0.08 at maximum speed per body weight). Standing speed, hip joint angle velocity, knee joint angle velocity and hip joint extension torque in movement with vocalization were significantly higher than in movement without vocalization both at voluntary and maximum speed. Knee joint extension torque in movement with vocalization was approximately the same as in movement without vocalization both at voluntary and maximum speed. Integrated EMG during standing movement from VL and BF was almost the same in movements with and without vocalization both at voluntary and maximum speed. Almost all subjects vocalized around the moment the floor reaction force reached peak levels. **Conclusion** These results suggest that vocalizing “Yo” during standing movement improves standing speed and force in elderly people. Timing of vocalization might be around the return action phase. **References** Ploutz-Snyder LL, Manini T, Ploutz-Snyder RJ, Wolf DA. Functionally relevant thresholds of quadriceps femoris strength. THE EFFECT OF RESISTANCE EXERCISE TRAINING ON THE BIOMECHANICS OF STAIR ASCENT IN OLDER PEOPLE

Maganaris, C.N.1, Gavin, J.P.1, Reeves, N.D.2, Baltzopoulos, V.3

1: Liverpool John Moores University, 2: Manchester Metropolitan University, 3: Brunel University

Introduction Stair ascent is biomechanically challenging, demanding high joint moments and large ranges of motion from the lower limbs (Reeves et al. 2009). Physical capacities decline with ageing making stair negotiation challenging and potentially dangerous. The aim of the present study was to examine the effect of resistance exercise training on the biomechanics of stair ascent in older adults for standard and higher rise steps. **Methods** Fifteen older adults (4 men; 75±3 yr, 162±7 cm, 69±11 kg) performed stair ascent trials on four separate occasions; two before, and two after an exercise training regimen. Self-paced ascents of standard (17 cm) and increased (25.5 cm) step-rise were performed on a four-step staircase instrumented with four Kistler platforms. VICON motion capture system was used to collect and compare kinematic and kinetic data before and after training. Parameters of interest in stair ascent were joint angles and moments, foot-step clearance, and centre of mass (COM)-centre of pressure (COP) separation. Resistance exercise training involved leg-press, knee extension and calf raise exercises (3 x 8–12 repetitions at 80% 3 repetition maximum), and plantarflexor static stretching (30 s per leg), twice per week for 16 consecutive weeks. Two-way repeated measures ANOVA compared training and step rise effects and a Bonferroni test located step rise-specific training effects. **Results** Post-training, ankle plantarflexion increased at foot off for both step rises (P=0.001), without affecting knee angle. Post-training, hip flexion decreased at foot off for standard rise only (P=0.0001). At foot contact with the above step, hip flexion (P=0.03) and abduction (P=0.01) angles increased after training for both rises. Post-training, pelvic tilt increased (P<0.05) in standard rise, but decreased at initial foot contact in increased rise ascent (P=0.01). Ankle joint moment in single-leg stance decreased for standard rise and increased for increased rise steps (P=0.003) after training. Hip flexion (P=0.03) and abduction (P=0.0001) moments decreased in single-leg stance post-training for both rises. Accompanying these, COM-COP separation reduced anteriorly on standard steps (-3.8 cm; P=0.01) and increased medially for both rises (P=0.009). Post-training, toe clearances reduced for standard rise only (P<0.01), but clearance variability was reduced in the trail-toe on increased rise steps (P=0.03). **Discussion** Increased plantarflexion and reduced hip flexion at foot off, preceding reduced step clearance, would suggest an altered gait pattern when ascending standard stairs post-training. Higher task-demand of increased rise ascent may explain why training reduced step clearance variability, but not clearance distance. Training seemed to ameliorate stair ascent trip risk in the old, depending upon step rise. **References** Reeves et al. (2009). J Electromyogr Kinesiol 19(2): e57–68. FOOT SHAPE CHARACTERISTICS USING 3D ANTHROPOMETRY METHOD IN SPRINTER

Kashiwagi, Y.1, Hirano, T.1, Yamagishi, M.3, Hakamada, N.2, Mizuno, M.3, Funato, K.3

1: Graduate school of Health and Sport Science, Nippon Sport Science University, 2: Japan institute sports science, 3: Nippon Sport Science University, Tokyo, Japan

Introduction Foot anthropometry data is important for sports footwear design. An athlete in particular may have specific configuration of a foot for doing effective force output. The purpose of this study was to evaluate to foot shape obtained from 3D foot scanning anthropometry and to describe anthropometric characteristics in foot shape for sprinter. **Methods** The subjects were twenty Japanese college sprinter (100m; 6 sprinters, age : 19.6±1.24years, body height: 172.9±3.9cm, body mass: 69.6±6.2kg, 100m time: 11.0±0.33sec, 200m; 5 sprinters, age: 19.8±0.7years, body height: 174.9±6.2cm, body mass: 68.3±5.1kg, 200m time: 22.9±0.44sec, 400m; 9 sprinters, age: 20.3±0.6years, body height: 174.3±6.0cm, body mass: 66.4±7.1kg, 400m time: 49.6±1.53sec) and 15 non-athletes (age: 20.5±2.3years, body height: 172.6±5.8cm, body mass: 64.1±9.1kg). Foot anthropometry was measured by using three dimensional whole foot scanner

(INFOOT: I-Ware Laboratory Co.Ltd). Barefoot subjects standing upright with both feet apart 15-20cm, and weight distributed equally on both feet. Whole foot scanning data was analysis according to refer the preliminary research in Kouchi, 1998[1]. Ankle to metatarsal head length (AML) was calculated from ankle joint center of medial malleolus to lateral malleolus and metatarsal midpoint was calculated from first metatarsal to fifth metatarsal and mark points. Horizontal distance (heel to ankle length: HAL) between ankle joint center and heel and the ratio of HAL for AML (HAL/AML) were also calculated. Foot anthropometry data were normalized as foot length. Results and discussion Foot anthropometry data was not significantly different by comparing sprinters with non-athletes. However, Sprinter had significantly longer AML and % AML was compared to non-athletes (AML: $133\pm6\text{mm}$ vs. $127\pm6\text{mm}$, $p<0.01$, % AML: $52\pm2\%$ vs. $50\pm1\%$, $p<0.01$). In addition, sprinter's HAL/ AML was smaller than non-athletes (0.38 ± 0.33 vs. 0.40 ± 0.33 , $p<0.05$). In particular, 100m sprinter showed a tendency to show large % AML compared to other sprinters (200m, 400m) and non-athletes. These results suggest that long AML which might be external moment arm larger and advantage gear ratio in efficient foot for explosive force output were characterized as beneficial foot shape in sprinters. Conclusions It was concluded that sprinters had a foot anthropometric characteristics in long AML, which might be efficient foot for explosive force output for sprint performance. NEUROMUSCULAR FUNCTIONS DURING THE 10 WEEKS OF MILITARY TRAINING IN NON-OVERREACHED AND OVER-REACHED FINNISH CONSCRIPTS.

Piirainen, J.M., Tanskanen, M., Kyröläinen, H., Huovinen, J., Häkkinen, K., Linnamo, V.

University of Jyväskylä

INTRODUCTION It has been shown that physical fitness of young Finnish males has decreased during the past 20 years (Santtila et al. 2006). At the same time, drop outs of the conscripts during the first 8 weeks of basic military training have increased. Therefore, it has been suggested that physical fitness of the young males may be insufficient for the demands of military training (MT) and may lead to poor recovery and, moreover, to an overtraining state during MT (Tanskanen et al. 2011). However, how the basic training affects neuromuscular functions has not been well investigated. It was hypothesized that in conscripts who were suggested to be overreached after 10 weeks of MT, the improvements of the neuromuscular functions would be also limited or even decreased. **METHODS** Totally 24 subjects were divided in the non-overreached (NOR n=16) and overreached (OR n=8) groups based on 5 criterions (Tanskanen et al. 2011). Passive twitch response was measured from plantar flexors and twitch torque (TT) and time to twitch torque (TTT) were analysed. H-reflex ($H_{\text{max}}/M_{\text{max}}$) and V-wave (V/M_{max}) responses were measured and analysed from the soleus muscle. Maximal isometric knee extension torque was measured. All measurements were performed in the beginning (1 week), middle (5 week) and twice after the basic training period (8 and 10 weeks). **RESULTS** There were no changes in TT either in NOR or OR during the entire 10-week period. However, TTT increased in OR from 5 to 8 weeks (31.2% $p<0.05$) and more clearly from 5 to 10 weeks (43.6% $p<0.01$), which was not observed in NOR. No significant changes were observed in the $H_{\text{max}}/M_{\text{max}}$ -ratio or V/M_{max} -ratio in either of the groups. Maximal isometric knee extension torque increased in NOR after 8 weeks of training (23.2% $p<0.001$) but not in OR (-1.1% $p>0.05$). **DISCUSSION** Based on the present results, it seems that MT leading to overtraining symptoms may also cause problems in the function of the neuromuscular system. While the MT did not lead to any neural changes in either group, increased contraction time during the passive twitch, observed in the OR group, suggests slower contraction of the muscle (Kawakami et al. 2000). This result together with differences in the development of maximal knee extension torque indicates that the training program for OR has been too strenuous. Possibly a different periodization of MT could help to avoid overreaching and secure positive training development for all conscripts. **REFERENCES** Santtila et al. 2006, Med Sci Sports Exerc, 38(11):1990-1994 Tanskanen et al. 2011, Med Sci Sports Exerc, 43(8):1552-1560 Kawakami et al. 2000, J Appl Physiol 88:1969-1975

COMPARISON OF ASYMMETRY IN BILATERAL AND UNILATERAL MOVEMENTS

Graham Smith, P.1, Al Dukhail, A.2

1. *Aspire Academy, Qatar.* 2. *University of Salford, UK*

Introduction Bilateral asymmetry is a term used to describe deviations in functional performance between left and right limbs. The underlying premise is that substantial deviations create compensatory movements, modify loading patterns and may lead to injury. Whilst the theory seems plausible, limited evidence exists to substantiate the argument. Before any association with injury is established clear criteria and thresholds need to be set for different tests and parameters of interest in order to diagnose asymmetry. The purpose of this study was to set thresholds and to examine the level of 'agreement' between diagnoses of asymmetry for a bilateral CMJ and a functional unilateral movement (running). **Methods** 144 student athletes aged between 12 and 18 were tested. Three CMJ's were performed on two Kistler 9286AA portable force platforms sampling at 1000Hz. Left and right leg forces were summed to establish total force and the point of maximal displacement was used to define the transition between eccentric (Ecc) and concentric (Con) phases. Average forces in the Ecc and Con phases and the peak forces were extracted. Asymmetry was expressed as the absolute difference between limbs % contribution to the total force. Athletes then ran on a Woodway treadmill at 12km/h for 30s whilst been recorded on six Quintic high speed video cameras (125fps). Mean contact time, swing time and step length over 6 strides were calculated. Asymmetry was determined as the absolute % difference between left and right values divided by the mean of left and right. Asymmetry thresholds for each parameter were determined as the mean absolute difference plus one SD of all athletes. **Results** To be classified as asymmetrical differences had to exceed at least one of the 3 thresholds per test: CMJ (7.6% peak force, 11.7% average Ecc force, 7.3% average Con force), Running (9.1% contact time, 5.3% swing time and 8.9% step length). Using this criteria 64 athletes exhibited an asymmetry (jumping only 30, running only 22 and both 12), showing an agreement of 18.75% between the diagnosis of asymmetries in the two tests. **Discussion** Assessing the absolute difference between limbs has allowed us to develop criteria and set thresholds in which to diagnose asymmetry in a movement. From a screening perspective this is preferential over adopting arbitrary differences of between 10-15%, which tends to occur in practise. Whilst past studies have adopted correlation and repeated measures ANOVA to compare tests of asymmetry this study examined the agreement in diagnosis. An agreement of 18.75% suggests that the movements are distinct and therefore both unilateral and bilateral tests should be performed to examine their potential effects of on performance and injury risk. RELIABILITY OF THE CROSS SECTIONAL AREA ASSESMENT OF SUPRASPINATUS MUSCLE BY ULTRASONOGRAPHY

Papatzika, F.1, Papandreou, M.2, Ekizos, A.1, Panteli, C.1, Arampatzis, A.1

1: HU (Berlin, Germany), 2: TEI-A (Athens, Greece)

Introduction The rotator cuff muscles (supraspinatus, infraspinatus, teres minor and subscapularis) are the substantial dynamic stabilizers of the glenohumeral joint during motion, especially for elevation and rotation of the arm. The muscle size comprehends the cross sectional area (CSA) and muscle length, are important factors for the functionality of the muscle during movement (Lieber R., 1992). The objective of this study was to evaluate the reliability of the CSA assessment of the supraspinatus muscle using brightness mode ultrasonography, and to compare two different methodologies. **Methods** The supraspinatus muscle CSA of sixteen participants was examined with two different methods, which were based on previous standardized protocols (Tae Im Yi et al., 2012; Juul-Kristensen et al., 2000) and on two different days. Five trials per day were conducted in each method, by replacing the ultrasound probe on every trial. The reliability of the two methodologies for the measurement of the supraspinatus CSA has been investigated using the intraclass correlation coefficient (ICC) within the five trials of the first and second day, as well as between the ten trials of both days for each method separately. Further, Bland and Altman plots were performed and a two-way analysis of variance with repeated measurements was calculated in order to determine the day effect and the effect of different methods. **Results** The average values of the CSA of the supraspinatus muscle were for method one $7.24 \pm 2.18 \text{ cm}^2$ (day one: $7.19 \pm 2.20 \text{ cm}^2$, day two: $7.29 \pm 2.17 \text{ cm}^2$) and for method two $6.91 \pm 2.22 \text{ cm}^2$ (day one: $6.82 \pm 2.18 \text{ cm}^2$, day two: $7.00 \pm 2.28 \text{ cm}^2$). There were no statistically significant differences ($p > 0.05$) in the CSA values between day one and day two as well as between method one and method two, while the average ICC was ranged from 0.987 to 0.997. A high relationship showed between the two methods ($R^2 = 0.91$) and the limits of agreement were about $\pm 1 \text{ cm}^2$, deducted from the Bland and Altman Plots. **Discussion** Our findings show high reliability on the measurements of the supraspinatus CSA using ultrasonography. Both methodologies are able to distinguish differences on the supraspinatus muscle CSA of about 1 cm^2 between groups or after interventions. We conclude that the measurement of the supraspinatus muscle CSA using ultrasonography provides reliable results, and can be used as assessment of the supraspinatus CSA. **References** Lieber R., Usa: Williams and Wilkins, 1992: 1-48 Tae Im Yi, M.D., In Soo Han, M.D., Joo Sup Kim, M.D. Ju Ryeon Jin, M.D. Jea Shin Han, M.D. Ann Rehabil Med 2012; 36: 488-495 B. RUNNING PATTERN DYNAMICS IN A SIMULATED REDUCED GRAVITY.

Sainton, P.1, Nicol, C.1,2, Berton, B.1, Cabri, J.2, Chavet, P.1

1: aix marseille université, cnrs, ism umr 7287 (marseille, france). 2: nss (oslo, norway)

Introduction Most studies on simulated gravity showed reduced vertical ground reaction forces (Minetti et al. 2012) and longer contact time (Donelan and Kram 1997). The aim of this study was to identify the temporal and dynamical features of the running pattern when controlled external forces are continuously providing body unweighting and reloading. **Methods** Seven healthy male adults volunteered for this study on AlterG treadmill®. The test included 2 randomized running series of 9 min performed at preferred speed and separated by a 5 min walk. Each series included 3 successive steps of 3 min (at 100% BW, 60 or 80% BW, and 100% BW). Reduced gravity was provided by positive lower body pressure technology. The air pressure variation inside the harness was measured to assess the partial body support provided by AlterG technology. Vertical reaction force and centre of mass accelerations were simultaneously recorded at 1 kHz. Initial impact peak force, tolerance to impact, loading rate and active peak force were analysed. Braking and push-off phase durations, and impulses were calculated as well vertical stiffness. The temporal analysis included flight, contact, braking and push-off phase durations as well as step frequency. The two running series were analysed separately using repeated-measures ANOVA for Body weight, Limb and Time (first vs. last 30 sec of each step) effects, with $p = 0.05$ and Bonferroni's post-hoc. **Results** For both running series, there was no interaction, but a main Body weight effect on most parameters. Independently of the limb and time period, unweighting led to increased flight time ($p < 0.001$) and decreased contact time ($p < 0.001$) that resulted in decreased step frequency ($p < 0.001$). Only the braking phase duration was reduced ($p < 0.001$). Despite the decreases of impact peak force ($p < 0.05$) and loading rate ($p < 0.05$), tolerance to impact was not improved. Active peak force ($p < 0.001$) and the push-off impulse were also reduced ($p < 0.001$) whereas harness pressure and vertical stiffness increased ($p < 0.05$). All parameters came back to their initial values after reloading, except for the braking duration. **Discussion** Temporal and dynamical changes of the running pattern of the healthy runners operated within 3 min when body weight was modified. Unweighting allowed runners to face lower impact peak force, produce lesser force during push-off and reduce minimally contact time. The associated increases in vertical stiffness and flight time give support to the energy recoil provided by the harness. **In conclusion** such technology appears as useful for rehabilitation purpose as it reduces external forces and lowers internal forces on lower limb joints. **References** Donelan MJ, Kram R (1997). SWING LEG KINETICS OF HUMAN MAXIMAL ACCELERATED SPRINTING

Nagahara, R.1, Matsubayashi, T.2, Matsuo, A.3, Zushi, K.1

1: University of Tsukuba (Tsukuba, Japan), 2: Japan Institute of Sports Sciences (Akabane, Japan), 3: National Institute of Fitness and Sports in Kanoya (Kanoya, Japan)

Introduction Accelerated sprinting is one of the important abilities for athletes in many sports. This study aimed to investigate the step-to-step changes in kinetics of swing leg during the entire acceleration phase of maximal sprinting. **Methods** Twelve male sprinters ran 60-m with maximal effort, during which three dimensional kinematics of the sprinters for 50 m from starting line were obtained. Based on the coordinate data, swing leg joint torque and power at each stride were calculated. **Results** Peak hip extension and flexion torques during the swing phase increased rapidly with increasing running speed up to the 5th or 6th step (ca. 5.0 and 5.1 Nm/kg) and leveled off thereafter when the running speed still increased toward maximal running speed (10.1 m/s) which appeared at the 23rd step. Peak knee extension torque during the swing phase slightly increased step to step through the entire acceleration phase, while peak knee flexion torque during the swing phase increased acutely until the 8th step and then the tendency of increase became small (maximum values were 0.8 and 2.3 Nm/kg). In regard to joint torque power, positive and negative peaks at the hip in the sagittal plane increased to the 7th or 8th step (ca. 2.8 and 3.1 kW/kg) and the magnitudes were subsequently maintained. On the other hand, for the knee joint torque power, positive and negative peaks in the sagittal plane increased during the entire acceleration phase (maximum values were 0.7 and 2.6 kW/kg). **Discussion** Although running speed increased rapidly and then did gradually during the entire acceleration phase, peak hip extension and flexion torques and positive and negative powers in the sagittal plane roughly reached the maximum values at the early stage of the acceleration. Nagahara et al. (in press) have recently verified that there are three sections which are delimited at the 4th and

16th step during the entire acceleration phase. Moreover, they speculated that the different acceleration strategies are needed during the respective acceleration sections. The characteristics of changes in kinetics during maximal accelerated sprinting in the present study support their speculation. Moreover, it seems that the force productions at the hip in the sagittal plane during the swing phase assume a large role in acceleration during the early stage of acceleration phase and those at the knee contribute for further increase in speed during the latter stage of the entire acceleration phase. EFFECTS OF CRANK FORCE AND VELOCITY TO THE ANAEROBIC POWER OUTPUT DURING MAXIMAL PEDALING.

Tanaka, S.I, Hiratsuka, K.I, Tsunoda, N.2

1: Kokushikan University (Tokyo, Japan), 2: Graduate School of Sport System, Kokushikan University (Tokyo, Japan)

Introduction The anaerobic power generation capacity during pedaling exercise affected by magnitude of crank force produced by work load and frequency. We investigated the effects of force and velocity in crank on anaerobic power output during maximal pedaling exercise. **Methods** Subjects were 60 male collegiate athletes who were divided into high-power (HG) and low-power (LG) groups on the basis of the regression line between lean body mass and maximal anaerobic power, which correlated significantly. The anaerobic power, crank force and crank angular velocity were measured using an electrically braked cycling ergometer with a custom-made measurement analysis system. All subjects performed three pedaling sessions of 10 s each with different loads at maximal intensity. **Results** Results revealed that the crank force generated on each work load was closely related to pedaling power output. In the heavy load setting, crank force and angular velocity on HG were significantly higher than that of LG. In addition, the pedaling due to high load, the ratio of the anaerobic power per crank force, a significant difference was observed between the LG and HG. When pedaling at peak power, the output aspect of the crank force and crank angular velocity differs between the LG and HG. **Discussion** In this study, crank force and angular velocity reach the peak power in HG was significantly higher than that of LG. From these results, it was considered that pedaling power output may affected by cranking force at the heavy load rather than cranking velocity. **References** Hintzy F, Belli A, Grappe F, Rouillon J. THE FORCE-VELOCITY RELATION OF MULTI-JOINT LEG EXTENSION IS NEITHER LINEAR NOR HYPERBOLIC

Hahn, D.

Faculty of Sport Science, Ruhr-Universität Bochum

Introduction Force and torque production of muscles depends upon their lengths and contraction velocity and for multi-joint leg extensions force-velocity relations have been reported to be linear rather than hyperbolic (Bobbert, 2012). However, since such relations have been limited to external forces and optimal joint angle configurations the purpose of this study was to determine angle specific force/torque-angular velocity properties. **Methods** Human leg extension was investigated (n=18) on a motor driven leg press dynamometer while measuring external reaction forces at the feet. Extensor torque in the knee joint was calculated using inverse dynamics. Maximum voluntary concentric contractions were performed over a ROM from 100°-30° knee flexion at mean knee angular velocities of 30, 60, 120, 180 and 240°/s. Additionally, maximum angular velocity of the knee was obtained during unresisted shortening. **Results** For contractions of increasing velocity, external forces and knee joint torques decreased for all joint angles analysed and we observed a shift of optimum knee angle from 52±7°-64±4° knee flexion with increasing velocity. Further, depending on knee joint angle, maximum angular velocities increased from 866±79°/s-1238±132°/s for 90°-50° knee flexion so that the curvature of the force/torque-angular velocity relations varied with joint angles. Both, force-velocity relations calculated by linear regression and Hills hyperbolic function showed good agreement with experimental data ($r = .86 \pm .12$ to $.94 \pm .03$) with slightly better correlations for Hill's hyperbola. However, maximum angle specific isometric force/torque as determined by extrapolation was always too low for linear and hyperbolic functions whereas maximum angular velocity was overestimated when using the hyperbolic function but underestimated by linear regression. **Discussion** Our results demonstrate that the shapes of multi-joint leg extension force-velocity relations change with joint angle, suggesting that a proper representation of such relations should be based on measurements at different muscle lengths. Despite good correlations between experimental data and linear as well as hyperbolic functions, none of the functions was able to predict maximum isometric forces/torques and angular velocities properly. We therefore suppose that force-velocity relations of multi-joint leg extension have neither a linear nor a hyperbolic but a concave-convex shape. From a biomechanical and physiological point of view, this might be due to MTC elasticity, biarticular effects, changes in lattice spacing and/or muscle length dependent Ca²⁺-sensitivity. **References** Bobbert, M.F., 2012. Why is the force-velocity relationship in leg press tasks quasi-linear rather than hyperbolic? *Journal of Applied Physiology* 112, 1975-1983. Contact daniel.hahn@rub.de

3D ANALYSIS AND DETERMINATION OF STRIDE PARAMETERS FOR DIFFERENT TYPES OF FOOT STRIKE IN RUNNING

Deflandre, D., Schwartz, C., Weerts, J.P., Croisier, J.L., Bury, T.

université de Liege

Introduction In running, the analysis of the stride has been investigated in different studies. There are a lot of kinematics and kinetics differences between runners (Dicharry, 2010; Larson et al, 2011). The purpose of this study was to compare methods for the calculation of various parameters of the stride for runners with different foot strike patterns. A 3D optoelectronic system usually used in motion laboratories was compared with tools commonly used on the field: an optical based detection system (Optogait) and an accelerometer based system (Myotest). **Methods** Twenty male subjects (33±10 yrs), all practicing athletics, were divided in two groups: the Heel group; attack the ground with the heel (n=12), and the Toe group; attack the ground with the middle or front of the foot (n=8). They performed a 30 seconds trial at speeds of 8 then 16 km/h for 3D analysis, and repeated the trial for the Optogait-Myotest analysis. Six 3D algorithms to determine contact time were compared. **Results** To detect foot strike, the use of the first peak velocity between two different 3D markers provided the best results. For the heel group of runners, the first peak velocity was coming from a marker placed at the center of the heel, while a marker facing the fifth metatarsal head provided the first peak for the Toe group. To detect the toe off, the minimum vertical position of a 3D marker placed in line with the big toe gives the most satisfactory results for both groups. Using these peak velocities and these markers, there were no significant differences with the Optogait values ($P>0.05$). Regarding the entire group (n=20), the method taking the first peak velocity between the heel marker and the fifth metatarsal marker to detect foot strike seemed the most convenient. This method is statically equivalent ($p>0.05$) to the results of the Optogait (leg: contact time=227±16ms for 3D vs 222±14 for Optogait at

16km/h) for the entire group, whatever type of foot strike a runner has. Discussion The main objective of this study was to validate a 3D method of calculating the strides parameters, focusing primarily on the contact time. Once the contact time methods are validated, other strides parameters such as fly time, reactivity, stride length and stride frequency can also be assessed, based on the same detection of event. However, it seems that the most valid method to determine foot strike differs with the type of runner. In conclusion, 3D analysis provides interesting opportunities for calculation of the stride analysis, allowing to give precise numerical feedback on athletes running strides. References Dicharry J. FORCE-CONTROLLED BITING AFFECTS POSTURAL CONTROL IN BIPEDAL AND UNIPEDAL STANCE

Ringhof, S., Hellmann, D., Schindler, H.J., Potthast, W., Stein, T.

Karlsruhe Institute of Technology (KIT)

Introduction Impaired postural control is associated with an increased risk of falling and, as a consequence, may lead to functional impairments concomitant with high medical treatment costs (Granacher et al., 2010). Balance training is an established measure to reduce the incidence of falls. Besides, the potential of biting to improve postural control has recently been reported (Hellmann et al., 2011). The mechanisms by which the craniomandibular system (CMS) and human posture are functionally coupled are not yet fully understood, however. The aim of this study was, therefore, to investigate the effects of force-controlled biting (FB) on postural balance and kinematics of the trunk and head in upright bipedal and unipedal stance. Methods Twelve healthy subjects randomly performed FB (150 N) and non-biting (NB, mandible at rest) during bipedal narrow stance (Bp) and unipedal stance on dominant (Up-D) and non-dominant (Up-N) legs. Bite forces were measured by using a hydrostatic system consisting of liquid-filled pads. The increase in pressure corresponded directly to the total force exerted, which was visible to the subjects as numerical real-time feedback. While balancing in bipedal or unipedal stance, center of pressure (COP) displacements and kinematics of the pelvis, thorax and head were monitored by means of a force platform and biomechanical motion analysis, respectively. Different balance and kinematic variables were calculated and compared by two-way (biting task, support condition) repeated-measures ANOVA. Results The results showed that FB significantly improved postural control in terms of reduced COP path lengths (AP: $p = 0.003$; ML: $p = 0.020$) and a decreased COP sway area ($p = 0.022$). These reductions were accompanied by decreases in oscillations of the pelvis, thorax and head, respectively. The study, moreover, revealed that COP displacements were significantly less in Bp than in Up-D and Up-N, whereas there were no differences between Up-D and Up-N, and no interaction effects between biting tasks and support conditions. Discussion The reduced COP displacements are further evidence of the functional coupling of the CMS and human posture. The study also showed, for the first time, that sway reductions during FB are concomitant with enhanced stability of the trunk and head, but no changes in coordination among the body segments were observed. To elucidate the efficiency of oral motor activity to prevent falls, however, further research addressing dynamic stability is necessary. EVALUATION OF SPATIO-TEMPORAL GAIT PARAMETERS WITH AND WITHOUT A PREGNANCY BODYSUIT

Lucciola, A.Q., Cortis, C., Rodio, A.

University of Cassino e Lazio Meridionale

Introduction During pregnancy, various postural and biomechanical changes occur including weight gain, shifted center of gravity, anterior pelvic tilt, increase of lumbar lordosis and decrease abdominal muscle strength (Borg-Stein et al., 2005). Such changes can substantially modify the gait pattern, contributing to an overuse on the musculoskeletal system (increased demand on hip extensor and ankle plantar flexor muscles) that could cause lower limbs, hip and lower back pain (Foti et al., 2000). Therefore, the purpose of this study is to evaluate the influence of an innovative bodysuit with differentiated elasticities (ComfortBody®) designed to reorganize the augmented load from the lumbar area to the entire back, on spatio-temporal gait parameters during walking on a treadmill when compared to a placebo bodysuit in pregnant women. Methods After giving their informed consent of participation, 15 pregnant women (age: 30.6 ± 3.8 yrs; weight gain: 10.1 ± 2.5 kg) between 24th and 38th gestation week were included in a single-blind, randomized, placebo-controlled study. Participants were asked to walk 10-min on a treadmill (speed: 3km/h; slope: 0%) during 3 experimental sessions (familiarization, wearing the ComfortBody-B and placebo-P) with a 30-min recovery in between. Experimental sessions were scheduled on sessions 2 and 3 (B, P) through permuted-block randomization. At the end of B and P, participants were asked to rate the most comfortable session. Computerized stride analysis was used to measure spatial-temporal parameters of the walking pattern. Data normality was confirmed applying Shapiro-Wilk's test and paired t-test was used to assess differences ($p < 0.05$). Results Spatio-temporal showed significant ($p < 0.05$) differences in stride length ($B = 1.11 \pm 0.06$ m, $P = 1.10 \pm 0.06$ m), cadence ($B = 90.4 \pm 4.9$ steps/m, $P = 91.1 \pm 4.9$ steps/m) and stance phase ($B = 0.89 \pm 0.04$ s; $P = 0.88 \pm 0.04$ s) while no difference emerged in swing phase. Most of the subjects (73%) indicated B as the most comfortable session. Discussion ComfortBody reducing thoracolumbar and lumbosacral angle (Federico et al., 2007), generating a reduction of anterior pelvic tilt would seem to ensure a greater hip extension in late stance phase and improve knee extension during terminal swing. These changes results in an increase stride length that ensure greater anterior-posterior stability (McAndrew Young & Dingwell 2012). ComfortBody could be a useful mean for the prevention of falls and the possible development of inflammatory diseases providing comfort, security and support in pregnant women. PREPARATION TIME INFLUENCES KNEE AND ANKLE JOINT MECHANICS DURING DYNAMIC CHANGE OF DIRECTION MOVEMENTS

Fuerst, P., Gehring, D., Gollhofer, A.

University of Freiburg

Introduction Ankle and knee joint injuries are the most common injuries in sports (Fong et al., 2007). High loads and extreme joint angles in the frontal plane, as reached in dynamic movements, present most danger to joint ligaments. It has been shown that reduced time to plan a change of direction increases knee abduction loading, which is known as a predictor of anterior cruciate ligament injuries (Besier et al., 2001). However, the influence of these more realistic sports situations on ankle inversion injury risk is still unknown. Therefore, the aim of this study was to analyse whether less preparation time has similar effects on the ankle joint. Methods Directed by light signals, 9

male athletes performed 45° cutting (CUT) and 180° turning (TURN) movements after an approach run with 4 m/s. Both movements were performed under three conditions (EASY/MEDIUM/HARD), which differed in preparation time before foot strike (CUT: 900/700/600ms, TURN: 1350/1050/900ms). 3-dimensional motion capturing together with force plate data was used to calculate kinematic and kinetic parameters in the frontal plane at the knee and ankle joint. Data were tested for significance with repeated measures ANOVA and post-hoc t-tests. Results Preparation time had a significant influence on peak ankle inversion velocity during TURNS ($p=0.045$) and by tendency during CUTs ($p=0.066$). Velocities were significantly increased in the HARD compared to the EASY condition (CUT: 332°/s vs. 263°/s, $p=0.033$; TURN: 551°/s vs. 477°/s, $p=0.044$). No statistically significant differences were found for peak ankle inversion angle and peak inversion moment. In CUTs, peak knee abduction angle was significantly increased in HARD compared to MEDIUM and EASY ($p\leq 0.006$). Discussion Our results confirm that less preparation time results in increased knee abduction angles during CUTs, which is associated with increased anterior cruciate ligament injury risk. This study adds that preparation time also influences ankle mechanics, as higher inversion velocities were observed under increasing time pressure. This may put higher demands on movement control in order to keep joint excursions in a healthy range (Granata et al., 2007). Our results therefore suggest that preparation time may be an essential factor in ankle sprains and should be considered in ankle injury research to reflect realistic sports settings more closely. TRANSMISSION OF VERTICAL ACCELERATION IN TRAINED AND UNTRAINED INDIVIDUALS DURING WHOLE-BODY VIBRATION EXERCISE

Lienhard, K.1,2,3, Vienneau, J.1, Friesenbichler, B.1, Nigg, S.1, Meste, O.2, Nigg, B.M.1, Colson, S.S.2,3

1: University of Calgary (Calgary, Canada), 2: I3S (Sophia Antipolis, France), 3: LAMHESS (Nice, France)

Introduction Transmission of acceleration to bony structures during whole-body vibration (WBV) has been described (Kiiski et al., 2008), but never been compared between populations with different fitness levels. Therefore, the goal of this study was to compare transmission of acceleration during WBV between trained and untrained individuals. Methods Fifty-eight adults were divided according to their physical activity level into two subgroups of 30 trained (≥ 5 h of exercising per week) and 28 untrained individuals (≤ 2 h of exercising per week). WBV was induced with a side-alternating platform at a frequency of 16Hz and an amplitude (displacement from baseline to peak) of 4mm. Vertical acceleration of the platform, as well as of the participants' lateral malleolus, patella, anterior superior iliac spine, and frontal head were measured with 1D accelerometers while they were standing (20° knee flexion, 0° corresponding to fully extended) and squatting (60° knee flexion) on the oscillating platform. Transmissibility values were obtained by dividing the acceleration magnitude of each bony structure by the acceleration magnitude of the platform. One-way ANOVAs were performed to compare transmissibility between groups. Results During standing, the transmissibility values were the same between the trained and untrained participants, with the exception of the patella, where transmissibility was significantly higher in the trained than the untrained participants ($F = 4.30$, $P < 0.05$). During squatting, the trained showed significantly higher transmissibility values than the untrained participants on all bony structures, i.e., the lateral malleolus ($F = 9.39$, $P < 0.01$), the patella ($F = 8.10$, $P < 0.01$), the anterior superior iliac spine ($F = 4.40$, $P < 0.05$), and the frontal head ($F = 11.67$, $P < 0.001$). Discussion The higher transmissibility in the trained participants could be explained by greater muscle stiffness as an adaptation to regular exercising (Pearson and McMahon, 2012), which was more pronounced during squatting than standing. Further, transmission of the vibration may have shown to be higher in the trained group due to their ability to better stabilize the ankle and knee joints. It can be assumed that the untrained participants dampened the vibration better because they utilized higher muscle force levels and activity (Wakeling and Nigg, 2001) during the squatting exercise. RELATIONSHIP OF DYNAMIC RESPONSE OF THE HEAD IMPACT WITH TIME LOST FROM CONCUSSIONS IN ELITE HOCKEY PLAYERS

Janie, C.

University of Ottawa

Introduction In elite hockey, it is reported that the incidence of concussions is 5.8 injuries per 100 players (1). Most players return to play within 10 days, yet some require a longer recovery which may take months (1). Concussive events can be studied using biomechanics in an effort to identify differences in impact mechanism between short and long recovery times. This could help sports medical teams to develop an accurate prognostic tool to ensure a player's safety. The purpose of this study was to investigate the relationship between dynamic response of the head impact and recovery time. Methods A search for videos of elite ice hockey players struck to the head was performed on the Internet using strict criteria to allow for physical reconstruction. A helmeted Hybrid III headform equipped with nine single-axis accelerometers with a 3-2-2-2 array was struck three times at three velocities (calculated velocity, $\pm 5\%$) for a total of nine impacts. Shoulder impacts were reconstructed using a pneumatic piston while elbow impacts were reconstructed using two swinging pendulums. Results Three events resulting in concussion lasting less than 10 days and five events resulting in concussion lasting more than one month were reconstructed. Mean peak linear acceleration was 24 ± 7 g for the short recovery time and 22 ± 13 g for the long recovery. Mean peak angular acceleration was 3.1 ± 0.7 krad/s² for the short recovery time and 2.7 ± 0.6 krad/s² for the long recovery time. No significant difference was found between the two groups. Discussion The results suggest that dynamic response of the head upon impact is not an influencing factor on the duration of recovery time in the cases included in this study. Research suggests that the explanation for inter-individual differences in concussion recovery time is likely more physiological such as number and severity of previous concussions, age, sex, and intrinsic factors such as morphology of the cranial vasculature and differences in cerebral metabolic factors, as opposed to a characteristic of the force experienced by the head itself (2). The data presented in this study supports this hypothesis. The small sample size and the specificity of the inclusion criteria are limitations that need to be considered when considering the results in this study. References 1. Wennberg RA, Tator CH. ACCELEROMETERS AS A TOOL FOR ANALYZING THE BIOMECHANICS OF ICE HOCKEY SKATING

Stetter, B.1, Buckeridge, E.2, LeVangie, M.2, Nigg, S.2, Nigg, B.2

1: Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany, 2: Human Performance Laboratory, Calgary, Canada

Introduction Despite ice hockey's widespread popularity, the biomechanical contributions to successful skating performance is poorly understood (Lafontaine, 2007). This lack of knowledge may be explained by the difficulty of collecting data on ice (Upjohn et al., 2008). Therefore, the primary aim of this study was to use simple, lightweight accelerometers as a viable means of biomechanical data collection on ice. A secondary aim was to use data derived from accelerometers to quantify stride timing characteristics and whole body intensity during forward skating. **Methods** Twenty four ice hockey players of three levels of ability were equipped with two 3D accelerometers as they performed 30 m skating sprints on an ice rink. The first 10 m were considered the acceleration phase while the final 10 m were considered the maximum velocity phase. Temporal stride information (i.e. total stride time and ice-contact time) was extracted from the first accelerometer, located on the center of the skate chassis. The second accelerometer, fixed to the skin overlying the 5th lumbar vertebra was used to estimate whole body intensity of a skating stride (i.e. stride intensity). Timing lights were set up in order to obtain overall sprint times as a performance variable. Two-way ANOVAs were used to compare player caliber (high, medium, low) and stride type (acceleration and maximum velocity). Pearson's correlations were calculated to identify relationships with performance. Results Acceleration strides had a significantly shorter stride time, shorter contact time and a higher stride intensity compared to maximum velocity strides ($p < 0.05$). When comparing participant abilities, high caliber players had significantly shorter contacts time than low caliber players, in addition to a significantly higher stride intensity than both medium and low caliber players ($p < 0.05$). A negative correlation between stride intensity and total sprint time was found, indicating that sprint times decrease as stride intensity increases. **Discussion** The significant differences between stride types support the notion that as a skater increases their speed, their skating motion changes (Lafontaine, 2007). Higher stride intensities found for high caliber players, as well as the negative correlation between stride intensity and total sprint time suggests that high performance is related to greater effort. Future research should attempt to apply this new approach to other skating movements to both detect temporal skating patterns and advance the understanding of the biomechanics of ice hockey skating. **References** Lafontaine D (2007) Sports Biom 6(3):391-406 Upjohn T, Turcotte R, Pearsall DJ, Loh J (2008) Sports Biom 7(2):206-221 Contact Bernd.Stetter@outlook.com

HANDBALL'S INFLUENCE ON ELEMENTARY SCHOOL CHILDREN'S CIRCUMSTANTIAL JUDGMENT CAPABILITY

Murakami, K.1, Yamamoto, T.2, Nakamura, M.2, Akihara, Y.2, Ichitani, K.3, Kojima, M.4, Nakatani, T.1, Terada, K.1, Shirai-shi, A.1, Umesaki, S.1

1: Tenri University (Nara, Japan), 2: Hyogo University of Teacher Education (Hyogo, Japan), 3: Osaka Electro-Communication University (Osaka, Japan), 4: Kokugakuin University (Tokyo, Japan)

Introduction: The confusing mix of offense and defense in certain ballgames, in this case handball, requires players to make many quick decisions. This repetitive practice seems to raise players' circumstantial judgment capability. Thus, this study attempts to determine whether playing handball actually influences circumstantial judgment capability of school children. **Methods:** The participants were ordinary elementary school children from the 4th to 6th grades (19 boys and 14 girls) and children from a handball club (15 boys and 15 girls). First, we contrived experimental situations that required the children to use their judgment. In these situations, we measured circumference information cognitive reaction time, posture form cognitive reaction time, a correct answer score, and simple stimulus reaction time. Our experiments were performed with the consent of children's guardians/parents. **Results:** In all three grades, children belonging to the handball club tended to be quicker than the mean of each reaction time—unlike other children. In posture form cognitive reaction time, a significant difference was shown among the 6th graders. Furthermore, a significant difference was revealed among the 4th and 6th graders in simple stimulus reaction time. In other words, years of handball experience tended to shorten reaction times. In particular, the 5th and 6th graders showed significantly different reaction times. These results suggest that experience in handball contributes to quicker reaction time in situations requiring circumstantial judgment capability.

VALIDITY OF DATA ANALYSIS USING DATA ANALYSIS SOFTWARE IN UNIVERSITY WOMEN'S VOLLEYBALL

Onuma, N., Kushi, H., Yoshida, A., Hukada, K., Takashina, T.

Nihon University

[Introduction] Various volleyball tactics such as quick- and back-attack have been utilized to overwhelm opposing teams. Computer software designed to analyze these tactics infiltrated the world of volleyball in the 1980s. In many countries, data analysis is conducted using Data Volley (DATA PROJECT, Italy), a data analysis software for volleyball. The aim of this study is to evaluate the effectiveness of Data Volley in analyzing the data on volleyball tactics. [Subjects and Methods] We evaluated volleyball games played by university women's leagues. We conducted two methods of analyzing game data: one method involved data analysis using Data Volley, and the other involved analyzing "by hand" (i.e., without the use of computer). Then we compared the results of both methods. With Data Volley, the analysis results are calculated automatically by feeding the data into a computer. In contrast, data analysis by hand requires that we fill in the game data on a sheet of paper, and calculate the data ourselves. The basic techniques of volleyball are "service," "receive," "attack," and "block." In this study, we analyzed the data pertaining to attack and service but not receive or block; we focused on techniques that are not dependent upon the opponent's technique. [Results] ©Advantages of using Data Volley for the data – analysis: • After finishing the data input, the results of the analysis are provided quickly, and are easy to grasp. • The course, number of times at bat, determination number, number of mistakes, determination rate, rate of an effect, and mistake rate of an attack or service were analyzed for every player and team. • In the data – analysis on attack, a player's attack is analyzed according to its type. • By creating a graphics function, intelligible data creation is visually possible. ©Disadvantages of using Data Volley for the Data – analysis: • A mistake may be made in typing, when inputting game information. • In order to perform data input correctly, a check by two or three persons is needed. • The price of software is cost-prohibitive. [Conclusion] Skills is needed to feed the data into a computer quickly while looking at the game. However, once the input is complete, it does not take much time for the data analysis using Data Volley. In addition, with the shooting rate and rate of failure, it is possible to determine the starting lineup and, to change the member and tactics immediately, even if time is limited (e. g., during an interval). Data analysis using Data Volley enables us to monitor the condi-

tions of the game based on the analyzed data-, because we can observe the results quickly compared to data analysis by hand. Therefore, Data Volley allows us to evaluate the conditions of the game in an objective manner.

IS COACHING EVALUATION ASSOCIATED WITH COLLECTIVE EFFICACY, SUBJECTIVE PERFORMANCE AND ATHLETIC BURNOUT OF UNIVERSITY BASEBALL ATHLETES?

Shimizu, Y., Miyazaki, M.

International Christian University and J.F. Oberlin University

Introduction Baseball coaching requires high competitive strategies, instruction skills and team leading competency. Prior studies have found that positive evaluation of baseball coaching by college baseball athletes is positively associated with their collective efficacy (Shimizu & Miyazaki, 2011). The purpose of this study was to examine the relationship among Coaching Evaluation Scale for Baseball Managers and Coaches (CESBMC), Collective Efficacy Scale for Baseball Athletic Teams (CESBAT), Subjective Performance Scale for Baseball Athletes (SPSBA) and Athletic Burnout Scale for Baseball Athletes (ABSBA). **Methods** The subjects of 264 baseball athletes (mean age=19.45, SD=0.89, mean baseball experience=11.30, SD=2.24) in four high competitive university baseball teams were asked to answer a questionnaire composed of question items on socio-demographic background as well as 32 question items of CESBMC, 42 question items of CESBAT, 12 question items of SPSBA and 30 question items of ABSBA. These four scales had been developed in our prior studies in 2010. Covariance structure analysis was conducted in order to examine our two hypothetical socio-psychological models: CCS model (CESBMC, CESBAT and SPSBA) and CCA model (CESBMC, CESBAT and ABSBA). **Results** The results of covariance structure analysis showed that both CCS model and CCA model had statistically acceptable structural validities (CCS: GFI=0.909, AGFI=0.867, CFI=0.962, RMSEA=0.068; CCA: GFI=0.903, AGFI=0.859, CFI=0.958, RMSEA=0.072). In the CCS model, the pass coefficients from CESBMC to CESBAT (0.54, $p<0.001$) and from CESBAT to SPSBA (0.35, $p<0.001$) were statistically significant while the pass coefficient from CESBMC to SPSBA (0.08, ns) was not statistically significant. In the CCA model, the pass coefficients from CESBMC to CESBAT (0.54, $p<0.001$) and from CESBMC to ABSBA (-0.15, $p<0.05$) were statistically significant while the pass coefficient from CESBAT to ABSBA (0.12, ns) was not statistically significant. **Discussion** The results of the hypothetic models above has implications for baseball coaching interventions. High coaching evaluation from baseball athletes is positively associated with high subjective performance only via high collective efficacy. This implies that coaching with focus on building mutual trust among team members and teams confidence in their success is more likely to lead to better baseball performance. **References** Yasuo SHIMIZU, Mitsuji Miyazaki (2011) Is Coaching Evaluation Associated with Collective Efficacy on University Baseball Athletes? 16th European College of Sport Science.

IMMUNE RESPONSE AND TOLERANCE OF SEDATED RATS TO LETHAL HEAT EXPOSURE FOLLOWING 5 DAYS OF PRE-CONDITIONING

Fun, D.

DSO National Laboratories

Introduction Heat stroke remains a threat to personnel operating under hot and humid conditions. It was observed that prolong period of intense training can induce mild endotoxemia due to leakage of gut-related endotoxins into central circulation. This may trigger systemic inflammatory response that drives the pathway of heat stroke (Lim & Mackinnon, 2007). This project aimed to examine immune response and tolerance of sedated rats to lethal heat exposure following 5 days of sleep deprivation and physical exertion. **Methods** Ninety 11-week old male Wistar rats, weighing between 350 – 370 g were divided into over training (OT), over training and sleep deprived (OT+SD) and Control (CTL) groups. The OT and OT + SD groups were exposed to daily pre-conditioning exercise for 5 days. In addition, the OT + SD group was exposed to sleep deprivation during this period. Animals in the CTL group were kept in the cage under normal condition during this phase. After the 5th day, all the animals in the OT, OT + SD and CTL groups were randomly sub-divided into heat treatment (HT) or non-heat treatment (NH) groups. Passive heat stress we induced to the HT rats to elicit a core temperature of 42 oC while core temperature of the NH rats was maintained at 37 oC. **Results** The OT+SD rats (36.6 ± 4.8 min) survived longer than the CTL rats (13.2 ± 2.6 min; $p<0.05$). Survival times were similar between the CTL and OT rats (21.1 ± 3.2 min; $p>0.05$). Baseline concentrations of IL-1A (CTL: 687 ± 99 pg/ml; OT: 345 ± 84 ; OT + SD: 462 ± 49), IL-1B (CTL: 2617 ± 893 ; OT: 1046 ± 272 ; OT + SD: 556 ± 346), IL-2 (CTL: 855 ± 114 ; OT: 667 ± 119 ; OT + SD: 677 ± 87), GM-CSF (CTL: 562 ± 72 ; OT: 297 ± 99 ; OT + SD: 340 ± 34), IL-4 (CTL: 582 ± 81 ; OT: 299 ± 57 ; OT + SD: 388 ± 37) and IL-13 (CTL: 724 ± 87 ; OT: 382 ± 93 ; OT + SD: 519 ± 58) were lowered after 5 days of pre conditioning exercise ($p<0.05$). **Conclusion** This study showed that rats that underwent OT + SD conditioning survived longer under lethal heat stress. This observation is coupled with a lowered baseline blood cytokine levels. These findings suggest that the increased survivability could be linked to a suppressive effect of the general adaption syndrome to physiological stress. **References** Lim CL, Wilson G, Brown L, Coombes JS, Mackinnon LT (2007). Pre-existing inflammatory state compromises heat tolerance in rats exposed to heat stress. *Am J Physiol Regul Integr Comp Physiol*, 292: R186•R184.

NEW PERSPECTIVES FOR THE PHYSICAL PREPARATION IN ARTISTIC GYMNASTICS

Toledo, E.I, Antualpa, K.2

Faculdade de Ciências Aplicadas - UNICAMP

Introduction Since its origin Rhythmic Gymnastics (RG) has had a strong link with art. In the last decades it has not stood out neither through the code of points nor through the University, leading to the artistic impoverishment of both series and modality. The new punctuation code (FIG, 2013) changed this situation, generating new reflection and adoption of proposals. Thereby, the objective of the research is to bring into the academic field some reflections and propositions about physical preparation in artistic gymnastics. **Method** Bibliographical and documentary research, with a qualitative approach in the analysis of data. The search was done in: RG books published in Brazil, some international books, RG's code of points, Proceedings of SIGARC and data bases (SciELO and CAPES); using key-words: physical preparation, artistic preparation, rhythmic gymnastics. **Results** The major part of the literature highlights the relationship of RG to art, since its origin till the present time (VIDAL, 1997; TOLEDO, 2010). Some works mention the importance of increasing the value of the artistic element, both in the beginning and in the training (BOBO and SIERRA, 1998). Some authors mention that as the former codes did not give value to this artistic element, the result was its scarce presence in the series, making them repetitive, not harmonic and not very meaningful. Among the proposals for developing the artistic element we saw a prevalence of ballet and, in some cases, the folklore and the modern dance (LISITSKAYA, 1995; VELARDI, M. E MIRANDA, M.L.J., 2010). **Discussion** The classical ballet maintains its importance to the RG technical and artistic development, but new proposals are needed for the artistic preparation and should arise from: other gymnastics

practices, Dance, Scholarly and Popular Culture and Performing Arts. It also needs a greater investment in this preparation (time and variety of strategies), from initiation to training. COMPARATIVE MUSCLE ACTIVITIES OF THE ROTATIONAL AND GLIDE TECHNIQUE IN SHOT PUT

Aoyama, S.1, Aoyama, T.2, Tsunoda, N.2

1 *Kokushikan University, Japan*. 2 *Graduate School of Sport System of Kokushikan University, Japan*.

Introduction A lot of shot put studies have examined the biomechanics and optimal release conditions, such as release speed, release angle and release height. Although these parameters directly determine the performance, there is no study for same subject of using rotational and glide technique in shot put. Therefore, the purpose of this study was to analysis the muscle activities of trunk and lower limb in shot put of two different technique, especially release-phase, and these differences are able to help determination to coaching. **Methods** The subjects were seven male shot put throwers who can use rotational and glide technique (age:22.7±2.3yrs, height:176.6±6.8cm, body weight:107.6±15.1kg, rotational throw:14.1±1.3m, glide throw:13.4±1.5m). All the subjects performed three rotational throws and three glide throws same as a competition rule with recorded best throw from both techniques. Muscle activities were measured by electromyography of trunk (latissimus dorsi muscle, external oblique muscle) and lower limb (vastus lateralis, biceps femoris muscle, adductor muscle gastrocnemius) muscle on right and left, which was calculated of iEMG from EMG. Throwing movements were measured by 3-D analysis that defined by the divided turn-phase and release-phase with two positions. **Results** The results of this study were as follows: Muscle activities of the rotational technique in the trunk and lower limb muscle were showed higher iEMG values than the glide technique, and especially external oblique muscle, biceps femoris muscle, right and left adductor muscle and left gastrocnemius of rotational technique were significantly higher than the glide technique ($p<0.05$). **Discussion** In this study, it was a significantly higher iEMG value of left side muscle activities in trunk and lower limb of the rotational technique than the glide technique. These results suggested that the rotational technique is greater eccentric contraction with the left side (leg and trunk) of the release phase than the glide technique, thus this means that the necessary for an effective block action of left side during release phase. In addition, the rotational technique of muscle activities in the left side might be enhanced the accretion of shot during release phase than the glide technique. Therefore, coaches are advised to pay particular attention to the left side muscle during the release phase for the especially rotational technique. **References** Bartonietz K. (1994). *Modern athlete and coach*. 32,7-10 Luhtanen P, Blonqvist M, Vanttinen T. (1977) New studies in athletics. 12,25-33

SPORT CAREER IN 400 M HURDLE RUN IN VARIOUS GROUPS OF THE BEST ATHLETES IN THE WORLD

Iskra, J.1, Przednowek, K.2, Walaszczyk, A.1

1: *AWF (Katowice, Poland)*, 2: *UR (Rzeszow, Poland)*

Introduction Sport ontogenesis is a part of participations in training and competition activities. Olympic medallist in men's 400 m hurdle run was 18-23 years old. Training in "low" hurdles (= 400 m hurdles) was started in early school phase (c. 10 years) and was continued even to 40 years (Iskra 2013). **Methods** This study regarded the best 400 m hurdlers in the world ($n=48$, average result: 47.67±0.34 s, age: 25.60±2.14 years). In the analysis hurdlers were divided into two groups, according to the period they developed their personal best results (A=period 1980-99, B=period after 2000). In the analysis we used three basic protocols: (1) chronological development of one's hurdle run results (according to age; from 16 to 39 years old), (2) the basis was the year of personal best result (PB) and (3) following years of athletic development (the length of sport career). Because data distribution was not normal, the non-parametric test U Mann-Whitney's was applied to determine the differences between groups. In research of connections between age and sport results we used Spearman's rank correlation. **Results** According to the first protocol, the best results (in both groups) were performed between the age of 25 and 27. Dynamics of sport career in two groups (A1, A2) varied only among 19 years old (approximately 50.82 ± 1.31 v 49.87 ± 1.27 s; $p \leq 0.005$). In the whole group we observed the highest correlation between the best result and age 27 ($r=0.72$, $p \leq 0.01$). According to the second protocol the best results in 400 m hurdles start from the 6th year of specialisation and continue till the 11th year of career. In this aspect there're no differences between groups. According to the third protocol in the group of world best 400 m hurdlers we can't accurately predict the best results 1 – 4 years ahead of this time ($r=0.41-0.46$, $p \geq 0.05$). **Discussion** Each of the human activities has its own "peak performance" (Ericsson, 1993). In the athletic events Olympic medals are won by runners from 17 to 40 years old (Butler 2012). Previous studies showed that the best results in men's 400 m hurdle run obtained in the age of 25 (Dickwach and Wagner, 1997). In our study we observed that this optimal age is 2 years higher. Harsanyi and Martin (1985) claimed that in junior-age category (=19 years old) the best hurdlers obtained 96% of future best records. In our group, in the age of 19 hurdlers obtained 93.7% (A) and 95.7% (B) of their personal records in the future. **References** Butler M. (2012). *Athletics Statistics Book*. IAAF, Monaco. A PHENOMENOLOGICAL STUDY ON A VALUATION OF THE DECISION-MAKING ABILITY

Sato, M.

Numazu College of Technology

In ball games, it is important that the player always grasps the constantly changing game situations and copes with each situation by optimal actions. Such ability is called the decision-making ability. Although a large number of studies have been made on the decision-making ability in a field of sports psychology, the results of those researches do not function effectively in practice (Akira, N., 1985; Hiroshi, A., 2012). As this cause, I offer a next reason. It is to break up the decision-making ability into the tactical thinking ability (to analyze a game situation and to select a play) and the execution ability in a play. Therefore the aims of this study are to clarify a valuation of the

decision-making ability as the unified ability to select the optimal play (action) in a game situation and to execute this play (action). In order to achieve this aim, the following consideration procedures were taken in this study. First, influential factors on the decision-making ability were clarified and classified in two subjects (one is the structural factor of a game situation and the other is the situational factor of a game situation). Secondly, it was investigated how the superiority or inferiority of the decision-making ability should be considered. The following two points became clear from the result of two above-mentioned considerations in conclusion. 1. The superiority or inferiority of the decision-making ability is influenced by technical ability (execution ability in a play). Therefore, the play (action) which should be chosen as the best play in a situation should change according to the technical ability (execution ability). An important thing for player is not choosing the best play in a situation, but is choosing the optimal play. In short, the optimal play in a game situation must be considered based on the player's technical ability (execution ability). 2. A valuation of the decision-making ability should rather be synthetically judged from plays (actions) in many situations than be judged from a play in a limited situation. Therefore, the valuation of the decision-making ability is impossible in the form of an image test with VTR. In short, a valuation of the decision-making ability should be relatively judged through observing the play in various situations. References Akira, N. (1985). DEVELOPMENT OF EVALUATION SYSTEM OF SAILING PERFORMANCES ON WATER FOR JAPANESE OLYMPIC SAILING TEAM

Hagiwara, M.1, Katori, M.2

1) Japan Institute of Sports Sciences (Tokyo, Japan), 2) North Sail Japan (Kanagawa, Japan)

Introduction During sailing races and training, the performance changes from hour to hour depending on weather and marine condition. Therefore, it is extremely difficult to evaluate the detailed sailing performance accurately on water. The primary purpose of this study was to obtain evaluation index, which would be useful for athletes and coaches in improving their sailing performances. The second aim of this study was to develop an evaluation system for obtaining the index described above. **Methods** Athletes of four Olympic classes of sailing (470, RSX, Laser, and Laser Radial) and their coaches attended the National Training Camp. The camps were held three times. In the first camp, we discussed about important indices of sailing performances on water with the athletes and the coaches. We tried creating two types of our own system software with Global Positioning System (GPS), using the indices obtained from discussion in the first camp. In the second and the third camp, we supported the athletes and coaches using the system we developed. Then, we discussed again about the software for improvement, and modified it by trial and error. **Results** As a result of our discussion with the athletes and the coaches, we obtained the important indices of performances related to sailing for the athletes and the coaches, and those were classified into two categories. The first of these was related to comprehensive assessment of the sailing race. Another one focused on Boat/Board speed (BS) during sailing. We created our own two system software with GPS as suitable for these categories. The classified indices were described below. 1. Index of performances related to sailing race 1) Sailing performances (Speed, Timing, Positioning) 2) Performances of Up/Down-wind (Average speed and distance for Top/Bottom-mark, Tacking/Gybing, Strategy, Tactics) 3) Mark rounding (Positioning, for study of rule in the mark area) 2. Index of performances related to BS during sailing 1) A detailed assessment of BS (Velocity Made Good: VMG) Discussion As a result, evaluation indices were classified into two categories; the index related to sailing race, and the index of performances related to BS during sailing. Therefore, it was necessary to create two types of evaluation system software to evaluate sailing performances on water. Actually, we used these systems for the athletes and coaches during the camp. They expressed positive opinions on these systems. We think that the most important parts of this study were having exhaustive discussions with the athletes, coaches, and the specialized scientist of sailing. In the future, it is expected that these systems are used daily to accumulate various data for evaluation of training effect.

EMPIRICAL EXAMINATION OF HUNGARIAN GYMNASTS' MOTIVATION AND COMPETITIVE ANXIETY

Boldizsár, D.1, Soós, I.2, Hamar, P.1

1:Semmelweis University, 2:University of Sunderland

Introduction Cremades and Wiggings (2008), reported that coaches can gain benefit out of the knowledge of their athlete's psychological distinctiveness in competitive conditions. Regarding this expertise coaches can contribute with promoting, supportive techniques in pre-season. (Cremades and Wiggings, 2008). The aim of study was to find out what sport psychological qualities can be characterized during competition season in gymnastics in order to enhance their performance. **Methods** The Sport Motivation Scale (Pelletier et al., 1995) as well as Task and Ego Orientation in Sport Questionnaire (Duda, 1989) and in addition the Competitive State Anxiety Inventory-2 (Martens et al., 1990) were filled out by 254 Hungarian gymnasts. They completed the questionnaires in spring 2013 in their native language. **Results** In the investigation of motivation there were no significant differences between the extrinsic and intrinsic motivation factors. By analyzing the goal orientation, it was found that the task orientation factor have significantly higher value than ego orientation factor. The analysis of CSAI-2 highlights the facts that there were no significant differences between the 3 factors (somatic anxiety, cognitive anxiety, self-confidence) but the somatic anxiety factor have significantly higher value than cognitive anxiety factor, and the self-confidence factor shows significantly higher value than the two anxiety factors. **Discussion** According to Markland, athletes who have intrinsic motivation enjoy doing sport more and irrespectively of performance they more likely willing to do it in the long term (Markland, 1999). In our examination there were no significant differences between the motivational factors. According to Goudas (1998), athletes are motivated more in a task-oriented environment; they can achieve goals better, as well as they have lower anxiety level (Goudas, 1998). In the case of our examination, the task-orientation factor was the most emphatic. In conclusion, in our sample, the somatic anxiety factor was significantly higher than the cognitive one, which should be taken into consideration by coaches in order to achieve performance enhancement in their athletes. **References** Cremades, J., Wiggings, M.S. APNEA, BLOOD LACTATE AND HEART RATE IN MALE FREESTYLE SWIMMERS AGED 15-17 YEARS: A PILOT STUDY

Thanopoulos, V.1, Rozi, G.1, Lampadari, V.1, Dopsaj, M.2, Okicic, T.3, Geru, E.4

National & Kapodistrian University of Athens

Introduction Apnea is a non breathing situation. It can be static or dynamic. During both the static and dynamic apnea (Joulia et al., 2003) increase in blood lactate concentration is observed. The purpose of this study was to investigate the maximum concentration of lactic acid in blood (LaMAX), heart rate (HR) and performance time (PT) of 4x50m freestyle swimming test (Pelayo et al. 1996) with two different protocols of maximum intensity a) with normal breathing, 3 strokes followed by one breath and b) 14-15m underwater dolphin kicks followed by freestyle swimming every 3 strokes a breath. **Methods** The sample consisted of seven competitive level male swimmers, aged 16 ± 1.0 years, BH 171 ± 12.8 cm and BW 66.07 ± 16.3 kg. Freestyle was their basic swimming style and all of them were swimmers of short and middle distances. Subjects participated in both protocols of 4x50m of maximum intensity freestyle swimming and 10 sec break. Blood samples were taken in order to determine LaMAX, at 3, 5 and 7 sec after each test and were analyzed by Lactate Scout Germany. PT and HR were recorded after each test. **Results** ANOVA analysis showed that there were no statistical significant differences between the two protocols. According to the results of our study, apnea during high intensity freestyle swimming does not cause different responses in HR, PT and LaMAX compared to freestyle swimming without apnea in competitive level swimmers aged 16 years old (Sig. .567, .292, .338 respectively). **Discussion** In the present study, LaMAX, HR and PT were not affected by the form of apnea applied. Guimard et al (2013) observed a decrease in HR and PT after repeated efforts of maximum intensity swimming and apneas. LaMAX was not affected. In contrast to the results of this investigation Lemaître et al. (2007) observed a decrease in LaMAX after repeated efforts of apnea with immersion of the face in the water during moderate intensity exercise on the ergometer. Apnea deserves further investigation as a form of exercise in swimming, using different swimming styles and protocols of apnea. **References** Guimard A, Prieur F, Zorgati H, Morin D, Lasne F, Collomp K. EVALUATION OF UK COACHES SPORTS NUTRITION KNOWLEDGE

Cockburn, E.1, Fortune, A.2, Rumbold, P.2

Middlesex University (1); Northumbria University, Department of Sport, Exercise and Rehabilitation (2)

Introduction Optimal nutrition can have positive effects on health, the immune system, general well-being, and the development of peak sporting performance. Research has demonstrated athletes' lack sufficient nutritional knowledge (Hornstrom et al., 2011; Torres-McGehee et al., 2012). Athletes obtain nutritional information from their coaches (Burns et al., 2004) yet their competency in this area is lacking (Torres-McGehee et al., 2011; Smith-Rockwell et al., 2001). Currently no research exists in the UK, which has a different coach education system to many other countries. Therefore, the aim of this study was to evaluate the sports nutrition knowledge of UKCC level 2 and 3 qualified coaches. **Methods** One-hundred and sixty three UK level 2 (n=136) and level 3 (n = 27) hockey (n=58) and netball (n=105) coaches took part in the study. All coaches completed a previously validated and reliable sports nutrition questionnaire (Zinn, Schofield & Wall, 2005) via SurveyMonkey® to identify (a) if they provided nutritional advice, (b) their level of sport nutrition knowledge and (c) factors that may have contributed to their level of knowledge. **Results** Over half the coaches provided advice to their athletes (n = 93, 57.1%), while 65 coaches (39.9%) did not provide any nutritional advice. Coaches responded correctly to $60.3 \pm 10.5\%$ of all knowledge questions, with no significant differences between those providing advice and those who did not ($P > 0.05$). A repeated-measures one-way ANOVA demonstrated that those coaches who had undertaken formal nutrition training achieved significantly higher scores than those who had not ($P < 0.05$). **Discussion** The results indicate that more than half of the coaches in this study provided nutritional advice to their athletes, even though they were not competent to do so. Those coaches who had completed formal nutrition training scored significantly better in comparison to those who had not completed any formal training. In conclusion, UK sports coaches would benefit from continued professional development in sports nutrition to enhance their coaching practice. **References** Burns, R.D., Schiller, R., Merrick, M.A., Wolf, K.N. THE EFFECTS OF POST-ACTIVATION POTENTIATION USING RESISTED SLED ON SPRINT PERFORMANCE

Argeitaki, P.1, Matiatos, G.1, Paradisis, G.1, Zacharogiannis, E.1, Pilianidis, T.2, Smirniotou, A.1

1:Faculty of Physical Education and Sport Science, University of Athens, Greece 2:Dep. of Physical Education and Sport Science, University of Thrace, Greece

Introduction: The effects of resisting training program have been found to increase the rate of force development which is the main parameter that affects sprinting performance. Resisted sled is usually used in sprint training. The purpose of this study was to investigate the effects of post-activation potentiation (PAP) on sprinting using resisted sled (RS). **Methods:** Eleven sprint athletes, (mean \pm SD: age 24.3 ± 3.1 y, height 175.3 ± 6.6 cm, body mass 71.2 ± 9.3 kg and BMI 23.0 ± 1.5 kg/m²) performed a 60m sprint from starting blocks before and after 40m run using a resisted sled. The intervention was consisted by a 40m run towing resisted sled (12% load of body mass) followed by a 5 min rest. The performance of 10m, 20m, 30m, 40m, 50m and 60m from the start line, was measured by 6 pairs of photocells (photocells, Microgate, It). A control group executed the same intervention without towing a resisted sled. A t-test for dependent samples was used (SPSS, Chicago, US). **Results:** The RS use improved significantly the performance in the 2nd 60m sprint compared to the 1st 60m sprint ($p=0.000$). The performance in the sections 0-30m, 0-40m, 0-50m were also improved significantly after towing RS ($p=0.013$, $p=0.020$, $p=0.034$ respectively). In contrast, there was not a significant improvement in sections 0-10m, 0-20m after towing the RS. The control group did not show any significant differences in all sections before and after the intervention condition without towing the resisted sled. **Conclusion:** The findings of this study indicate that the performance from 20 to 60m in a 60m sprint seems to be enhancing after a resisted training program using sled loaded with 12% of body mass. Thus, to obtain PAP a "resisted method" would be useful to be applied, in order to improve performance in sprinting although further research is required. **References:** Docherty D, Hodgson M. Health and Fitness

THE TECHNIQUE OF USING HEALTH-IMPROVING AEROBICS FOR STUDENTS WITH DISEASES OF THE RESPIRATORY SYSTEM

Kovalenko, T.I, Shklyarenko, A.2, Pologova, N.3, Ulyanov, D.

1: *Volgograd State University, (Volgograd, Russia)* 2: *Kuban State University branch in Slavyansk-on-Kuban (Slavyansk-on-Kuban, Russia)*

Introduction The studying success rate at a university is closely related with functional state and health. The issues, associated with health worsening, can lead to performance decrement and fatigability increment among the students. **Methods** The proposed technique of carrying out and organizing special medical groups (SMG) consists of basic (cyclic aerobic-oriented exercises) and variative (corrigent exercises) components. We have fitted the basic aerobics in the classes, the one consisting of three parts: stretching, aerobic-oriented dancelike and cyclic exercises, power exercises. **Results** We have developed a program, including three stages: 1. The recovery of respiratory and cardiovascular body system functioning. 2. The shaping of core muscles and strengthening of upper shoulder girdle muscles. 3. The increasing of aerobic endurance during moderate intensity working. The training exercise classes were given 3 times a week for 60 minutes each. At the heart of it there was an annual educational cycle consisting of two semesters: the autumn and the spring ones. Each semester, the health-improving aerobics in the course of girl-students' physical education was carried out taking into account three stages: preparatory, training and supporting. The duration of aerobic training – 20 minutes, power training – 10 minutes at each training class. During the preparatory period, moderate aerobic power stressing was used with the purpose of organism adaptation (65 – 70 % of maximum Cardiac Rate in the 1 semester) for 20 minutes, which corresponded to the Cardiac Rate of 130 – 140 per minute. This aerobic stressing did not implement the efficient endurance development; however, it created prerequisites for vascular tree expansion, skeletal and cardiac muscles enhancement. The duration of this period – 1 month. During the training period, the content of health-improving aerobics set exercises included the high-intensity exercises (75 – 80 % of maximum Cardiac Rate), geared towards the development of general endurance, the increasing of functional capabilities of respiratory and cardiovascular systems. The intensity of stressing at the beginning of the training period did not exceed 75 % of maximum Cardiac Rate, and then it was gradually raised to 80 %, which corresponded to 150 – 160 per minute. The total duration of the period was equal to 3 months. **Discussion** According to preliminary data, may be said, that the results increased reasonably both in the control group and in the experimental group, but the increment in the experimental group was more significant. The respiratory rate decrement is of particular interest; that factor which characterizes the performance of respiratory system. We consider it, in particular, to cause also the alteration of other factors, those we have taken for the controlling of performance efficiency and capacity of respiratory system (Stange's and Genchi's tests).

PEDOMETER DETERMINED PHYSICAL ACTIVITY IN CHILDREN: COMPARISONS BETWEEN THE UNITED KINGDOM AND BELGIUM

Duncan, M.J.1, Birch, S.L.1, Eyre, E.1, Bryant, E.1, Ruffen, C.2, Boen, F.2, Seghers, J.2

1: *Coventry University (UK)*, 2: *KU Leuven (Belgium)*

Introduction The positive effects of regular physical activity (PA) on health are indisputable but many children do not engage in sufficient PA for benefit (Hallal et al., 2012). However, substantial variation in PA exists between countries, suggesting that PA levels are influenced by geographical location (Nilsson et al., 2009). For this reason cross-cultural research is important in guiding interventions and PA policy. However, data comparing objectively measured PA levels in children across Europe are lacking. This study compared pedometer determined PA in children from the UK and Belgium. **Methods** Following ethics approval and informed consent, 2760 children (1247 boys, 1513 girls) aged 9-14 years from Leuven, Belgium (n = 1614) and the West Midlands, UK (n = 1146) wore a Pedometer (Yamax Digiwalker SW-200) for at least 4 days including at least 1 weekend day and had their height (m) and body mass (kg) assessed from which Body Mass Index (BMI) was determined. Average Steps/day were taken as a measure of PA and the proportion of children meeting internationally recommended cut-offs for PA (Tudor-Locke et al., 2004) were calculated. Data were analysed using 2(gender) X 2 (country) way ANCOVA controlling for age and BMI. **Results** Results indicated a significant country by gender interaction for steps/day ($P = .0001$). In both Belgium and the UK boys were more physically active than girls ($P = .0001$ in both cases) but the difference between boys and girls was greater for Belgian children than UK children. Mean \pm SE of average steps/day was $16,799 \pm 163.1$ and $13,488 \pm 149.4$ for Belgian boys and girls respectively compared to $12,637 \pm 199.2$ and $11,782 \pm 178.3$ for UK boys and girls respectively. BMI was also significant as a covariate ($P = .001$) with every increase in kg/m^2 associated with a decrease of 142.6 steps/day for Belgian children and 231.4 steps/day for UK children. Overweight/obesity prevalence was higher (20.6%) and the proportion of children meeting steps/day cut-points for health lower (37.2%) in UK children compared to Belgian children (15.5% and 59.9% respectively). **Discussion** These results suggest that there are differences in PA levels between boys and girls in Belgium and the UK. Moreover, although girls in both countries accumulated significantly fewer steps/day than boys, the difference between boys and girls was less in the UK compared to Belgium. Such data is important in understanding cross-cultural differences in PA levels between European children. **References** Hallal, P.C. et al. (2012) *Lancet*, 380, 247-257. Nilsson, A. et al. THE RELATIONSHIP BETWEEN HABITUAL EXERCISE AND A TENDENCY TOWARD SPIRITUALITY.

Nigorikawa, T.

Rikkyo University

Introduction The World Health Organization (WHO) stated spirituality should be included in the definition of human health in 1983. Many studies have shown that there is in fact a strong relationship between one's quality of life (QOL) and a tendency toward spirituality. Additionally, there is much research on the relationship between habitual exercise and certain psychological conditions. However, there is virtually no research on the relationship between habitual exercise and a tendency toward spirituality. Accordingly this study investigated this relationship. **Method** The subjects of the study consisted of 312 male and 76 female university students. The subjects were divided into two groups: the Exercise Group (n=309) and the Non-exercise Group (n=79). The Exercise Group consisted of students who habitually performed at thirty minutes or more of exercise more than twice a week. The Non-exercise Group was made up of students who undertook less exercise than this. Their tendency toward spirituality was measured using two different scales. One was the Rikkyo University

Spirituality Rating Scale (RSS). Under the RSS, spirituality comprises of five factors: harmonizing with nature, ikigai (the Japanese word for one's sense of purpose in life), a feeling of awe regarding invisible existence, connecting with one's ancestors, and self-determination. The other was the Self-Transcendence Scale (STS). Results The Exercise Group had higher RSS and STS scores than those of the Non-exercise Group. These results show that the Exercise Group has a stronger tendency toward spirituality. There was almost no difference in the results between males and females. Discussion There is no doubt that habitual exercise contributes to the improvement of one's health at the physiological level. The results of this study suggested that there was also a relationship between habitual exercise and a tendency toward spirituality. Of course, it is not certain that habitual exercise promotes a tendency toward spirituality from these results, but rather that there is a high probability that exercise contributes to spiritual health as well as at the physiological and psychological levels. Further investigation is needed to clarify this. Contact e-mail : nigo@rikkyo.ac.jp

IDENTIFICATION AND EXPLORATION OF HEALTH PERCEPTIONS IN KU STUDENTS

Whiteley, S.W., Moir, H.J., Ogunrinde, A., Elnabhani, S., Mulrooney, H.

Kingston University

Introduction Student health and wellbeing potentially affects engagement, participation and achievement at University. Identifying lifestyle risks experienced by students will enable tailored interventions which may encourage engagement in positive health-related behaviours. Currently there is little research on interventions with students. This study investigated the health perceptions of students at a UK University to identify their key health habits and concerns. Methods A questionnaire was developed and administered to students, regarding their current lifestyle behaviours and concerns, including stress, diet, physical activity, alcohol and drug use. The results of 191 completed questionnaires were analysed in SPSS 19, IBM SPSS Statistics. Frequencies were analysed to identify the main health concerns. Correlations and crosstabs were used to explore relationships between variables. Significance was set at $p < 0.05$. Additionally three focus groups were held with students to further explore their perceptions using a topic guide developed from the questionnaire results. Questions such as "How do you feel about the above statistics?" and "What can the University do to help?" were used to stimulate discussion. The focus group interviews were digitally recorded and transcribed, and the main themes and ideas were identified. Results The three main concerns identified from the questionnaires were exam and assignment stress (78.5%), getting a job (56.5%) and the future (54.2%). Overall physical activity levels were low, with almost two thirds of students spending no time performing exercise at all. Additionally, the majority did not consume sufficient fruit and vegetables, and one in five students were current smokers. Perceived barriers to health included the availability and price of healthy food in campus canteens, and a need for exercise facilities on campus was expressed. Students showed interest in schemes such as a healthy points reward card for use in canteens and technology such as health-promoting apps. Discussion In line with national data, results of this research highlighted poor nutritional intakes, lack of physical activity and high rates of smoking among young adults. Despite perceived high levels of stress, especially related to study, careers and employability, student awareness of University support services was poor. Technology and apps were perceived as good ways to reach students; this is supported by previous research in young people (although the success of such interventions is unclear). This research will help to appropriately tailor future health campaigns at Universities. Contact K1021754@kingston.ac.uk

PHYSICAL ACTIVITY BEHAVIOR, COGNITION, AND PHYSICAL FITNESS CHANGED AS A FUNCTION OF LIFESTYLE AND EXERCISE INTERVENTIONS

Lee, L.C.1, Jwo, J.L.2

1: University of Taipei (Taipei, Taiwan), 2: National Taiwan Normal University (Taipei, Taiwan)

Introduction Recommendations to exercise regularly are not necessary by the majority of people. Specific efforts need to be made to develop effective interventions for promoting physical activity. This study, utilized the Trans-theoretical Model to investigate the effects of lifestyle and exercise interventions on physical activity behavior, cognition, and physical fitness in adults. Methods Quasi design experiment was utilized with a total of 60 middle-age adults (mean age = 40.2 ± 7.6 years) randomly assigned randomly to either lifestyle group (LG), exercise group (EG), or control group (CG). Three months of intervention and six months of follow-up were conducted. Physical activity behaviour, cognition, and physical fitness were assessed at the beginning and end of the intervention, and 9 months. The questionnaires included the self-administered Seven-Day Physical Activity Recall Questionnaire, Stage of Change for Physical Activity Questionnaire, Decisional Balance Questionnaire and Self Efficacy questionnaire. The physical fitness instrument were used to examine fitness Results 1. Physical activity in both LG and EG showed significant improvement compared to CG at the end of the intervention. Stage of change in both LG and EG also showed significant improvement. 2. Cardiovascular respiratory endurance in EG showed significant improvement compared to both LG and CG. 3. Physical activity in both LG and EG showed significant improvement compared to CG in the follow-up assessments. Stage of change was significantly enhanced in LG only. Furthermore, both exercise self-efficacy and decision balance were significantly improved in LG compared to both EG and CG. 4. Muscular fitness in LG showed significant improvement in the follow-up assessments compared to both EG and CG. Discussion It was concluded that among middle-aged adults, 1. Both lifestyle and exercise interventions are effective in enhancing physical activity behaviour and stage of change. 2. Exercise intervention is effective in improving cardiovascular endurance. 3. Both lifestyle and exercise interventions are effective in improving physical activity behaviour and stage of change at the 6-month follow-up period; while self-efficacy and decision balance were enhanced only in the LG. 4. Lifestyle intervention is effective in improving the muscular fitness in the follow-up assessments.

THE ARRANGEMENT OF SHORT EXERCISE INTERVALS OF DIFFERENT INTENSITIES INFLUENCES THE AMOUNT OF FAT OXIDATION IN SEDENTARY OVERWEIGHT ADULT MEN

von Oetinger, A.1,2, Cancino, J.3, Villanueva, B.4, Urzúa, R.2,5, Muñoz, M.5, Villanueva, S.4

1: Universidad Nacional Andrés Bello, 2: Universidad Diego Portales, 3: Universidad Mayor, 4: Universidad de Chile, 5: Hospital del Trabajador (Santiago, Chile)

Introduction Since sedentarism is an important cause of obesity, it is relevant to design simple exercise protocols that maximize fat oxidation. The aim of this study was to analyse whether the sequence in which three short periods of exercise of different intensities are arranged influences the oxidation of fat in sedentary overweight adult men. Methods Peak aerobic power (pAP) was determined for ten sedentary male subjects, 30 to 39 years old (33.9 ± 0.9 years), with an elevated body mass index (30.1 ± 0.8 kg/m²). Subsequently, they completed three sessions of equivalent interval-exercise protocols on different days. Each session consisted of three 15 min-exercise periods separated by 5 min of rest between them. In one of these protocols ("constant intensity protocol", C) all three exercise periods

were executed at 55% of pAP. In the other two protocols, the exercise periods were done at 40%, 55% and 70% of pAP, in that sequence ("increasing intensity protocol", I) or in inverse order ("decreasing intensity protocol", D). Indirect calorimetry measurements showed that the exercise protocols produced the same caloric expenditure (5.9 ± 0.2 kcal/kg for C, 6.0 ± 0.2 kcal/kg for I and 6.1 ± 0.2 kcal/kg for D; $p > 0.01$). Results Respiratory exchange ratio data revealed that the proportion of calories contributed by the oxidation of fat (F) and carbohydrate (CH) to the total energy expenditure was significantly different in each exercise protocol (F/CH ratio values: 0.37 ± 0.02 for C, 0.29 ± 0.01 for I and 0.44 ± 0.02 for D; $p < 0.01$). In addition, the perception of exertion (Borg, 1982) by the subjects was significantly lower in the decreasing intensity protocol (scale of perceived exertion ratings: 14.1 ± 0.4 for C, 16.4 ± 0.7 for I and 12.2 ± 0.3 for D; $p < 0.01$). Discussion Our results showed that an interval-exercise protocol of decreasing intensity was more efficient in fat oxidation and caused a diminished sensation of exhaustion than equivalent (isocaloric) exercise protocols of constant or increasing intensities. Based on the inhibitory effect of glycogen content on muscle fat oxidation (Philp et al., 2012), it is hypothesized that the highest intensity exercise interval at the beginning of the protocol could deplete muscular glycogen, allowing greater fat utilization during the following intervals. PREDICTION AND VALIDITY OF O₂MAX FROM SUBMAXIMAL EXERCISE IN KOREAN MEN.

Jeon, Y.J., Im, J.H.

KAIST(Korea Advanced Institute of Science & Technology)

Introduction. The purpose of this study is to develop VO₂max prediction model with variables from submaximal exercise, and to verify prediction model. The prediction of maximal oxygen uptake simply develops an equation to predict oxygen consumption by combining metabolic variables identified during the easy submaximal exercise with maximal oxygen uptake. **Method.** The subjects are consisted of 401 people aged from 20's, and we separated them into sample group(n=283) and cross-validation group(n=118). We developed a model from running multiple regression analysis to the sample group, and verified it with cross-validation group. Sample group's input variables are metabolic variables measured at 3 minute and 6 minute of Bruce treadmill protocol. From these, HR150, 6 minuteVO₂, weight, 6 minuteVCO₂, 3 minuteVCO₂, 6HR are chosen for prediction model. **Results.** Model 1 is $VO_{2max}=64.133+0.019(6 \text{ minuteVO}_2)-0.380(\text{weight})-0.011(6 \text{ minuteVCO}_2)+0.005(3\text{minVCO}_2)-0.120(6\text{minHR})$, model 2 is $VO_{2max}=56.628+0.007(HR150)+0.019(6 \text{ minuteVO}_2)-0.373(\text{weight})-0.011(6 \text{ minuteVCO}_2)+0.005(3\text{minVCO}_2)-0.087(6\text{minHR})$, model 3 is $VO_{2max}=40.201+0.019(HR150)+0.019(6 \text{ minuteVO}_2)-0.358(\text{weight})-0.012(6 \text{ minuteVCO}_2)+0.005(3\text{minVCO}_2)$, model 4 is $VO_{2max}=40.436+0.019(HR150)+0.019(6 \text{ minuteVO}_2)-0.325(\text{weight})-0.010(6 \text{ minuteVCO}_2)$. All 4 models have high R value($R=0.61\sim0.63$, $p<.01$), low SEE($\pm 4.56\sim\pm 4.64$), and SEE%($10.78\sim10.97$, $p<.01$). Also, they did not show multicollinearity. From Cross-validation, we found significant correlation between predicted and measured VO₂max($R=0.54\sim0.61$, $P<.01$). In addition, both %error($-12.42\sim15.01$) and %TE($5.89\sim6.73$) were very low, confirming its accuracy and validity. **Discussion & Conclusion.** This study developed prediction equation, targeting a relatively large number of healthy Korean males. According to a survey of previous studies by Malek et al(2004), Cooper and Store(2001) developed a prediction equation, targeting a prediction group of 522 subject(male 328, female 194). Furthermore, the models having low prediction error were identified(%TE=4.67~6.36). Bland-Altman plotting confirmed that the estimation models are reliable and have low systematic error. Thus, models from this study can be effectively utilized in exercise prescription field, and in any hospitals that can conduct graded exercise tests. **Reference.** Malek, M.H., Berger, D.E., Housh, T.J., Coburn, J.W., & Beck, T.W(2004). EFFECTS OF VARIOUS EXERCISE POSTURES ON HEART RATE AND ENERGY EXPENDITURE IN PREGNANT WOMEN

Ajjimaporn, A., Nakkanung, N., Pintong, M., Chauchaiyakul, R.

Sports Science and Technology

Introduction Posture is known to have important physiologic effects on the cardiovascular system both at rest and during exercise. In pregnant woman, it is well known that cardiorespiratory and metabolic changes occur with advancing gestation. The role of body positions affected changes in these variables during exercise in pregnancy needs further investigation. The aim of this study was to measure heart rate (HR), oxygen consumption (V'O₂), carbon dioxide production (V'CO₂), minute ventilation (VE), and metabolic equivalent (MET) during exercise in supine (Sup), side-lying (Side-lying), sitting (Sit), standing (St) and walking position at the 1st (G1), the 2nd (G2), and the 3rd (G3) trimester in pregnant Thai women. **Methods** Forty- two healthy active non-smoking pregnant women participated in this study and divided into G1, G2 and G3 groups depending on mean gestational ages at the time of testing which was 10.5 ± 2.9 , 19.2 ± 3.4 , and 33.3 ± 2.4 weeks of gestation respectively. The values for HR, V'O₂, V'CO₂, VE and MET were measured using indirect calorimetry (IC, gas analyser) at rest and during exercise. Baseline assessments were made in the sitting recumbent position after a 30-minute stabilization period. Sequential measurements were then obtained in the following exercise positions; Sup, Side-lying, Sit, St and walking position, respectively. **Results** The profiles of changing for all variables were similar among G1, G2 and G3 at the same exercise position. At rest compared with exercising in Sup position, the subject had tendency to decrease in HR, but statistically significant difference was found only in G3 group ($P<0.05$). St positions and Walking accelerated and increased HR, V'O₂, V'CO₂, and VE more than the other three positions with the same of patterns in all gestation groups. The percentage of change in MET relative to resting position was significantly higher in walking than the other positions in all gestation groups ($P<0.05$). **Discussion** Our data strongly correlates with the American College of Obstetricians and Gynecologists guideline that recommends avoiding the Sup position post G1. We did not find a significant change in the value for HR, V'O₂, V'CO₂ and VE during exercise in Side-lying and Sit positions suggesting these were safe positions to exercise during pregnancy. We found walking to be the most spending cost of energy with respect to maternal MET output. Thus, we highly recommend pregnant women walk on a regular basis throughout pregnancy as this will also help maintain their aerobic fitness during pregnancy (Ruchat SM, 2012). **References** Ruchat SM, Davenport MH, Giroux I, Hillier M, Batada A, Sopper MM (2012). *Int J Sports Med.*, 33(8):661-666. A RANDOMIZED CONTROLLED TRIAL OF AN EXERGAME USING KINECT FOR ELDERLY INDIVIDUALS

Sato, K., Kuroki, K., Saiki, S., Nagatomi, R.

Tohoku University

Introduction As Japan is developing into a super aging society, dramatic increases in medical and care costs for elderly individuals are becoming social problems. Decreased motor function and a reduced level of activity associated with aging are referred to as "locomotive syndrome" (LS) (Nakamura, 2011). In recent years, the effects of exercise intervention using video games have been reported. These games, called "exergames," have been used as a form of exercise intervention for various age groups. Video game intervention for elderly individuals has been reported to increase motivation to exercise and improving strength and balance function (Osorio et al., 2012) (Jorgensen et al., 2013). We created a game using a Kinect sensor (Microsoft) for LS prevention in elderly individuals and conducted a randomized controlled trial to verify its effects. **Methods** A total of 57 community-dwelling, healthy elderly individuals with no motor function problems participated in this study. They were randomly assigned to either an intervention (n = 29) or a non-intervention group (n = 28). All participants gave their consent after receiving an explanation of the study. The present study was conducted after receiving the approval of the Tohoku Fukushi University research ethics committee. Four types of games were created using a Kinect sensor. These comprised an arm game, a one-leg standing game, a tandem standing game, and a squat game. The intervention group played the games a total of 24 times at a rate of once or twice a week for approximately 40 min each time. Three-dimensional motion analysis equipment was used to analyze walking and lower limb muscle strength (hip joint flexion, knee flexion/extension, ankle dorsiflexion) before and after intervention, and the 30 second chair sitting test (CS-30), one-leg stand time, and functional reach test (FRT) were conducted to compare the effects of the exergame. **Results** In the intervention group, walking speed significantly improved after intervention when compared with that before intervention. All muscle strength items except ankle dorsiflexion and CS-30, FRT significantly improved. **Discussion** One benefit of intervention for elderly people involving exergames is the fact that no exercise instructor is required, which leads to decreased costs while allowing them to engage in sufficient levels of exercise at a sufficient frequency. The fact that our results showed improved muscle strength and test scores in elderly individuals indicates that exergames contribute to improved motor function. The use of exergames, which can be easily performed, enables elderly individuals to frequently engage in effective exercise. Therefore, we conclude that exergames could become a new method of exercise instruction. **References** Jorgensen, M. G., Laessoe, U., Hendriksen, C., Nielsen, O. AGE-RELATED CHANGES IN LOWER-EXTREMITY MUSCLE POWER IN HEALTHY JAPANESE MEN

Nakatani, T., Nadamoto, M., Terada, K., Shiraishi, A., Umezaki, S., Murakami, K., Miura, S.

Human Performance Laboratory

Introduction Muscle mass and strength, especially of the knee extensor muscles, decrease with advancing age. Previous studies have reported that maximal muscle power (MP) declines with age (Martin et al., 2000; Kostka et al., 2009). The decline in maximal MP with age is greater than that of maximal muscle strength (Bean et al., 2003). Few studies suggest an age-related decline in physical function, i.e., the MP of knee extension (KE), bicycle pedaling, and vertical jump (VJ) (Bean et al., 2003). Therefore, the purpose of this study was to investigate the relationship between lower-extremity MP and age in healthy Japanese men. **Methods** Sixty-seven healthy men aged between 21 and 69 years, with no disease or impairment affecting the musculoskeletal system, were enrolled in this study. All the participants were divided into 10-year age groups as follows: 20s, 30s, 40s, 50s, and 60s. An isokinetic KE power test at 80 cm/s and an 8-s explosive power (EP) test on a bicycle ergometer were performed, and VJ power was measured. The MP was expressed relative to body weight. An analysis of variance test was used to compare the differences in MP across age groups, and linear regression was used to analyze the relationship between MP and age. **Results** The results indicate a decline in lower-extremity MP with age. The decline in the MP of KE, EP, and VJ power seemed to increase gradually with advancing age. MP significantly decreased after the third decade. A negative correlation was identified between KE power and age ($r = -0.70$, $P < 0.001$), EP and age ($r = -0.80$, $P < 0.001$), and VJ power and age ($r = -0.69$, $P < 0.001$). The rate of age-related decrease in the MP of KE (9.5% per decade) was faster than the decline in EP (7.5% per decade) and VJ power (4.6% per decade). **Discussion** This study demonstrated an age-related decline in MP in men, which varied according to lower-extremity MP. This decrease in lower-extremity MP ranged in magnitude from 4.6% to 9.5% per decade. These data are in agreement with the findings of previous studies on age-related decline in MP (Martin et al., 2000; Kostka et al., 2009). To conclude, the findings of this study revealed a clear age-related decline in lower-extremity MP in healthy Japanese men. **References** Bean JF, Leveille SG, Kiely DK, Bandinelli S, Guralnik JM, Ferrucci L. QUALITY OF LIFE, PHYSICAL ACTIVITY LEVEL AND BODY MASS INDEX IN POLICEMEN OF BRAZIL

Barbosa, W., Silva, M., Caduff, L., Santos, T.

UnB (Brasília, Brazil)

Introduction In policemen, physical activity level and body mass index are related to quality of life and labor performance. Furthermore, individual quality of life of policemen is associated to police institutional improvement (LEAL; BORTOLI, 2012). Thus, the purpose of present study was to evaluate the quality of life, physical activity level and body mass index in policemen of Brazil. **Methods** It was an analytical and descriptive epidemiological study. The instruments employed were the International Physical Activity Questionnaire short version (IPAQ-Short), the World Health Organization Quality of Life brief version (WHOQOL-Brief) and a social and demographic questionnaire. At a universe of 3.988 policemen, sample size calculation indicated the necessity of 351 individuals. The study included 431 volunteers from Military Police at Tocantins State - Brazil. Data was analyzed with descriptive statistics. **Results** According IPAQ-Short, 75.4% of sample is physically active, and according WHOQOL-Brief 67% of sample is classified with a good quality of life. However, 64% of sample is in overweight and obesity body mass index classification. **Discussion** The results of this study shows that despite be physically active, and have a good quality of life, the majority of policemen in Brazil are overweight and obese. Therefore, we suggest the development of institutional politics with a public health viewpoint to remediate this situation. **References** FLECK, M. P. A., LOUZADA, S.; XAVIER, M. EVALUATION OF QUALITY OF LIFE AND PHYSICAL ACTIVITY LEVELS IN BRAZILIANS WITH PARKINSON'S DISEASE

Silva, M., Santos, S., Castro, L., Filho, A., Lima, F., Barbosa, W., Caduff, L., Oliveira, R.J.

Universidade de Brasília

Introduction: Individuals with Parkinson's disease reduces the physical activity level younger than the general population (Fertil et al., 1993). Considering the various health benefits of physical activity for this population (Gallo, 2011), the present study has the purpose of evaluate the physical activity level and quality of life in individuals with Parkinson's disease in Brazil. **Methods:** Sample was composed by 68 volunteers with Parkinson's disease, 19 women (68 ± 6.03) and 49 men (65 ± 10.5). The instruments employed were the International Physical Activity Questionnaire (IPAQ) and the Parkinson's Disease Quality of Life questionnaire (PDQL). All subjects were evaluated under "on" pharmacological condition, between 60 and 90 minutes after drug administration. Data was analyzed with descriptive statistics. **Results:** Physical inactivity was prevalent in 31.88% of individuals with Parkinson's disease, which are divided into irregularly active (23.19%) and sedentary (8.69%). About the quality of life, the result was $47.44 (\pm 4.24)$ for the physical domain, $33.75 (\pm 0.70)$ for the social function, and $24.44 (\pm 0.70)$ for the emotional domain. **Discussion:** Physical activity level of individuals with Parkinson's disease was inferior to the general Brazilian population in the same age group (Porto et al. 2012). In relation to the quality of life, despite the physical symptoms of the pathology, the individuals with Parkinson's disease showed the perception of physical domain 15% superior than the general Brazilian population, the perception of social function 7.56% inferior than the general Brazilian population, and the same psychological domain (Porto et al., 2012).

THE EFFECTS OF COMBINED EXERCISE TRAINING ON VEGF MRNA AND PROTEIN EXPRESSION FROM SKELETAL MUSCLE IN OVARECTOMIZED RAT

KIM, J.Y.1, KIM, H.J.1, SEO, J.H.2, Kim, C.S.1

1: Dongduk women's university, 2: Baeksoek university

Introduction The purpose of this study is to evaluate the effects of combined exercise on Vascular Endothelial Growth Factor(VEGF), angiogenesis factor, mRNA and protein expression from skeletal muscle in postmenopausal period. **Methods** To achieve this purpose, a postmenopausal model was made from a rat by ovariectomized. Thirty nine female Sprague-Dawley rats (aged 8 weeks) were divided into four groups: Sham operated non-exercise control group(SN, n=9), Sham operated exercise group(SE, n=10), OVX operated non-exercise control group(ON, n=10), OVX operated exercise group(OE, n=10). The experimental rats were housed under controlled temperature ($22 \pm 2^\circ\text{C}$) and were maintained on a photocycle of 12 hr of light and 12 hr of darkness, with food and water being made available ad libitum. Exercise group was performed the combined exercise by the treadmill and tower climbing exercise. The treadmill exercise consisted of running on a motorized treadmill (JEUNGDO Bio Plant, Korea), 11m/min for 30 min, three times per week, and tower climbing exercise also loaded 4 times per a day, three times per week for 8 weeks. Skeletal muscles mass and muscle strength were determined, and expression of VEGF mRNA and amount of protein production in skeletal muscles were studied. **Results** 8 weeks after OVX surgery, although weight and body fat of OVX rat showed a significant increase more than sham rats($p < .001$), 8-week combined exercise significantly decreased weight and body fat of OE group compared with those of ON group($p < .05$), respectively. In a comparison of muscle mass and grip strength, SE group showed a increase($p < .05$) in muscle mass of biceps brachii while OE group did not show a significant increase. Although VEGF, protein production of SE group showed high expression($p < .05$), OE group showed high expression for level of VEGF mRNA($p < .05$) compared to non exercise group, respectively. **Discussion** These result suggested that combined exercise treatment to OVX rats restrains increase of the skeletal muscles mass and decreases protein expression of VEGF compared to normal sham rats. Therefore, it is implied that muscular hypertrophy by exercise might be impeded in a menopause. Meanwhile, from the result that VEGF mRNA increases only in OE group, it is proved that expression of VEGF mRNA increases in menopause despite delay of muscular hypertrophy by exercise.

THE BREAK OF THE STAGNATION IN WEIGHT LOSS USING INTERVENTION PROGRAM

Štohanzl, M., Bunc, V.

Faculty of Physical Education and Sport, Charles University in Prague

Introduction Overweight and obesity are expanded mainly in a developing country and the Czech Republic is no exception. Intervention programs are considered the best way to non-pharmacological treatment of overweight and obesity (Tsigos et al., 2008). They consist of physical activity, diet and psychological support. A common goal of modern therapy of obesity is weight reduction of 5-10 % and it maintains this loss for beneficial health effects (Goldstein, 1992). During our study, we worked with several women, who have carried out this reduction, but later their weight loss stopped. The aim of this study was to break the stagnation in weight loss and to reduce body fat mass percentage. **Methods** We worked with 17 (BMI 31.2 ± 3.42) women without the movement restriction and without the associated medical complications. These women underwent 12-week-long intervention program. During this program we focused on aforementioned spheres - physical activity, diet and psychological support. The energy intake was reduced by 10 % in comparison to state before the intervention. The qualitative ratio of food accepting was set on 30% proteins, 30% fats and 40 % carbohydrates during the first four weeks, during the rest of intervention on 25 %, 30 % and 45 %. The amount of physical activity was 200-300 minutes per week. Greater part was realized by aerobic activity namely by walking and smaller part (90 min) was provided by weight training. Every week these women participated in therapy, which was focused on overweight problems and healthy lifestyle. **Results** The entire intervention program was accomplished by 10 women. The drop out was caused by an injury in one case, pregnancy in another case and the end of cooperation in five cases. The remaining women reduced their weight by 3.1 ± 2.76 kg, which was 3.5 ± 2.97 % of their original weight. The percentage of fat mass was reduced by 2.2 ± 2.83 %. **Discussion** The intervention program was successful. In most cases, we have achieved the significant improvement. We confirmed, that appropriate intervention program may lead to break of the stagnation in weight loss and to influence body composition. We are going to observe the longitudinal effect of this program because keeping the obtained state seems to be the biggest problem of weight loss intervention programs (Wing & Phelan, 2005). **References** Goldstein D.J. IMPACT OF SHOCK PLYOMETRIC TRAINING ON BONE DENSITY FOR SOCCER PLAYERS

Kasem, M., Abdelkader, M.

Mansoura University

Introduction The study of biological responses of regular sport training on health and quality of skeleton in athletes is one of the topics that contribute in raising the levels of sport achievement. The stimulation of bones for growth through physical activities represents in shock training which characterized by plyometric training on skeleton as it is a way of stimulating bones growth. **Methods** This study was conducted on 30 soccer players 16-18 years old. They were divided into two groups. The experiment was performed in three steps; first step was doing pre-measurement for Bone Density, Minerals BMD. The measurements of bone density were conducted under the supervision of specialist doctors in radiology and bone in the Faculty of Medicine, dept. of radiology orthopedics dual using – Energy –x-ray absorptiometry (DEXA) methods. Second step was applying program of shock training for six weeks three times/week on the experimental group only. The third step was the post-measurements of BMD. **Results** There are significant differences between pre and post measurements of experimental group in BMD for post measurement. Hence this illustrates the program effect of plyometric shock exercises. There is no significant differences between pre and post measurements of control group in BMD. There are significant differences between control and experimental groups in post measurements for the experimental group in BMD. **Discussion** The results showed significant differences between pre & post measurements of experimental group in BMD for post measurement. Increasing rate was between 20.2% and 25.9% which showed that exercises effect of shock polymeric program on quality and health of bone because of exercises of jump and strike to land lead to direct loading on bone during myospasia which have helped increasing their strength and solidity and was evident in increasing BMD. (Peer, k. 2004; Taaffe & Marcvs 2004; Abdelrahman, O. 2008). There are significant differences ranged from 13.08 % to 19.2 % among these two groups in post measurements for the experimental group. Researcher attributes the increasing level of BMD of experimental group to their regularity in programs of plyometric shock training compared to control group, as it requires load on the bone and shock of legs movement which is reflected in increasing the quality and health of bone of lower limbs. Results agree with what (Witzke KA, Snow CM.2000; Zribi A, Zouch M, Chaari H, Bouajina E, Zouali M, Tabka Z. 2013) indicated that exercise practice especially exercise of muscles strength and high shocking necessary to growth and density of bone by sliding more minerals which increase strength. **References** Peer KS. CHARACTERISTIC OF BACK EXTENSION INDEX JUNIOR AND HIGH SCHOOL STUDENES IN JAPAN

Okawa, M., Shikano, A., Ide, Y., Kobayashi, M., Sakurai, T., Noi, S.

Nippon Sport Science University

Introduction The back extension strength measurement has been deleted from a new test of physical fitness at 1999 in Japan. But, back extension strength is reported to be effective for the improvement in walking ability of obese person and elderly who has chronic low back pain (Vincent et al., 2013). It is preferable to have back extension strength of 1.5 times over caregiver's own weight for infant care and 2.0 times for elderly care (Shimizu et al., 2004). It is important for one of nursing techniques that a caregiver pulls a patient near to his own body for lifting a patient from a wheelchair and kicks floor for standing (Katsuhira et al., 2010). **Methods** 393 boys and 215 girls, totally 608 students aged from 13 to 18 who were almost same in national average were applied in this study obtained their parents' informed consent. They were measured back extension strength with muscle strength meter applied previous methods (Hirano et al., 2012). η^2 , ηp^2 , ω^2 , ωp^2 and d were used for effect size and p_{rep} were used for reproducibility. The significance level were set at $\alpha = .05$ and $\beta = .20$ and then level for power test were set as $1 - \beta = .80$. **Results** Gender difference existed in back strength and was expanded three times or more from junior high school students to high school students ($\eta^2 = .03$ to $.11$, $\eta p^2 = .05$ to $.16$, $\omega^2 = .03$ to $.10$, $\omega p^2 = .05$ to $.16$ and all p_{rep} were 1.00). The change of the boys' strength were ten times greater than the girls ($\eta^2 = .01$ to $.13$, $\eta p^2 = .02$ to $.20$, $\omega^2 = .01$ to $.13$, $\omega p^2 = .02$ to $.19$ and p_{rep} were .97 and 1.00) and reached the recommended value at second high school year. The back strength among girls was unchanged from second junior high school year and didn't reach to the recommended value to last year. **Discussion** The gender difference was seen excess of the back extension index in Japan, which was their back extension strength divided by their body weight, and was recommended 2.0 for boys and 1.5 for girls. The body growth between girls and boys were differed from 14 years old in muscular strength. The reason of gender difference based on muscle mass and muscular fiber type, especially body fat in girls increase from puberty (Dore et al., 2005). Therefore, active approach was requested for girls after the entrance of high school about back extend strength and continuous measurement was necessary for it. It is considered that patients with low back pain decreased in numbers in the near future by the active approach. **References** Doré E, Martin R, Ratel S, Duché P, Bedu M, Van Praagh E (2005). RELATIONSHIP BETWEEN AMOUNT OF PHYSICAL ACTIVITY AND SLEEP HABITS FOR ELDERLY LIVING IN THE NORTHERN REGION

Sasaki, H.1, Kinoshita, N.1, Oda, S.2

Hokusho University

Introduction It has been reported that people having sleep problem is about 13% in Japan (Ministry of Health, Labour and Welfare, Japan, 2011). In addition, those are over sixty percent of elderly people aged seventy and over. It has also been reported that increased amount of physical activity improved sleep quality (King et al., 1997). However, it has been reported that people living in northern regions have a decreased amount of physical activity in winter (Marchant et al., 2007). The purpose of this study is to examine the amount of physical activity and sleep habits in elderly people living in a northern region. **Methods** Subjects in this study were 35 people over the age of 65 with a mean age of 77.2 ± 5.0 , and living in the northern region of Japan. We carried out a questionnaire from August to September 2011. The subjects who had a missing value were excluded from the analysis beforehand. The questionnaire was composed of personal profiles, Life-style, including physical activity and sleep habits. Eating habits and psychological measurement also were included. Sleep quality was assessed by Athens Insomnia Scale (AIS). It consists of eight items and creates point for each item. The minimum is zero points, the maximum is 24 points, and any score over six points is an assessment for some trouble of insomnia. Statistical analysis used

SPSS ver.21.0. Statistical analysis used by analysis of variance, χ^2 test, Mann-Whitney U-test, correlative analysis and multiple regression analysis. Results The amount of physical activity divided into three levels, those were non-exercise, low level of physical activity and high level of physical activity. There was not significant difference between male and female. Compared with physical activity level, non-exercise group was lower level of subjective eating condition than exercise group. There were significant differences between three levels of physical activities in AIS scores. However, there were not significant differences between three levels of physical activities in psychological measurement. Discussion It became clear that the condition of insomnia has a difference according to the level of physical activity in elderly people of northern area. However, psychological measurement was not affected by level of physical activity. It was suggested that the Athens Insomnia Scale was better useful index to catch elderly people's insomnia than psychological measurement, GHQ30. PHYSIQUE OF ATHLETIC GIRLS IN RESPECT OF THEIR MENARCHEAL STATUS

Farkas, A., Tóth, M., Szmodis, M.

Semmelweis University, Faculty of Physical Education and Sport Sciences

Introduction Among the basic studies a lot of reports are published on the growth and developmental process in both sexes. The maturational level, as a part of the developmental process, have a great extent on the relationships with and within body parameters. When investigating girls, the body measurements, body composition, i.e. body fat content and regional accumulation differ in pre- and post-menarcheal girls. The aim of this study was to analyze the differences, if any, between anthropometric characteristics over time in prepubertal and pubertal athletic girls. Methods The subjects were Hungarian handball player and rower girls. The sum of the two samples was 170 girls (rowers n=52, handball players n=118). The mean age of the rowers was 12,29 ($\pm 1,38$) ranged between 9,15 to 13,99 years and 12,33 ($\pm 1,21$) ranged between 9,86 to 14,75 years for the handball players, respectively. When taking altogether 24 anthropometric measurements we followed the suggestions of the International Biological Program (Weiner and Lourie 1969). Body fat percentage was assessed by method of Pařížková's (1961) and body composition was assessed by the Drinkwater and Ross (1980) technique. Basic statistics, interrelationships and Student t-test were ($p < 0,05$) used by Statistica Statsoft Version 9 computer programme. Differences of the respective subgroup means were tested by Tukey's post-hoc tests at the level of 5% random error. Results Evidently, there was an age-dependent increase in the anthropometric measurements. When considering maturational levels (non-maturated and maturated subgroups) significant and tendentious differences were found. The menarcheal age of the postmenarcheal rowers (n=25) was 11,46 ($\pm 1,10$), ranged between 8,72 and 13,55 years, while the same for handball players (n=48) was 11,86 ($\pm 0,95$), ranged between 9,23 and 13,78 years, respectively. The rowers were non-significantly taller and heavier than handball player girls for the whole sample supposed to have high variability level, though within the subsamples there were significant differences between pre- and postmenarcheal subgroups. Discussion In all parameters referring to body composition tendentious differences were found, more markedly occurred when considering developmental status. The magnitude of the differences in the subgroups in body measurements were significantly larger in the rower girls, especially because of the demands of the sport event, the higher power level. This phenomenon is the base of the main differences between more dynamic ball-game players and the more static power performance of the rowers, irrespective of the sexes. SEDENTARY BEHAVIOUR AND HEALTH – A SELECTIVE LITERATURE REVIEW

Füzéki, E., Vogt, L., Banzer, W.

Goethe University

Introduction Exercise related public health recommendations and research for increased fitness and health had long focused on vigorous exercise or the lack thereof. Recently scientific interest in possible effects of sedentary behaviour (SB) (sitting) independent of moderate-vigorous intensity exercise has been growing. A considerable body of research has emerged on various health related endpoints; this however, has not yet been synthesized. The aim of this review is to summarize and critically assess current literature on sedentary behavior and health. Methods We conducted a selective literature search in Pubmed and the Sedentary Research Database with the outcomes SB, risk factors, mortality and morbidity in adults. We included only reviews and systematic reviews. Results We identified 14 reviews. Because of the heterogeneity of original articles, most of them did not perform a meta-analysis. Observational studies suggest an association between SB and all-cause (in three reviews: pooled HR 1,49; pooled RR 1,13 and HRs of 1.00, 1.02 and 1.05 for every 1-hour increase in sitting time in intervals between 0-3, >3-7 and >7 h/day total sitting, respectively) and cardiovascular (in two reviews: pooled HR 1,9 and pooled RR 1,15 respectively) but not cancer mortality. One study found SB also seems to be associated with diabetes (in two reviews: pooled RR 2,12) and overweight/weight gain. Evidence on other diseases, such as cardiovascular diseases, hypertension, cancer, and mental diseases is limited also because of the heterogeneity and poor methodology of the studies. Intervention studies found inconsistent evidence that SB is associated with detrimental effects on markers of cardiometabolic risk. Conclusions Evidence on detrimental effects of sedentary behavior is decreasingly convincing with the endpoints of mortality, morbidity, and markers of metabolic risk, in that order. Higher TV and screen time, but not total SB seems to be associated with higher all-cause and cardiovascular, but not cancer mortality. Further intervention studies are needed to establish dose-response relationships and the potential of cardiorespiratory fitness and physical activity. IMPACT OF WEARING SAUNA SUITS ON THERMAL RESPONSES, IS THERE A RISK?

Agape, F., Voelcker, T., Piechaud, S., Fournet, D.

Oxylane Research

INTRODUCTION A sauna suit is an impermeable clothing (PVC or Polyurethane fabric) designed to make recreational and professional athletes sweat profusely. It is sometimes used under high thermal stress. By reducing sweat evaporation, the sauna suit can increase water loss and skin temperature (Tsk) which could lead to dehydration and elevated core temperature (Tcore) with a risk of hyperthermia and even heat stroke. The aim of the study was to evaluate the influence of sauna suit construction on thermal responses during exercise in a neutral environment. METHOD Two complementary assessments were performed in a climatic chamber, using the same scenario:

45 minutes of moderate intensity exercise at 22°C, 50%RH. Three different sauna suits were compared: a fully covered impermeable PVC suit (A), a partially covered impermeable PU suit (B) and a non-impermeable suit (C): 1- A trial test was carried out with 8 males and 8 females running on a treadmill during 45 minutes (10km/h and 8km/h, respectively) with wind 0.7m/s. Tsk (10 body sites) was measured by I-buttons (Maxim, USA) and sweat loss (SwL) was obtained from measurement of pre and post body mass using an electronic scale (Kern KMB). 2- In order to evaluate the real-time dynamics of sweating and Tcore, a thermal walking manikin (Newton, MTNW USA) controlled by a multi-segment physiological model (Redortier et al. 2011) was used in similar condition. RESULTS Tsk for all upper body sites was significantly higher with suit A than B and C. Among all body sites, the warmest Tsk was found at the back for man (36.3±0.4°C). SwL with suit A (641±170g/m2/h) was significantly higher compared to C (544±155g/m2/h) without being significantly different to B (15% less than A). Regarding manikin results, Tcore with suit A was significantly higher (38.3±0.01°C) compared to B and C (37.7±0.01°C and 37.5±0.01°C, respectively). And unlike B and C, it didn't achieve a plateau until the end of 45 minutes. SwL for A increased faster than B and C. DISCUSSION This study demonstrated that there is a potential risk of hyperthermia to use a fully covered sauna suit during exercise under neutral conditions, even under low thermal stress. Tcore for full coverage was the highest and thermal heat balance could not be reached in light of its continuous increase. Partial coverage still allows the user to sweat profusely with less thermal risks (stabilized Tcore) than full coverage (Candas et al.1992). However, all sauna suits may lead to dehydration and hidromeiosis (Candas et al. 1980), which can be dangerous, especially under higher thermal stress. THE PREVALENCE OF CARDIOVASCULAR RISK FACTORS IN A DISADVANTAGED NORTHEAST BRAZILIAN COMMUNITY: PRÓ-SAÚDE PROJECT

Cavalcante, S., Franchi, K., Lamboglia, C., Bohn, L., Braid, L.

Faculdade de Desporto da Universidade do Porto

INTRODUCTION Non-communicable diseases, including cardiovascular diseases, were in 2008 responsible for 74% of deaths in Brazil. In Fortaleza city, it was developed the National Program of Professional Reorientation in Health (Pró-Saúde) (Lamboglia et al., 2012), both with a physical activity component. We aimed to describe the prevalence of cardiovascular risk factors and physical activity in a disadvantaged northeast Brazilian community that was involved in the PRÓ-SAÚDE program. METHODS Seventy nine patients of the Primary Health Care Unit 'Maria de Lourdes Jereissati' (Fortaleza, Ceará, Brazil) were allocated or as Participant Group (PG) (N:34, mean age: 59.59 ± 10.08) or as Non-Participant Group (NPG) (N:45, mean age: 58.66 ± 10.00) of the multidisciplinary program PRO-SAÚDE. Inclusion criteria of the PG was belong to the Pro-Saúde program for at least 6 month of physical activity sessions (multicomponent exercises) twice a week during 50 minutes, plus 2 sessions per month (10 minutes each one) of general health counseling. NPG were recruited from the physicians' queue. Participants self-report questions regarding the prevalence of hypertension, diabetes, hypercholesterolemia, obesity, smoking habits and physical activity. Descriptive and t-test were the statistical tests used. RESULTS Eighty four percent were women in PG and 94% in NPG. Regarding the cardiovascular risk factors, in the PG the prevalence of obesity, hypertension, diabetes, hypercholesterolemia and smoking habits were 73.5%, 52.9%, 29.4%, 11.8% e 2.9%, respectively. In the NPG, those percentages were 66.7%, 62.2%, 15.6%, 11.1%, 20%, respectively. In the PG, physical activity were 249.71 ± 231.73 minutes per week vs 46.22 ± 49.89 minutes per week on the NPG. The results of the comparison between groups show that the PG report more physical activity per week (p: 0.00). DISCUSSION Both groups had similar prevalences of cardiovascular risk factors. According with international guidelines, at least 150 minutes of moderate intensity of physical activity are necessary to promote health benefits. Our PG self-report the mean of 250 minutes of total physical activity (without information about intensity) and with a standard deviation of a similar magnitude. It is important to point out that the self-report method has limitations and could not correspond to reality. However, longitudinal studies, based on public strategies, must be carried out to help on the understanding of its real effect on population. REFERENCES Lamboglia, C. et al. (2012). PERIODIZATION: A SIMPLIFIED MODEL FOR HEALTH

Silva, I.L.1,2, Lima, A.T.A.C.2, Silva, F.T.1,2

1:University Center of Estácio-Ceará – Brazil, 2:Origo treinamento individualizado – Brazil

Introduction: The System of Periodization created by Ph.D. Leev Matveyev, based on the theory of the general adaptation syndrome, served as inspiration for later models(1). The periodized training was often used by coaches and athletes in the planning aiming at maximal performances in physical performance. More recently, the fitness coaches and personal trainers also started to use periodized training plans(2). The proposed application of the simplified model allows on health an objective way its monitoring and control, even for coaches still with little practical experience(3). Methods: The training loads are posted on the control map and allow a simplified way direct the planning of individualized exercises. Currently the simplified model is being used and tested in academic discussion and practice, focusing on prevention, maintenance and recovery in chronic degenerative diseases (CDD). Results: The overview of the steps of the training plan, in this study, presented as Training Map for Health, shows the stages of Adaptation, Development, Maintenance and Transition. One way to quick indication pointing trends in training loads and was used the geometry of the triangle, positioned near the line performance, determining the increase, maintenance or reduction of charges for training volume and intensity. Conclusion: It is concluded that the Training Map for Health proposed in this work may facilitate steps and direction of loads of training to health, even coaches with a little experience. A 2-YEAR FOLLOW-UP STUDY OF CHANGES IN SEDENTARY BEHAVIOUR OF ADOLESCENTS IN COASTAL AREAS DAMAGED BY THE 2011 GREAT EASTERN JAPAN EARTHQUAKE

Okazaki, K.1, Suzuki, K.1, Sakamoto, Y.2, Sasaki, K.1

1.Tohoku Gakuin University 2.Tohoku Institute of Technology

Introduction The 2011 Great Eastern Japan Earthquake had a significant effect on the lifestyle of Japanese adolescents; in particular, the physical activity of victims from submerged coastal areas levels seems to have deteriorated. This longitudinal study aimed to examine the

changes in sedentary behaviour among middle school students in a submerged coastal area. Methods A total 158 middle school students in 7th and 8th grades from the submerged coastal areas in Miyagi were enrolled. Students were asked to report their personal and demographic characteristics and their activities at 6 months, 1 year and 2 years after the earthquake. The activities were measured by the World Health Organization's Health Behaviour in Schoolchildren (WHO HBSC) questionnaire to determine the physical activity levels and time spent sitting during weekdays and weekends. Linear mixed model analyses were used to examine the effects of time, grade, gender, WHO HBSC physical activity level, club membership, whether or not they were living in temporary housing and body mass index on the time spent in sitting. The time spent in sitting was calculated via base-10 log transformation. Results There was a significant interaction effects between the time and the temporary housing variables on time spent sitting during both weekdays ($p = 0.020$) and weekends ($p = 0.034$). At 2-years after the earthquake, time spent sitting among students living in temporary housing during weekdays and weekends had increased compared with those not living in temporary housing. Discussion It appears important to promote the physical activity of these children through school-based interventions where all students have equal access (Lanningham-Foster et al., 2008; Dobbins et al., 2013). It may be difficult for some students living in temporary housing to go outside to play after returning to temporary housing due to inconvenient environment (e.g. poor road infrastructure, difficulty of communication). Neighbourhood environment differs depending on temporary housings: some are built in restricted areas where there is no playground. Tester (2009) recommended that neighbourhoods should be designed or modified in order to promote the overall activity levels. Further studies are needed to examine the influence of temporary housing neighbourhoods on activity levels. References Dobbins M, Husson H, Decorby K, Larocca RL (2013) Cochrane Database Syst Rev. Lanningham-Foster L, Foster RC, McCrady SK, Manohar CU, Jensen TB, Mitre NG, Hill JO (2008) Obesity, 16, 1849-1853. Tester JM (2009) Pediatrics, 123, 1591-1598.

THE EFFECTS OF TAI CHI ON MENTAL STATES AND MUCOSAL IMMUNE FUNCTION.

Lee, E., Eda, N., Sato A., Suzuki, S., Shimizu, K., Akama, T.

Waseda University

Introduction Tai Chi is low-intensity exercise with moving slowly and breathing deeply. Therefore, Tai Chi can be done comfortably and easily by elderly people to compensate for lack of exercise or poor health maintenance. The purpose of this study was to determine the effect of Tai Chi on secretory immunoglobulin A (SIgA) in saliva and mental states. Methods 42 healthy adults (18 males and 24 females; age, 66.0 ± 11.5 years) participated in this study. 21 participants (12 males and 9 females; age, 70.4 ± 5.6 years) performed Tai Chi (90min) in the morning (Morning Group; MG), and 21 participants (6 males and 15 females; age, 61.5 ± 14.0 years) performed that in the afternoon (Afternoon Group; AG). Saliva collection and mental states measurement were carried out before and after Tai Chi. Mental state was used to assess the Profile of Mood States (POMS)—Brief Form (Kanekoshobo, Tokyo, Japan) (Yokoyama et al. 1990). The POMS questionnaire rated six mood subscales (Tension–Anxiety, T–A; Depression, D; Anger–Hostility, A–H; Vigor, V; Fatigue, F; Confusion, C) on a 5-point scale and computed standardized points (t points). Results In female and AG, SIgA concentration was significantly increased after Tai Chi ($p < 0.05$). POMS scores of D, A–H and C significantly decreased after Tai Chi in male, and those of T–A and D showed significant decreases after that in female. Additionally, POMS scores of D and A–H showed significant decreases after Tai Chi in MG, and those of D, F and C significantly decreased after that in AG. Discussion In this study, POMS scores of T–A, D, A–H, F and C significantly decreased after Tai Chi. Therefore, we suggested that Tai Chi had the relaxation effect on elderly people and improved their mental states. SIgA concentration significantly increased after Tai Chi in female and AG. Relaxation techniques are known to enhance immune function (Diego et al. 2004; Field et al. 2007). However, in this study, SIgA secretion rate showed no significant change. Therefore, we suggested that a significant increase in SIgA concentration was resulted of drying in the mouth after exercise. References Yokoyama K, et al. EFFECTS OF PILATES ON THE VOLUME OF GLUTEAL MUSCLES: A LONGITUDINAL MRI STUDY

Dorado, C., Calbet, J.A.L., López Gordillo, A., Sanchis Moysi, J.

University of Las Palmas de Gran Canaria

Introduction. Pilates method has become very popular in fitness programs and rehabilitation (Dunleavy, 2010), especially to prevent low back pain (Posadzki et al., 2011). Pilates emphasizes the strengthening of abdominal and lumbo-pelvic muscles. Abdominal muscle hypertrophy after Pilates has been recently documented (Dorado et al., 2012). It remains unknown whether Pilates induces the hypertrophy of other lumbo-pelvic muscles. The purpose of the present study was to analyze the effects of Pilates on the volume of gluteus maximus (Gmax), gluteus medius (Gmed) and gluteus minimus (Gmin). Methods. Magnetic resonance imaging (MRI) was used to determine the volume of gluteal muscles in 9 non-active healthy women, before and after 36 wk of a standardized Pilates training program (50 min/session, 2 sessions/wk) (Dorado et al., 2012). The MRI images (L1-L2 intervertebral disc to a pubic symphysis) were used to calculate the volume of Gmax, Gmed and Gmin. Pre- and post-training comparisons were carried out using the paired Student's t-test. Significant differences were assumed when $P < 0.05$. Results The volume of gluteal muscles (cm³) was similar before and after Pilates in the dominant (Gmax: 239.1 ± 101 vs 237.4 ± 92.8 , $P = 0.9$; Gmed: 219.2 ± 22 vs 206.17 ± 40.2 , $P = 0.4$; Gmin: 82.3 ± 16.5 vs 78.4 ± 18.9 , $P = 0.7$) and non-dominant side (Gmax: 243.8 ± 103.2 vs 225.4 ± 82.4 , $P = 0.7$; Gmed: 220.6 ± 30.4 vs 208.5 ± 32.4 , $P = 0.4$; Gmin: 77.2 ± 15.6 vs 74.5 ± 15.1 , $P = 0.8$). Total volume of gluteal muscles was also similar before and after Pilates in the dominant (540.6 ± 127.7 vs 521.9 ± 144.1 , $P = 0.8$) and non-dominant side (541.6 ± 130.1 vs 508.4 ± 120.5 , $P = 0.6$). Discussion We have previously reported rectus abdominis m. (21%) and the lateral abdominal wall (8%) hypertrophy in these subjects with Pilates (Dorado et al., 2012). The lack of significant muscle hypertrophy in the gluteal muscles reflects the focused attention on the abdominal muscles during the training sessions while controlling pelvic oscillations. Conclusions Thirty-six wk of Pilates training does not increase the volume of gluteal muscles in healthy women. THE RELATIONSHIP BETWEEN CARDIORESPIRATORY FITNESS AND SELF-REPORTED OR MEASURED PHYSICAL ACTIVITY – PRELIMINARY RESULTS

Ginsel, S., Brandes, M.

CVO-University of Oldenburg

Introduction Cardiorespiratory fitness (CRF) as a health related element depends on the one hand on unchangeable variables, age, sex and genotype, and on the other hand on decisive factors as physical activity (PA) (Lee et al., 2010). The aim of the present study was to investigate the correlation between CRF and self-reported as well as measured PA. **Methods** 51 men (46.2 ± 7.5 years, BMI 28.4 ± 3.7) participated in the IPAQ-questionnaire for the assessment of their physical activity within the last seven days. Additionally, daily steps were measured by a pedometer for 14 days (StepWatch, Orthocare Innovations, USA). CRF was expressed as relative maximum oxygen uptake (VO₂max) during bicycle ergometry until (subjective) peak performance. Participants were categorized into VO₂max-classes according to the American Heart Association. **Results** The IPAQ showed a mean score of $4,021.9 \pm 4,001.9$ MET min/week (N=49). The pedometer measurement revealed an average count of $88,191 \pm 23,847$ steps/week (N=48). VO₂max was on an average of 35.56 ± 7.39 ml/min/kg (N=51). Those with a low CRF made on average $66,660 \pm 18,202$ steps/week and those with a high CRF made on average $97,020 \pm 32,437$ steps/week. On average the class "medium VO₂max" made 131.7% more steps compared to the subjects of class "low VO₂max". Class "good VO₂max" made 145.8% more and "high VO₂max" 145.4%. PA represented by the number of steps/week showed a significant moderate correlation with CRF ($p=0.028$; $r=0.317$). IPAQ score did not correlate significantly with CRF ($p=0.971$; $r=0.005$) and steps/week ($p=0.125$; $r=0.230$). **Discussion** The participants were more active compared to reference values for IPAQ score (3699 MET min/week, Craig et al., 2003) and weekly step counts ($70,000$ steps/week, Wallmann et al. 2011). Looking at the relation between low and high CRF and steps/week, this shows above $30,000$ steps/week less in low CRF. The number of steps/week increased with higher CRF-classes. Following the present results it is not possible to draw conclusions from the IPAQ score to the CRF. The results show an increased number of steps with higher CRF-classes, thus, a moderate correlation between measured PA (in terms of weekly steps) and CRF was obtained. Further analysis will include the walking intensity expressed in steps/minute as a possible significant factor. **References** Craig CL, Marshall AL, Sjöström M, Bauman AE, Booth ML, Ainsworth BE, Pratt M, Ekelund U, Yngve A, Sallis JF, Oja P (2003). *Med Sci Sport Exerc*, 35 (8), 1381-95. MIXED METHOD EVALUATION OF AN OFFICE-BASED SIT-STAND WORKSTATION INTERVENTION: A PROTOCOL

Hall, J., Mansfield, L.I, Kay, T.I, McConnell, A.I

1: Brunel University (London, UK)

Introduction Some research evidence suggests that sedentary behaviour may be a risk factor, independent from physical activity, for negative health outcomes (Thorp et al., 2011). Current estimates are that office-based employees sit for 6 hours in an 8 hour working day (Ryan et al., 2011). One response to reducing sitting time in the workplace is the installation of sit-stand workstations, allowing employees a choice of desk-based working positions. While it has been identified that sit-stand workstations are associated with some positive health outcomes there remains a reported problem with compliance, attitudes and satisfaction (Wilks et al., 2006). Furthermore, few studies have included controlled designs and adequate follow-up periods, and no studies have employed systematic and rigorous qualitative methods to assess processes that influence compliance and satisfaction (Tudor-Locke et al., 2013). **Methods** We propose a rigorous and systematic mixed method evaluation of a multi-component sit-stand intervention to address the principle research question "what is the effect of office-based sit-stand workstations on total daily physical activity". The research design employs two intervention arms: sit-stand workstation only; and a multi-component sit-stand workstation plus individual and organisational level support for use and engagement. The design also includes a 'usual office practice' control group (no sit-stand workstation). Participants will be randomly allocated to the study arms, and will be recruited from two workplaces. We will employ objective measures of sitting, standing, and physical activity using ActivPAL and GT3X monitors concurrently. We will collect data at baseline and 3, 6 and 12 months following intervention initiation. Qualitative explorations of occupational physical activity and inactivity will include activity diaries, ethnographic participant observation and interviews with key workplace personnel. **Discussion** This approach will enable exploration of the contribution of sit-stand workstations to the overall physical activity profile of office workers over 12 months. The qualitative package will provide insights concerning attitudes and compliance and will enable the development of good practice guidelines for the wider implementation of sit-stand workstations across office-based workplaces. **References** Ryan C, Dall P, Granat M, Grant P. SCALE VO₂PEAK IN OBESE CHILDREN AND ADOLESCENTS BY DIFFERENT METHODS

Montoro, S.B.C.1, Moraes, A.M.1, Sant Martin, J.E.S.1, Bicudo, A.M.B.1, Arruda, M.2, Filho, A.B.1, Antônio, M.A.R.G.1, Zambon, M.P.1, Mendes, R.T.1

1-Department. of Pediatrics /Faculty of Medical Sciences / State University of Campinas, UNICAMP - Brazil. 2- Department of Science of Sports / Faculty of Physical Education / UNICAMP - Brazil.

Introduction A review of aerobic fitness can be expressed as relative to body mass, however, such a procedure cannot fully remove differences when obese individuals are evaluated. Thus, the allometric scaling procedure is an attractive strategy to compare individuals with these characteristics. Therefore, the aim of this study was to assess VO₂peak in obese boys and girls. **Methods** A total of 33 patients (boys = 17, girls = 18, 7-17 years) of the Obesity Clinic of the Hospital, UNICAMP, with BMI ≥ 95 th percentile (CDC), followed for one year. Test Course-Navette (Leger et al, 1988) was used to obtain VO₂peak. Two physical assessments were made at the beginning and end of the period. The allometric exponent was calculated based on individual body mass. Then, VO₂peak was corrected by the allometric exponent (Welsman JR, Armstrong N, 2000). Differences between mean values were established using Student's t-test for dependent variables ($p<0.05$) (for comparison of baseline and follow-up measurements). **Results** The first review found the exponents were 0.63 for girls and 0.59 for boys, in the second evaluation of the exponents were 0.58 and 0.55 respectively. With respect to conventional VO₂peak significant difference was observed between assessments in girls (40.32 ± 5.15 to 37.49 ± 5.41), but not in boys (39.94 ± 5.62 to 38.56 ± 6.28). Already Allometric VO₂peak showed significant differences for both boys (57.72 ± 6.32 to 55.15 ± 7.70) and for girls (58.68 ± 5.59 to 54.19 ± 6.95). **Discussion** Normalizing data using allometric scaling is an efficient method when large differences in body mass are present, since the existence of a negative association VO₂peak (ml.kg⁻¹.min⁻¹) And weight of the body is typically reported. Consequently,

dividing VO₂ by body weight does not create an independent variable mass (Katch VL, Katch FI, 1974). Therefore, it has been suggested that the allometric scaling may produce a more realistic value of VO₂peak. VO₂PEAK PROFILE OF OBESE CHILDREN AND ADOLESCENTS IN THE CLINIC CHILD AND ADOLESCENT - UNICAMP

Mendes, R.T.1, Montoro, S.B.C.1, Samur San, M.J.E.1, Moraes, A.M.1, Arruda, M.2, Filho, A.B.1, Antônio, M.A.R.G.1, Zambon, M.P.1, Bicudo, A.M.

State University of Campinas, Unicamp

1-Department. of Pediatrics /Faculty of Medical Sciences / State University of Campinas, Unicamp, Campinas, SP, Brazil. 2- Department of Science of Sports / Faculty of Physical Education / State University of Campinas - UNICAMP, Campinas, SP, Brazil. Introduction In clinicians attendance has been growing presence of obese children and adolescents worrying factor for health professionals. The objective of the study is to investigate the VO₂peak in obese children and adolescents using the conventional method and the method Allometric. Method VO₂peak relative to body mass was calculated by the Course-Navette test (Leger 1998) in 77 children and adolescents of both sexes attended at the Hospital of Unicamp, aged 7 to 18 years and IMC ≥ 95th percentile (CDC). The allometric exponent was calculated taking into account individual body mass. So VO₂peak was corrected by the allometric exponent (Welsman JR, Armstrong N, 2000). Comparisons were performed using the independent test ($p < 0.05$) Results Similar allometric exponents were found in boys (0.60) and obese girls (0.62). The results showed no significant differences in conventional VO₂peak between boys and girls (40.07 ± 5.02 to 39.49 ± 5.32) and the Allometric (57.54 ± 5.4 to 57.53 ± 6.00), respectively. Discussion In obese children and adolescents VO₂peak values may be influenced by excess body fat (Pettersen, Fredriksen, Ingjer, 2001). To minimize this influence, have been suggested the use of allometric scaling (Lofin et al., 2001; Jesen K et al., 2001), since this group has absolute VO₂peak like to have greater body surface (Lofin et al., 2001). THE INFLUENCE OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON PARAMETERS OF MUSCLE DAMAGE INDUCED BY EXERCISE.

Barros, J.F.1, Marinheiro, R.C.2, Nunes, R.N.1, Silva, H.M.1, Oliveira, P.3, Coquerel, P.R.S.1

Universidade Federal do Rio Grande do Norte

1. Universidade Federal do Rio Grande Norte 2. Instituto Federal da Paraíba, 3. Instituto Federal de Brasília –Brasil The transcranial direct current stimulation (tDCS) is a noninvasive technique that has characteristics analgesic and anti-fatiguing. In order to test their effects on the reduction of the strength and appearance of delayed onset muscle soreness (DOMS), presented after an event of exercise-induced muscle damage (DMIE), we used a clinical study of an experimental, controlled, randomized and double-blind. The sample consisted of 24 male teenagers apparently healthy (19.7 ± 1.8 years, BMI 23.6 ± 3.65), which were allocated randomly and stratified into the following groups: G1: control group, G2: stimulation group after the damage and G3: group with stimulation before and after muscle damage. The data were submitted to descriptive statistics and ANOVA, adopting a significance level of 5%. The increase in serum CK (56.18%) and LDH (24.15%) confirmed the occurrence of DMIE. In contrast, after the analysis of variance for comparison of the treatments, it can be observed that there were no significant differences in CK levels ($p = 0.3514$) and muscle strength ($p = 0.9702$). The DOMS unfolded as expected, but no significant difference between groups ($p = 0.4861$). These data demonstrated that tDCS was not capable of modulating the DOMS and decreased muscle strength after DMIE in apparently healthy young. References: HOWATSON, G; SOMEREN K. DIAGNOSTIC INDICATORS OF METABOLIC SYNDROME AND ITS RELATIONSHIP WITH BUTYRYLCHOLINESTERASE ACTIVITY AND VO₂ MAX. IN OBESE AND EUTROPHIC ADOLESCENTS

Neiva, C., Carbonari, B., Fernandes, C.R., Terra, G.D.S.V., Pessoa Filho, D.M., Verardi, C.E.L., Ciolac, E.G.

UNESP, UNAERP, UNIFRAN and UNIFENAS

The rapid growth of obesity in Brazil and in the world in the last two decades is associated with Metabolic Syndrome (SM), growth promoting a virtuous public health costs increase. Silent and showing different diagnostic criteria around the world, SM becomes very dangerous. The butyrylcholinesterase (BChE) a serum esterase associated with cardiovascular risk factors, obesity and SM in adults, it has also been pointed with a secondary early indicator for SM. The objective of the present study was to evaluate the presence of SM indicators according to the criteria of the international Diabetic Federation (IDF) as well as serum BChE enzyme activity and the possible existence of correlation with the inflammatory cytokine Interleukin 6 (IL-6) and the State of physical fitness (VO₂ max.). Participated in this study 236 healthy college students between 18 to 19 years, of both sexes, which were divided into 2 large groups, one of them being composed of participants with over weight and obese (BMI > 27Kg/m² – Obesity Group - GO) N = 152 and other of eutrophic participants (BMI

from 20 until a 24.9 kg/ m² – Control Group – CG), N = 84. The results showed the existence of significant difference (t student) in the activity of BChE (KU/L) with values on average 4.5 times higher for OG group than those found for the OC group and on e no VO₂ max. (OC 42 ± 6 ml/kg/min x OG 27.5 ± 5 ml/kg/min). Also significant differences were found for triglyceride (TG) (CG 135 ± 26 mg/dL x OG 285 ± 38 mg/dL), for IL-6 (CG 1.2 ± 0.1ngmL x OG 3.65 ± 0.25 mg/dL) and waist circumference (CG 85 ± 4 cm x OG 102 ± 9 cm). Finally the results revealed significant positive correlation between BMI x IL-6 (0.78), BMI x BChE and (0.82), BChE x IL-6 (0.71) and BChE x TG (0.74) and negative between VO₂ max. x IL-6 (-0.66), VO₂ max. x BChE (-0.80) and VO₂ max. x TG (-0.92). According to such differences and correlations it can be concluded that the activity of BChE demonstrates be strongly increased by elevation of the BMI, as well as responds negatively to VO₂ max. increase, showing that young eutrophic and with good physical conditioning feature appreciable reduction of early indicators for SM.

EXAMINATION OF THE RELATIONSHIPS BETWEEN STRENGTH, VERTICAL JUMP AND SPRINT PERFORMANCE

Goral, K., Saygin O., Ceylan, H.I.

Muğla Sıtkı Koçman University

Introduction Wrestling is a sport with a long history. It was first made an Olympic sport by the Greeks in 708 B.C., and thereafter became popular in the ancient world (Sharawy, 2013). Wrestling is a sport requiring endurance, strength, flexibility, speed, agility, balance, reaction and strategy (Yoon, 2002). The purpose of this study was to examine relationships between strength, vertical jump and sprint performance. **Method** Aged 15–17 years, totally 39 voluntary wrestlers (height; 158.7±10.5 cm, body mass; 53.95±16.21 kg) who practiced five times in a week, participated in this study. In this study, age, height, weight, strength, vertical jump and sprint performance values were determined by measuring instruments. The data obtained in this study was recorded in SPSS program. In order to examine the relationship between the characteristics, Pearson Correlation test was applied. **Results** Findings of the wrestlers were respectively as follows: dominant hand-grip strength 31.11±10.8 kg, back strength 92.06±37.41 kg, leg strength 82.12±32.65 kg, vertical jump 30.92±6.55 cm and 30 m Sprint performance 5.29±0.37 sec. The results indicated that significant correlations were found between dominant handgrip strength, back strength, leg strength, vertical jump and 30 m sprint performance in wrestlers (p<0.01). **Discussion** Cicioğlu et al., (2007) found that leg strength values of the wrestlers aged 15–17 years was 126,53±30,04 kg, dominant hand-grip strength values 33,63±6,82 kg. Sprint speed values of young wrestlers were found to be 4.94±0.36 (Bayraktar et al., 2012) and 5.20±0.24 sec. (Abbaszadegan et al., 2012). Results of this study are consistent with research in the literature. It can be concluded that wrestle coaches should give enough attention to trainings done in this period to acquire the optimal properties that are important for development of adolescence wrestlers and affect performance substantially. **References** Abbaszadegan M., Ramezani A., Azerbaijani M.A. (2012). THE ATTITUDE OF YOUTH TO THE HEALTH

Sivokhin, I., Baimyrzayev, K., Fyodorov, A.

Kostanay State Pedagogical Institute

Introduction The social and economic transformations which have occurred last 15-20 years in our countries, and also insufficient efficiency of domestic system of public health services cause system deterioration of a state of health, growth of disease and death rate of the population of Russia and Kazakhstan, including children, teenagers and learning youth [1]. In connection with above stated the problem of studying of social and pedagogical factors of health, the attitude of learning youth to the health is actual. The purpose of research – to analyse the various parameters describing students to the health. **Methods** Research was carried out within the framework of the research project «Health of Students» in 2009-2011. Students of the first-fourth rates of the Ural State University of Physical Education, the Southern-Ural State University (Chelyabinsk, Russia), and also students of Kostanay State Pedagogical Institute (Kostanay, Republic Kazakhstan). In total in research have taken part 800 person. **Results** At studying behavioural factors of health of learning youth, it is very important to take into account, that students are specific object of research; it causes occurrence of some complexities. As such complexities allocate, first, complexity of a choice of significant parameters of health of students; second, complexity of finding-out of the importance for students of problems of health in connection with existing risk factors. So original “counteraction” of two tendencies, in particular, is revealed. On the one hand, higher level of social support renders positive influence on health of students. However, on the other hand, is established, that, the more evenings young people carry out with friends, the above probability of their familiarizing to using of tobacco, to the use of alcoholic drinks and corresponding deterioration of health. In this case, the competing factor – aspiration to independence – appears more significant for young people, than the factor of social support [1]. **Discussion / Conclusion** Complexity of studying of a phenomenon “the attitude of students to the health” consists also that in a basis of behaviour of young people in sphere of health, lay various, sometimes mutually exclusive motives. Frequently behavioural acts which are important on a degree of influence on health of students, are caused by motives not connected directly with health. **References** 1. ASSOCIATION BETWEEN TOE GRIP STRENGTH AND PHYSICAL FUNCTION IN CHILDREN AGED 10–12 YEARS

Yuto, T.I, Takahiko, F.2, Tomoki, A.1

1: *Kyoto university(Japan)* 2: *Kio university(Japan)*

ASSOCIATION BETWEEN TOE GRIP STRENGTH AND PHYSICAL FUNCTION IN CHILDREN AGED 10–12 YEARS **Introduction** Toe grip strength (TGS) has been shown to be associated with physical function in adolescents (Soma et al., 2012). However, the association in children is not known. The purpose of this study was to investigate the association between TGS and physical function in children aged 10–12 years.

Methods The institutional review board approved this study. Physical fitness parameters included body height, body weight, side steps per 20sec, 20-m shuttle run test, 50-m run time, and standing long jump distance. We used a toe grip dynamometer to measure TGS. This scale can measure the pulling power of toes at 0.1–50.0 kg at a precision of 0.1 kg. We divided children into three groups according to TGS score tertiles. One-way analysis of variance (ANOVA) was used to identify differences in physical function test scores among the three groups. The level of significance was set at $p < 0.05$. **Results** Participants were 1,005 Japanese elementary school children aged 10–12 years (490 boys, 515 girls). The average TGS was 12.63 ± 3.60 kg. Tertile classifications were as follows: 338 in the first (T1), 333 in the second (T2), and 334 in the third (T3) (TGS: T1, 8.75 ± 1.82 kg; T2, 12.44 ± 0.86 kg; T3, 16.76 ± 2.64 kg). One-way ANOVA showed that TGS was significantly associated with all physical function test scores (F values and p values: side steps per 20sec, 31.4 and <0.01 ; 20-m shuttle run test, 12.9 and <0.01 ; 50-m run, 21.6 and <0.01 ; and standing long jump, 35.3 and <0.01 , respectively). Discussion TGS was associated with physical function test scores (side steps, 20-m shuttle run test, 50-m run, and standing long jump). Toe function has been shown to be related to various abilities such as walking, jogging, and running (Achini et al., 2012, Mann and Hagy, 1979), and this study demonstrated similar findings. Foot-gripping training improves foot-gripping strength and physical function in adolescents (Soma et al., 2012), and these findings suggest that the same may be possible in children aged 10–12 years. DEVELOPMENT OF ELDERLY FITNESS EQUIPMENT WITH ADJUSTABLE RESISTANCE IN NEIGHBORHOOD PARK

Tai, T.Y., Liu, C., Kuo, C.Y.

Institute of Mechanical Engineering

In this study, an upper and lower limb outdoor fitness equipment with adjustable resistance is developed specifically for elderly. This study investigated the health promotion of providing local facilities with ease of access that give elderly more opportunities for exercise and socialization in neighborhood parks. The hydraulic damper resistance sources is employed to replace the common damping oil with water to avoid blocking doing harm to the environment. The transmission mechanism of cam driven damper piston moves up and down to adjust the resistance. Through the discussion with the cam position, adjustable resistance and operating frequency, it revealed that the resistance produced has a positive relationship with operating frequency. Meanwhile, the resistance from the stroke during the compression process in hydraulic cylinder is much better than stretching process. Therefore, the compression stage, together with the core muscle contraction training can be chosen in these outdoor equipment for elderly. The operating frequency is adjusted for every elderly to achieve the optimal resistance. Finally, these equipment contain green design and can be involved into the park's surroundings. The muscle strengthening can be improved through this facility and hence provides a social activity and health promotion for aging in place.

EXERCISE AND DIET INTERVENTION IMPROVES LIPOPROTEIN PROFILE RATIOS IN OVERWEIGHT AND OBESE PEOPLE

Romero Moraleda, B., Peinado, A.B., Butragueño, J., Szendrei, B., Castillo, A., Benito, P.J., Calderón, F.J.

Universidad Politécnica de Madrid

Introduction Lipoprotein ratios have been proposed to provide information on cardiovascular diseases (CVD) risk, lipid profile, size and athero/antiatherogenicity [1]. Therefore, the aim of this study was to evaluate the effect of four different weight loss intervention programs on the lipoprotein profile ratios. **Methods** 180 overweight and obese subjects (96 women and 84 men; 18–50 years; BMI: >25 – <34.9 kg/m²) were included in the study and randomised into four supervised treatment groups: strength training (S), endurance training (E), combined S + E (SE), and recommendations of physical activity (PA; n=18 men and 18 women). All subjects followed a hypocaloric diet (70–75% of the daily energy expenditure) and trained 3 times/week (38–60 min/session for S, E and S+E). Blood lipid profile was measured to estimate lipoprotein profile ratios at baseline and after 24 weeks of intervention [2]. Atherogenic risk factor was calculated with total cholesterol/high density lipoprotein cholesterol (TC/HDL), low density lipoprotein (LDL)/HDL, ApolipoproteinB/ApolipoproteinA1 (ApoB/ApoA1), LDL/ApoB and triglycerides (TG)/HDL ratios. **Results** Women allocated in PA group and men of all groups showed a decrease in TC/HDL (–8.80%) and LDL/HDL (–11.91%) ($p < 0.01$). Men of the E group obtained more favourable change in ApoB/ApoA1 (–17.74%; $p < 0.01$). The TG/HDL ratio decreased in S and E men groups (–19.23% and 19.90% respectively; $p < 0.01$) suggesting LDL particle size enlargement. After intervention, LDL/ApoB ratio in E group men (7.73%) and women (9.57%) increased significantly with respect to S, SE and PA groups ($p < 0.01$). **Discussion** Weight loss achieved combining diet and different exercise modes resulted in CVD risk decrease due to improvement of lipoprotein ratios. The results of the present study are in agreement with recently reported results that showed improvements in lipid profile with aerobic training [3, 4], resistance training [5] and combination [6]. Present results suggest that E group seems to be the most favourable to improve lipoprotein ratios. 1. Maruyama, C., et al. J Ather Throm (2003); 10: 186-193. 2. Zapico, A., et al. THE EFFECT OF PHYSICAL ACTIVITY ON BODY COMPOSITION AND WEIGHT-HEIGHT PROPORTION IN THE ELDERLY

Stawińska, T., Ignasiak, Z., Rożek, K., Skrzek, A., Sebastjan, A.

University School of Physical Education in Wrocław

The Aim Health of the people is determined by a set of behaviours typical for their lifestyle. One of the most important factors is physical activity which shapes many features of the human organism (Ball et al. 2001, Gaba et al 2009, Jeffery et al. 2009). The aim of this study is: 1) to assess body composition and weight-height proportion of the elderly subjects in the aspect of age and gender, 2) to obtain information about physical activity of examined men and women 3) to determine the relationships between physical activity and various aspects of body composition in elderly. **Material and methods** The material comprises data of 116 men and 406 women, 60 to 80 years of age, living in Wrocław (Poland). The subjects were divided in two groups: younger – below 70 years and older – above 70 years. Based on the data from the questionnaire elderly people were divided into physically active and non-active. Body height and weight was measured with an electronic weighing and measuring station (SECA model 764, quality control no. C-2070). Based on those measurements, body mass index (BMI) was calculated. The components of body build (fat %, fat mass, lean body mass, total water and muscle mass) were determined with TANITA MC- 180 MA. Such statistical procedure was used as the analysis of variance, assuming $p < 0.05$ as the level of significance. **Results** The study suggests that physical activity has a positive effect on some aspects of body composition and BMI only in younger group (60-70 yrs). It can also be seen that physically active men have more profits from active style of life than physically

active women. Conclusions. The results indicate that physical activity taken by people 70+ is probably too low to cause changes in body composition because the fraction of high and very high energy expenditure, related to intensive exercise, is responsible for beneficial changes of body composition, such as the decrease of the amount of fat or the increase of lean body mass. The types of physical activity that require low or moderate energy expenditure do not cause the aforementioned changes in body composition. References 1. RESPIRATORY FUNCTION IN THE CONTEXT OF THE PHYSICAL ACTIVITY AND FITNESS IN ELDERLY

Rozek Piechura, K., Ignasiak, Z., Slawinska, T., Skrzek, A., Posluszny, P., Pokrywka, J.

University School of Physical Education

The aim of the study was to assess respiratory function parameters, level of fitness and physical activity in the elderly and to determine the relationship between these components. Material and methods The study was performed as a part of the Ministry of Science and Higher Education research project No. N N404 MNiSW 075,337. It was carried out in 2010-2012. The study involved 835 people, including 647 women and 188 men aged between 60 and 90 years. For this study the data of 510 women and 143 men was analyzed. All patients had pulmonary functions measured during spirometry using Flowscreen Jaeger apparatus. The following parameters: FVC, FEV1, PEF, MEF50 were taken into account during analysis. The values were expressed in absolute and percentage of predicted values. Physical fitness was assessed by the Senior Fitness Test. Level of physical activity was assessed by Paffenbarger Questionnaire. From the results basic descriptive characteristics were calculated and percentage distribution analysis of lung ventilation disorders. Relationships were assessed using Pearson's linear correlation. Results The results of lung function parameters in all patients had normal values. On the basis of the Pearson linear correlation there were significant associations between all the respiratory parameters and physical fitness assessed Senior Fitness Test in women, while in men between the parameters of FVC and FEV1, and all tests of physical fitness. In addition, a significant association was also observed between Peak Expiratory Flow and the tests determining strength of the upper and lower body parts. Among the parameters of physical activity only weekly intense energy expenditure during physical activity are significantly correlated with FEV1 in men, whereas in women FEV1 correlates with a moderate energy expenditure. Conclusions 1 Observed pulmonary function parameters were age-appropriate and fit within the norm. 2 Women demonstrated a significant relationship between all functional parameters of respiratory and physical fitness, also between moderate physical activity and peak expiratory flow. 3 In men, only two main respiratory volume parameters correlated significantly with tests of physical fitness and also intense physical activity with peak expiratory flow. 4 The study population was characterized by good health, as evidenced by the level of functional respiratory parameters analyzed, physical fitness and physical activity. THE INDEPENDENT ASSOCIATIONS OF SEDENTARY TIME, MODERATE TO VIGOROUS PHYSICAL ACTIVITY AND CARDIORESPIRATORY FITNESS ON CARDIO-METABOLIC RISK FACTORS IN US ADULTS; NHANES 2003-2004.

Van der Velde, J.H.P.M.1,2, Schaper, N.1, Savelberg, H.2, Koster, A.3

Maastricht University Medical Centre and Maastricht University

Introduction: This study examined the independent associations of objectively measured sedentary time, moderate to vigorous physical activity (MVPA) and cardiorespiratory fitness on cardio-metabolic risk factors (BMI, waist circumference, blood pressure, fasting glucose, HDL- and non HDL cholesterol, triglycerides, and C-reactive Protein (CRP)). Methods: Data were from 543 men and women (aged 18-49 years) from the National Health and Nutrition Examination Survey (NHANES) 2003-2004. Using an accelerometer, sedentary time (<100 cpm) and MVPA (>2020 cpm) were measured. Cardiorespiratory fitness (VO2max) was assessed with a submaximal treadmill test. These three measures were used as predictors for the cardio-metabolic outcome measures in a multiple regression analysis and standardized regression coefficients were computed. All models were adjusted for age, sex, ethnicity, health status, smoking status, and BMI. Results: Sedentary time was only significantly associated with levels of HDL-cholesterol ($B=-0.08$, $p=0.05$) and triglycerides ($B=0.08$, $p=0.04$). After additional adjustment for MVPA the associations became non-significant. When adjusted for VO2max they persisted. MVPA was negatively associated with BMI ($B=-0.257$, $p=0.02$), waist circumference ($B=-0.229$, $p=0.03$), glucose ($B=-0.080$, $p=0.04$), and triglycerides ($B=-0.102$, $p=0.02$) and positively associated with HDL cholesterol ($B=0.132$, $p=0.04$). Significant associations for BMI, waist circumference, and glucose remained after additional adjustment for sedentary time. Additional adjustment for VO2max resulted in significant associations for BMI, HDL cholesterol and triglycerides. VO2max was significantly associated with BMI ($B=-0.266$, $p<0.01$), waist circumference ($B=-0.287$, $p<0.01$), systolic blood pressure ($B=-0.159$, $p=0.03$), triglycerides ($B=-0.092$, $p<0.01$), and CRP ($B=-0.130$, $p<0.01$). These associations remained significant after adjustment for sedentary time and MVPA. Conclusion: Cardiorespiratory fitness was a strong predictor of several cardio-metabolic risk factors independent of sedentary time and MVPA. MVPA only showed significant independent associations for BMI and waist circumference and sedentary time showed no independent associations with cardio-metabolic factors. e-mail: jeroen.vandervelde@maastrichtuniversity.nl

COMPARISONS BETWEEN WEEKDAY AND WEEKEND PHYSICAL ACTIVITY IN BRITISH PRESCHOOL CHILDREN

Roscoe, C.M.P., Birch, S.L., James, R.S., Duncan, M.J.

Coventry University

Introduction Participation in physical activity (PA) is fundamental to children's future health (Adolph et al., 2012). However, data suggest that high amounts of time, ~43 min per hour, is spent in sedentary behaviour for 3-5 year olds (Pate et al., 2004). Studies examining the temporal pattern of PA between weekdays and weekends in British children are lacking. As different environments (e.g., preschool vs. home) may offer different opportunity to engage in PA (Söderström et al., 2012) examining weekday to weekend variation in pre-

schoolers PA may be useful for effective intervention targeting. This study compared weekday and weekend PA in British preschool children. Methods Following ethics approval and informed consent, 51 children (22 boys, 29 girls, aged 3-4 years from preschools in central England wore a triaxial accelerometer (GENEActiv) measuring at 10s epochs and 100Hz for 4 days, including at least one weekend day. Height (m) and body mass (kg) were measured, from which Body Mass Index (BMI) was determined. The proportion of time spent in light, moderate and vigorous PA was determined using specific cut-off points for counts per minute (cpm) related to children (Phillips et al., 2013). Results Preschool children spent 4.95% and 17.97% of time in sedentary and light PA on weekdays and 6.71% and 24.20% of time in sedentary and light PA at the weekend respectively. During weekdays, 27.23% and 49.66% of time was spent in Moderate and vigorous PA respectively. Corresponding values for weekends days were 24.12% of time in moderate and 44.63% of time in vigorous PA. There was no gender difference in BMI in the sample ($p < .05$). A series of 2 (weekday vs. weekend) X 2 (gender) repeated measures ANOVAS indicated significant main effects for day of the week for moderate PA ($p = .045$) and vigorous PA ($p = .021$). Gender was not significant in any analysis ($p < .01$). Bonferroni post-hoc pairwise comparisons indicated that children engaged in significantly greater vigorous PA on weekdays compared to weekends (51.1% vs. 44.8%). A similar pattern was evident for moderate PA (28% vs. 24%). Discussion These data show a substantial proportion of each day is spent in moderate and vigorous PA in British preschoolers. However, the amount of time spent in PA varies between weekdays and weekends, with less moderate and vigorous PA accrued during weekends. Such data would suggest that regular engagement in the preschool/nursery environment provides opportunities to accrue PA which may not be present in the home setting. References Adolph AL, et al. (2012) J Phys Act Health 9, 944-953. Pate RR, et al (2004) Pediatrics 114, 1258-1263. Phillips LRS, et al (2013) Sci Med Sport 16, 124-128. Söderström M, et al (2012) Acta Paediatrica 102, 83-91.

PHYSICAL ACTIVITY AND FITNESS VERSUS AUTONOMIC FUNCTION IN HEALTHY CHILDREN

Tanha, T., Thorsson, O., Karlsson, M.K., Andersen, L.B., Wollmer, P., Dencker, M.

Clinical Sciences

Aim: To evaluate potential correlations between physical activity and fitness versus autonomic function in healthy children. Methods: 102 children (girls = 43, boys = 59) between 10-13 years were included. Maximal oxygen uptake (VO2PEAK) was measured during a maximal exercise test. General physical activity (GPA, mean counts/min/day) and vigorous physical activity (VPA, >6000cpm/day) were assessed by accelerometers for four days. A standardized orthostatic test (tilt-test) was performed, measuring blood pressure and heart rate. Z-score was calculated for the autonomic test parameters, where differences (resting position-tilted position) of systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR) and also E/I ratio were included. Correlation analyses were performed between GPA, VPA and (VO2PEAK) versus Z-score from autonomic function test. Some children terminated the tilt-test due to dizziness, the physical activity measurements (GPA, VPA and VO2PEAK) were compared to those who completed the test using Pearson correlation. Results: No significant correlations were observed between Z-score for autonomic function and GPA, VPA or VO2PEAK ($p > 0.05$). Eight boys and 1 girl did not finish the test due to dizziness, with mean SBP drop 18mmHg vs those who did finish the test 3mmHg (boys). VPA was inversely correlated to the children not finishing the tilt-test (-0.27 , $p < 0.05$), no significant correlations were found for GPA and VO2PEAK. Conclusion: General and vigorous physical activity was not related to autonomic function in this study. However, it is of interest that the amount of vigorous physical activity was lower in children not able to complete the autonomic tilt-test than in the other children.

MOVEMENT DURING SEDENTARY TIME IS ASSOCIATED WITH CARDIO-METABOLIC OUTCOMES

Van der Berg, J., Bosma, H., Caserotti, P., Eiriksdottir, G., Arnardottir, N., van Domelen, D., Brychta, R., Chen, K., Sveinsson, T., Johannsson, E., Launer, L., Gudnason, V., Jonsson, P.

Maastricht University

Stehouwer, C., Harris, T., Koster, A. Dpt of Social Medicine/CAPHRI School for Public Health and Primary Care, Maastricht University, 2Inst of Sports Science and Clinical Biomechanics, University of Southern Denmark, 3Icelandic Heart Association, 4Res Ctr of Movement Science, University of Iceland, 5Diabetes Endocrinology and Obesity Branch, Nat Inst of Diabetes and Digestive and Kidney Diseases, 6Ctr for Sport and Health Sciences, Iceland University of Education, 7Lab of Epidemiology and Population Sciences, Intramural Research Program, Nat Inst on Aging, 8University of Iceland, 9Fac of Medicine, University of Iceland, 10Dpt of Geriatrics, Landspítali National University Hospital, 11Dpt of Internal Medicine/Cardiovascular Res Inst Maastricht, Maastricht University Medical Centre INTRODUCTION Studies have shown that more sedentary time is associated with adverse health effects and increased mortality risk. However, during sedentary time the degree of movement of the upper body can differ between individuals and this could be a relevant aspect of sedentary behavior. Whether movement during sedentary time is meaningful for health outcomes is not clear and therefore this study aims to examine the association between movement during sedentary time and cardio-metabolic health outcomes. METHODS 631 participants (aged 73-98 years) of the AGESII-Reykjavik Study wore a triaxial accelerometer (ActiGraph GT3X) for 7 consecutive days. Movement during sedentary time was defined as any activity in the anteroposterior and/or mediolateral axes with an intensity ≥ 100 counts per minute (cpm), during sedentary time (< 100 cpm in the vertical axis). Cardio-metabolic outcomes included body mass index (BMI), waist circumference (WC), levels of HDL-cholesterol (HDL), triglycerides (TG), fasting glucose (FG) and C-reactive protein (CRP). RESULTS Compared with those who had the most minutes with movements during sedentary time, participants with fewer movement minutes (quartiles 3, 2, 1) had a higher BMI ($B = 1.43$; $B = 1.97$; $B = 3.38$; all $p < 0.05$) and an up to 8.3 cm larger WC ($B = 4.66$; $B = 5.25$; $B = 8.30$; all $p < 0.05$) after adjusting for demographic and health factors, sedentary time, and MVPA. Fewer movement minutes were also associated with lower levels of HDL (Q3 $B = -0.11$; Q1 $B = -0.13$; all $p < 0.05$) and higher TG levels ($B = 1.10$; $B = 1.09$; $B = 1.10$; all $p < 0.05$, back transformed from log scale). CONCLUSIONS Movement during sedentary time was associated with cardio-metabolic outcomes; an up to 3.4 kg/m² higher BMI and 8.3 cm larger WC was seen in participants with less movement minutes. These findings suggest that movement during sedentary time could be a relevant aspect of sedentary behavior. EMAIL j.vanderberg@maastrichtuniversity.nl

ACUTE PILATES EXERCISE INDUCE OVEREXPRESSION OF BONE METABOLIC CYTOKINES MRNA IN OSTEOPENIA WOMEN

Kim, C.S.1, Kim, J.Y.1, Kim, H.J.1, Park, D.H.2, Min, S.K.3

1: Dongduk Women's University (Seoul, Korea), 2: Inha University (Incheon, Korea), 3: Korea Institute of Sport Science.

Introduction Tumor necrosis factor (TNF)- α and interleukin (IL)-6 have been reported to greatly stimulate bone resorption by accelerate the differentiation, proliferation, and activation of osteoclasts, and thus they are referred to as bone metabolic cytokines (Baldini et al., 2005; Inanir, 2004; Kumano, 2005). Nonetheless, the number of studies on changes in bone metabolic cytokine expression according to acute

exercise loading are limited. The purpose of this study was to elucidate changes of bone metabolic cytokines mRNA expression according to acute pilates exercise in osteopenia women. Methods Eleven osteopenia elderly women (aged 68.18 ± 3.19 yrs; T-score: -2.51 ± 0.47) underwent acute pilates exercise of 10-14 RPE intensity for 70 minute including warm up and cool down for 10 minute, respectively. Repeated measurements analysis was performed to determine the expressions of cytokine mRNA for reliability purpose. The expressions of TNF- α , IL-6 and INF-mRNA from PBMC and serum parameters were measured at before, immediately after exercise and recovery period (60 min later). Results There are significant interaction between group and time in Serum P ($p < .001$), those of control group showed a tendency of the increase but those of pilates group were significantly decreased at immediately after exercise and recovery period, respectively ($p < .05$). Also there are significant interaction between group and time in Serum CK ($p < .05$), those of pilates group were significantly increased at immediately after exercise and recovery period, respectively ($p < .05$). The expression of TNF- α mRNA from PBMC was significantly increased in pilates group compared with control group ($p < .01$), the expression of IL-6 mRNA was also significantly increased in pilates group ($p < .05$). The expression of INF-mRNA showed a tendency of the increase in pilates group but there was no significant difference (NS). Discussion Based on the results, it is suggested that acute pilates exercise induce temporarily hypophosphatemia with muscle damage in osteopenia women, and might occur high bone turnover condition with stimulating of bone formation and resorption. LACK OF CORRELATION BETWEEN MODE OF TRANSPORT FROM HOME TO SCHOOL WITH BODY MASS INDEX AND WAIST CIRCUMFERENCE

Brito, L.M.S., Boguszewski, M., Coelho-e-Silva, M., Moser, D.C., Titski, A.C.K., Mascarenha, L.P.G., Puzovic, V.S., Monteiro, V.A., Leite, N.

Federal University of Parana and CAPES

Introduction The low of physical activity (PA) and the increase in overweight/obesity in adolescents has been a concern for public health in Brazil. Programs had emerged in several countries to encourage an increase of PA, including walking or bicycling to school. The aim of this study was to evaluate whether the mode of transportation to school (motorized transport, walking or cycling) was associated BMI and WC. Methods 770 students, 378 boys (age 13.68 ± 1.14 yrs) and 392 girls (age 12.85 ± 1.10 yrs), from five public schools in Curitiba, Brazil. WC and BMI, body weight (kg), height (m) squared were evaluated at school. Mode of transport was evaluated by Self-Report Questionnaire 3DPAR1. Statistical analysis was performed using SPSS 18 program. The risks were assessed by calculating odd ratio. The dependence of WC and BMI on the mode of transport was assessed by qui-square test, - p values was set on < 0.05 . Results In this study, 54,65% of the girls used motorized transport and 45,45% bicycling or walking. For boys, corresponding numbers were 56,62% and 43,48%. Mode of transport (motorized) was not risk for girls for overweight [OR : 0.83 (0.57 to 1.53), $p=0.18$], obesity [OR: 1.12 (0.60 to 2.10), $p=0.27$] and WC [OR : 1.22 (0.80-1.87), $p=0.14$] and for in boys overweight [OR : 1.19 (0.74 to 1.90), $p=0.17$], obesity [OR: 0.79 (0.33 to 1.89), $p=0.40$] and WC [OR : 0.91 (0.58 to 1.45), $p=0.16$]. The dependence on the type of transport was not associated with BMI ($p=0.95$; $x^2=0,31$) and in boys BMI ($p=0.47$; $x^2=2,51$). Discussion In this study group, BMI and WC were not associated with model of transportation to school. However, in the 1995 National Personal Transportation Survey² indicated that, children and adolescents living up 1.6 Km from school improved the health indicators when walking or bicycling to school. The results did not evaluate the participation in extracurricular school activities and physical education class and foods habits. Conclusion Programs aimed to increase PA should be encouraged.

SIX MONTH OF EXERCISE TRAINING IN FITNESS CENTERS: EFFECTS ON PHYSICAL AND MENTAL HEALTH INDICATORS

Zahner, L., Bopp, M., Häfliger, M., Donath, L., Faude, O.

University of Basel

Introduction Regular physical activity and exercise training are considered to beneficially affect various cardiovascular and neuromuscular health outcomes. As the popularity of fitness centers grew during recent years, this particular real life fitness-center setting has to be evaluated regarding its effects on physical and mental health indicators. The purpose of this study was to examine the effects of endurance- and strength-accentuated fitness training on different physical fitness and health parameters. Methods Two-hundred fifty participants (novices from $n=8$ fitness centers) were assigned to either a control group (CG: $n=77$; age: 42 (SD 16) y, BMI: 23 (3) kg/m^2), an endurance group (EG: $n=110$; age: 46 (14) y, BMI: 28 (5) kg/m^2) or a strength group (SG: $n=63$; age: 41 (15) y, BMI: 26 (6) kg/m^2). Group assignment was done according to the recommendation of the fitness instructor to reflect the real life situation in a fitness-center setting. Both intervention groups were asked to train at least two times per week for a total of six months. Depending on the assigned groups (strength vs. endurance), participants had to complete 70% in either endurance or strength-related exercises. A training diary had to be kept. Pre- and post-tests included grip-strength, ventral core strength (hold prone plank position), submaximal heart-rate at constant workload, functional reach test (FRT), waist circumference, body fat as well as mental health parameters, such as perceived stress, sleep quality and quality of life. Results We found significant differences in pre-post changes between CG and EG for waist circumference (CG: $+0.5$ (3.1) cm, EG: -1.9 (5.0) cm, $p < 0.001$), submaximal exercise heart rate (CG: -2 (10) min^{-1} , EG: -8 (11) min^{-1} , $p < 0.001$), ventral core strength (CG: $+7$ (38) s, EG: $+20$ (24) s, $p=0.005$), sleep quality (CG: -2 (60) %, EG: $+20$ (65) %, $p=0.03$) and quality of life (CG: $+2$ (10) %, EG: $+6$ (12) %, $p=0.03$). Between CG and SG significantly different pre-post changes were observed for submaximal exercise heart rate (CG: -2 (10) min^{-1} , SG: -8 (9) min^{-1} , $p < 0.001$) and for ventral core strength (CG: $+7$ (38) s, SG: $+26$ (32) s, $p < 0.001$). In contrast, no significantly different pre-post changes between either intervention and the control group were present for grip-strength, FRT, body fat and perceived stress ($p > 0.07$). Discussion Our results show that six month of training in a fitness-center seems to improve different physical fitness and mental health parameters. The effects of endurance-related training seem to be broader as compared to strength-related training. Although the study design was not randomized, the present study mirrors a high external validity as we assessed the real life situation in a fitness-center setting.

EFFECTS OF HOME-BASED EXERCISE PROGRAM FOR FALL AND FRACTURE PREVENTION IN COMMUNITY DWELLING ELDERLY PEOPLE

Kimura, Y.

Research Center for Fitness and Health Sciences

Purpose Regularly performed physical activity is extremely important for elderly people to maintain their health status. However, falls must be prevented, in order to keep independent healthy longevity. The aim of this study is investigated the effectiveness of home-based

exercise intervention for fall and fracture prevention in community-dwelling elderly people. Methods Sixty-five volunteers participated in this study. The subjects were divided into two groups; fallers and non-fallers. Fall anxieties, fall risks, falls assessment, 15-item version of the Geriatric Depression Scale, Tokyo Metropolitan Institute of Gerontology Index (TMIGI) and physical capacity were compared. Home-based exercise included stretching, squat and balance training. Results Before intervention, fallers showed lower TMIGI (11 vs. 12 pts., $p < 0.05$) and higher falls assessment (4 vs. 2 pts., $p < 0.05$) than in non-fallers. After the intervention, it was found that the frequency of falls (0.7 to 0.3 times, $p < 0.05$), the number of fall risks (3.9 to 2.8 #, $p < 0.05$), one-leg standing with eyes open (25 to 30 sec, $p < 0.05$) and sit-to-stand (10 to 8 sec, $p < 0.05$) were improved in fallers. Conclusion These findings revealed that the home-based exercise seemed to be effective, along with fall-related informations, in falls prevention for community-dwelling elderly people.

GENDER DIFFERENCES BETWEEN OBJECTIVELY AND SUBJECTIVELY MEASURED PHYSICAL ACTIVITY AND HEALTH IN ELDERLY INDIVIDUALS

Kortajarena, M., Hoyos, I., Irazusta, A., Fraile, A.B., Ruiz, F., Irazusta, J., Gil, J.

Univeristy of the Basque Country

INTRODUCTION Recognizing the need to accurately measure physical activity in elderly individuals and its relation with health parameters, the aim this study was to explore the relationships between objectively and subjectively measured physical activity (PA) and health parameters related to cardiovascular health in both genders. **MATERIAL AND METHODS** In a sample of 100 elderly adults, we recorded the concentration of serum lipids, calculated the Framingham risk score, and assessed their PA by objective (Actigraph GT3X accelerometers) and subjective methods (Yale Physical Activity Survey). Data were analyzed by Pearson's partial correlation coefficient, using age as a covariate. **RESULTS** Comparing the blood parameters and objectively measured PA, there were positive ($p < 0.05$) correlations between counts per minute or moderate-vigorous PA (MVPA) and HDL cholesterol in women. In men, there were no statistically significant correlations. Total cholesterol in women was negatively associated with both light PA and lifestyle PA ($p < 0.05$). The Framingham risk scores were negatively related to MVPA in women. To summarize, when PA results were higher, our analysis suggested that cardiovascular risk was lower, especially in women. When we analyzed the relation between subjectively measured PA and health parameters, correlations were not as strong as in the case of objectively measured PA. In men, the vigorous and summary indices were negatively correlated with total cholesterol ($p < 0.05$), triglycerides ($p < 0.05$) and LDL cholesterol ($p < 0.05$); and the leisurely walk index with total cholesterol ($p < 0.05$) and LDL cholesterol ($p < 0.05$). There were no significant correlations between subjectively measured PA and measured health parameters in women. **DISCUSSION** Few published studies have assessed PA with both objective and subjective methods. In addition, most have been carried out in adult populations across a broad range of ages and without differentiating by gender (Celis-Morales et al., 2012; Sun et al., 2013). Objectively measured PA correlated better with health parameters in women. However, these parameters are related to subjective PA in men. Accelerometers may be more accurate for detecting some "invisible activities" in women. However, questionnaires could detect certain activities, undetected by accelerometers, which are performed mainly by men. It may be useful to combine these tools to assess PA in older adults more accurately (Miller et al., 2006). **REFERENCES** Celis-Morales, C.A., et al. (2012), PLoS One, 7(5), e36345. Miller, R., et al. (2006). JPAH, 3: 257-66. Sun, F., et al. (2013). BMC Public Health, 13: 449.

CARDIOVASCULAR, THERMOREGULATORY AND PERCEPTUAL RESPONSES WHEN CYCLING IN AN UNCOMPENSABLE ENVIRONMENT WEARING A HEAT DISSIPATION COMPRESSIVE GARMENT

Leoz, I., Aguado-Jiménez, R.

Universidad Pública de Navarra

Introduction It is well known that endurance can be impaired in hot compared with temperate climate (Nielsen, B., 1993, J. Physiol.). Even at modest environmental temperatures, some reduction in exercise capacity is apparent and the performance decrement becomes progressively greater as the environmental heat stress increases (Galloway, S. D., 1997, Med. Sci. Sports Exerc.). Lots of strategies have been put in practice in order to prevent or delay the increases in body temperature, to prevent hyperthermia and to improve athletic performance, such as, fluid replacement, convection through airflow, pre-cooling techniques or heat dissipation compression garments (CG). CGs in sport practice are becoming more and more popular, but fundamental effects on cardiovascular and thermoregulatory strain remain unclear (MacRae, B. A., 2012, Eur. J. Appl. Physiol.). The aim of the present study was to contrast the present literature results with the effects of CG published by the manufacturer comparing two types of garments; heat dissipation CG (EXP) and non-CG (CON) and examine the physiological and perceptual responses when exercising in an uncompensable hot environment. **Methods** 19 participants were randomly divided in two groups; EXP (n=9) and CON (n=10) performed a unique exercise trial in a hot-dry environment (40° C and, 34% \pm 3 RH) cycling at a fixed load (50% VO_{2peak}) for 30 min. Rectal temperature (T_{rec}) and heart rate (HR) were measured at rest, during exercise and at recovery. Body weight loss (W_{loss}) and perceptual responses were also measured. **Results** 1. Subject's characteristics: There were no differences between groups in age, height, weight, body fat, HR_{max} and VO_{2peak} reflecting the homogeneity of the groups. 2. Heart rate: EXP vs. CON at min 30 (187.1 \pm 8 bpm vs. 172.5 \pm 10 bpm) ($P < 0.05$). Wearing CG increased HR at the end of exercise. HR remained higher at recovery in EXP ($P < 0.05$). 3. Rectal temperature: EXP vs. CON at min 30 (38.3 \pm 0.2 °C vs. 37.9 \pm 0.3) ($P < 0.05$). T_{rec} was higher in EXP when exercise finished. T_{rec} remained higher in EXP at recovery ($P < 0.05$). 4. Body weight loss: EXP vs. CON (742.75 \pm 245g vs. 814.52 \pm 110 g) ($P > 0.05$). No differences between groups were found although wearing CG resulted in having numerically lower W_{loss}. 5. Perceptual responses: Thermal sensation at min 30; EXP vs. CON (8.3 \pm 0.5 vs. 7.7 \pm 0.7) ($P < 0.05$). Subjects perceived higher thermal sensation wearing CG. **Discussion** Wearing heat dissipation CG resulted in a greater T_{rec} probably due to compression that this garment exerted on the skin that could produce an inhibitory effect on sweating rate and therefore did not allow heat dissipation, experimenting higher thermal stress during exercise. The higher T_{rec} and thermal sensation could affect in cardiovascular responses experimenting greater HR during exercise and recovery. In conclusion, cycling in an uncompensable hot environment wearing heat dissipation CG increased cardiovascular strain, hyperthermia and thermal sensations and did not help in the recovery.

CYCLISTS' BODY WEIGHT AS A NEW PARAMETER FOR ERGONOMIC SADDLES

Feodoroff, B., Schepers, M., Stuckenschneider, T., Haatz, G.

German Sport University Cologne

Introduction Over the past years the bicycle manufacturing companies have dealt more and more with human factors and ergonomics. The key point to successfully develop an ergonomic saddle seems to be the consideration of individual aspects such as riding position, sex, cycling time and seat bone distance. The following study questions reasons for gender specific saddles and whether saddles with

variable softness levels can have a positive impact on pressure reduction and comfort for cyclists with different body weight. Methods To determine 240 test subjects' seat bone distances a standardized stool was used (sit and fit, SQ-lab®). This quick and reliable method is commonly used in the bicycle industry. 76 test-subjects then completed a ten seconds trial on a triathlon bike (Alhonga, Fuji®) with its rear-wheel in a static cycle-trainer (i-Genius Multiplayer T2000, Tacx®) in different riding positions of 45°, 60° and 90° of upper body inclination. The parameters speed, cadence and work load are standardized. Pressure areas as well as peak and average pressure are measured with a special 64 sensors pressure-sensor-foil (GP Bike Mess, Gebiomized®) on three customized saddles (Freedom, men, Selle Royal®) with different softness levels. Results Men (11.58cm) have a significant ($p < 0.05$) smaller seat bone distance than women (13.04cm). Yet, the ranges differ between 9.2–15.1cm for men and 9.0–17.2 cm for women, indicating that both groups are represented in smaller and bigger distances. No significant differences were found in pressure distribution between men and women in the three riding positions. The relative pressure scores become more alike the further upright the riding position. Subjects weighing less than 60kg have a significant pressure reduction when using the softer saddle. The harder saddle appears more beneficial the heavier the test subjects are. Discussion The individual and non-gender specific parameter seat bone distance appears to be more reliable for cyclists to find a saddle that meets their needs than a gender specific ready-made saddle. Recent studies have shown that the saddle's shape can affect penile perfusion and comfort. The softness level of a saddle seems to have similar effects. Weight categories under and over 60kg are recommended for the analyzed saddles to reduce pressure and increase comfort effectively. References Bressel, E., Cronin, J. DID THE CRISIS AFFECT THE DELIVERY OF PHYSICAL ACTIVITY PROGRAMMES FOR SENIORS IN PORTUGAL?

Marques, A.I.1,2, Oliveira Tavares, A.I.3, Soares, P.3

1. *Universidade Lusófona do Porto*; 2. *ESDJCCG*; 3. *ESJE*

Introduction: In Portugal, the economic and financial crisis caused major social transformations. The budgets for the municipalities became scarcer and priorities were redefined (Davey, 2011). In 2008 we conducted a study that found the general characteristics of the physical activity (PA) programmes developed by the Portuguese Local Public Administration (Marques et al., 2011). This paper aims to investigate whether these programmes are being developed and if their characteristics have changed and, if so, how they have evolved since the outbreak of the Euro-crisis. Methods: Data were collected by an on-line questionnaire sent to all Continental Municipalities with PA programmes in 2008 ($n = 97$). Categorical data were expressed as absolute counts and percentages. Continuous data were expressed as the mean and SD. Open-ended questions were analysed using qualitative content analysis with QSR NVivo software. Associations between categorical variables were tested by the use of contingency tables and the calculation of chi-square tests. Wilcoxon t-test was used to compare the results with baseline values. Significance level was set at $p \leq 0.05$. Results: Results showed: i) a total of 94 PA programmes were identified; ii) 7 municipalities lost their PA programmes; iii) the main goal of the majority of programmes (92.3%) was promotion of participants' health; iv) the majority of programmes had a minimum age of 55 years as a pre-requisite for admission; v) most of the programmes offered 3 activities taking place 2 times per week; vi) characteristics of the programmes were found to differ by regions of the country; vii) most programmes (51.3%) confirmed they had a containment strategy (e.g., reduction of participants or reduction of activities). Discussion: Some characteristics of the programmes had remained the same since the first study (Marques et al., 2011): specifically, the main goals of the programmes, minimum age for admission and weekly frequency of programmes. Nevertheless, there were some changes: a reduction in the number of PA programmes and a decrease in the number of activities, with consequent reduction in the number of participants. Most programmes justify budget reductions as crucial to their containment. These results suggest that, despite warnings about the low percentage of seniors who follow PA recommendations (Baptista et al., 2012), local authorities have not maintained their capacity to provide PA programmes for older people at the same level they did prior to the outbreak of the crisis. Do Introduction Studies have shown that physical activity level declines with age and show gender differences. In addition increased physical activity level is closely related with maintained body weight, low levels of fat percentage and proper levels of fat free mass. Hence the purpose of this study was to investigate age and gender related changes in physical activity and physical characteristics of Turkish adolescents. Methods A total of 997 adolescents (ngirls:481; nboys:516) between the ages of 11-18 yrs participated in this study voluntarily. Participants' physical activity level was determined by "Weekly Activity Checklist" (Sallis et al, 1993) and body composition characteristics like BMI, fat percentage and FFM were determined by BIA method. Results Physical activity level of boys was significantly higher than girls at all age levels except age 13, 14 and 18, in which no significant differences were found. For body weight boys were significantly heavier than girls between ages 15 to 18 yrs, while no significant differences were observed between ages 11 to 14 yrs. For height, boys were significantly taller than girls at ages 13, 15, 16, 17 and 18 yrs, while no significant differences were observed at ages 11, 12 and 14 yrs. For BMI, the only significant difference was observed at age 16 in which boys had higher BMI values than girls and no significant differences were observed at the rest of the age groups. For body fat percentage girls significantly had higher values than boys at all age levels and for fat mass girls have significantly higher values than boys at all age levels except at ages 11 and 18 yrs. Finally boys had significantly higher fat free mass values than girls at all age levels except age 12 in which no significant change was observed between boys and girls. Discussion The findings of the present study indicated that boys were more active than girls at all age groups similar to previous studies (Kin-Isler et al, 2009; Telama & Yang, 2000). For physical characteristics the findings also correspond to the existing literature (Malina et al, 2004). References Kin-Isler A, Asci FH, Altintas A, Guven-Karahan B. GENDER DIFFERENCES IN ANTHROPOMETRIC DATA AND IN BLOOD PRESSURE VALUES AFTER A 10 WEEKS TRAINING PROGRAM

Kneffel, Z.S., Wang, Y., Khelifi, M., Goebel, R.

Qatar University

Purpose: The prevalence of overweight and obesity and the incidence of non-communicable diseases increased dramatically over the past 20 years in GCC countries includes Qatar (1,2). The early screening and the propagation of the regular physical activity is essential in the country. The aims of the study were: 1. to map the body composition and blood pressure of young Qatari adults (18-30yr), 2. to determine changes in it after a 10 weeks training program. **Methods:** 158 Qataris were involved to the study (men (n=89), women (n=69)) from Qatar University (QU). We measured systolic (BPS) and diastolic (BPD) blood pressure, body height, body weight, % body fat and the regular physical activity (PA) was assessed by IPAQ. Pre-hypertensive/hypertensive and overweight/obese subjects (20 males and 20 females) were selected and involved into the 10 weeks training program (3-5 times/week, 30-60 minutes/session, 55-60% of the HRmax). The training sessions on 3 times/week were guided by an instructor, the other 2 trainings were individually performed by the subjects followed by a written training schedule. **Results:** 28.3% of males were overweight and 34.8% were obese; where females were 23.2% and 17.4%, respectively. Male subjects had significantly higher BMI values than females (27.38 ± 6.24 vs. 23.24 ± 5.57 $p < .001$). IPAQ results shown that vigorous, and moderate type activity didn't differ between genders, but in low intensity PA (walking) females were more active than males 111 min/week vs. 88 min/week , $p < .001$. Males attended frequently on the face-to-face training sessions than females (2.3 vs. 1.45 hours/week, $p < .05$). The 10 weeks training program induced significant reduction in BDP (78.00 ± 6.06 vs. 74.81 ± 10.2 mmHg, $p < .05$), BW (91.12 ± 16.31 vs. 85.2 ± 15.28 kg, $p < .01$), %BF (31.15 ± 9.0 vs. 21.19 ± 4.38 $p < .01$), in male subjects but we couldn't establish these differences in females. **Discussion:** The used intervention induced substantial changes in most of the measured parameters in males. The total PA in both genders was far away from the recommendation so it is crucial to pay attention its beneficial effects. Because the PA social image is different in Qatar than in other Western countries to maintain the motivation, the suitable duration and the intensity of the PA, continuous control by a sports expert seems to be effective. This study was made possible by a UREP award [UREP 12-048-3-009] from the Qatar National Research Fund (a member of The Qatar Foundation). The statements made herein are solely the responsibility of the authors. **References:** 1. Ng, S. W., Zaghoul, S., Ali, H. I., Harrison, G. and Popkin, B. M. BONE CHARACTERISTICS, BODY STRUCTURE AND MILK CONSUMPTION IN ATHLETIC AND NON-ATHLETIC 16-18-YEAR-OLD ADOLESCENTS

Szmodis, M., Bosnyák, E., Protzner, A., Trájer, E., Udvardi, A., Szóts, G., Tóth, M.

Faculty of Physical Education and Sport Sciences, Semmelweis University, Budapest, Hungary; Semmelweis University, Faculty of Physical Education and Sport Sciences

Introduction It is a well-known fact that regular physical activity has favourable influence on the bone status and on peak bone mass. A quantitative ultrasound measurements is relatively inexpensive, portable, non-invasive method of evaluating bone characteristics. The main goal of this study was to analyze relationships between habitual physical activity, some anthropometric variables, milk consumption and bone parameters in adolescents. **Material and Methods** The subjects were 16-18-year-old non-athletic boys (109) and girls (95) and athletic boys (104) and girls (69). Athletic adolescents' sport related experience was more than 4 years, minimum 3 times/week. Anthropometric measurements were taken by the suggestion of the International Biological Program (Weiner and Lourie 1969). Body fat percentage was estimated by Pařížková's method (1961), body composition by Drinkwater and Ross technique (1980). Calcaneal quantitative ultrasound (QUS) parameters were registered by Sonost 3000 bone densitometer. The analysis included speed of sound (SOS, m/s), broadband ultrasound attenuation (BUA, dB/MHz) and the calculated bone quantity index (BQI = $\alpha \text{SOS} + \beta \text{BUA}$, α, β : temperature corrections). Ca-uptake was assessed by daily milk consumption by using of food frequency questionnaire. Differences between athletic and non-athletic adolescent boys and girls were tested by Tukey's post-hoc test. Correlation patterns of the bone characteristics and milk consumption for total sample were analyzed. Differences between subgroups of milk consumption were tested by Student t-test ($p < .05$). **Results** There were significant differences between subgroups in body composition. In comparison of the athletic and non-athletic subgroups the bone parameters i.e. SOS (boys: 1508.03 ± 16.79 vs. 1495.6 ± 11.75 ; girls: 1501.18 ± 15.11 vs. 1490.66 ± 11.67), BUA (boys: 92.09 ± 18.16 vs. 83.79 ± 13.04 ; girls: 91.07 ± 14.43 vs. 85.65 ± 12.19) and BQI (boys: 78.21 ± 17.82 vs. 66.92 ± 12.87 ; girls: 73.16 ± 15.42 vs. 63.25 ± 12.43), athletic adolescents had the better values. There were slight significant relationships between bone parameters and milk consumption. The SOS, BUA, BQI for the whole sample differed significantly by the frequency of milk consumption: SOS (1502.25 ± 16.7 vs. 1495.9 ± 13.48), BUA (90.12 ± 15.9 vs. 85.79 ± 14.56) and BQI (73.29 ± 17.15 vs. 67.24 ± 14.3). **Conclusions** The regular physical activity helps to prevent osteopenia and osteoporosis. The bone variables differed in athletic and non-athletic adolescents. It seems that quantity bone parameters considerably related to the milk consumption. **References** Pařížková J (1961). ENVIRONMENTAL PERCEPTION AND PHYSICAL ACTIVITY IN YOUTH

García Cervantes, L., Rodríguez Romo, G., Castro Piñero, J., Esteban Cornejo, I., Delgado Alfonso, A., Marcos, A., Veiga, O.L.

Universidad Autónoma de Madrid

Introduction Several environmental factors such as recreation infrastructure, transport, aesthetic and safety perception have been investigated in relation to self-reported and objective physical activity (PA) in youth (Bauman et al., 2012). The study aims were: (i) to assess the relationship between environmental perception and objective PA, self-reported PA and self-reported active commuting (ii) to analyze differences regarding to the meeting PA recommendations in relation to environment perception in youth. **Methods** A total of 1520 youth (770 boys) aged 8-18 years from the UP&DOWN study were included. Self-reported PA was assessed by Physical Activity Questionnaire for Children, Physician-based Assessment and Counseling for Exercise questionnaire and Finnish Physical Activity Index. Objective PA was measured by accelerometry. Active commuting in leisure time was self-reported. Environmental perception was assessed using an

adapted version of ALPHA environmental questionnaire for youth. The associations between environmental perception and PA were analyzed by linear regression models. Differences in the meeting PA recommendations were examined by sex- and age-specific tertiles of environmental perception using logistic bivariate regression models. Results The ALPHA environmental score was associated with all self-reported PA variables for the total sample whereas active commuting in leisure time was associated for the overall sample and for the younger group. The ALPHA environmental score was related to objective PA variables for the whole sample. By sex, the association of the ALPHA environmental score with moderate and total PA was significant in boys while just vigorous PA was associated in girls. By age, ALPHA score was associated with moderate-vigorous PA and total PA in the older group while only with vigorous PA in the younger group. Additionally participants in the highest ALPHA score tertile were more likely for meeting youth PA recommendations (≥ 60 min/day MVPA) than participants in the lowest tertile. Discussion Environmental perception may be an important aspect to achieve higher levels of PA in youth, particularly in boys and in the older youth. It is possible that those groups have more parental permission to go out independently in their neighborhood (Van Loon et al., 2014). ASSOCIATION BETWEEN PRE-PREGNANCY PHYSICAL ACTIVITY AND PRENATAL LIFESTYLE OF PREGNANT WOMEN

Barka, N., Grencher, A., Balázs, P., Paulik, E.

University of Szeged

Introduction In Hungary, the infant mortality has been significantly decreased in the last decades, but about 70% of infant deaths are associated with preterm births; unfortunately the proportion of preterm births is continuously high in Hungary (HCSO, 2012). The lifestyle of pregnant women can influence both the health status of women and the outcome of the pregnancy (e.g., the risk of preterm birth). The aim of our study was to analyse the association between the lifestyle and the health status of pregnant women and their physical activity before pregnancy. Methods A retrospective interviewer administered questionnaire-based study was conducted among mothers who delivered a baby between 1 January and 31 December 2012 in County Csongrád, Hungary. The number of live births was 3110, the participation rate was 59.3%. We omitted 74 of the 1,846 respondents from this study because of missing data leaving a total sample of 1,772. The questionnaire included standardized measures of demographic, socioeconomic, and lifestyle characteristics. Informed written consent was obtained from all participants. Results In the sample, more than 30% of women reported to engage in some type of physical activity prior to pregnancy. Comparing women being physically active before pregnancy with those being inactive we found significant differences in their lifestyle characteristics during pregnancy. Prevalence of smoking was 3.6% among active, and 11.7% among inactive women ($p < 0.001$). Dietary habits were also different: the regular consumption of fruits and vegetables were significantly lower among inactive women. The frequency of preterm births were lower among pre-pregnancy active women, although the difference was not significant. Discussion Our results have shown the association between pre-pregnancy physical activity and the prenatal lifestyle of pregnant women. The improvement of the healthy way of life at population level, and especially during pregnancy plays significant role in the prevention of later chronic diseases, so young women have to be educated about the importance of healthy diet and lifestyle in women of childbearing age. EFFECTS OF MULTICOMPONENT EXERCISE TRAINING ON BONE METABOLIC MAKERS IN THE YOUNG AND ELDERLY ADULTS

Yen Ting, S., Linda, L., Tai You, L., Yueh Chang, T., Meng Yu, C.

National Cheng Kung University(NCKU), Tainan, Taiwan

Introduction Bone mineral density (BMD) and function are improved in the adults during exercise training. These improvements must result from alterations in the rates of bone formation and reabsorption. Markers of bone turnover have been estimate to provide a deeper understanding of the dynamic course of bone metabolic and remodeling. Exercise has been shown to be an effective method of preventing BMD in elderly individuals, especially when impact exercise and strength training are combined. Findings regarding as multi-component exercise effects between different generations are limited. The purpose of this study is to investigate the effects of multi-component exercise training on bone metabolic between young and elderly adults. Methods 13 young (19.70 ± 1.59 yr) and 13 elderly (61.57 ± 5.02 yr) adults participated in this study underwent 12 weeks of progressive multi-component exercise training. The training program consisted of 3 sessions of mechanical resistance exercise and low-impact aerobic exercise training, and flexibility exercises 2 times per week. Osteocalcin (OC), cross-linked carboxyl-terminal telopeptide of type I collagen (ICTP) and bone turnover were collected at pre- and post-training. Two-way ANOVA was used to determine the significance for changes in bone maker variables. Results After 12 weeks of training, ICTP were increased in both of young group (21.84%) and elderly group (7.42%). Osteocalcin increased in the young group (7.39%) and the elderly group (9.37%), however there were nosignificant between two groups in ICTP and Osteocalcin. Furthermore, the bone turnover was significantly lower in the young (-10.37%) and higher elderly group (6.96%) ($p < .05$). Discussion There was no significant improvement for single marker in short-term exercise training, but had significantly in bone turnover. Previous study showed that 10 weeks of upper-body resistance training can't improve BMD and bone metabolism (Liang et al., 2012). Our result was similar to other study and indicated that there was no significant difference in osteocalcin after 12 weeks resistance training in both group (Klentrou et al., 2007). Nevertheless, a high rate of bone turnover might be associated with an increased rate of bone loss in elderly which is a major determinant of osteoporosis. In this study, the young group showed a significant lower rate of bone turnover, which proved the benefit to bone formation. In conclusion, after 12 weeks multicomponent exercise training with the same exercise training volume, the young group is more effective than elderly group on bone metabolic to promote increase BMD. In future study, the index of bone mineral density (BMD) should be involved for further investigation and extending the training duration to observe the changes in bone metabolism. DOSE-RESPONSE EFFECTS OF RESISTANCE TRAINING INTENSITY ON THE BONE MINERAL DENSITY AND MUSCLE STRENGTH IN POSTMENOPAUSAL WOMEN

Chiao Hsin, C., Linda, L.

Chi Mei medical center, National Cheng Kung University

Introduction The aim of this study was to determine the effects of 24 weeks and 48 weeks different intensities with same training volumes on bone mineral density, and muscle strength in postmenopausal women. **Methods** 24 healthy volunteers completed the study. The experimental protocol utilized a random paired design to 3 groups high-intensity resistance group (n=8, age 58.6±2.1yrs), moderate-intensity resistance group (n=8, age 58.8±6.8 yrs), and control groups (n=8; age 56.7±3.4rs) by each subject's mean of upper and lower maximal strength. Subjects in training groups were engaged in exercise training with two times per week under supervision for 48 weeks. Data collected at 0 week, 24 weeks and 48 weeks included bone mineral density (BMD), one repetition-maximum(1-RM), elbow, knee extensors and flexors isokinetic strength's peak torque, peak torque/ weight. The data were analyzed by one-way ANCOVA. **Results** After the 24-week training intervention, the high- intensity group (+0.76%) significant higher than moderate-intensity (-1.62%) in leg BMD(p<.05). In the isokinetic strength, in percentage of triceps's peak torque at 45°/s had significant difference between groups in 0-24 weeks and 0-48 weeks(high and moderate-intensity significant higher than control, high :+24.5% and +30.8%, moderate:+18.9% and +15.7%, control :+3.2% and +6.4%) (p<.05). In percentage of triceps's peak torque / weight at 45°/s had significant difference between groups in 0-24 weeks(high and moderate-intensity significant higher than control, high :+24.4%, moderate:+18.8%, control :+1.8%) (p<.05); in 0-48 weeks(high intensity significant higher than control, high :+30.1%, control :+5.2%) (p<.05). In percentage of hamstring's peak torque at 180°/s had significant difference between groups in 0-24 weeks and 0-48 weeks(high and moderate-intensity significant higher than control, high :+25.0% and +28.3%, moderate:+12.0% and +26.0%, control :+12.5% and +12.2%)(p<.05). In percentage of hamstring's peak torque / weight at 180°/s had significant difference between groups in 0-24 weeks and 0-48 weeks(high and moderate-intensity significant higher than control, high :+25.1% and +28.3%, moderate:+11.9% and +25.8%, control : -13.7% and -13.4%)(p<.05). **Discussion** After 24 weeks of training, Leg BMD had significant difference between 0-24 weeks(high- intensity significant higher than moderate-intensity). However, there were same impact in BMD for any of the groups at the other sites(Vincent and Braith , 2002; Kerr et al., 1996). It had more improved isokinetic strength and rather to the antagonist muscle. Relatively few investigations have examined the dose-response effect of resistance training on bone in humans. In our study, the high and moderate-intensity programs were designed to produce similar total workloads in subjects with similar strength values. Therefore, different intensity of resistance training can be promoted to maintain health and encourage postmenopausal women to exercise for improving their function of life. TRAINING METHODS OF MASTERS CYCLISTS: AN AUSTRALIAN STUDY

Macgregor, C.I, Reaburn, P.I, Korhonen, M.2

1: CQUniversity Australia, 2: Univeristy of Jyväskylä, Finland

Introduction. In Australia, persons aged 65 years and over are expected to make up 25% of the population by 2050 (ABS, 2009). The number of older people involved in competitive endurance sports and activities has increased significantly in the last 20-30 years. This trend is likely to increase in Australian sport with participation moving to focus on more individual and lifestyle pursuits rather than traditional team sports (Hajkowicz et.al.2013). Suominen et.al.(2011) suggested that Masters athletes are challenging age-related changes in performance and health. With the world's population ageing, the importance of Masters athletes as models of successful aging is increasing. The present study examined gender and age-group differences in training methods among Queensland cyclists over the age of 35 years. **Methods.** Following institutional ethics approval, Cycling Queensland members were sent an invitation to complete an online survey examining the current training methods. **Results.** 181 males and 27 females responded and were then placed in three age groups: 35-44 yr (N=91), 45-54 yr (N=65), and 55+ yr (N=52). Both males and females undertake endurance, strength and speed power training on the bike. There is no difference when comparing gender or age when looking at training on the bike. Males do not train their endurance off the bike, whereas females do. The Chi-square resulted in a significant difference between genders $\chi^2(1, N = 208) = 7.37, p = 0.01$. The majority of both sexes do not undertake strength or power speed training off the bike and there is no difference for age. **Discussion.** Females prefer to undertake endurance training off the bike and the results also suggest no significant difference in any training variable between age groups. Lepers et.al. (2012), found that endurance appears to be maintained until approximately 35-40 years of age, followed by modest decreases until 50 years of age, then declining into older age. This is mainly because physiological factors contribute to age related declines, which can be regulated by changing the intensity and volume of the older endurance athletes' training (Reaburn and Dascombe, 2008). The present study also observed that Masters cyclists undertake minimal training off the bicycle. Kraemer et al 2002 states resistance training is believed to increase muscle strength, muscle endurance, and sprint performance which are considered to be important in improving maximal, endurance, and explosive muscle force which are determining factors of the performance achieved in sport. **References.** Australian Bureau of Statistics [ABS]. DETERMINANTS OF THE FINISH TIME AND STOPS OR WALKS IN THE CITY MARATHON

Mori, H.1,2, Yamamoto, M.1

1:National Institute of Fitness and Sports in Kanoya, 2:Research Fellow of Japan Society for the Promotion of Science

Introduction "Running" is one of the most popular recreational sports. The goal of a runner is to continue running until the finish line and complete the race as fast as possible. The purpose of this study was to determine the affective factors influencing the finish time and stops or walks in the city marathon. **Methods** The study took place during the 33rd IBUSUKI NANO HANA MARATHON, which is among the largest marathons held in Japan. The temperature and humidity levels, on the morning of the race held on January 12, 2014, were 12°C and 46.3% respectively. A total of 16,472 runners completed the marathon, out of which 534 runners responded to the survey. The survey questionnaire contained queries on the finish time, age, body mass index (BMI), training volume (the latest monthly distance covered), total number of marathon races participated in, and whether the respondents stopped and walked during the race. **Results** The runners' finish time decreased with increase in age, monthly covered distance, and number of marathons participated in. The runners who were aged 40 years and above, who had covered a monthly distance of over 200 km, and who had participated in over 10 times the number

of marathons, reported a finish time was little reduction from under 4-hour time span. The runners whose BMI was in the range of 19.0 to 22.9 had a faster finish time. The runners who ran until the finish line were older; registered a faster finish time; and had a greater monthly covered distance, higher marathon participation, and lesser BMI compared to those who stopped or walked during the race. Discussion This study has been consistent with previous research in establishing that the finish time of marathon races was connected with previous experience of long distance races and large training volume (Bale et al., 1985; Sjodin et al., 1985). However, when the finish time dropped below the 4-hour time span, other factors such as speed training and running economy could have been influential. The runners who stopped or walked during the race were younger in age and had participated in lesser number of marathon races compared to those who ran until the finish line. Moreover, they had covered only half of the monthly distance compared to those who ran until the finish line (85 km vs. 195 km). Hence, we concluded that running strategies and training volumes were important factors in running continuously until the finish line. Reference Bale P., Rowell S., Colley E. (1985). LOW BACK MOTION AND HAMSTRING FLEXIBILITY: EVALUATION FOLLOWING TWO DIFFERENT PROTOCOLS

Vago, P., Merati, M., Casolo, F., Lovecchio, N.

Università Cattolica Milano

Introduction Several tests are commonly used to evaluate the hamstring and low-back flexibility in health-related physical fitness batteries. They are, in general, referred to the sit-and-reach (SAR) test. The most popular and easy to perform are the V-shape leg position by American College Sport Medicine (1) and that proposed by the Eurofit Battery protocol (2). In this study, the correlation between anthropometric characteristic and the lower back RoM measure was analysed in female university students. **Materials and methods** A total of 106 female sport science university students (age range 23–19 yr; $SD \pm 1.2$ yr) volunteered to the study. The main inclusion criteria were the absence of musculoskeletal injuries and of low back pain. Each participant underwent two different SAR tests performed in two different days of the week. No warm up or specific exercises were performed prior the flexibility performance. Body mass was measured to the nearest 0.5 kg on a beam-balance scale and stature was measured to the nearest 1 cm with a stadiometer. Body Mass Index was calculated and the length between the greater trochanter and the lateral malleolus (with knee in full extension) was measured to define the proportion of lower limbs. The length of the spine (C7-L5) were also measured. All protocol procedures were carried out by the same operator and in the same gym. **Results** The anthropometric characteristic were for body mass 55.3 ± 5.2 kg and 1.67 ± 0.05 m for height. On average the BMI was 19.8 ± 1.5 . The SAR result was 47.2 ± 11.3 cm about V-leg position while the European protocol assessed 11.2 ± 7.6 cm. The coefficient of variation was 0.23 and 0.67, respectively. No significant correlations were found between the anthropometric and ROM. The underweight female performed 50 cm and 14.7 cm for American and European protocol respectively. **Discussion** These kind of test have a good relation with hamstring flexibility even if do not separate the muscular and joint effects (3); however our results do not show any real difference between the two tests from an anthropometric point of view. Indeed, the European protocol that reduces the intervention of lower back (and part of hip flexion) seems to exclude bias in the measure (4). The American protocol, on the other hand, seems more suited for assessing the muscular contribution to flexibility. **References** 1. ACSM. 2009. ASSOCIATION BETWEEN GENDER, BODY COMPOSITION AND INFLAMMATION IN ELITE ADOLESCENT CYCLISTS

Orysiak, J.1, Witek, K.1, Malczewska Lenczowska, J.1, Szczepanska, B.1, Pokrywka, A.1, Grochowska, J., Wiśniewska, K.1, Hübner Woźniak, E.2, Zembron Lacny, A.3

1:Institute of Sport (Warsaw, Poland), 2: Józef Piłsudski University of Physical Education in Warsaw (Warsaw, Poland), 3: University of Zielona Góra (Zielona Góra, Poland)

Introduction The effectiveness of physical training depends on the training load, the individual toleration ability and an imbalance between the two may lead to under or over-training. One of the unique features of an exercise is that it leads to a simultaneous increase of antagonistic mediators such as cortisol, testosterone, pro- and anti-inflammatory cytokines, growth factors, reactive oxygen species etc. (Roubenoff 2007, Nemet et al., 2012). The effect of a single exercise as well as physical training on catabolic and anabolic factors was studied mainly in adults participating in various sports. The gender-specific effect of exercise on these systems in adolescents is unknown. Therefore, the purpose of this study was to evaluate the levels of inflammatory mediators in elite female and male adolescent cyclists, and its relation with body composition. **Methods** Female (n=36) and male (n=53) road cyclists at age of 18.3 ± 1.9 yr participated in the study during preparatory period. Blood samples were taken after night fasting from healthy, medically examined athletes. The levels of H2O2, IL-1 β , TNF α , cortisol, CRP, WBC and total CK activity were determined. The percentage of body fat (FM%) was calculated using the equation of Durnin and Womersley (Durnin & Womersley, 1974). **Results** There were significant differences in body composition (FM and FFM), WBC, neutrophil and monocyte counts, as well as, CK, cortisol and cytokine levels between females and males. Furthermore, lymphocyte counts negatively correlated with FM% in male athletes ($P < 0.05$). **Conclusion** The results showed the gender-dependent differences in inflammatory response to training and association of body composition with inflammation in elite adolescents cyclists. The study was financially supported by Ministry of Sport and Tourism (agreement numbers: 2013 053/40/BP/DWM, and 2013/0209/0223/SubB/DSW/DK/JD- Fund for Development of Physical Culture). **References** Durnin JV, Womersley J. DIFFERENCES IN EXERCISE-INDUCED REDUCTION OF VISCERAL AND SUBCUTANEOUS FAT IN OBESE SUBJECTS

Kawasaki, H.1, Ichikawa, M.1, Tobina, T.2, Yoshimura, E.3, Kumahara, H.4, Ayabe, M.5, Michishita, R.1,6, Matsuda, T.6, Kiyonaga, A.1,6, Tanaka, H.1,6, Higaki, Y.1,6

1:Fukuoka University, 2:University of Nagasaki, 3:Prefectural University of Kumamoto, 4:Nakamura Gakuen University, 5:Okayama Prefectural University, 6:Central Research Institute for Physical Activity

Introduction Obese individuals can be classified as having a visceral fat (VF) or subcutaneous fat (SF) obesity phenotype. The degree of accumulation of VF and SF differs among individuals. Evidence suggests that visceral adipose tissue is more pathogenic than subcutaneous adipose tissue; thus, it is desirable to reduce VF in obese individuals regardless of their obesity type. The purpose of this study was to

determine the degree of decrease in VF and SF induced by an aerobic exercise training intervention. Methods Eighty-nine obese subjects (40 males and 49 females, mean age 56.1 ± 10.1) who participated in a Metabolic Syndrome Intervention Program were randomly allocated to exercise training (Ex; 24 males and 20 females) or control groups (16 males and 29 females). Subjects in the Ex group performed 300 minutes of aerobic exercise per week for 12 weeks. This consisted of three 60-minute sessions of supervised exercise weekly, and an additional 120 minutes per week of unsupervised exercise on their own at home. The exercise intensity was set at the lactate threshold (LT). Abdominal SF area (SFA) and VF area (VFA) were measured by computed tomography scanning at the level of navel before and after the intervention. Results After the 12-week intervention, VFA and SFA were significantly reduced from pre-intervention values in males in the Ex group ($p < 0.01$). In females, VFA was also significantly reduced in the Ex group ($p < 0.05$), but the SFA did not significantly differ. In the control group, there were no significant differences in VFA or SFA in either gender. The percent change in VFA and SFA in Ex group participants did not significantly differ in either gender (males; VFA: $-19.1 \pm 18.1\%$, SFA: $-13.4 \pm 15.5\%$, female; VFA: $-7.7 \pm 16.1\%$, SFA: $-1.9 \pm 8.6\%$). However, in some individuals either VFA or SFA increased despite a decrease in total abdominal fat (TAF). Or, conversely, despite an increase in TAF, either VFA or SFA decreased. Conclusions These results suggest that there were no differences in the percent reduction of VFA and SFA after 12 weeks of aerobic exercise training. However, the degree of change in VFA and SFA induced by exercise appears to vary among individuals. References Osamu Saiki, Ai Soejima, Ayumi Kimura, Makihiko Kuhara, Hiroshi Uda. SEDENTARY/LIGHT BEHAVIOR AND OBESITY

Oliveira, T., Costa, M., Mota, J., Silva, G., Ribeiro, J.

Sports Faculty, University of Porto

Introduction: Prevalence of overweight and obesity, highly sedentary behaviors (SB) and a lack of physical activity (PA) among young children and adolescent are a major public concern. They are important risk factors for many chronic diseases such as diabetes, and cardiovascular disease. However evidence has shown that most children and adolescents do not meet the recommended 60 minutes per day of moderate to vigorous PA and instead, spend the majority of their daily time engaged in sedentary/light PA. Several studies also suggest also that sedentary time per se represents a major risk factor for several chronic diseases. In fact, SB has become more common among younger generations and it's important to know the association with overweight and obesity in children and adolescents. Methods: The sample comprised 474 subject, 266 girls and 208 boys (aged 13.71 ± 2.53 , and 13.33 ± 2.67 , respectively). PA was measured using Actigraph accelerometers model GT3Xs. Participants were instructed to use the accelerometer according to standard procedures, and data analyzed using the recommended guidelines. The body mass index (BMI) was assessed and classified in normal, overweight and obese, according to standard recommendations. ANalysis Of VAriance was used to test the results, using SPSS. Results: Overweight (763min.) and obese (787min.) subjects accumulated more SB and light physical activity ($p \leq 0.05$) than the subjects with normal weight. The results showed significant differences between overweight (755min.), obesity (781min.) and normal boys (718min.), $p < 0.05$. Overweight (769min.), obesity (792min.) and normal girls (770min.) didn't have significant differences, but demonstrated a positive trend. Discussion: The results indicate that overweight/obese children have higher overall SB time and light physical activity compared to normal weight children. These results are similar to those that were found by Herman et al., (2014). Therefore, according to some studies, overweight and obese children tend to drift from lower levels of physical activity and to increase sedentary behavior (Marshall et al., 2004), however, research is needed to continue to develop means of gathering more comprehensive data in order to better elucidate the full nature of SB. PEDOMETER DETERMINED PHYSICAL ACTIVITY, BONE MINERAL CONTENT AND DENSITY OF PREMENARCHEAL GIRLS

Kambas, A., Leontini, D., Chatzinikolaou, A., Avloniti, A., Stamboulis, T., Gounelas, G., Karagiannopoulou, S., Protopapa, M., Pontidis, T., Mavropalias, G., Giannakidou, D.

Democritus University of Thrace

Draganidis, D., Ioannou, D. Introduction There is evidence that physical activity (PA) early in life promotes bone health and prevents osteoporosis later in life (Baxter-Jones et. al., 2008). However, current literature lacks comprehensive data on physical activity's contribution to bone mineral content and density in prepubescent girls. Methods Sixty prepubescent girls (age 11.00 ± 0.93 yr, weight 36.52 ± 9.7 kg., height 1.44 ± 0.07 cm; %fat 17.19 ± 9.91) participated in the study. PA was assessed using piezoelectric pedometers (Omron HJ-720IT-E2) and bone parameters at lumbar spine and hip (BMDLS, BMDHIP, BMDNECK, BMDTRO) were measured with dual-energy densitometry (Lunar DPX NT). A one-way Anova with adjustment for weight was conducted to check the effects of PA on bone parameters. A Sidak test was applied for post-hoc comparisons. Results A visual-binning procedure was used to classify step counts into categories, resulting three groups (low: 5,800-8,531 steps/day; mod: 8,561-16,000 steps/day and high: 17,460-21,094 steps/day). Results revealed significant effects of PA on BMDLS ($F=7.17$, $p < 0.005$), BMDHIP ($F=8.19$, $p < 0.001$), BMDNECK ($F=5.87$, $p < 0.005$), BMDTRO ($F=7.45$, $p < 0.001$) and BMDWARD ($F=13.38$, $p < 0.001$). Post-hoc tests showed that in all comparisons the 'high' PA group demonstrated better values than the other two groups ($p < 0.005$). Discussion The results of this study suggest that PA (steps/day) might affect bone mineral content and density in LS, HIP, NECK, and TRO areas. More specifically, it appears that prepubescent girls taking more than 17,000 steps/day demonstrate greater osteogenic benefits than their counterparts taking less than 16,000 steps/day. ASSOCIATIONS OF PHYSICAL ACTIVITY WITH BLOOD PRESSURE, BODY COMPOSITION AND MATURATION LEVEL IN ADOLESCENTS: THE GEOS STUDY

Benítez Porres, J., Correias Gomez, L., Carrillo, M., Martín Sanz, N., Alvero Cruz, J.R., Carnero, E.A.

University of Málaga

Introduction The association between physical activity (PA) and resting blood pressure (BP) is poorly understood in adolescents (Kelley, Kelley, & Tran, 2003), since several variables such as body composition, maturation level or sex, which interfere with, must be analyzed (Muntner, He, Cutler, Wildman, & Whelton, 2004). Therefore, the aim of this study was to explore the association of PA, body composition, blood pressure, and maturation in adolescent boys and girls. **Methods:** Two hundred and nine (n=114 boys, n=95 girls) healthy adolescents (15.6±1.6 years, 21.9±4.3 BMI) were volunteers. A PA score was estimated by Physical Activity Questionnaire (PAQ-A). BMI, waist circumference (WC) and fat mass percent (%FM) were assessed by anthropometric measurements as adiposity markers. Tanner's maturation stages were evaluated and systolic and diastolic blood pressure (SBP and DBP) were measured by OMRON sphygmomanometer. SBP and DBP indexes (SBPI and DBPI) were calculated as mmHg/height (cm). Spearman rank order correlations were used to explore associations between variables after control to maturation. **Results:** All the relationships between parameters showed a positive correlation. There were significant associations between BP variables and BMI (SBP $r=0.202$, $P<0.01$; DBP $r=0.305$, $P<0.001$), and WC (SBP $r=0.197$, $P<0.01$; DBP $r=0.295$, $P<0.001$). PA score was only related with body composition variables either girls or boys. Also, there were significant correlations between %FM and BP variables (SBP $r=0.332$, $P<0.01$; DBP $r=0.330$, $P<0.01$; DBPI $r=0.308$, $P<0.01$) in girls but not in boys. **Discussion:** Our data confirm the relationship between BP and body composition variables as WC and BMI (Rosa, Fonseca, Oigman, & Mesquita, 2006). Nevertheless, we could not find any association between PA and BP. The recently developed SBPI and DBPI were not better associated with any variable than simple BP. These results should be considered carefully since measuring physical activity by objective methods could have changed the conclusions. So, other studies have reported a negative association between PA measured by accelerometry and BP (Hearst, Sirard, Lytle, Dengel, & Berrigan, 2012; Kelley, Kelley, & Tran, 2003). Further prospective studies using accelerometry or larger samples must be needed in order to explore deeply the impact of PA on BP in adolescents. **References** Hearst, M. O., Sirard, J. EFFECT OF THREE METHODS OF PHYSICAL ACTIVITY ON BALANCE, FUNCTIONAL CAPACITY, RISK OF FALLING IN ELDERLY.

Costa, A.S., Xavier, R.N., Braga, M.M., Mendonça, P.C.L.M., Carvalho, P.R., Damasceno, V.O.

Federal University of Pernambuco

Introduction - Falls are a common problem affecting older people, and their consequences are reduced quality of life, disability and financial costs to individuals and the government. One of the ways interventions to prevent falls in elderly is the practice of physical activity. Therefore, the aim of this study was to analyze the effects of three types of physical activity: general physical activity, weight training and aerobic training, on balance, functional capacity, and risk of falling in elderly. **Methods** - The sample included 39 seniors (general physical activity - GPA, n=16; weight training - WT, n=13; aerobic training - AT, n=10) with a mean age of 68.10 ± 4.72 years, who participated in a physical activity program (sixteen weeks) offered by the physical education department of the Federal University of Pernambuco (UFPE). For the evaluation we used the Fullerton Advance Balance - FAB, short form (Hernandez & Rose, 2008), Timed up and go test - TUG (Eyigor, Karapolat, Durmaz, 2007), and getting up from ventral decubitus position (GUVDP) and walk for ten meters (W10m), according to the GDLM protocol. **Results** - In relation to the FAB test, the WT group score was significantly higher compared to the AT and GPA groups ($p=0.0018$). There were significant between-group differences in GUVDP ($p=0.0465$) and W10m ($p=0.0008$) tests, for the AT and WT groups compared to the GPA group, respectively. The three groups showed no significant differences in TUG scores. **Discussion** - In our study, we investigated the effects of GPA, WT and AT on the balance, functional capacity, and risk of falling in elderly. The functional capacity (FC), according to Clark (1989) is defined as the capacity to perform the ordinary and unexpected activities of daily life, safely and effectively and without excessive fatigue. Our main finding was that specific training (WT and AT) promoted the elderly adaptations that classified with good performance in FC (LPDV and W10M tests) compared to the general physical training (GPA), classified with regular and poor performance, respectively. However, in the TUG test, recommended as a screening test for fall risk (American Geriatrics Society, British Geriatrics Society, 2001), the elderly people who participated in any of the three methods of physical activity so classified as low risk of falls. In agreement with these data, the scores achieved in the FAB test also classifies the three groups with low risk of falls. In conclusion, although the three methods of promoting physical activity have different results on the functional capacity of the elderly, our data reinforced that regular physical activity, it is still an important form of intervention to decrease in the risk of falls in this population. **References** Guideline for the prevention of falls in older persons. COMPLIANCE OF DAILY PHYSICAL ACTIVITY RECOMMENDATIONS AND OBESITY STATUS IN PRESCHOOL CHILDREN

Santos, A., Santos, S.S., Mota, J., Vale, S.

Universidade do Porto

Introduction: The benefits of promoting physical activity (PA) in counteracting the high prevalence of childhood obesity have become increasingly important in the past decade. The aim of this study was to examine the association between compliance of daily PA recommendations and the risk of being overweight or obese in preschool-aged children. **Methods:** The sample comprised 877 children aged 3-6 years, recruited from kindergartens located in the metropolitan area of Porto, Portugal. Preschooler's body mass index (BMI) was classified according to International Obesity Task Force. PA was assessed during 7 consecutive days by accelerometer. Children were classified as meeting or not meeting PA recommendations (at least 3 hrs per day of total PA (TPA)) using ≥ 800 cpm cutoff. **Results:** The prevalence of overweight and obesity was 23.6% and 10.4% in girls and 19.1% and 7.6% in boys. 21% girls and 36% boys met the ≥ 3 h TPA recommendations. Boys were significantly more likely to achieve the ≥ 3 h TPA recommendations than girls ($p \leq 0.001$). Not meeting the ≥ 3 h TPA guideline was associated with obesity (OR: 3.1; IC: 1.1 - 9.1), in girls, but not boys. No other statistically significant associations were found. **Conclusions:** These findings suggest that only 30% of children met the recommended guidelines. There is an association

with low levels of TPA and obesity among pre-school girls. Further longitudinal studies are needed to confirm this data. Contact: aman-da637@hotmail.com

EFFECTS OF THE LEISURE TIME SPORT ACTIVITY ON THE CHANGES IN DYNAMICAL MARKS AND THE BODYCOMPOSITION IN DIFFERENT BODY FAT PERCENTAGE CATEGORY AT THE MIDDLE AGE PEOPLE

Szablics, P.1, Orbán, K.1, Szabó, S.1, Dvorák, M.1, Ungvári, M.1, Balogh, L.1, Molnár, A.H.1, Pintér, Z.2, Posa, A.2, Kupai, K.2, László, F.1,2, Varga, C.S.2

1: *Institute of Physical Education and Sport Sciences, 2: Department of Physiology, Anatomy and Neuroscience University of Szeged*

Introduction: Obesity is associated with impairments of physical function, muscle strength and the capacity to perform activities of daily living. This research examines the effects of leisure sport activity in relation to body composition and physical function demonstrated by changes in the muscle strength and the dynamic of the movements when obese adults. We investigated the changes in body composition, changes in dynamical marks of center of gravity (CG) pending movements before and after the research program. **Methods:** 23 participants were divided into 3 groups based on body fat percentage: normal, overweight and obese. They did 60 minute long recreation trainings 3 times a week for 5 months. The examination was performed in the beginning and at the end of training program. Changes of body composition were determined by InBody230. APAS 3D system used for movement analysis. Participants were crouched and jumped in front of a camera. Position, velocity and acceleration of CG were analyzed. **Results:** Recreational training significantly decreased the body weight (over weight: $-6.07 \pm 2.36\%$), fat mass (normal: $-4.33 \pm 1.7\%$; over weight: $-16.01 \pm 6.55\%$; obese: $-8.23 \pm 2.87\%$), fat mass - body weight ratio (over weight: $-11.5 \pm 5.17\%$; obese: $-6.67 \pm 2.2\%$) and increased the amount of the muscle mass - body weight ratio (over weight: $5.89 \pm 2.49\%$; obese: $2.82 \pm 1.26\%$). Our results demonstrated that dynamical marks of the movement of CG were improved during jump (changes of position: over weight: $22.73 \pm 8.33\%$; changes of velocity: over weight: $21.52 \pm 4.96\%$; obese: $26.55 \pm 6.41\%$; changes of acceleration: obese: $42.97 \pm 9.78\%$) and crouch (changes of velocity: obese: $120.62 \pm 22.32\%$). **Discussion:** Based on these results we conclude that changing in body composition caused by 5 month recreational training could be a good strategy to improve the dynamic of the movement and well-being. **References:** Katzmarzyk PT and Lear SA. RELATIONSHIP BETWEEN LOW-BODY MUSCLE STRENGTH AND FUNCTIONALITY IN ELDERLY INDIVIDUALS

Araujo, C., Simon Neto, D., Alves, J.S., Kanegusuku, H., Forjaz, C.

University of São Paulo, Recanto das Velhinhas de Valinhos

Introduction Aging process reduces muscle strength, which compromises the ability to perform daily activities in elderly individuals. The objective of this study was to verify the relationship between lower-body muscle strength and other physical fitness components related to elderly functionality. **Methods:** Thirty-two subjects (80 ± 8 years, 13 men) who lived in a rest home for elderly individuals underwent a test for evaluating lower body strength (Chair Stand Test). In addition, upper body muscle strength (Arm Curl Test), lower body flexibility (Sit and Reach Test), balance (Unipedal Stance Test), and aerobic fitness (6-min Walking Test) were measured. Finally, subjects underwent two functional tests that involved multiple motor capacities: the Timed "Up & Go" test (agility and balance) and a walking circuit with different degrees of instability (speed, agility and balance). Data that did not present normal distribution was mathematically transformed. Pearson correlation was employed ($P < 0.05$). **Results:** Lower body muscle strength did not correlated with balance (left leg $r = 0.355$ and right leg $r = 0.227$, $P > 0.05$) and lower-body flexibility ($r = 0.145$, $P > 0.05$). However, a significant and positive correlation was identified between lower body strength and upper-body strength ($r = 0.620$, $P < 0.05$) and aerobic fitness ($r = 0.571$, $P < 0.05$). In addition, lower body strength correlated negatively and significantly with time for the execution of "Up & Go" test ($r = -0.643$, $P < 0.05$) and the walking circuit ($r = -0.558$, $P < 0.05$). **Discussion:** Although lower-body muscle strength was not associated to balance and flexibility, it was associated to aerobic fitness and the ability to perform complex tasks, such as the "Up & Go" test and the instability Walking Circuit. As these tasks resembles the daily activities performed by old people, the results reinforce the importance of strength maintenance in elderly. **References** Peiffer JJ, Galvao DA, Gibbs Z, Smith K, Turner D, Foster J, Martins R, and Newton RU. ASSOCIATION BETWEEN MAXIMAL OXYGEN UPTAKE IMPROVEMENT AND BODY COMPOSITION CHANGES AFTER A WEIGHT LOSS PROGRAM

Castro, E.A.1, Peinado, A.B.1, Cupeiro, R.1,2, Benito, P.J.1, Szendrei, B.1, Gómez, C.3

1: *UPM (Madrid, Spain)*, 2: *UFV (Madrid, Spain)*, 3: *IdiPAZ (Madrid, Spain)*

Introduction The association between $\text{VO}_{2\text{max}}$ and body composition (BC) has been widely studied, however few studies have evaluated the relation of these variables in response to a weight loss program (WLP). The aim of this study was to analyse the association between the change in $\text{VO}_{2\text{max}}$ and the changes in BC variables after a WLP. **Methods** One hundred sixty-seven (77 males and 90 females) overweight and obese participants (body mass index $25\text{--}34.9 \text{ kg/m}^2$), aged 18–50 years, performed a modified Bruce protocol before (pre) and after (post) a 24 weeks weight loss intervention. Subjects were randomized into three training groups (strength training, endurance training or a combination of strength and endurance; training frequency 3 times/week) or a physical activity recommendations group (C). All of them in combination with a 25–30 % caloric restriction diet. BC variables were measured with DXA (Zapico, et al. 2012). Pearson and Spearman's correlations were used to determine the association between $\text{VO}_{2\text{max}}$ change and BC variables changes and a two-way ANOVA with repeated measures to analyse differences between pre and post intervention. The tests were performed in men and women separately. The percentage of change was defined as $(\text{pre-post})/\text{pre} \times 100$. **Results** In women, all changes in BC variables showed a poor correlation with relative $\text{VO}_{2\text{max}}$ change (fat-free mass: $r = 0.27$, $p = 0.01$; android body fat: $r = -0.31$, $p = 0.003$; gynoid body fat: $r = -0.26$, $p = 0.01$, total body fat: $r = -0.30$, $p = 0.004$). In men the results were similar (fat-free mass: $r = 0.29$, $p = 0.01$; android body fat: $r = -0.26$, $p = 0.02$; total body fat: $r = -0.28$, $p = 0.01$) being the gynoid body fat the only variable not correlated to relative $\text{VO}_{2\text{max}}$. Absolute $\text{VO}_{2\text{max}}$ did not show correlation with BC variables in any gender. Moreover, relative and absolute $\text{VO}_{2\text{max}}$ and fat-free mass in-

creased while body fat (android, gynoid and total) decreased significantly in both genders after the intervention ($p < 0.05$). Discussion Recent studies prove the relation between BC and VO2max changes (Ermolao, et al. 2011; Lamina, et al. 2013). Our results show that the improvement in VO2max was weakly related with the BC changes after a WLP, indicating that intervention improved VO2max independent of changes to BC, also in agreement with others findings (Smith, et al. 2013). ACQUISITION OF PHYSICAL FITNESS AND MOTOR SKILLS PROMOTES PHYSICAL ACTIVITY IN ELEMENTARY SCHOOL CHILDREN: A ONE-YEAR FOLLOW-UP STUDY

Hikihara, Y.1, Watanabe, M.3, Wakabayashi, H.1, Hanawa, S.4, Aoyama, T.5, Omi, N.6, Tanaka, S.2

1: Chiba Institute of Technology, 2: National Institute of Health and Nutrition, 3: Ibaraki Univ, 4: Ritsumeikan Univ, 5: Research Fellowship of Japan Society for the Promotion of Science 6: Univ of T

Introduction: The causal association between physical activity (PA) and both physical fitness and motor skills in young children remains unclear. As approaches to estimate PA and fitness in this research field have been inaccurate, findings have varied among previous studies. This study investigated the influence of acquiring physical fitness and motor skills on daily PA in young children with a follow-up study. **Methods:** Participants were 85 first-grade Japanese children including 65 boys and 20 girls (7.0 \pm 0.3 years). Participants performed 11 physical fitness tests (e.g. hand grip, 25m run, standing long jump, side step, VO2 max etc.) and 12 motor skill tests to measure proficiency of motion in the first year. Motor skills were tested by Test of Gross Motor Development 2nd edition (TGMD-2). This consisted of 6 locomotor tests (run, gallop, hop, leap, jump and slide), and 6 object control tests (striking, dribble, catch, kick, throw and roll). Each motion skill test was recorded by high-speed video camera and scored by standardized check criteria. Daily PA, which in this case was time spent in moderate-to-vigorous PA (MVPA), and daily step counts were assessed using a tri-axial accelerometer in the first and second year. We asked participants to continuously wear the device on their waist for two weeks. Data that did not meet our study criteria of more than 10 hours a day and 7 days including 2 weekends were excluded from analysis. **Results and Discussion:** MVPA and daily step counts both significantly correlated with average Z score of physical fitness in the first year ($r=0.34$ and $r=0.22$). Object control ability also significantly correlated with MVPA and daily step counts ($r=0.31$ and $r=0.32$). However, locomotor ability did not correlate with PA parameters. Interestingly, physical fitness and object control ability tend to more strongly correlate with MVPA in the second year than that in the first year (physical fitness: $r=0.42$, object skill: $r=0.34$). Several studies have reported that children's PA tends to decrease as they progress to more senior years in school. However, our findings suggest that sufficient acquisition of physical fitness and motor skills in first grade, in particular object control ability, may increase the opportunity not only to participate in sports activity but also to be more active in later life. **Conclusion:** Acquisition of physical fitness and motor skills in early childhood may play a significant role in the maintenance and promotion of daily PA in elementary school children.

RISK OF FALLS IN ELDERLY IN THE ASPECT OF PHYSICAL ACTIVITY

Ignasiak, Z., Skrzek, A., Rożek, K., Stawińska, T., Postuszny, P., Pokrywka, J.

University School of Physical Education

Introduction Injuries from falls are a major cause of disability in the elderly. Improving physical fitness and especially, balance, muscle strength and endurance can reduce the risk of incidents related to falls. (Delbaere, et al. 2010, Kemmler et al., 2010 Toraman and Yildirim, 2010). There are many tests to measure the level of physical fitness. A multitude of research tools used and the results obtained thus makes it necessary to continue research in this topic. For people over age 60 one of the most commonly used protocols is Senior Fitness Test (Rikli and Jones, 2013). The risk of falls can be assessed using the FallScreen Physiological Profile Assessment (Lord et al. 2003). The aim of the study was to determine the relationship between the selected elements of physical fitness and the risk of falls. **Methods** The study was performed as a part of the Ministry of Science and Higher Education research project in Poland No. N N404 075337. In the trial 235 people were tested, including 175 women and 60 men, whose age range was between 60 and 89 years. To assess the level of physical fitness Senior Fitness Test (Rikli and Jones, 2013) was used. The level of risk of falls was determined by FallScreen Physiological Profile Assessment (short form) developed and used with the consent of the Prince of Wales Medical Research Institute in New South Wales, Australia (Lord et al. 2003). **Results** The level of risk of falls in older people in the observed group shows minor correlations with selected elements of physical fitness. The largest statistically significant correlations occurred in the group of women in dynamic balance (up-and-go subtest) and endurance (6-min walking subtest). The difference in physical fitness and risk of falls among men and women clearly decreases with age. The relationship of physical fitness and risk of falls is clearly visible in the younger group of patients (up to 70 years of age) compared with older (over 70 years). Similar observations were made by other authors (Kemmler et al., 2010, Toraman and Yildirim 2010). **References** 1. Delbaere, K., Close, J. C., Heim, J., Sachdev, P. S., Brodaty, H., Slavin, M. SEX DIFFERENCES IN FITNESS AND MOTOR COORDINATION IN PREPUBERTAL CHILDREN BEFORE AND AFTER CONTROLLING FOR MATURATION

Luz, L.G.O., Macedo do Carmo, B.C., Valente dos Santos, J., Duarte, J., Padez, C., Seabra, A., Coelho e Silva, M.J.

(1)Federal University of Alagoas (UFAL), Arapiraca, Brazil; (2)CIDAF, University of Coimbra, Portugal; (3)CIAS, University of Coimbra, Portugal; (4)CIAFEL, University of Porto, Portugal.

INTRODUCTION Childhood is a period of acquisition and refinement of fundamental motor skills believed to be essential determinants to future lifestyle. Fitness corresponds to a condition that permits the individual to carry out daily activities. Few studies devoted to sex differences considered the interrelationship among morphology, maturation, fitness and motor coordination. This study examines sex differences in fitness and coordination in prepubertal children before and after controlling for biological maturation. **METHODS** The sample

included 128 children (males: n=61; females: n=67) aged 8.0-8.9 years. The battery comprised stature (S), body mass (BM) and measurements needed to estimate fat mass (FM) and fat-free mass (FFM), and to predict mature stature (PMS). Fitness was assessed as hand grip (HG), 2-kg ball throw (2-kbBT), 60-s sit-ups (SUP), standing broad jump (SBJ), sit-and-reach (SAR), 25-m sprint (SPR), 10x5-m agility (10x5-m) and 20-m aerobic endurance run test (PACER). The Körperkoordinationstest für Kinder (KTK) was also used. Somatic maturation was expressed as % of PMS. Descriptive statistics was presented by sex and differences between males and females were initially tested using t-student test and afterwards analyses of covariance controlling for maturation. RESULTS Comparisons between sexes were significant for maturation ($t=-15.289$, $p<0.001$) and estimated FFM ($t=2.762$, $p<0.01$). No differences were founded for chronological age, S, BM neither FM. In addition, differences were noted for all physical fitness tests with the exception of SAR and PACER. Effect sizes were moderate for 2-kgBT, HG, SBJ, and 10x5-m and small for SUP and SPR. For KTK, differences between males and females were noted for one of the four items (jumping for height: $t=2.498$, $p<0.05$, small effect size). Correlations between maturation and motor items were trivial or small except for HG (males: $r=0.481$, 95%CI: 0.261 to 0.654; females: $r=0.531$, 95%CI: 0.333 to 0.684). FFM only correlated as large ($r>0.50$) for two tasks (2-kgBT and HG). When controlling for maturation boys were taller, heavier and obtain better performances in 2-kgBT, HG, and SPR. In contrast, girls performed better in PACER and in one KTK item: walking backward. DISCUSSION Interpretation of sex differences needs to be considered in the context of growth, maturation and the biological principle of scaling may be central in studies devoted to sex differences in the transition from childhood to pubertal years. EFFECTS OF AEROBIC DANCE EXERCISE ON THE LOWER LIMBS ISOMETRIC MUSCLE STRENGTH OF ELDERLY PEOPLE.

Nishizawa, T.

sigakkan junior university

In this study, aerobic dance exercise habitual to consider whether affect the prevention of sarcopenia and muscle strength in the elderly. Nowadays, as bedridden elderly persons and the nursing thereof have been the top issue which the society faces, from the viewpoint of health and welfare. It is important that elderly persons should live on their own without difficulties, it is necessary for the prevention of muscle weakness and sarcopenia for that. For prevention of muscular atrophy, muscle training is considered to be effective (Poter, 1995). Therefore, we imposed aerobic dance exercise (ADEx) once a week in health exercise class in the elderly. <Method>The period of the research is between October 8 and December 12 in 2013. During such periods, shape, physical strength, and muscle strength are monitored. The test subjects are healthy females(n=21) and their average age and standard deviation thereof are 63.63 ± 6.66 . Program of aerobic dancing exercise (ADEx): The running time of each ADEx program is around 30 minutes, with BPM of from 125 to 135. Shape measurement: Height, weight, BMI, body fat percentage (TANITA Inner scan) and hip calf, thigh circumference are measured. Test of physical strength: Stand on one leg (ability of balancing) Isometric leg muscular strength: the strength of knee flexor muscle, knee extension muscle, hip joint flexor muscle, and hip joint extension muscle are measured by Myutasu FI (Anima Corp.). <Result>Morphological changes due to ADEx were not observed. On the other hand, the balancing ability has increased which is shown in the period extension of one step stand due to the effect of the leg activity. The ADEx has not resulted in muscular hypertrophy, on the other hand, tended to be improved neuromuscular function. As for the isometric leg muscular strength, strength of all of the knee flexor muscle, knee extension muscle, hip joint flexor muscle, and hip joint extension muscle has not changed with the ADEx. The results of the calf circumference, everyone is more than 30cm. In addition, skeletal muscle mass indexes showed $6.82 \text{ kg/m}^2 \pm 1.03$, which was higher than the cut-off value of sarcopenia. There was not suspected of sarcopenia. <Conclusion>In this research, ADEx program for prevention of sarcopenia has been created and the effect on the test subjects are examined. Due to ADEx, changes in muscle hypertrophy and morphological changes were expected but did not occur. The sarcopenia has been proposed decrease in muscle strength, with a significant decrease in muscle mass. In aerobic dance, effect can be expected to prevent weakness of muscle strength. Or rather, ADEx has effective neuromuscular function improvement.

VO2MAX PREDICTION AND VALIDITY FROM EXERCISE GAS EXCHANGE IN KOREAN.

Im, J.

KAIST(Korea Advanced Institute of Science & Technology)

Introduction. The purpose of this study is to develop VO2max prediction model with variables from gas exchange, and to verify prediction model. The prediction of maximal oxygen uptake simply develops an equation to predict oxygen consumption by combining metabolic variables identified during the easy submaximal exercise and non-exercise body index correlating with maximal oxygen uptake. Method. The subjects are consisted of 590 people aged from 20's, and we separated them into sample group(n=420) and cross-validation group(n=170). We developed a model from running multiple regression analysis to the sample group, and verified it with cross-validation group. Sample group's input variables are body indexes and metabolic variables measured at 3 minute and 6 minute of Bruce treadmill protocol. From these, gender, 6 minuteVO2, weight, 6 minute HR, 6 minuteVCO2, 3 minuteVCO2 are chosen for prediction model. Results. Model 1 is $\text{VO2max}=67.486-6.323(\text{gender})+0.020(6 \text{ minuteVO2})-0.363(\text{weight})-0.107(6 \text{ minute HR})-0.012(6\text{minVCO2})+0.005(3\text{minVO2})$, model 2 is $\text{VO2max}=68.858-6.539(\text{gender})+0.020(6 \text{ minuteVO2})-0.338(\text{weight})-0.112(6 \text{ minute HR})-0.010(6\text{minVCO2})$, model 3 is $\text{VO2max}=70.960-5.897(\text{gender})+0.012(6 \text{ minuteVO2})-0.363(\text{weight})-0.142(6 \text{ minute HR})$, model 4 is $\text{VO2max}=53.456-7.368(\text{gender})+0.010(6 \text{ minuteVO2})-0.335(\text{weight})$. All 4 models have high R value($R=0.68\sim0.76$, $p<0.01$), low SEE($\pm 4.13\sim\pm 4.69$), and SEE%($10.35\sim11.75$, $p<0.01$). Also, they did not show multicollinearity. From Cross-validation, we found significant correlation between predicted and measured VO2max($R=0.70\sim0.76$, $P<0.01$). In addition, both %error($-12.13\sim14.67$) and %TE($17.1\sim22.0$) were very low, confirming its accuracy and validity. Discussion & Conclusion. This study developed prediction equation, targeting a relatively large number of healthy Korean males and females. According to a survey of previous studies by Malek et al(2004), Cooper and Store(2001) developed a prediction equation, targeting a prediction group of 522 subject(male 328, female 194). Furthermore, the models having low prediction error were identified(%TE=4.67~6.36). Bland-Altman plotting confirmed that the estimation models are reliable and have low systematic error. Thus, models from this study can be effectively utilized in exercise prescription field, and in any hospitals that can conduct graded exercise tests. Reference. THE DEVELOPMENT OF PREDICTION EQUATION FOR ESTIMATING VO₂MAX FROM THE 20M PSRT IN KOREAN MIDDLE-SCHOOL GIRLS

Park, D.H.¹, Song, J.R.¹, Lee, S.H.¹, Kim, J.S.¹, Kim, K.H.¹, Kwak, H.B.¹, Kim, C.S.²

¹Inha University (Incheon, Korea), ²Dongduk Womens University (Seoul, Korea)

Introduction Validity and reliability of the 20m progressive shuttle run test (20m PSRT) have been examined in several studies (Flouris et al., 2010; Leger and Lambert, 1982; Quinart et al., 2013), but mainly in Westerners. To date, the 20m PSRT has not been validated using Korean population. The purpose of this study was to develop and validate regression models to estimate maximal oxygen uptake (VO₂max) from the 20m PSRT in Korean middle-school girls aged 13-15 years. **Methods** The 20m PSRT and VO₂max were assessed in a sample of 194 subjects. The sample was randomly split into validation (n=127) and test-retest reliability (n=99, 32 out of 127 subjects also performed validity test) groups. 127 subjects performed a graded exercise test (GXT, stationary gas analyzer) and a 20m PSRT (portable gas analyzer) once to develop a VO₂max prediction model and to analyze the validity of the modified 20m PSRT protocol (starting at 7.5km/h and increasing by 0.5 km/h every 1min). 99 subjects performed the 20m PSRT twice for test-retest reliability purpose. **Results** Mean measured VO₂max (39.2±5.1 ml/kg/min) from portable gas analyzer was significantly increased from that measured during the GXT from stationary gas analyzer (37.7±5.7 ml/kg/min, p=.001) using the modified 20m PSRT. But it was a narrow range (1.5 ml/kg/min). The measured VO₂max from portable and stationary gas analyzers correlated at r=.88 (p<.001). Test-retest of the 20m PSRT yielded comparable results (Laps, r=.88 and final speed, r=.85). New regression equations were developed from the present data to predict VO₂max for middle-school girls: $y = .231 \times \text{Laps} - .311 \times \text{weight (in kg)} + 46.201$ (r=.74, SEE=4.29 ml/kg/min). **Discussion** There are some limitations to the study. Even if participants could be defined as a relatively heterogeneous group, the measured VO₂max did cover only a range from 23.7 to 51.3 ml/kg/min. A sample with higher diversity regarding aerobic capacity would probably have produced a more precise and strong regression equation. Another limitation is that this study validated only the 20m PSRT in Korean female aged 13-15 years. Consequently, the validity of our new equation is undetermined when applied to male subjects. Based on the results, it is concluded that (a) the modified 20mPSRT is a valid and reliable test and (b) this equation developed in this study provides valid estimates of VO₂max of Korean middle-school girls aged 13-15 years. **References** Flouris AD, Metsios GS, Famisis K, Geladas N, Koutedakis Y. SPECIFIC NECK/SHOULDER EXERCISES FOR REDUCING MUSCULOSKELETAL DISORDERS AMONG EMPLOYEES IN DENTISTRY.

Fredslund, G., Sjogaard, G.

University of Southern Denmark

Background: The prevalence of neck and shoulder pain is high among employees in dentistry being exposed to highly monotonous and repetitive work. Physical exercise in the terms of specific neck and shoulder strength training for as little as 12 minutes and up to 1 hour per week has proven to be effective in relieving neck pain among workers with monotonous repetitive work such as office workers and industrial workers (Andersen LL et al, 2011; Blangsted AK et al, 2008, Zebis MK, 2011). **Objectives:** This study determined the effect of 6 minutes strength training a day, 5 days a week, for relieving neck and shoulder pain among employees in dentistry with frequent symptoms. **Methods:** In all 41 women and 2 men with neck and shoulder pain (intensity ≥ 2 the last 3 month on a scale 0-9 and duration, ≥ 8 days the last year) were cluster randomized to a reference group (REF) or a training group (TG), who were training with elastic tubing including the exercises: shrugs, lateral raise, reverse flies, and front raise. Primary outcome was intensity of neck and shoulder pain and secondary outcome was changes in work ability on a scale 0-4. **Results:** At baseline the mean (\pm SD) pain intensity was: in the neck 5,0 (\pm 1,7) the last 3 month, and in the right shoulder 4,0 (\pm 3,1) the last week for the training group. There were no significant differences between REF and TG. Compared with REF neck and right shoulder pain in TG decreased significantly 1,22 point (TG -2,3 (\pm 1,97) and REF -1,1 (\pm 2,03)) and 1,62 point (TG -2,05 (\pm 1,78) and REF -0,43 (\pm 2,64)), respectively. In the TG - but not in REF - the work ability improved significantly from base line 1,21 (\pm 0,98) to follow-up 0,53 (\pm 0,70) compared with REF. **Conclusion:** A small amount of daily specific neck and shoulder strength training reduced neck- and shoulder pain and improve workability among employees in dentistry. **References** Andersen LL, Saervoll CA, Mortensen OS, Poulsen OM, Hannerz H, Zebis MK. FAT OXIDATION DURING EXERCISE BEFORE AND AFTER WEIGHT LOSS

Jørgensen, A.L., Lund, M., Hansen, M., Helge, J., Dela, F.

University of Copenhagen

Introduction The effects of weight loss on fat oxidation during exercise in patients with type 2 diabetes (DM2) and normal glucose tolerant subjects (NGT) are inconsistent, with findings of both elevated and decreased fat oxidation. The aim of this study was to investigate the effect of a diet and subsequent gastric bypass surgery induced weight loss on maximal fat oxidation (MFO) and Fatmax during exercise in obese men and women with and without DM2. We hypothesized that fat oxidation during exercise would increase with weight loss. **Method** 18 obese NGT and 13 obese DM2 (Age 37±2 and 40±2 yrs.; gender: 4/14 and 6/7 m/f; BMI: 44±1 and 42±1 kg/m²; FFM: 61±2 and 65±3 kg and VO₂max: 2.7±0.2 and 2.7±0.2 L/min, respectively) were included. Subjects reported to the lab four times: (A) baseline prior to weight loss, (B) after an 8% diet induced weight loss before surgery, (C) four months post-surgery and (D) 1.5 yrs. post-surgery. At each visit a Fatmax test (15W warm-up 4 min., increase 25W/3 min.) that elicits MFO and the relative intensity at which it occurs (Fatmax), a VO₂max test (75W warm-up 2min., increase 25W/1min.) and a DXA scan was performed, and fasting plasma Free fatty acids (FFA) were assessed. Results were analyzed by two way repeated measures anova. **Results** At present time 13 NGT and 9DM2 have completed the study. There was no difference in MFO, Fatmax, VO₂max, BMI, FFA and FFM. Weight loss significantly decreased MFO (NGT: (A: 328±32 B: 331±26 C:283±21 D: 237±22 mg/min) DM2: (A: 351±27 B: 326±16 C: 292±17 D: 264±27 mg/min), p<0.01), Fatmax (NGT: (A: 40±2 B: 37±1 C: 37±1 D: 33±1%), DM2: (A: 42±1 B: 39±1 C:34±2 D: 32±2%), p<0.05), FFA (NGT: (A: 702±42, B: 718±38 C: 659±29 D: 453±52 pmol/L) and DM2 (A: 645±51 B: 657±52 C: 587±61 D: 525±46 pmol/L), p<0.006), FFM (NGT: (A: 61±2 B: 60±2 C: 55±2 D: 55±3 kg) DM2: (A: 65±3 B: 62±3 C: 62±4 D: 63±5 kg) p<0.001) and BMI (NGT: (A: 44±1 B: 41±1 C: 34±1 D: 29±1 kg/m²) DM2: (A: 42±1 B: 41±1 C: 33±1 D: 31±1kg/m²), p<0.001). VO₂max (NGT: (A: 2.7±0.2 B: 2.8±0.2 C: 2.6±0.2 D: 2.6±0.2 L/min) DM2: (A: 2.7±0.2 B: 2.7±0.2 C: 2.7±0.2

D: 2.9 ± 0.3 L/min.) $p=0.12$) did not change with weight loss. There was no interaction between group and time for any parameter. Conclusion Our results show that MFO during exercise in obese is decreased and Fatmax is reached at a lower relative workload as body weight is lowered. The lower MFO may be explained by the gradually lower plasma FFA levels and thus exogenous availability of fat and the unchanged activity levels we observed. Furthermore, when MFO is corrected for the loss of FFM due to the weight loss there was no change in MFO with weight loss. We found no difference between DM2 and NGT in any parameter, suggesting that they have similar fat oxidation capacity during submaximal work.

EFFECT OF INTERACTIVE VIDEO GAMES TRAINING ON HYPERTENSION IN ELDERLY

Widjaja, W., Nguanboonmak, P., Chentanez, T.

College of Sports Science and Technology, Mahidol University

Introduction World population especially in elderly gradually increases. Elderly have a risk of suffering from various diseases because the functions of their bodies is degenerated. Although having physical activity can reduce morbidity, reverse physiological impairment and can prevent chronic disease such as hypertension. However, the elderly often engage in sedentary behaviors. An interactive video game is a virtual reality based game in which body movement is used to control the game displayed on a television screen (Maddison et al., 2007). It becomes popular in children and adolescents. It can be developed to promote health, fitness and fun. The aim of this study was to investigate the effect of exercise training using interactive video game on hypertension in elderly. **Methods** Ten volunteers with the age range of 59-69 years old and height of 150-168 cm from an elderly group at Abhakornkiartiwong Hospital, Sattahip Naval Base, participated in this study. The systolic and diastolic blood pressures of the participants were not more than 160/90 mmHg after taking the antihypertensive drugs. They were trained by using the interactive video games (Wii Fit, Nintendo), 30 min per day, 3 days per week for 14 weeks. The intensity of the game was gradually increased from 55-70% of maximum heart rate every 4 weeks until 14 weeks. Heart rate, systolic and diastolic blood pressures, oxygen consumption, percent body fat, and body weight were measured before, at the 4th week and after 14 weeks of training. **Results** The average systolic and diastolic blood pressures before, at the 4th week, and after 14 weeks training were 138, 129, 125 mmHg, and 78, 74, 72 mmHg, respectively. The oxygen consumptions were 18.5, 19.83, 21.01 ml/kg/min, respectively, before, at the 4th week, and after 14 weeks training. These results showed that heart rate, percentage of body fat, systolic and diastolic blood pressure were trend to decrease, although they did not significantly change. The oxygen consumption was increased significantly. **Discussion** The above results showed that the cardiovascular and the body composition of the hypertension patients can be improved by playing the interactive video games with the intensity of the game 70% of maximum heart rate, 30 min per day for 14 weeks as recommended by the American College of Sports Medicine (Nelson et al., 2007). Unlike conventional exercise training, the interactive video games offer fun fitness which is suitable for elderly people. **References** Maddison R, et al.(2007). *Pediatr Exerc Sci*, 19, 334-343. EFFECTS OF INCREASING THE DAILY STEP COUNT ON PHYSICAL INACTIVITY AND MENTAL HEALTH IN YOUNG ADULT FEMALES

Kumahara, H.1, Ayabe, M.2

1: Nakamura Gakuen University (Fukuoka, Japan), 2: Okayama Prefectural University (Okayama, Japan)

Introduction The understanding of the associations between the moderate-vigorous physical activity (MVPA), sedentary activity (SA) and concomitant effects on mental health in increasing the daily step count is limited. Therefore, the purpose of this study was to assess the effects of pedometer-based interventions on changes in physical activity, including the SA, and explore whether there is a concomitant effect on mental health under free-living conditions in young adult females. **Methods** Thirty young adult females, ranging from 21 to 37 years of age, were randomly assigned to an 8-week of intervention group that wore an accelerometer and were instructed to increase their daily step count by 3,000 or more from baseline ($n=16$) or a group that wore an accelerometer (with a blank display) and were instructed to maintain their usual lifestyle (control) ($n=14$), followed by a 7-week observation period. The changes in the step count and time spent engaging in physical activity of light intensity (LPA), MVPA and SA were measured by the accelerometer and self-reported during sleep and the times not wearing the device. Depressive symptoms and mood were assessed according to the CES-D Scale, at baseline, one and eight weeks of intervention and at the 7-week post intervention follow-up. A two-way repeated measures ANOVA (group \times period) was applied. **Results** After one and eight weeks of intervention and seven weeks of observation, the step count and %MVPA of the total time during which the accelerometer was worn were significantly increased compared to the baseline values ($p<0.05$). The %SA was significantly decreased ($p<0.05$), whereas the %LPA was significantly increased only at one week of intervention ($p<0.05$). Moreover, a significant correlation was found between the daily step count and volume of MVPA ($\text{METs} \cdot \text{hrs/wk}$) in the intervention group during each period of the assessment. No obvious intervention effects on the CES-D variables were observed. However, there was a significant correlation between the changes in time for LPA and the CES-D scores ($r=-0.546$, $p<0.05$) in the intervention group at eight weeks of the intervention. **Discussion** A pedometer-based intervention program increased both the daily step count and METs \cdot hrs, accompanied by an increase in the proportion of MVPA and a decrease in the proportion of SA of day-time physical activity in young adult females. However, interindividual variability in the interrelationship between the changes in the step count and MVPA was also indicated. Further studies are needed to explore the effects of physical activity interventions based on free-living conditions on mental health. **References** Bankoski A et al. INTENSITY AND VOLUME OF PHYSICAL ACTIVITY ARE ASSOCIATED WITH GOOD SLEEP QUALITY IN OLDER ADULTS

Kitano, N.1,2, Jindo, T.1, Tsunoda, K.3, Soma, Y.1, Sato, A.1, Abe, T.1, Okura, T.1

1: University of Tsukuba, 2: Research Fellow of the Japan Society for the Promotion of Science, 3: Meiji Yasuda Life Foundation of Health and Welfare

Introduction In recent years, substantial effort has been made to determine if physical activity (PA) affects the sleep of older adults. However, little is known about the intensity of PA needed to obtain a good night's sleep. Furthermore, few studies have investigated the relationship between PA and sleep using the World Health Organization (WHO) PA recommendation. The purpose of this study was to examine which intensity or volume of PA was strongly related to a good sleep in older adults. **Methods** We conducted an inventory survey of

older adults aged 65 years and older living in Kasama city, Japan who did not require nursing care or other support. Out of 10,339 participants, 6,628 had complete data (average age 73.2±6.3 years; 3,292 men, 3,336 women). To evaluate sleep, we investigated subjective sleep quality on a 4-point Likert scale, where "Very good" or "Good" and "Bad" or "Very bad" were defined as sufficient sleep and insufficient sleep, respectively. We used the international physical activity questionnaire short version to assess PA intensity and volume, and classified the amount of PA into three groups: (1) sufficiently active, i.e. meeting the WHO recommendation; (2) insufficiently active, i.e. engaging in PA but not enough to meet the recommendation; and (3) inactive, i.e. not engaging in PA. We performed logistic regression analysis adjusting for age, hypnotic use, depressive symptoms and other PA intensities that were not used as independent variables. Results Sufficiently active older men who engaged in vigorous-intensity activity were less likely to perceive of having insufficient sleep than inactive people (OR = 0.701, 95%CI = 0.500-0.983). Sufficiently active individuals who engaged in moderate-intensity activity were less likely to perceive of having insufficient sleep than inactive older women (OR = 0.647, 95%CI = 0.483-0.867). Insufficient activity was not related to good sleep quality. Discussion Our results suggest gender differences in the relationship between PA and sleep in older adults. Furthermore, following the WHO recommendation for PA may be necessary to achieve a good night's sleep. Although a number of previous studies revealed that engaging in PA is related to adequate sleep, few studies reference any gender difference in that relationship. For older men, it is possible that engaging in relatively high-intensity activity is important to obtain a good sleep, whereas low-intensity activity might be effective in older women. ASSOCIATION BETWEEN CARDIOVASCULAR AND METABOLIC DISEASE RISK MARKERS AND PHYSICAL ACTIVITY STATUS IN ADOLESCENTS

Aljaloud, K.

KING SAUD UNIVERSITY

Abstract Introduction: Some of the chronic diseases that appear in adulthood are developed in childhood stage. There are few studies investigate the association between physical activity (PA) and cardiovascular and metabolic disease risk markers using objective measurement for apparently healthy adolescents. Aim: The primary aim of the study was to investigate some of the important cardiovascular and metabolic disease risk markers in relation to PA status in apparently healthy lean adolescents. Methods: A 20 adolescents (12-17yr) (male n=12 and female n=8) attended the laboratory on two occasions. On the first session body mass, height, BMI, body fat and resting heart rate and blood pressure were recorded. Free living activity intensity was monitored using ActiGraph accelerometer (AG) for two periods of 6 consecutive days. Participants were instructed to wear AG for at least 10 hours of waking time per day. Based on the PA status, adolescents were grouped into normally active (NA) group (MVPA>300min.w-1) and low active (LA) group (MVPA<150min.w-1). Fasting blood samples (>10hrs) were obtained from participants early morning for analysis of cardiovascular and metabolic disease risk markers. Results: Physical activity status of the participants showed that NA group spend more time in moderate, moderate to vigorous (P<0.001) and vigor. & very vigorous intensity (P<0.05). In addition, LA group have higher body fat percentage significantly (P<0.01). On the other hand, NA group recorded a significantly higher predicted VO2max than LA group (P<0.05). Although cardiovascular and metabolic disease risk markers were not significantly different between groups in most examined blood marker except for fasting glucose (P<0.05), there was a strong association between active time, MVPA, and vigorous and very vigorous time with glucose, insulin and HOMA-IR (r(CI)=-0.48, P=0.03) which indicates the potential for signs of progression to metabolic disease. Conclusion: Low physical activity status (MVPA<150min.w-1) could be a sign of higher fasting insulin and HOMA-IR that could progress if physical activity is not increased to meet the recommended physical activity guidelines for adolescents. Therefore, policy makers should give a priority to enhance adolescents to achieve physical activity recommended guidelines.

HABITUAL PHYSICAL ACTIVITY, AND MOTOR COORDINATION IN CHILDREN

Draganidis, D., Stamboulis, T., Gounelas, G., Karagiannopoulou, S., Protopapa, M., Pontidis, T., Mavropalias, G., Giannakidou, D., Ermidis, G., Chatzinikolaou, A., Avloniti, A., Kambas, A.

Democritus University of Thrace

Introduction There is evidence that PA early in life promotes bone health and prevents osteoporosis later in life (Baxter-Jones et. al., 2008). However, current literature lacks comprehensive data on physical activity's contribution to bone mineral content and density in prepubescent girls. **Methods** One hundred and seventy girls were recruited from 14 primary schools in Komotini. The sample comprised 60 girls (means ± SD), age 11.00±.93 yr, weight 36.52±9.7kg., height 1.44±.07cm. PA was assessed using piezoelectric pedometers (Omron HJ-720IT-E2) and bone mineral content and density parameters were measured with dual-energy densitometry (Lunar DPX NT). A one-way Anova with adjustment for weight was conducted to check the effects of PA on bone parameters. A Sidak test was applied for post-hoc comparisons. Results A visual-binning procedure was used to classified step counts in to categories, resulting three groups (low: 5,800-8,531 steps/day; mod: 8,561-16,000 steps/day and high: 17,460-21,094 steps/day). Results revealed significant effects of PA on BMDLS (F=7.17, p<.005), BMDHIP (F=8.19, p<.001), BMDNECK (F=5.87, p<.005), BMDTRO (F=7.45, P,.001) and BMDWARD (F=13.38, p<.001). Post-hoc comparisons showed that in all comparison the 'high' PA group demonstrated better values than the other two groups (p<.005). **Discussion** A great determinant of BMD in girls is puberty (Annemieke et.al. 1997), and physical activity appears to be an important determinant too. The results of this study suggest that pedometer determined PA quantity might affect bone mineral content and density in LS, HIP, NECK, and TRO areas. More specifically, it appears that pre-pubertal girls demonstrating more than 17,000 steps/day benefited more than their counterparts with less of 16,000 steps/day. These differences were translated to higher bone strength. References Annemieke M. Boot, Maria A. J. de Ridder, Huibert A. P. Pols, et. al. (1997) Bone Mineral Density in Children and Adolescents: Relation to Puberty, Calcium Intake, and Physical Activity. EFFECTS OF FUNCTIONAL STOCKING WEARING ON REPETITION, TOTAL WORK, AND HEART RATE DURING SQUATS IN COLLEGE MALE STUDENTS

Kim, K.H.1, Lee, B.K.2, Cho, M.H.3, Shin, J.M.2, Kang, H.J.

1: DKU(Korea), 2: SMU(Korea), 3: Sikma(Seoul, Korea), *: SCHU(Korea)

Introduction Compression the knee area with a functional stocking wearing might increase performance and relieve pain. However, review of the literature revealed minimal evidence to support the use of the functional stocking. The aim of the study were to investigate

the effectiveness of functional stocking wearing on repetition, total work, and heart rate during squats in college students. Methods Healthy college 7 male students participated in this study and subjects had been involved in a weight training(22.0±2.8yrs, 174.0±5.8cm, 75.2±11.0kg). Participants performed two bouts of test in wearing and non-wearing of functional stocking by randomized order. Functional stocking(Sikma, S. Korea) was made using Osgood-Schlatter's disease and Runner's Knee taping technique. Test protocol consisted one set and four sets using 10-RM on squat exercise and measured repetition, total work, and heart rate response. Results 1-RM of subjects was 177.8±24.5kg, and 1-RM was 132.6±19.1kg. Our study showed that repetition(12.42±1.27 vs 10.00±1.1) and total work(1648.42±288.06 vs 1325.71±191.82) had significant improvement following the wearing of functional stocking compared to the non-wearing of functional stocking. There were a significant difference between Non-Stocking 4set 10-RM repetitions and Stocking 4set Max RM repetitions(6.6±1.0 & 7.3±1.1). The repetition of stocking exercise were increased 2.4 and 0.7 on 1 set and 4 set. There wasn't a significant interaction of time(after-exercise HR, 1minute HR, and 2minute HR) and on group, and a significant difference on time only. The responses of HR depend on Non-Stocking and Stocking exercise wasn't a significant difference. Discussion RM increasement by stocking was similar with kinsio taping(Lee, 2012). Possible mechanism behind functional stocking efficacy include stretch-shortening cycle by flexion resistance and extension stimulation, and improved ability to tolerate greater knee extension moments. Functional stocking application, however, didn't affect the heart rate response during squat exercise. References Lee, B.K. (2012). Effects of repetition and EMG responses of Kinesio taping on Bench press 10-RM. J. KINESIOLOGY, 14(4); 27-36. Contact * violethjk@naver.com

HEART RATE ANALASYS DURING TIPICAL SEVEN DAYS ALPINE SKIING ACTIVITY IN SEDENTARY MEN

Perić, R., Sekulić, Ž.

Institute for Sports Medicine Banja Luka. Institute for Sports Science Banja Luka

Introduction. Skiing sport enjoys more popularity than ever with this being Olympic year but nevertheless there are still high prejudices regarding this sport. It is considered to be a type of sport for high class athletes and well trained individuals. There for, the aim of this study was to prove and show high demanding skiing actually is. Methods. Four sedentary men with no physical activity in the last six months prior to the study, with no sport related professional background, age 30 ± 2, weight 100 ± 8kg and height 190 ± 8cm were examined in this study. During typical 7 days skiing holiday period they were monitored with Polar RCX5 heart rate monitor. Time spent on slopes, average heart rate (HR), maximum and minimum heart rate and calories used were monitored. Results. The study has showed that in all four subjects despite their sedentary active style, this activity did not represent a high burden for their cardiovascular system. There are five basic zones based on HR used to classify different intensities of training. First zone is used for recovery (50%-65% HR) and it's considered very light intensity activity. Second zone represents light activity (65%-75%HR) and it's used for endurance training and fat burning. Third zone is moderate (75%-85%HR) and represent the high activity. Our subjects averaged HR 105bpm, with average 50% of time spent in first zone, 42% time spent in second zone and only 6% time spent in third zone. Heart rate variability was 61bpm to 161bpm. Average time spent on the slopes daily was 5:11:31 h. Average daily calories usage was 2865 cal or averaging 561cal/h. In energy production fat percentage of calories was average 33%. Discussion Based on data obtained we can conclude that this training improved their general base fitness and basic aerobic endurance, and boosted their metabolism. Their body ability to store oxygen within the cardio system and muscles improved. Because the training session was long (>5h), effects are expected to be stronger. Fat is the main energy source that their body uses at this training intensity, thus preserving their glucose storage's. With time spent on the slopes and time spent on the lifts, this form of activity was defined as interval training. With averaging 561cal/h their activity should be considered high but according to their HR it was low to moderate. We can conclude that during typical seven days skiing holiday with long time spent on slopes, skiing did not represent any workload on cardiovascular system and there for can be recommended as an physical activity for young, old, active, sedentary, man and women looking to improve their basic fitness without any hazard for cardiovascular system. Although skiing can be great for the body, individuals need to careful in order to avoid any injuries. References. none Contact. ratkoperic@yahoo.com

EFFECT OF A PUBLIC HEALTH PHYSICAL EXERCISE PROGRAM ON CARDIORESPIRATORY FITNESS AND INFLAMMATORY BIOMARKERS

Papini, C.B.1, Nakamura, P.M.1, Zorzetto, L.P.1, Bertucci, D.R.2, Thompson, J.L.3, Kokubun, E.1

1: UNESP (Rio Claro, Brazil), 2: UFSCar (Sao Carlos, Brazil), 3: UoB (Birmingham, United Kingdom)

Introduction "Saúde Ativa Rio Claro" (SARC) is a public health physical exercise intervention designed to promote and maintain physical activity levels of residents in Rio Claro City, Brazil. It reaches approximately 400 low-income adults (aged 35 years or older) (Nakamura et al., 2010). Evidence suggests this program improves blood cholesterol, LDL, HDL and glucose (Zorzetto et al., 2013). The aim of this study was to analyze the impact of SARC on Cardiorespiratory Fitness (CF) and Inflammatory Biomarkers (IB). Methods This 1-year quasi-experimental study involved 18 women (mean age=56.6±12.3 years). The intervention was comprised of 2, 60-minute sessions/week of moderate intensity aerobic and strength-training exercises. Changes in CF were measured via submaximal incremental treadmill test (85% HRmax) at baseline (BL) and 1 year (1Y) using indirect calorimetry. IB (IL10, IL6, TNF-α and insulin) were measured in a fasting blood sample at BL, 6 months (6M), and 1Y using Luminex Kits. Paired student t-test was used to test for differences in CF; ANOVA and Scheffe post-hoc tests were used to test changes in IB. Statistical analyses were conducted using SPSS 17.0 (significance p<0.05). Results Analyses indicated significant decreases in TNFα (pg/ml) at 6M and 1Y (BL=11.92±6.4, 6M=7.37±4.1, 1Y=5.65±3.1, p=0.04), significant increases in CF (BL=18.9±6.2 ml.(kg.min)⁻¹, 1Y=21.3±5.5 ml.(kg.min)⁻¹, p=.001). Participants significantly increased the final stage completed during the treadmill test (BL=2.8±1.7 and 1Y=4.6±2.3, p=0.02). There were no significant changes in IL10, IL6 or insulin. Discussion SARC was effective in reducing TNFα. There is lack of consensus in the literature as to whether physical activity can lower systemic inflammation (Halle et al., 1998). It may be that the frequency, intensity and duration of the intervention were not sufficient to improve insulin or other IB. The increase in submaximal oxygen uptake suggests that SARC may be effective in improving CF, with the increase in the final treadmill stage at 1Y suggesting improved lower limb strength. These results illustrate that a public health exercise intervention can be delivered in low-income communities. Future research should test the effectiveness of this intervention within a definitive, large-scale randomized controlled trial. References Nakamura PM, Papini CB, Chiyoda A et al. IMPACT OF TRAINING FREQUENCY AND SUPERVISION ON COMPLIANCE WITH STRENGTH TRAINING AND SUBSEQUENT CHANGES IN NECK PAIN AND MUSCLE PERFORMANCE

Dalager, T.1, Bredahl, T.1, Pedersen, M.T.2, Boyle, E.1, Andersen, L.L.3, Sjøgaard, G.1

1: University of Southern Denmark, 2: University of Copenhagen, 3: National Research Centre for the Working Environment

Background: The workplace as a setting for implementing physical exercise programs has increased over the last decades. However, compliance among study participants is still a challenge, which may influence the effectiveness of studies. The aim of the present study was – for training with the same total target training volume/week, performed with differently scheduled training frequencies/durations or with different levels of training supervision - to determine the effect on 1) compliance, 2) neck pain, and 3) muscle performance. **Method:** A total of 571 office workers were cluster-randomized to: 1) one 60-min session/week with supervision (1WS), 2) three 20-min sessions/week with supervision (3WS), 3) nine 7-min sessions/week with supervision (9WS), 4) three 20-min sessions/week with minimal supervision (3MS), or 5) a reference group without training (REF). One hour of strength training for neck and shoulders was applied for 20 weeks within working hours, progressing from 20RM to 8RM (Repetition Maximum). Outcomes were diary-based compliance and training volume, self-reported neck pain (0-9, VAS scale) and muscle performance (1RM lateral raise for strength and no. reps for 1RM-1kg for endurance). Comparisons were made across 1WS, 3WS and 9WS, and between 3WS and 3MS. If no difference, training groups were collapsed (TG) and compared with REF. Means and proportions with 95 % confidence intervals adjusted for clusters were calculated for differences across groups, and paired t-test was conducted to determine significant changes. Analyses were performed on diaries (N=361) and compliant study participants (N=328), though test of muscle performance only was performed by 198 representative participants. **Results:** Compliance was similar across 1WS, 3WS and 9WS as well as between 3WS and 3MS, mean(range): 39(33-45) % of all sessions. Training volume ranged from 11977 kg for 3MS to 15297 kg for 9WS, with no significant difference across groups. Neck pain did not differ across groups at baseline, mean(SD): 3.3(2.3), and improved significantly in all five groups, TG by 40(60) % but by only 22(56) % in REF. Strength/endurance was not different across groups at baseline: 7(3) kg / 11(4) reps, and increased significantly in the four training groups (TG: 9(15) % / 33(48) %), the latter being significantly larger than in REF. **Conclusion:** Regardless of training schedule and training supervision, similar degrees of compliance were shown together with improved neck pain and muscle performance. These findings provide evidence that a great degree of flexibility is legitimate for companies and employees in planning future implementation of physical exercise programs at the workplace.

History

RESEARCH REGARDING THE OCCURRENCE OF NEW ELEMENTS FOR VAULTING TABLE PERFORMANCE IN WOMEN'S ARTISTIC GYMNASTICS

Nakasone, M.

university of Biwakoseikei sports

Introduction More recently a total of 600 elements have been recorded in the Gymnastics Code of Points. However there are few theses on elements of gymnastics history. As such we wonder by whom, when or where these various elements are performed. The purpose of this study was to collate data elements on the Vaulting Table (VT) in women's artistic gymnastics and to suggest new elements in the future. **Methods** The method of study was undertaken by bibliographic analysis. This article refers mainly to journals that were published by the Japan Gymnastic Association, and a list that was made regarding the occurrence of new elements on VT in women's artistic gymnastics. **Results** From the analysis, the author gathered data regarding various elements that were performed. For example, the round off, backward handspring and salto stretch (Yurchenko) was performed by YURCHENKO.N in the 1982 Moscow Newscup. A Yurchenko stretch with a double twist was performed by AMANAR.S in the 2000 European Championships. This element is performed by many top women gymnasts. Another example, a sideward handspring with a 1/4 twist and backward tucked salto (Tsukahara) was performed by TURISCHEVA.L in the 1974 World Championships. Additionally, the Tsukahara stretch with a double twist was performed by a Cuban woman gymnast. In recent years, the round off, 1/2 twist and forward handspring and forward stretched salto with a 3/2 twist was performed by CHENG.F in the 2005 World Championships. From 2005 onwards, new elements on the VT in women's artistic gymnastics were not performed. **Discussion** In conclusion, developments of VT elements are greatly influenced by the improvement of apparatus, rules of the era and improved skills of men's gymnastics. As a result, we have to pay attention to changes to the Men's Code of Points. In the near future, directions of new occurring elements on the VT may add twists to the existing elements. **References** Mitsuhiro.N.(1972).Japan gymnastics association Study of information, 30 29-33. Molecular Biology

EFFECTS OF 6WEEKS SWIMMING TRAINING ON AMMONIA METABOLISM IN SKELETAL MUSCLE IN MICE.

Takeda, K., Takemasa, T.

University of Tsukuba

Introduction During exercise, skeletal muscle release ammonia, which is thought to be one of the factors for fatigue. Therefore, suppression of ammonia production and immediate ammonia detoxification is desirable. However, the effects of training on ammonia metabolism, and its related factors in skeletal muscle are not clarified. The aim of this study was to investigate effects of 6 weeks swimming training on blood ammonia level and changes of ammonia metabolism in skeletal muscle. **Methods** Thirty-six mice were divided into three groups (n=12 per each group), and training groups (END or HIIT) performed swimming training 5 times per week for 6 weeks. END (Endurance) group swam without any weight burden for 30 minutes for 2week, then exercise duration increased 30 minutes every 2 weeks. HIIT (High-intensity interval training) group repeated 10 sets of 20 seconds swimming with a load of 10% body weight attached to their tails, with 10 inter-set seconds rest. Con (Control) group did not any swimming training. After 6 weeks training, mice were carried out swimming performance test with a load of 9 % body weight until exhaustion. Then blood and skeletal muscle samples were collected. **Results** HIIT showed significant prolongation of the swimming duration to exhaustion compared with Con. END also have tendency to be prolonged the exercise time. Though blood lactate at the end of swimming performance test significantly increased by exhaustive swimming in all groups, no significantly differences were observed among the groups. Blood ammonia increased by exhaustive swimming in all groups. However, both END and HIIT showed lower level of ammonia than Con. Glutamine Synthetase (GS), participate ammonia

detoxification, significantly increased in END group, and similar trend was observed in HIIT. AMP is deaminated to IMP during the resynthesis of ATP, which is catalyzed by AMP deaminase (AMPD). AMPD expression did not alter in both trained groups. Rhbg and Rhcg are the mammalian ammonium transporter family. There were no changes in Rhbg and Rhcg protein level by swimming training. Discussion 6 weeks swimming training, both endurance and high intensity interval, enhanced exercise performance and depressed blood ammonia level. These results suggest that suppression of ammonia during exercise may participate progression of exercise performance. But, ammonia metabolism related factor, except for GS protein, did not alter by swimming training. We could not find the differences between skeletal muscle types. Since critical factor contributing ammonia metabolism could not be identified in this study, further researches are needed to clarify the mechanism of ammonia metabolism during physical exercise. OXIDATIVE STRESS AND AGING: THE RELATIVE ROLE OF REGULAR EXERCISE

Mota, P.1, Soares, J.F.1, Santos, Z.A.1, Pereira, A.2, João, P.V.1, Oliveira, M.M.3, Peixoto, F.4, Gaivão, I.4

1: UTAD (Vila Real, Portugal), CIDESD; 2: IPS (Setúbal, Portugal), CIDESD; 3: UTAD (Vila Real, Portugal), CQ; 4: UTAD (Vila Real, Portugal), CCAV

The oxidative stress theory of aging states that an imbalance between oxidants, antioxidant and repair cell mechanisms, in favor of the primer one, should promote degenerative processes accelerating aging. However, several behaviors that improve health and possibly decrease the rate of aging also favor oxidative stress. Exercise is one of these factors but in what concerns to human studies, there are some inconsistencies in oxidative stress results, though functionality and health parameters usually improve. These inconsistencies might result from methodological constraints related with the blood sample collection, which may have occurred inside the acute physiological response to exercise period. Having this in mind, the main aim of this study was to verify the effects of an exercise program on oxidative stress parameters in human lymphocyte and plasma. Methods Forty five males and fifty two women over 40 years of age (from 40 to 82 yrs) engaged in an exercise program that lasted for 16 weeks (3 sessions of 60-90 min per week on non-consecutive days of aerobic and resistance training). DNA damage was quantified by comet assay with FPG enzyme. Lipid peroxidation was addressed through TBARS and total antioxidant capacity was measured by ABTS method. Blood sample collection occurred in fasting condition, being the subjects advised not to perform any intense activity in the previous 72 hours. An ANOVA with repeated measures was used to analyze differences between groups, and the effect of exercise. Significant level was set at $p < 0.05$. Results Our results revealed that exercise program induced significant lower DNA damage in both men and women, and a tendency to decrease TBARS concentration. Total antioxidant capacity increased significantly in women but not in men. All the subjects increased their functional capacity with the exercise program. Discussion Our results pointed to the importance of exercise in oxidative damage regulation, decreasing damage parameters and increasing preventive mechanisms of antioxidant capacity. This study was supported by Foundation of Science and Technology, project PTDC/DES/121575/2010.

WNT INDUCES SATELLITE CELL ACTIVATION IN ADULT AND AGED MICE AFTER VOLUNTARY WHEEL RUNNING

Fujimaki, S.1, Hidaka, R.2, Asashima, M.2, Takemasa, T.1, Kuwabara, T.2

1: University of Tsukuba, 2: National Institute of Advanced Industrial Science and Technology (AIST)

Introduction Muscle represents an abundant, accessible, and replenishable source of adult stem cells. Skeletal muscle-derived stem cells, called satellite cells, play essential roles in regeneration after muscle injury in adult skeletal muscle (Fujimaki et al., 2013). Although the molecular mechanism of muscle regeneration process after an injury has been extensively investigated (Charge and Rudnicki, 2004), the regulation of satellite cells under the steady state during the adult stage, including the reaction to exercise stimuli, is relatively unknown. Here, we investigated the effects of exercise in adult satellite cell conversion focusing on Wnt signaling, which plays important roles in lineage control during embryonic myogenesis and postnatal development. Methods Male C57BL/6J mice ages 8–12 weeks (adult) and 24 months (aged) were used and divided into control group and runner group in this study. Runner group mice were housed individually in cages equipped with a running wheel and performed voluntary wheel running for 4 weeks. Control group mice were housed in cages without a running wheel. After 4 weeks of exercise, mice were sacrificed and the gastrocnemius muscles were dissected out quickly from each mouse for subsequent analyses. Results & Discussion We demonstrated that voluntary wheel running exercise, which was a low-stress exercise, converted satellite cells to activated state due to accelerated Wnt signaling. Our analyses showed that upregulated canonical Wnt/ β -catenin signaling directly modulated chromatin structures of both MyoD and Myf5 genes, resulting in increases in the mRNA expression of Myf5 and MyoD and the number of proliferative Pax7(+)Myf5(+) and Pax7(+)MyoD(+) cells in skeletal muscle. The effect of Wnt signaling on the activation of satellite cells, rather than Wnt-mediated fibrosis, was observed in both adult and aged mice. The association of β -catenin, TCF, and LEF transcription factors of multiple TCF/LEF regulatory elements, conserved in mouse, rat, and human species, with the promoters of both the Myf5 and MyoD genes drives the de novo myogenesis in satellite cells even in aged muscle. These results indicate that exercise-stimulated extracellular Wnts play a critical role in the regulation of satellite cells in adult and aged skeletal muscle. References Charge, S. MOLECULAR ADAPTATIONS IN MOUSE SKELETAL MUSCLE FOLLOWING ECCENTRICALLY VERSUS CONCENTRICALLY BIASED TRAINING

Hody, S.1, Lacrosse, Z.1, Simonet, A.2, Leprince, P.1, Croisier, J.L.2, Rogister, B.1

University of Liege

Introduction The molecular adaptations specifically induced by different muscle contraction types have only been partially elucidated. We previously demonstrated that eccentric contractions in human quadriceps elicited proteome modifications that suggest a muscle fiber typology adaptation (Hody et al. 2011). We address this question in a more systematic way by examining the effects of different running modes on the mouse muscle proteome and the muscle fiber typology on the whole quadriceps. Methods Male adult mice (C57BL6) were randomly divided into downhill running (DHR, quadriceps eccentrically biased contractions), uphill running (UHR, quadriceps concentrically biased contractions) and untrained control (CONT) groups. Running groups performed five training sessions on an inclined treadmill for 75 to 135 min/day and the quadriceps muscles were dissected 96 hours after the last session. Muscle protein extracts of DHR and UHR groups (n=4/group) were subjected to a 2D-DIGE analysis coupled with mass spectrometry. The assessment of fiber type, size and number was performed on the rectus femoris of the three groups (n=6/group) using myosin heavy chain (MHC) immunofluorescence.

Results In the proteomic analysis, eight spots identified as the fast MHC isoforms exhibited a lower abundance in DHR compared to UHR ($p < 0.05$, t-test). In contrast, ATP synthase subunit α and tubulin β were more expressed in DHR ($p < 0.05$). Immunohistological analysis revealed a significant higher proportion of type I and IIa fibers for DHR compared to UHR or CONT groups ($p < 0.05$, one-way ANOVA). Discussion Our data demonstrate that the eccentrically biased contractions in mice induced specific adaptations in protein expression as well as in muscle fiber type and size which may reflect a more oxidative muscle phenotype. The differences in stress placed on the muscle between both trainings may be responsible for some unique adaptations resulting from the eccentrically biased training. Eccentric training is known to protect skeletal muscles against exercise-induced muscle damage (EIMD) which may occur after intense eccentric contractions (Chen et al. 2010; Hody et al. 2011). It is also suggested that fast glycolytic muscle fibers are more vulnerable to EIMD than oxidative fibers (Lieber and Friden, 1988). Therefore, it would be interesting to investigate whether the molecular changes induced by an eccentrically biased training are involved in protection against EIMD. CHRONIC PHYSICAL EXERCISE DECREASES GLUCONEOGENESIS AND FASTING PLASMA GLUCOSE THROUGH MODULATION OF MKP-3 AND FOXO1 PROTEIN IN THE LIVER OF OBESE MICE

Moura, L.P.1, Pauli, L.S.S.2, Ropelle, E.C.C.2, Souza, C.T.3, Cintra, D.E.2, Silva, A.S.R.4, Rodrigues, B.A.2, Marinho, R.1, Oliveira, V.2, Katashima, C.K.2, Ropelle, E.R.2, Pauli, J.R.2

1: UNESP (Rio Claro, Brazil), 2: UNICAMP (Limeira, Brazil), 3: UNESC (Criciúma, Brazil), 4: USP (Ribeirão Preto)

Introduction: Insulin resistant is commonly associated with excessive hepatic glucose production. In this regard, increased activity of phosphatases may contribute to the dysregulation of gluconeogenesis. MKP-3 (mitogen-activated protein phosphatase-3) is a key protein involved in the control of gluconeogenesis. MKP-3-mediated dephosphorylation activates FoxO1 (a member of forkhead family of transcription factors) and subsequently promotes its nuclear translocation and binding to the promoters of gluconeogenic genes such as phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6Pase). Aim and methods: Once that the physical exercise has been reported as an important tool in the treatment of obesity and diabetes, in this study, we investigated the effects of exercise training on the expression of MKP-3 and its interaction with FoxO1 and the expression of gluconeogenic genes (PEPCK and G6Pase) in the livers of obese animals (high fat chow ingestion) after an moderate aerobic training program. Firstly, mice were divided into two groups: regular (control) and high fat chow during 8 weeks. After that, four groups were created: Control and Obese mice, sedentary or submitted to swimming exercise (1h/day, 5 days/week, during 8 weeks), wearing caudal dumbbells weighing 5% of their individual body weight. To assess physiological alterations, the insulin tolerance test (ITT), pyruvate tolerance test (PTT), fasting glucose and serum insulin were analysed. To assess protein expression and association the immunoprecipitation and immunoblotting process were used. Results and Discussion: Exercised obese mice had lower expression of MKP-3 and FoxO1/MKP-3 association in the liver. Further, the exercise training decreased FoxO1 phosphorylation and protein levels of PGC-1 α and gluconeogenic enzymes (PEPCK and G6Pase). These molecular results were accompanied by physiological changes, including increased insulin sensitivity and attenuated hyperglycemia, not associated to reductions in total body mass. In conclusion, in this study we demonstrated that physical training is capable of reducing insulin resistance in the liver, by reducing the inflammatory process, through the inhibition of MKP-3 and subsequent suppression of the gluconeogenic program in obesity rats. TRANSCRIPTIONAL CHANGES IN BLOOD AFTER AEROBIC TRAINING IN URBAN VERSUS RURAL ENVIRONMENT

Bos, I.1,2, De Boever, P.2, Int Panis, L.2, Meeusen, R.1

1: VUB (Brussels, Belgium); 2: VITO (Mol, Belgium)

Introduction Particulate matter (PM) exposure was ranked 9th among the leading risk factors for global disease burden in 2010 due to negative health effects (Lim et al., 2012). The aim was to investigate for the first time transcriptional changes in blood leukocytes in response to aerobic training in a rural location compared to an urban location where PM levels are substantially higher. Methods Healthy, untrained subjects participated in a 12-wk aerobic training program (3x/wk), one group in an urban location (n=15), another in a rural location (n=9). Ultrafine particle (UFP) levels at the training locations were measured during the training sessions. Before and after the training program fitness levels were measured via the Cooper test and blood leukocyte gene expression profiles were determined using the Whole Human Genome microarray kit (Agilent Technologies). Differential gene expression (FDR-corrected P-value < 0.05, absolute FC > 1.5) was identified using the Bioconductor Limma package in R and classified using DAVID Bioinformatics Resources v 6.7 and the databases Gene Ontology (GO) biological process and Kyoto Encyclopedia of Genes and Genomes (KEGG) biochemical pathways. Results UFP levels were higher ($p < 0.01$) in the urban location (7240 particles/cc) compared to the rural location (5621 particles/cc). Fitness levels improved ($p < 0.001$) in both groups equally. We found that 317 genes (288 up, 29 down regulated) were similarly affected after the training in both locations. The up regulated gene expression was linked to GO biological processes defense response, cell death, wound healing, blood circulation, hormone-mediated signaling, regulation of leukocyte mediated immunity, and activation of MAP kinase activity and KEGG pathways hematopoietic cell lineage, chemokine signaling pathway and cytokine-cytokine receptor interaction ($p < 0.05$). We found an interaction effect between exercise and training location for 148 genes (9 up, 139 down regulated) and 23 genes (4 up, 19 down regulated) that were differentially expressed after the training program in the urban and the rural location, respectively. The down regulation in response to urban training was linked to GO biological processes cell death, cellular metabolism and energy, vesicle mediated transport and the KEGG lysosome pathway ($p < 0.05$). Discussion The findings show a partly overlapping gene expression response to training in both locations. The overlap might reflect training-related adaptations. However, we found a different response in the expression of a group of genes linked to cell death, cellular metabolism and energy, vesicle-mediated transport and the lysosome after the training in the urban location compared to the rural location. VARIATION WITHIN THE MMP3 GENE AS A RISK FACTOR FOR ACHILLES TENDON PATHOLOGY IN A BRITISH POPULATION

El Khoury, L., Ribbans, W.J., Raleigh, S.M.

University of Northampton

Objective: Achilles tendon pathology (ATP) is a multifactorial condition with a recognised genetic component. The MMP-3 enzyme regulates extracellular matrix homeostasis by degrading various types of collagens. The matrix metalloproteinase 3 (MMP3) gene has previ-

ously been associated with the risk of developing ATP in a South African Caucasian population. The purpose of this study was to determine whether the MMP3 rs679620 variant that was associated with ATP in South Africans was also a risk factor for ATP in a recently recruited British Caucasian population. We also sought to establish, in a preliminary manner, whether the variant was associated with additional clinicopathological characteristics of our cohort. Methods: 252 (121 cases with ATP and 131 asymptomatic controls) British Caucasian participants were recruited for this case-control genetic association study. All participants were genotyped for the MMP3 G/A rs679620 variant using TaqMan technology. Data was analysed using chi-squared and ANOVA tests with significance set at $p < 0.05$. Results: There was no significant ($p = 0.349$) difference in genotype distribution frequency between the ATP and control groups. However, when we restricted our analysis to include only individuals with Achilles tendon rupture, we found a significant ($p = 0.029$) difference in genotype distribution frequency between this group (AA, 31.4%; AG, 31.4%; GG, 37.1%) and the controls (AA, 26.7%; AG, 54.2%; GG, 19.1%). Furthermore, we found that male participants with tendinosis and the GG genotype had significantly ($p = 0.007$) thicker Achilles tendons compared to the AG and AA genotypes. Conclusion: This study shows that the MMP3 rs679620 variant was not associated with ATP when the condition was analysed as a single clinical entity. However, we did show that the GG genotype was significantly associated with both the risk of Achilles tendon rupture and increased tendon width in males with tendinosis. Although these data show some contrasts with a previously published study in South Africans they do enhance our understanding of the role of the MMP3 rs679620 variant in predisposing to Achilles tendon injury.

THE EFFECTS OF LACTATE ON SKELETAL MUSCLE ADAPTATION

Willkomm, L., Gehlert, S., Schubert, S., Borde, J., Jacko, D., Bloch, W.

German Sports University Cologne

Regular exercise and physical activity are cornerstones in the prevention and treatment of numerous chronic conditions. The associated health benefits arise from a number of tissues but due to its high plasticity skeletal muscle plays a pivotal role. The resident stem cells of skeletal muscle tissue, so called Satellite cells (SCs), contribute significantly to skeletal muscle adaptation and hence, maintenance of healthy tissue. The specific stimuli regulating SC development, i.e. activation, proliferation, and differentiation, depend on the form of exercise and consist of hormonal, mechanical, and metabolic signals. Among these, the importance of metabolic stimuli such as Lactate (La) remains least described. La is produced continuously under aerobic conditions, but elevated levels occur during exercise when glycolysis is increased. Therefore, one aim of this study was to identify the phenotypical effects of high La levels as observed during resistance or high intensity endurance training on the proliferation and differentiation in a model of activated SCs, C2C12 cells. Furthermore, possible signalling targets for La, such as p38 mitogen-activated protein kinase (p38 MAPK), and subsequent histone modifications were investigated. Lastly, to confirm the observed mechanisms in vivo, a human intervention study was conducted. Treatment with La (10 mM, 20 mM) increased withdrawal from the cell cycle and initiated early differentiation in C2C12 cells as analysis of gene expression and protein patterns of cell cycle and differentiation markers revealed. However, La delays late differentiation in a dose-dependent manner. La-induced production of ROS might at least be partly responsible as the effects were reversible by the addition of several antioxidants. Observed downregulation of p38 MAPK activation and its downstream modifications histone 3 lysine 4 (H3K4) and histone 3 lysine 27 (H3K27) trimethylation suggests that La inhibits late differentiation progress by this mechanism which is crucial for muscle specific gene transcription. Additionally, it was demonstrated that diminished p38 MAPK activation and subsequent histone modifications are conserved during differentiation and in differentiated muscle tissue in vivo. Conclusively, the reported data confirm that La modifies skeletal muscle adaptation via a ROS-sensitive signalling network by delaying late differentiation of SCs, an important mechanism of skeletal muscle adaptation. This conclusion implies reassessment of traditional views on training design and periodisation in order to accelerate skeletal muscle adaptation.

Motor Learning

DOES BANDWIDTH-FEEDBACK FACILITATE MOTOR AUTOMATIZATION?

Agethen, M., Krause, D.

University of Paderborn

Introduction According to Maxwell et al. (2001) we assume that feedback (FB) schedules with a high error frequency (EF) are supposed to induce more attentional control processes with the aim of correcting the movement and therefore explicit learning. However, automatization, hallmarked by the formation of a representation that is mostly attention-independent therefore becomes limited, whereas FB with lower EF (e.g. bandwidth-feedback) could positively influence the automatization process. This assumption, which has not been taken into account in earlier studies (e.g. Lee & Carnahan, 1990), is examined in the present experiment. Methods 48 Subjects had to learn to trigger three turning points as precisely as possible in an el-bow-extension-flexion-sequence on a lever device. In both, a pre- and retention-test (factor time of measurement (TOM)), this movement as well as an n-back-task were conducted as a single- and a dual-task (factor STDT; criterion-task prioritised). Parallelized according to pre-test results, the subjects were assigned to 3 interventional (IG) and 1 control group (CG). The groups IG-100 (100 percent quantitative FB), IG-BW (bandwidth: quantitative FB or positive qualitative FB on errors < 10 deg.) and IG-Yoked (only quantitative FB on the same trials as the research-twin from IG-BW) practiced the movement on 5 consecutive sessions with a total of 760 repetitions. Dependent variables were errors per trial for the cognitive task (n-back-error) and the absolute error (AE) Results The IG-BW, $p = .001$, part. $\eta^2 = .66$, and IG-Yoked, $p = .017$, part. $\eta^2 = .42$, show a re-duction of dual-task costs (DTC) for the n-back-error (interaction TOM x STDT). The IG-100, $p = .793$, part. $\eta^2 < .01$ and CG, $p > .999$, part. $\eta^2 < .01$, do not show a re-duction in DTC. The interaction (TOM x STDT x group) for the IG-BW and the IG-Yoked is not significant, $p = .056$, part. $\eta^2 = .16$. There are no significant effects, for the AE with the factor group. Discussion Only the IG-BW and the IG-Yoked show a significant reduction of DTC for the variable n-back-error. This is interpreted in terms of an automatization of the arm movement, as there is no indication for effective task integration as an alternative explanation (no reduction of DTC in the CG). Since the interaction (group x STDT x TOM) between the IG-BW and the IG-Yoked fails to reach significance very short, there might be a positive effect by the additional positive quantitative feedback in the IG-BW. The more considerable part of the DTC reduction seems to be justified in the reduced frequency of error feedback. References Lee TD, Carnahan H (1990). Quart J Exp Psychol [A], 42A, 777-789. TO INVESTIGATE THE BASIC MOTOR CHARACTERISTIC DIFFERENCES BETWEEN 7 YEARS OLD STUDENTS LIVING IN CITIES AND RURAL AREAS OF KUTAHYA

Gulac, M.1, Kalkavan, A.2

1Dumlupınar University, 2Karadeniz Technical University

Introduction: Urban and rural environmental differences in growth of children have come into focus of interest in the last years. There are several studies which have reported contradictory evidences in samples from various countries and cultures and with various age ranges. (Amir D., et al., 2011). Time spent outdoors and availability of space in close proximity may be especially important for younger children, as they need to depend on other people for their transportation to places where they can be physically active (Constantinos A. et al., 2004). The purpose of this study is to investigate The Basic Motor Characteristic differences between 7 years old female students living in cities and rural areas of Kutahya. **Methods:** The sample consisted of 40 (20 urban and 20 rural; age 7 years) girls with no medical history of disease. The test of TGMD-II which widely used to measure basic motor characteristics was applied as measurement method. As statistics method, Firstly Kolmogorov-Smirnov normality tests was performed. To determine whether there is a significant difference between the groups, Independent-Samples T-Test was performed in the level of significant $\alpha=0.05$. **Results and Discussion:** The average height of the participating in the study is $111,70 \pm 6,65$ and the average of body weight in the participating is $19,91 \pm 3,41$. The results of this study were showed that significant difference between TGMD-II locomotors test scores ($p < 0.05$), between TGMD-II object control test scores ($p < 0.05$) and between the total scores of TGMD-II who lives in city center and rural areas in Kutahya ($p < 0.05$). The obtained results of this research were same as these researches (Esmail Z.S., 2010, Norbakhsh, P., 2007) based on that rural students were more better than urban students in motor-perceptual abilities. These results determined that the rural environment is rich for obtaining experiences because rural children have less environmental constraints & have more freedom action for doing motor activities. **References** A, Dana, Z. AUGMENTED FEEDBACK VERSUS FOCUS OF ATTENTION: EFFECTS ON JUMP PERFORMANCE

Ruffieux, J., Taube, W., Gottschalk, M., Keller, M.

University of Fribourg

For both, elite sports and rehabilitation, it is essential to use training regimens that lead to maximum adaptations. Factors like an external focus of attention (EF) or provision of augmented feedback (AF) have been shown to improve performance (Wulf & Dufek, 2009; Figoni & Morris, 1984). However, it is not known whether AF simply shifts the focus of attention to an external target or whether AF acts differently than EF. The aim of the present study therefore was to compare the efficacy of providing AF with the effects of EF or an internal focus of attention (IF). For this purpose, the performance in a countermovement jump (CMJ) was assessed as outcome parameter in the three conditions (AF, EF, and IF). Nineteen volunteers performed twelve series of maximum CMJs. Differences between conditions and alterations of jump height within the series were analyzed. Ground reaction forces as well as electromyographic activity were recorded. Jump heights differed between conditions ($p < 0.001$) and the highest one was observed in AF (32.04 ± 7.11 cm), followed by EF (31.21 ± 6.67 cm) and IF (30.77 ± 6.87 cm). Significantly different ($p < 0.001$) within-session effects with higher jump heights at the end of the series in AF (+1.45%) and lower jump heights in EF (-2.06%) and IF (-1.92%) were observed. Muscular activity and onset times did not change between conditions. However, we found differences in ground reaction forces that might (partly) explain the differences in jump height. The present study reports for the first time that providing AF leads to better performance and better progression within one series than using an EF or an IF. Thus, the increased performance in response to AF cannot simply be attributed to a shift of the attention towards an external target. The most likely explanation in our point of view is an increase in motivation due to the fact that the first jump of the AF condition was already higher than the jumps in the IF and EF conditions. Consequently, AF should be preferentially included into the daily training of athletes. Wulf, G., & Dufek, J. S. (2009). PERFORMANCE IN PRACTICAL TRAINING SETTINGS CAN ONLY BE IMPROVED WITH USE OF AUGMENTED FEEDBACK

Leukel, C., Coza, A., Gollhofer, A.

University of Freiburg

Introduction: Motor learning most often requires sensory feedback (e.g. vision, proprioception). A special type of feedback, termed augmented feedback (aF), refers to explicit information about movement performance. So far, many studies showed that aF may improve performance to a higher extent than with just "natural" sensation (Leukel and Lundbye-Jensen, 2012). However, most previous experiments were conducted in the laboratory and not designed to be applicable in praxis. The aim of the present study was therefore to investigate the use of aF in two practical settings. **Methods:** 40 healthy subjects (24 ± 4 years) participated. The influence of aF on performance improvements were tested in two settings, i) vertical jumps performed in basketball training ($N = 18$, 9 subject aF, 9 subjects no aF), and ii) lateral shuttle runs performed in soccer training ($N = 22$, 11 subjects aF, 11 subjects no aF). Subjects exercising i) vertical jumps received aF about their jump height directly after performing jumping exercises with a basketball. We instructed subjects to jump as high as possible. Subjects completed 6 training sessions (30 jumps each session). Subjects exercising ii) lateral shuttle movements performed shuttle runs with the turn point after 4 meters with respect to the starting position. aF was provided on the total time to complete the movement. Subjects were instructed to perform the task as fast as possible. 3 training sessions were performed (30 runs each). Performance was evaluated before and directly after the training program. **Results:** We used a repeated-measures Analysis of Variance with the factors TIME (before versus after training) and GROUP (aF versus no aF) to evaluate performance improvements. In i) vertical jumps we found a TIME \times GROUP effect ($F_{1,8} = 8.45$, $P < 0.05$). The values indicate that only the aF group significantly improved performance (+8% in the aF group, -4% in the no aF group). In ii) lateral shuttle movements, we found a TIME \times GROUP effect ($F_{1,10} = 5.94$, $P < 0.05$). Subjects in the aF group improved by 5.5% (no changes, i.e. 0%, in the no aF group). This again clearly indicates that only the aF group improved in

the time necessary to complete the shuttle run. Discussion: The main finding of the present study was that movement performance in a practical jump and shuttle run setting could only be improved with use of aF about jump height and the time to complete the shuttle run, respectively. The effectiveness of aF may further be improved when adjusting variables like the frequency and the timing of aF. Overall, the results suggest that aF should be considered in practical training. EFFECTS OF 18 WEEKS VOLLEYBALL TRAINING TO IMPROVE PHYSICAL FITNESS AND VISUAL TEMPORAL DISCRIMINATION

YU CHUN, C., YU LING, S.

National Taiwan University of Physical Education and Sport

EFFECTS OF 18 WEEKS VOLLEYBALL TRAINING TO IMPROVE PHYSICAL FITNESS AND VISUAL TEMPORAL DISCRIMINATION Introduction For maintaining health, people often do exercise to enhance physical fitness. However, exercise may have beneficial effects other than physical fitness. For instance, volleyball is an open skill which requires agility for body movement and muscle fitness of the abdominal and arm muscles for ball control. In addition, it also requires aerobic fitness for completing the game. In addition to physical fitness, past literature shows that professional volleyball players also have better temporal discrimination in visual perception. Therefore, this study aims at exploring whether physical fitness and visual temporal discrimination can be improved by volleyball training. Methods A total of 14 female university students without regular exercise were recruited in the experiment. They were arranged to receive volleyball training for three months. Both physical fitness, including 12-minute run-walk, push-ups and sit-ups, and visual temporal discrimination were tested before training and every 6 weeks during the training period. These three measures were compared by the paired-t test in order to investigate the effects of volleyball training. Results By comparing the results obtained from the first and the third tests, the participants showed shorter reaction time in pure visual temporal discrimination and higher accuracy rate in audiovisual temporal discrimination significantly. As far as the physical fitness was concerned, only the measures for muscle endurance, i.e. push-ups and sit-ups, showed significant improvement and that for aerobic fitness, i.e. 12-minute run-walk, did not. Discussion The results of the present experiment suggest that both muscle endurance and visual temporal discrimination can be improved by three-month volleyball training. In contrast, no significant training effect was found in cardiorespiratory endurance. This may result from that volleyball is an intermittent sport. Consequently, it is unable to observe effective improvement of cardiorespiratory endurance from volleyball training. References American college of sports medicine (2007). REDUCED ERRORS IN OVERHAND THROWING PRACTICE OF CHILDREN: ANALYSIS OF MOVEMENT COMPONENTS

Capio, C.M.1, Poolton, J.M.1, Choi, C.S.Y.1, Masters, R.S.W.1,2

1:University of Hong Kong, 2: University of Waikato (New Zealand)

Introduction Fundamental movement skills (FMS) are important as they form the basis of more complex movements in sports and recreation. Training FMS is therefore likely to be valuable in child development. Previous research has shown that training interventions that reduce errors during practice of a FMS (i.e., overhand throwing), are beneficial for children's learning. This study aimed to gain a better understanding of error-reduced training by analyzing change in four components of an overhand throwing movement pattern. **Methods** Children aged 8–10 years (n=108), practiced 120 trials of overhand throwing in an outcome error-reduced (ER) or an outcome error-strewn (ES) practice condition. Task difficulty was manipulated so that children in the ER group had significantly more successful practice trials than children in the ES group. Using a pretest-posttest study design, the overhand throwing movement was examined using the Test of Gross Motor Development-2, which is a validated process-oriented assessment of the following components: (1) hand/arm windup, (2) hip/shoulder rotation, (3) weight shift, and (4) follow through. A performance measure of throwing accuracy was also conducted. **Results** Analysis of variance (ANOVA) showed that the ER practice condition resulted in greater improvements in throwing accuracy than the ES practice condition ($p=.02$). ANOVAs of the change in each of the four movement components showed that the ER practice condition resulted in improvements in only the follow through component of throwing ($p=.03$), whereas the ES practice condition did not result in any significant improvements. Follow-up correlational analysis showed that improved throwing accuracy of children in the ER practice condition was associated with improvements in hand/arm wind-up ($r=.44$, $p=.002$) and hip/shoulder rotation ($r=.31$, $p=.04$) movement components. No associations were found between improved throwing accuracy of children in the ES practice condition and changes in the four movement components. **Discussion** The study findings suggest that the beneficial effect of error-reduced training on overhand throwing in children may be localized to the final and more distal component of the throwing pattern, the diagonal follow through. Whether this is associated with force production and/or movement trajectory can be explored in future research using more quantitative methodology (e.g. 3D motion analysis). Furthermore, variability in learning of children in the ER practice condition may be explained by the two most proximal components of the throwing pattern. Contact ccapio@hku.hk

EEG BRAIN ACTIVATION PATTERNS IN DIFFERENTIAL AND MENTAL DIFFERENTIAL SOCCER SHOOTING TRAINING

Henz, D., Leinberger, O., Schöllhorn, W.I.

University of Mainz

Introduction Several studies demonstrate higher learning rates in differential compared to classical repetition oriented training (e.g. Schöllhorn, Hegen & Davids, 2012; Schöllhorn, Michelbrink, Welmski & Davids, 2009). To our knowledge, little is known about the underlying neuronal processes. In a previous study, effects of differential training on EEG alpha and theta activity indicating somatosensory working memory processes in differential badminton serve training were shown (Henz, Hofmann & Schöllhorn, 2013). In the current study, we tested whether there are similar activation patterns of EEG spontaneous activity in physical and mental differential soccer shooting training. **Methods** Eight semi-professional soccer players performed repetition-oriented classical, differential, and mental-differential training in a randomized within-subjects design. Spontaneous resting EEG was recorded from nineteen electrodes according to the international 10-20 system under resting conditions before and after each training session. **Results** EEG-data show increased theta activity in left fronto-central areas (F3, C3) after physical differential training, $F(2,14) = 4.29$, $p < .05$. There was no difference in mental differential training compared to baseline EEG activity. Increased Mu-wave activity was observed in left central regions Cz and C3, $F(2,14) = 3.72$, $p <$

.05. Alpha-activity (8-13 Hz) was decreased in left occipital regions after mental-differential training, $F(2,14) = 3.91$, $p < .05$. Discussion Results of contralateral activation in left frontal theta and left central alpha activity indicate that differential training stimulates the motor areas in an extensive way which could not be induced by repetitional training or mental practice. In mental differential training different neural processes seem to be involved. Therefore, we suppose that kinaesthetic information derived from differential training is one of the mediating variables in differential training to build a motor working memory representation. DIFFERENTIAL TRAINING AS AN INTERVENTION STRATEGY TO PREVENT CHOKING UNDER PRESSURE IN BASKETBALL FREE-THROW

Lattwein, M., Henz, D., Schöllhorn, W.I.

University of Mainz

Introduction Choking under pressure is a common phenomenon observed in sports competitions performing more poorly than expected given one's skill level and is thought to occur where incentives for optimal performance are at a maximum (Beilock & Gray, 2007). In the current study, we tested whether differential compared to classical repetition oriented basketball free-throw training has a beneficial effect on performance in a high pressure competitive situation. Methods Thirty-two subjects (mean age = 24.87, age range 21-29 years) participated in the current study. Subjects underwent either classical or differential training for four weeks (2 training sessions per week). All subjects were tested prior to training and after the four week training period under low pressure conditions. Subsequently, follow-up tests were performed three weeks after the last training session in a competing situation including spectators and a jury. Results Results show a significant main effect of time, $F(2,27) = 55.42$, $p < .001$, $\eta^2 = .53$, with a significant interaction of training and test, $F(2,27) = 15.14$, $p < .001$, $\eta^2 = .07$, but not for training. A separate analysis of variance for the retention test shows a significant main effect of training, $F(18,11) = 3.52$, $p < .05$, $\eta^2 = .33$, with a significant interaction of training and situation, $F(18,11) = 2.74$, $p < .05$, $\eta^2 = .80$. Further analyses show a higher ratio of airballs in classical training ($p < .05$). Discussion Results indicate that differential training enables to maintain a more skillful motion in basketball free throws under pressure compared to repetitional training. Results from a previous EEG study show that differential training relies on a sensorimotor motor working memory representation that is more resistant to attention distracting influences than classical repetition oriented training which activates primarily brain areas engaged in executive control of actions (Henz, Hofmann & Schöllhorn, 2013). For that reason, we conclude that differential training might contribute to a reduction of choking under pressure. References Beilock, S.L., & Gray, R. (2007). Why do athletes "choke" under pressure? In G. Tenenbaum & R.C. Eklund (Eds.), Handbook of sport psychology (3rd ed.) (pp.425-444). Hoboken, N.J.: John Wiley. Henz, D., Hofmann, M., & Schöllhorn, W.I. (2013). INFLUENCE OF PRESSURE ON POSTURAL ADJUSTMENTS IN AN ACCURACY DEMANDING SINGLE-FORWARD-STEPPING TASK

Sasaki, J., Sekiya, H.

Hiroshima University

The purpose of this study was to investigate the influence of pressure on an initial postural adjustment and an anticipatory postural adjustment (APA) during a single forward stepping task that required accuracy of landing position. Fourteen male participants made a single step toward a circular target (10cm in diameter). They performed 10 trials each ten in non-pressure and pressure conditions and order of the conditions was counter-balanced among participants. In performing the task, participants were required accuracy of landing position on the target. Pressure was induced by a small audience and false instructions about starting over the same experiment on another day for worse performance and the presentation of video-taped worse performance in a sports science class. Results showed that subjective state anxiety increased from 41.6 (± 8.1) to 51.9 (± 9.9) ($p < .01$), and heart rate also increased from 75.5 (± 7.0) bpm to 89.9 (± 6.6) bpm ($p < .01$) by the pressure manipulation, indicating that the a low level of pressure was added in both psychological and physiological aspects. Mean radial error ($p < .05$) and bivariate variable error ($p < .05$) were also increased, indicating that accuracy of landing position was reduced under pressure. Furthermore, in APA phase, mean backward force measured by a force plate decreased under pressure, indicating that APA was inhibited in the pressure condition. It has been reported that APA in the single forward stepping task declined when accuracy demand of landing position was increased by using a smaller target (Brunt et al., 2000). The findings in this study suggest that APA is changed by pressure as much as that of when accuracy demand is manipulated by target size. However, this change in APA did not enhance accuracy of landing position in the present study.

CORRELATION AMONG BODY CHARACTERISTICS, WHOLE BODY COORDINATION MOTOR TEST AND EMG BASED COHERENCE INDEX OF WALKING IN 6 YEARS OLD CHILDREN

Plevnik, M., Geržević, M., Marušić, U., Pišot, R.

University of Primorska

Introduction Sedentary lifestyle is already present in early childhood, which could influence the development and acquiring of fundamental motor patterns (Pišot, 2012). Qualitative methods as a "golden standard" for evaluation of children's movements, as well as quantitative approaches, based on the results of different motor tests, could not offer objective information about quality of movement structures (Hands, 2002). On the basis of electromyography (EMG) measurements, it was the aim of this study to assess the correlations among an objective quantitative measure of coherence of walking, a whole body coordination (WBC) motor test and body characteristics in 6 years old children. Methods Twenty 6 years old children (85% of girls) walked 4 times for 20 m at their self-selected comfortable speed. EMG signals were recorded from left (L) and right (R) m. tibialis anterior (TA), m. soleus (SO), m. rectus femoris (RF) and m. biceps femoris (BF).

After EMG processing (Butterworth band-pass filtering 10-500 Hz, full-wave rectification, RMS averaging on 100-ms window, MVC normalization; 62.1 ± 16.0 strides/subject analyzed) a Coherence Index (CI) was calculated for each % of the stride time adapting the equation of the Dispersion Index proposed by Rejc et al. (2010): $CI = [LTA-RTA] + [LSO-RSO] + [LRF-RRF] + [LBF-RBF]$. Average value of CIs of each subject's stride was considered for further analysis and was correlated with the time of the WBC motor test (Pišot & Planinšec, 2010) and body characteristic parameters (BM, BH, MM, FM, FFM, BMI), measured with a Maltron bioimpedance. Spearman's correlation was used for statistical analysis. Results The results showed that the time of the whole body coordination motor test was positively related to FM ($r = .456$, $p = .043$) and negatively to FFM ($r = -.456$, $p = .043$). However, there were no significant correlation between the EMG based CI of walking and WBC ($r = .224$, $p = .342$), neither between the CI and body characteristic parameters ($p < .05$). Discussion EMG based CI seems to be an inappropriate parameter for evaluating the development of walking in children aged 6. In early childhood EMG measurements and its derived parameters probably have too many methodological limitations and they could be influenced by several developmental factors. The validation of CI still needs to be performed on adults, children and adolescents. References Hands BP (2002). 23rd Int Conf: Inter Health & Phy Ed, Launceston. Pišot R (2012). IN EXPERTS, EXPLICIT PROCESSES ARE MORE INVOLVED IN VISUOMOTOR ADAPTATIONS THAN IN NOVICES

Wälchli, M., Taube, W., Gollhofer, A., Leukel, C.

University of Fribourg

The "three stage model" of Fitts and Posner (1967) describes three different levels of expertise in motor learning. In the initial, termed "cognitive" stage, learners would extensively use explicit knowledge to accomplish the task. In the second, "associative stage", learners change from a more general focus to specific details of the task to be learned. Finally, in the "autonomous stage", behaviour is dominantly controlled by implicit and therefore subconscious processes. Very recently, this view was theoretically questioned in an article by Stanley and Krakauer (2013). They argued against the idea that experts do not longer use explicit processes. However, although implicit and explicit processes in motor learning has been extensively studied in visuomotor adaptation experiments, previous studies always tested subjects inexperienced to the adaptation task. Thus, it is not known whether an experienced subject would adapt differently. In this study we therefore aimed to compare visuomotor adaptation in subjects with low expertise (Novices) and high expertise (Experts). We hypothesized that adaptation might differ with respect to expertise. Subjects in the present study were experienced handball players ($n=20$) and novices ($n=20$) performing free throws. Subjects were required to hit a predefined target on a wall (3.5 m in front of the subjects) with the handball. Visual feedback was biased with prism glasses (40cm/m). In a first experiment, subjects were allowed to use strategies (conscious adaptation in aiming) whereas in a second experiment strategies were banned by verbal instructions. In the first experiment, both groups showed the same rate of adaptation to target error. In experts, explicit processes were stronger involved than in novices. This stronger contribution of explicit processes caused a slower rate of adaptation in experts in experiment 2. These differences in behaviour during adaptation between the two groups indicate that experts use more explicit processes than novices. In line with Stanley and Krakauer (2013) we argue that experts develop strategic knowledge as they develop implicit knowledge. The use of explicit processes, e.g. with changes in the environment like in the present study, makes sense as they are more flexibly applicable than implicit processes.

EFFECTS OF A SIMULTANEOUS COGNITIVE AND COORDINATION TRAINING ON POSTURAL CONTROL AND DUAL-TASK PERFORMANCE IN OBESE CHILDREN

Kreuser, F.1,2, Gollhofer, A.1, Korsten-Reck, U.2, Roettger, K.1

(1) Institute of Sport and Sport Science, University of Freiburg, Germany, (2) University Medical Center, University of Freiburg, Germany

Introduction Compared to normal-weight children, obese children show poorer performance in balance and dual-task abilities, as well as in reading, spelling and arithmetic (Deforche et al., 2009; Kamijo et al., 2012). To counteract this development, interventions including cognitive and postural tasks simultaneously could be useful. Therefore, the aim of the present study is to evaluate the influence of a simultaneous cognitive and coordination training on postural control and dual-task performance in obese children. Methods 26 obese children were either assigned to an intervention group (IG) ($n=12$; 10, age 10.2 ± 1.3) or a control group (CG) ($n=14$, age 10.8 ± 1.2). IG took part once a week in a cognitive and coordination training (Life Kinetik training), whereas CG took part in a normal physical education class. Before and after 3 month of intervention, postural sway-paths medio-lateral (ml) and anterior-posterior (ap) were measured in a transfer-test on Posturomed. Furthermore, walking-time without interference was determined during a 10m walkway, followed by dual-task performances: 1. walking with an additional cognitive interference task (CI); 2. walking with a motor interference task (MI). Results Groups did not show any differences in the tests before intervention (all values: $p > 0.13$). After intervention the two groups differed significantly in their sway paths (ml and ap) (time*group interaction: ml $p=0.008$ /ap $p=0.027$) and in dual-task performance (time*group interaction: CI $p=0.034$ /MI $p=0.038$). No significant differences were found between groups for walking without additional interference task. Conclusion The results indicate an improved postural balance and dual task-performance after a Life Kinetik training in obese children. Importantly the improvements occurred in tasks that were not part of the training program. In conclusion, this kind of intervention may have potential to promote cognitive performance and to reduce deficits in balance connected with a higher risk of falls (Williams et al., 2008) in obese children. Neuromuscular Physiology

CNV RESPONSE TO BADMINTON VIDEO CLIP

Suda, K., Umekawa, T., Hasegawa, S., Kodera, T., Usui, S., Fumoto, M.

Tokyo Institute of Technology

Introduction We are interested in what kind of brain activity occurs at badminton stroke. Usually this kind of research is conducted as reaction time to light signals. Concerning brain activity, electroencephalography (EEG) is used to analyze it. But the results from these methods are not badminton specific. EEG recording during badminton play is difficult because of artifacts. Event related potential (ERP) can be one of good methods to analyze brain activity in badminton. ERP analysis needs to be averaged, so the same situation is necessary but the exact same situation never occurs during badminton match or practice. Therefore we used badminton video clips as stimuli and analyzed CNV (Contingent Negative Variation) (Walter, 1967). Method We shot two badminton players from their side with high speed camera (300 f/sec). One player on the right served to the opponent. The opponent on the left side made one of the following flights, clear,

drop or smash. The server hit the shuttlecock. We made video clips from the data of the camera which contains the frame of the impacts. Similar video clips were made in which circle moves from the right side to the left side and returned to the right side just as the same timing of the shuttlecock. 6 badminton experts and 6 novices were participated in this study. They were asked to push button when the server received the opponent shots or the signal of the circles reached the line on the right side. We made one more video clip in which fixed circles appeared and disappeared. The EEG were averaged to record CNV. Artifact contained trials were omitted from the averaging. Results CNV like recording was obtained under both situations of watching Badminton video clips and circle movies. We considered this as CNV. The CNV amplitudes from the electrode on the central parts of the scalp were dominant. The amplitudes were larger when the participant responded to the badminton video clip than they responded to the moving circle. The latencies of CNV recordings were different among the three strokes. CNV began to rise before the opponents' stroke. Discussion CNV amplitude dominance in the central part of the scalp in this study and this is general pattern of CNV recordings. Many exercise related CNV have been reported such as Kamijo K. et al. (2004). Although event related potential with badminton video clip was reported by Jin H. et al.(2011), researches on CNV in response to badminton clip are few. In this study, it was suggested that CNV concerning activity began before the opponents' impact in badminton. References Walter WG.(1967) Electroencephalogr Clin Neurophysiol. ,23(5):489. RELATIONSHIP BETWEEN ACTN3 R577X POLYMORPHISM AND H-REFLEX IN YOUNG CANOEISTS

Mazur Różycka, J.1, Orysiak, J.1, Gajewski, J.1,2, Łach, P.1, Michalski, R.1, Busko, K.3, Różycki, S.2

1: Institute of Sport (Warsaw, Poland), 2: University of Physical Education (Warsaw, Poland), 3: Kazimierz Wielki University (Bydgoszcz, Poland)

Introduction Some studies have demonstrated that the frequency of the RR genotype of the ACTN3 gene is higher in power/sprint athletes than in controls and/or endurance athletes in contrast to the XX genotype, which benefits endurance performance (Holdys et al. 2011). The H/M ratio has been found to be greater in power-trained than endurance-trained athletes (Rochcongar et al. 1979). The aim of the study was to examine the association between ACTN3 R577X polymorphism and electromyographic characteristics of soleus maximal H-reflex and direct M response among canoeists. **Methods** Twenty five young male canoeists (age 17.3 ± 1.6 year, body mass 74.0 ± 7.8 kg, body height 181.0 ± 6.3 cm) served as subjects in the study. None of the participants had any history of neuromuscular disorders. For each participant, peak-to-peak amplitudes of the soleus Hmax and Mmax wave were recorded in lying position. Then, stimulus intensity was adjusted to obtain 20% of the maximal M wave. Genotyping for ACTN3 gene was performed using polymerase chain reaction. The three genotypes were extracted: XX, RX and RR. The significance of differences was assessed using one-way ANOVA. Results Amplitude of Hmax was 6.22 ± 3.89 mV in XX genotype group while lower values were observed in RX and RR groups (4.78 ± 2.82 mV and 5.13 ± 1.64 mV, respectively). Amplitudes of Mmax were 7.33 ± 3.46 mV, 8.18 ± 1.83 mV and 7.75 ± 2.04 mV in XX, RX and RR groups, respectively. The H/M20% ratio was 4.43 ± 1.79 , 3.03 ± 1.78 and 3.09 ± 0.99 in XX, RX and RR groups, respectively. No significant association between ACTN3 R577X polymorphism and Hmax, Mmax, H/M ratio and H/M20% was found ($F=0.526$, $p=0.829$). **Discussion** We hypothesized that the ACTN3 R577X polymorphism is associated with electromyographic characteristics of soleus maximal H-reflex and direct M response in athletes, and athletes with RR genotype have lowest amplitudes of Hmax and H/M ratio than athletes with XX or RX genotype. In the present study we found no association between ACTN3 genotype and characteristics of H-reflex. However, the group with XX genotype has the highest amplitude of the Hmax as suggested for endurance trained athletes. **Acknowledgements** The study was supported by Ministry of Science and Higher Education No. NRSAT 001051 and Fund for Development of Physical Culture References Holdys J., Kryściak J., Stanisławski D., Groniek P. CORTICOSPINAL EXCITABILITY AND INTERLIMB COORDINATION IN KARATE ATHLETES: A MAGNETIC STIMULATION STUDY

Moscatelli, F.1,2, Valenzano, A.1, Triggiani, A.1,1, Petito, A.1, Bellomo, A.1, Capranica, L.2, Ciliberti, M.A.P.1, Babiloni, C.3, Cibelli, G.1

Introduction Activity-dependent neural plasticity is associated with altered correlation in neuronal discharge. Transcranial magnetic stimulation (TMS) can be used to monitor the functional state of the corticospinal system. By using single-pulse TMS we studied the ongoing neural activity in the primary motor cortex (M1) of karate athletes and the interlimb coordination performance was considered as a functional assessment of the corticospinal system excitability. **Methods** Thirteen right-handed male karate athletes (25 ± 5 years) and 13 matched non-athletes (28.7 ± 16.2 years) were enrolled, after signing informed consent. The TMS was applied using a figure-of-eight coil (outer coil diameter 70 mm) powered by the Magstim Rapid2 stimulator. Resting motor threshold (rMT) was determined according to Rossini et al. (1994). Surface electromyography was recorded from the first dorsal interosseus muscle. The MEP latency and amplitude at rMT and 110-120% of rMT were considered. Interlimb coordination was investigated according to Capranica et al. (2004) and correlated to corticospinal excitability. Results In comparison to non-athletes, karate athletes showed statistically significant lower rMT, shorter MEP latency and higher MEP amplitude. Similar results were obtained at 110-120% of rMT. Overall correlation between rMT and MEP latency and amplitude were significant. Interlimb coordination performances were more pronounced in athletes, than in their counterpart non-athletes. As expected, correct executions were better during the in-phase, than anti-phase condition, with a significant decrement from 80 to 180 bpm frequencies. Correlation analysis between rMT and interlimb coordination tasks showed an overall highly significant relationship at 120-180 bpm, in both phase and antiphase conditions. **Discussion** Athletes practicing karate showed increased corticospinal excitability in a small hand-muscle, compared with non-athlete counterparts. These findings indicate that activity-dependent alteration in the balance and interactions between inhibitory and facilitatory circuits determine the final output from the M1, which characterized karate athletes. Our results also revealed a close correspondence between corticospinal excitability and interlimb coordination performance, as a neurophysiological correlate of sport practice in karate athletes. THE EFFECT OF ORAL ADMINISTRATION OF SODIUM BICARBONATE ON NEUROMUSCULAR ACTIVITY AT A FIXED RPE

Browne, S.

University of Worcester

Introduction Studies have suggested performance is regulated through afferent feedback (AF) which consequentially determines our conscious RPE (Tucker 2009). It has been proposed that exercise-induced declines in intramuscular pH inhibit afferent signalling, thereby influencing the magnitude of central motor drive during exercise (Amann 2011). It is suggested that the manipulation of intramuscular pH will affect muscular recruitment strategy. Additionally, if the conscious RPE is indeed generated as a result of AF, ingestion of a peripherally acting substance would be expected to alter the nature of this feedback, influencing work rate at the same conscious level of exertion. Methods Participants completed two cycling trials following ingestion of 0.2g.kg⁻¹ of NaHCO₃ or a placebo. Throughout exercise participants were required to cycle at an intensity equivalent to their perception of an RPE of 16 on the C20 Category Scale. Surface electromyogram activity (SEMG), power output and heart rate were recorded throughout exercise whilst blood pH and plasma HCO₃⁻ concentration ([HCO₃⁻]) were measured pre- and post-exercise and blood lactate concentrations immediately post-exercise. Exercise was terminated when power output fell below 80% of the average recorded over the first 3 minutes of each trial. Results Exercise duration was 21% longer following NaHCO₃ ingestion. Despite power output and heart rate being similar throughout trials, SEMG activity was greater during the placebo trial and significantly greater ($P < 0.05$) within the 50-75% epoch. Plasma [HCO₃⁻] and pH pre-exercise were significantly higher following NaHCO₃ ingestion whilst post-exercise values did not differ. Discussion Greater neuromuscular (NM) activity in the placebo trial despite similar power outputs is suggestive of NM compensation (Bundle et al. 2006), where a greater degree of muscular recruitment was required to produce the same absolute work rate in order to maintain a fixed perceived intensity. The differing levels of NM activity during the trials indicate muscular recruitment was regulated to achieve the required sensation of effort. It is suggested that perception of effort may be based on absolute work rate rather than AF. References Amann, M. DIFFERENT ANKLE MUSCLE COORDINATION PATTERNS DURING QUIET STANCE BETWEEN YOUNG AND OLD ADULTS

Kurz, E., Roth, R., Zahner, L., Faude, O., Donath, L.

University of Basel

Introduction Static balance tasks are frequently employed to test and train postural control in various age- groups. A body of evidence suggests that young adults and seniors use different strategies to adjust for increasing body sway during quiet standing (Laughton et al. 2003). It is, however, unclear whether different ankle muscle coordination patterns may account for this finding. We aimed to address whether aging may lead to altered ankle muscle coordination patterns during quiet stance and if these changes are associated with postural sway. Methods Twenty seniors (age: 70.0 (SD 3.8)) and twenty young adults (age: 27.1 (SD 3.0)) were enrolled in the present study. Standing balance was tested during double limb stance with eyes closed (DLEC) and single limb stance with eyes open (SLEO) on a piezoelectric force-plate (KIS, Type 9286, Winterthur, Switzerland). The task order was randomly assigned. Three attempts for each standing condition were achieved. Tests were performed without shoes, with feet placed shoulder-width apart, hands placed at the hip and slightly bent knees. Data were collected for 10 s at 40/s using a low pass cut-off frequency of 10 Hz. Center of pressure (COP) path length served as outcome measure. Surface electromyography was captured above soleus (SOL), medial gastrocnemius (MG), tibialis anterior (TA) and peroneus longus (PL) muscles at the dominant leg. The amplitude ratios (AR) were calculated for each muscle (e.g. TA [%] = $(TA \times 100) / (MG + SOL + PL + TA)$) in order to assess the inter-muscular coordination. Results A muscle \times age interaction effect for the AR was found for SLEO ($p < 0.001$). For seniors, post hoc analyses revealed decreased AR for SOL ($p = 0.02$, between-group difference $\Delta 10\%$, Cohen's $d = 1.3$) and for MG ($p = 0.03$, $\Delta 9\%$, $d = 0.9$) as well as increased AR for TA ($p = 0.001$, $\Delta 20\%$, $d = 1.6$). DLEC did not differ between the two groups. A moderate correlation ($r = 0.64$, $p = 0.02$) between the AR of TA and postural sway during single leg stance was observed for seniors but not for the young adults ($r = -0.11$, $p = 0.62$). Discussion Compared to young adults, healthy seniors showed inverted ankle coordination patterns during single leg standing. This finding may point towards different postural strategies in both age groups during demanding balance tasks. Training recommendations for young adults are, thus, not necessarily appropriate for seniors and vice versa. References Laughton et al. (2003). *Gait Posture*, 18, 101-108.

PERCEIVED EXERTION AND ELECTROMYOGRAPHY DURING CORE EXERCISES

Cugliari, G.1,4, Boccia, G.1,2,3, Rainoldi, A.1,2,3

1:Motor Science Research Center (Turin, Italy), 2:School of Exercise & Sport Sciences, SUISM (Turin, Italy), 4:University of Pavia (Pavia, Italy)

Introduction In recent years, with the aim of promoting the effective planning of training sessions and reducing the risk of injury researchers are increased the use of measurement scales of perceived exertion (RPE scale) during various sporting activities. This study examined the relationship between OMNI-RPE scale values and the relative levels of muscle activity during core exercises. Methods Eighteen young male volunteers performed 16 exercises in random order: three traditional exercises in stable condition; nine exercises in unstable conditions four out of which were executed for both left and right sides since they were asymmetric. Exercises are aimed to the strengthening of abdominal and lumbosacral muscles. Surface electromyographic (EMG) signals were recorded from upper rectus abdominis (URA), lower rectus abdominis (LRA), external oblique (EO), internal oblique (IO), upper erector spinae (UES) and lower erector spinae (LES) muscles using concentric bipolar electrodes. The average rectified values (ARV) of EMG signals were computed for each muscle along two repetitions of each exercise. ARV values of each muscle were normalized with respect to the maximum ARV obtained during the correspondent maximal voluntary isometric contraction (MVIC) performed against operator resistance. At the end of each exercise subjects were requested to determine the OMNI-RPE. Friedman's test showed differences, while the Spearman's correlation showed the relationship between the RPE values in all exercises. A linear regression between RPE and EMG values was estimated. For the analysis the level of significance was set at $p < 0.01$. Results Traditional exercises (stable condition) showed lower RPE values compared to all exercises performed in unstable condition. In general unilateral exercises showed higher RPE values than symmetric exercises. The increase in one point of the RPE scale corresponds to changes in EMG values: during exercises with the opening of the trunk-upper limbs angle there is a greater activation of the LRA (+15%), while in the exercises with the closure of the trunk-lower limbs angle there is a greater activation of

the URA (+15%); during back extension obliques are activated in opposite way, IO increases (+3%) while EO decreases (-3%) EMG values. Discussion These findings presented a significant relationship between RPE and EMG activity. Not all the six muscles showed a linear trend. Stability/instability, bilateral/unilateral and joints most widely used during exercises influenced in different way the specific activation of each muscle and the level of perceived exertion during core exercises. Results show different activations of the two portions of the rectus abdominis and obliques muscles in relation to RPE values. Hence electromyography can be a valuable method to estimate the relationship between perceived exertion (global output) and muscle activation (specific output) during core training exercises with the aim to increase the knowledge of a functional physiological-perceptual link. MAXIMAL VOLUNTARY CONTRACTION ASSESSMENT: IMPACT OF REAL-TIME VISUAL FEEDBACK OF PERFORMANCE

Simoneau Buessinger, E., Toumi, A.

Université de Valenciennes et du Hainaut Cambresis

Introduction The capacity for force production changes under the influence of endogenous or exogenous factors such as aging, injury, training or detraining. The assessment of maximal voluntary contraction (MVC) torque is widely used to evaluate this plasticity of the muscle. However, cautions need to be taken while performing this assessment since maximal force production can be influenced by the nature of the testing environment. For example, it is well known that providing strong verbal encouragements and/or a real-time visual feedback of the torque can stimulate the participants to maximally activate their muscles. So far, the quantitative impact of such experimental conditions has never been investigated. Then the aim of this study was to assess the impact of the provision of a real-time visual feedback to the participant while performing MVC with ankle joint muscles. **Methods** Twelve young healthy adults took part in this investigation. Plantar-flexion (PF) and dorsi-flexion (DF) isometric MVC torques were randomly measured using an ankle ergometer. A computer screen was placed at gaze level. At least 3 trials were performed for each of the 3 experimental conditions: i) without any feedback (noFB), ii) with real-time visual feedback of torque (FB) and iii) real-time visual feedback and target line (FBTL). For the FBTL condition, participants first performed an MVC with a visual feedback and then a target line was displayed on the screen at 105% of the previous MVC for further trials. **Results** While there was no significant effect of experimental condition on DF MVC ($p > 0.05$), there was a significant effect on PF MVC ($p < 0.001$). Statistical analysis showed that FB and FBTL PF were significantly higher than noFB PF (+19% and +25%, respectively) ($p < 0.001$). However, there was no significant difference between FBTL and FB PF ($p = 0.45$). **Discussion** Providing a visual FB to the participant increased PF MVC torque to a great extent. The provision of an additional target line did not seem to be essential. Contrary to what was expected, a FB had no significant impact on DF MVC. These discrepancies between PF and DF could be explained by the fact that, during maximal effort, complete activation of motor units, assessed by the interpolated twitch technique, is usually easily reached for the dorsi-flexors, and with difficulty for the plantar-flexors (Belanger and McComas, 1981; Simoneau et al., 2005). In conclusion, in PF, contrary to DF, the provision of a visual FB of torque is critical to assess MVC. **References** Belanger AY, McComas AJ. TRICEPS SURAE ACTIVATION DURING PLANTAR FLEXION IS AFFECTED BY KNEE EXTENSION

Suzuki, T., Shioda, K., Kinugasa, R.

Kanagawa University

Introduction It has been discussed that muscles are controlled as functional groups, so-called synergy. One muscle is included in various synergies, and it is activated depending on the number of recruited synergies (Mussa-Ivaldi et al., 1994). If so, its voluntary activation would increase with increasing related synergies, resulting in higher torque. We therefore investigated the effect of knee extension on triceps surae activation during voluntary plantar flexion. **Methods** Six healthy male volunteers performed maximum voluntary isometric plantar flexion with or without knee extension. Ten trials were conducted at each condition. Electromyographic activity was recorded from the triceps surae. **Results** The average rectified value of electromyographic activity of the triceps surae was significantly altered with quadriceps activation, and also, plantar flexion torque significantly increased. **Discussion** The plantar flexor synergists would be categorized to one synergy. On the other hand, knee extensors and plantar flexors would be included in another synergy during some human movements (De Marchis et al., 2013). Compared with plantar flexion alone, simultaneous motion of plantar flexion and knee extension is related to at least one more synergy. Therefore, this simultaneous motion results in greater activation of the triceps surae and higher plantar flexion torque. **References** De Marchis C, Schmid M, Bibbo D, Bernabucci I, Conforto S. (2013). *Hum Mov Sci*, 32, 1480-94. Mussa-Ivaldi FA, Giszter SF, Bizzi E. 1994. *Proc Natl Acad Sci U S A*, 91(16), 7534-8.

MOTOR SYSTEM ALTERATION UNDER THE SPINAL CORD STIMULATION

Mikhaylova, E.I, Ershov, V.Y.I, Gerasimenko, Y.P.2, Shlyakhtov, V.N.I, Gorodnichev, R.M.I

1.Velikiye Luki State Academy of Physical Education and Sports, 2.I.P. Pavlov Institute of Physiology of RAS

Introduction The research goal was to study the spinal cord electric stimulation influence on the sportsman motor system. **Methods** 12 sportsmen divided into 2 groups – a control ($n=6$) and an experimental ($n=6$) ones underwent the experiment. All the participants therein were warned of the experimentation conditions and they gave their written consent to participate. The experiment consisted of two training micro-cycles, each lasting 5 days. The people from both groups would daily do a running load of 5 eight-second repetitions to run with a maximal speed on the treadmill (HP Cosmos Saturn) in its passive regime. The experimental group sportsmen, while running, were constantly spinal marrow stimulated at levels T11-T12 and T12-L1 with a 2-channel stimulator KULON (GUAP, St-Petersburg). The intensity of stimulation was chosen individually in each case; the signal frequency was 30 Hz. The control group sportsmen were not electrically stimulated. Maximal anaerobic power (MAP), force-and-speed capacity of shank muscles, M-wave and H-reflex were tested before the experiment, then after 5 and 10 training days. MAP was tested with the help of the 10-second veloergometry test. The Biodex Medical Systems PRO-3 (USA, 2006) was employed to assess the force-and-speed capacity of shank muscles by the maximal number of flexions during an 11-second interval. **Results** After 5 days the experimental group witnessed an increase of 19,9% ($p > 0,05$) of the total work at the plantar flexion, after 10 days - 27,7% ($p < 0,05$). This group also showed an increase of foot movement number at the constant amplitude, which was not the case with the control group. Among MAP factors statistically relevant was the minimal capacity after the 10th training day, an increase made up to 23,4% ($p < 0,05$). After 10 days the the amplitude of the M-wave with all muscles under study in the control group was higher than the background value, the amplitude of the m. tibialis anterior increased by 78,5% ($p < 0,05$). The amplitude of all muscle H-reflexes became lower after 5 training days. The m. soleus factor became significantly lower by 34,5% ($p < 0,05$). The

experimental data make it evident that force-and-speed capacity of sportsmen can be developed with the electrostimulation of the spinal cord at the training time.

IDENTIFICATION OF GAIT TRANSITION IN HUMANS BASED ON MUSCLE SYNERGIES

Hagio, S., Fukuda, M., Kouzaki, M.

Kyoto University

Introduction As changing gait speed, people shift their gait pattern between walk and run. Although researchers energetically and mechanically investigated gait transition (Minetti et al., 1994), it is still unclear how the central nervous system (CNS) controls the gait transition, which requires more variety of muscles activations. To simplify such a redundant motor control, muscle synergies are believed to organize functionally similar groups of muscles (Tresch et al., 1999). We hypothesized that gait transition is managed at a low level by muscle synergies. The purpose of this study was to examine motor control in gait transition between walk and run based on muscle synergies. **Methods** Five healthy male subjects (23 ~ 27 years) performed their preferred gait pattern, i.e. walk or run, on a treadmill. Tasks were constructed two different parts; (1) changing speed task, in which subjects voluntarily changed their gait pattern as increasing or decreasing speed of the treadmill; (2) constant speed task, in which subjects instantly changed their gait pattern by experimenter's instruction during preferred walk to run transition speed. During tasks, surface electromyograms (EMGs) were recorded from 11 lower limb muscles in both sides. We then extracted muscle synergies weightings and their activations coefficients from EMG data matrix composed of 22 muscles \times analyzed gait cycles, using non-negative matrix factorization (NMF; Lee and Seung, 1999). **Results** We extracted a few muscle synergies, which reflected the interaction of muscles between both sides. The activation profiles of a few muscle synergies, which included the peak activation levels and phases, were different between walk and run and shifted before and after gait transition. In the changing speed task, the activation profiles of a few synergies were gradually changed around gait transition, whereas they were switched at several steps in the constant speed task. **Discussion** The phase shift of a few specific synergies activations induced gait transition, which characterized the difference between walk and run (Cappellini et al., 2006). As increasing gait speed, the CNS gradually prepared and induced walk-to-run gait transition and vice versa (in the changing speed task). Moreover, gait transition required several steps to steady the next gait pattern, even if transition was forcibly and instantly induced (in the constant speed task). **References** Cappellini G, Ivanenko YP, Poppele RE, Lacquaniti F. MUSCLE FIBER CONDUCTION VELOCITY AND ISOMETRIC RATE OF FORCE DEVELOPMENT

Methenitis, S.I, Karandreas, N.2, Spengos, K.2, Stasinaki, A.1, Zaras, N.1, Karampatsos, G.1, Georgiadis, G.1, Terzis, G.1

National and Kapodestrian University of Athens,

Introduction Muscle power is influenced by several neuromuscular variables (Cormie et al. 2011). An essential part of the neuromuscular structure is the system which propagates the action potentials along the muscle fibers. However, the velocity of this propagation, i.e. the muscle fiber conduction velocity (MFCV) has received little attention as a variable which might influence performance in power-demanding activities. The rate of force development (RFD), which is linked with neural activation, is strongly correlated with power performance and considered as a significant factor of success in power sports. Aim of the study was to examine possible differences in MFCV among athletes with different explosive training background and assess the relationship between MFCV and isometric RFD. **Methods** Thirty nine young healthy men (26.3 ± 4 yrs) were recruited according to their training background: Power athletes (N=11), Strength-trained (N=10), Marathon runners (N=8), Sedentary (N=10). They performed an isometric leg press test for the assessment of max force (MIF) and RFD, on a force-platform (1KHz sampling, WP800, Applied Measurements Limited, UK). Vastus lateralis MFCV was measured with intramuscular microelectrodes at rest in supine position: electrode length 20mm, diameter 0.45mm, recording surface 0.07mm²; stimulation signal set at 0.05ms duration, 1Hz frequency, 2-15mA, filtered between 2kHz-20kHz. The mean fiber conduction velocity (MFCV_{total}), type II fiber conduction velocity (MFCV_{Type II}) and maximum conduction velocity (MFCV_{max}) of 85 \pm 10 muscle fibers per subject were determined and further used in statistics (one way ANOVA, Pearson r, significance $p < 0.05$). **Results** Significant differences in performance and MFCV were observed among the groups: Power athletes > Strength-trained > Marathon runners = Sedentary ($p < 0.01$, except between Sedentary and Marathon runners, $p > 0.05$). With all subjects considered together, significant correlations were found between MFCV_{total}, MFCV_{Type II}, MFCV_{max}, and MIF, RFD and impulse, at all-time points of the RFD curve ($r = 0.687-0.952$, $p < 0.001$). When these relationships were investigated for each group separately, higher correlations were found for the Power athletes ($r = 0.683-0.967$, $p < 0.001$). **Discussion** The present results suggest that MFCV is related to performance in explosive activities; i.e. individuals with higher MFCV have larger values of RFD. This is probably due to the specific neuromuscular adaptations observed with specific power training or due to genetic differences among subjects. **References** Cormie P, et al. (2011). *Sports Med*, 41(1):17-38.

COP-SWAY CHANGES WHICH APPEARED DEPENDING ON FATIGUE PROTOCOL

Kirkaya, I., Şimşek, Y.D., Özsu, İ., Ertan, H.

Anadolu University

Introduction Proper timing of joint movement is quite important for practicing a successful and professional jump. During the pushing phase; for instance from proximal to distal by the joint movements' alternating quickly, maximum angular velocity occurs consecutively in hips and then in ankles (Enoka, 2002; Whiting, 2006). This order is necessary for transferring energy effectively from a limb to another one and the performance of optimal jump. When the athlete gets tired, this order changes and this also changes the mechanics of jumping and so causes lower jump height (Whiting, 2006). It is almost impossible to form neuromuscular fatigue controllably in competition atmosphere. Therefore, methods which are aimed at determining the relationship of neuromuscular fatigue with various parameter by being spoiled the cycle mentioned above controllably in the laboratory environment are present. One of the methods which are occurred to be able to be evaluated postural stability under dynamic conditions is vibration stimulus which is given to the postural muscles and this affects the duration of controlling balance significantly. **Method** We tested 14 healthy female volleyball players (22.3 ± 2.6 years; $60.72 \text{ kg} \pm 1.74 \text{ kg}$; $1.79 \text{ cm} \pm \text{cm}$). Proprioceptive stimulation was applied by Compex WINPLATE Whole Body Vibration (40Hz 4mm-60sec-90sec rest). The anteroposterior (Ax), mediolateral (Ay) ground reaction forces were measured at a sampling frequency of 2000 Hz using a Kistler forceplate (Type Kistler, 9281EA) and normalized according to body weight. Drop jump trials were applied each subjects' max jumping height. **Results** In our study, it was observed after repetitions of jump drop which were occurred after vibration, range values before

fatigue was Ax (0,06), Ay (0,53); range values after fatigue was Ax (0,37), Ay(0,15). Conclusion A significant difference between the value of Cop sway range before fatigue and measurements which were made after fatigue. It was thought that this situation changes the jump mechanics (decrease in the height of leap) by joints' spoiling the order of kinetic chain from proximal to distal as the result of fatigue. It was also stated as postural muscles activate rapidly in order to control the loss of balance which appeared based on proprioceptive stimulus. NEUROMUSCULAR ADJUSTMENTS IN PLANTAR FLEXORS IN YOUNG ADULTS WITH CEREBRAL PALSY

Neyroud, D., Armand, S., De Coulon, G., Kayser, B., Place, N.

University of Lausanne

Introduction Cerebral palsy (CP), caused by a non-progressive perinatal brain lesion resulting in secondary muscle pathologies, has a prevalence of 2:1000 live births in Europe (3). Chronic fatigue is the most frequent debilitating symptom in adults with CP (1), and is associated with muscle weakness (2) leading to greatly reduced functional capacity. At odds with the reported muscle weakness, several studies reported that CP patients might have greater resistance to muscle fatigue compared to healthy subjects (4). However, these studies were performed on children and CP manifestations might evolve with age. The aim of this study was thus to assess the neuromuscular function in both a fresh and fatigued state in young adults with CP. **Methods** Twelve CP subjects (6 female, 20.5 ± 4.3 yrs) and 12 healthy aged-matched controls (6 female, 20.4 ± 4.1 yrs) performed maximal voluntary contractions (MVC) of the plantar flexors before and after a fatiguing task (i.e. after a 2-min sustained isometric MVC). MVC force loss after the fatiguing task was considered as the index of muscle fatigue. Voluntary activation level (VAL, twitch interpolation technique) and potentiated twitch force were used as indexes of central and peripheral fatigue, respectively. **Results** CP subjects were weaker than controls as revealed by the reduced MVC force (340.9 ± 133.6 N vs. 864.0 ± 150.6 N, p<0.001), peak twitch (97.4 ± 28.4 N vs. 201.4 ± 43.9 N p<0.001), and VAL (73.0 ± 19.1% in CP vs. 88.6 ± 10.9% in controls, p<0.05). In the fatigued state, both MVC force and VAL were reduced in controls (MVC force: -28.4 ± 12.5% and VAL: -18.6 ± 15.3 %, p<0.01) but no significant decrease were found in CP (MVC force: -9.9 ± 23.3% and VAL: 0.9 ± 21.2 %, p>0.05). Evoked force was similarly reduced in both groups (-12.3 ± 16.8% in controls and -5.0 ± 13.1% in CP, p<0.05). **Conclusion** CP young adults thus appear to be weaker than their non CP peers but are more resistant to fatigue suggesting that the perceived everyday muscle fatigue experienced by CP might result from a greater relative force required for daily activities. 1. ACUTE ORAL TYROSINE SUPPLEMENTATION DOES NOT PREVENT THE DECLINE IN MAXIMAL HANDGRIP FORCE IN HYPERTHERMIC SUBJECTS.

Tumilty, L.I, Davison, G.2, Beckmann, M.1, Thatcher, R.1

1: Aberystwyth University (Wales, UK), 2: University of Kent at Medway, (Chatham, UK)

Introduction Acute oral administration of the catecholamine precursor tyrosine is associated with increased submaximal cycling capacity in the heat. This study explored whether oral tyrosine administration would prevent the hyperthermia-induced decrement in single limb muscle force output. **Methods** Following familiarisation, seven male endurance-trained subjects (median age, 20 (range, 26) years; median stature, 1.83 (0.13) m; mean ± SD body mass, 77.9 ± 11.7 kg; peak oxygen uptake, 4.6 ± 0.6 L/min), unacclimated to exercise in the heat, carried out two crossover trials, at least 7 d apart. Subjects ingested 150 mg/kg body mass tyrosine (TYR) or a placebo containing an isocaloric quantity of hydrolysed whey powder, to distinguish any performance effects of TYR due to energy content (PLA), in 500 mL of sugar-free flavoured tap water (11.6 ± 1.6 g tyrosine or 6.1 ± 0.8 g whey protein; 22 ± 3 kcal) in a randomised, double-blind fashion. One hour later, subjects cycled for 60 min at 57 ± 4% peak oxygen uptake, then performed a simulated cycling time trial, approximately 35 min in duration, in 30°C and 60% relative humidity. Maximal, isotonic handgrip exercise was performed (each bout involved 3 brief, 3-s Maximal Voluntary Contractions (MVCs) and a 1-min sustained MVC, each separated by 7 s of passive rest) at rest before drinks administration (Rest), when hyperthermic following 60 min submaximal exercise (Post 60) and following the time trial (Post TT). Handgrip exercise was adopted to highlight a central effect of exercise in the heat and the effect of TYR upon this, on a muscle group not primarily active during cycling exercise. **Results** Rectal temperature gradually increased in both trials (P = 0.003) to 39.0 ± 0.7°C in TYR and 38.9 ± 0.6 in PLA. Plasma concentration of tyrosine plus phenylalanine (tyrosine precursor): large neutral amino acids (free-tryptophan, leucine, isoleucine, valine, methionine, threonine, lysine), a key determinant of brain uptake, increased 2.5-fold from rest in TYR (P < 0.001), but declined in PLA pre-exercise (P = 0.004). Brief, 3-s handgrip force was unaffected by exercise in the heat (P > 0.05), but peak force in the 1-min contraction had declined from Rest at Post TT (-26 ± 11% in TYR and -17 ± 14% in PLA; P < 0.05). Mean force over the 1-min contraction declined from Rest at Post 60 (-27 ± 7% in TYR and -13 ± 7% in PLA; P < 0.05) and Post TT (-25 ± 5% in TYR and -26 ± 5% in PLA; P < 0.05). Neither TYR nor PLA affected the decline in peak or mean force (P > 0.05). **Discussion** Acute tyrosine administration, previously reported to extend exercise time in the heat, did not prevent the decline in peak and sustained handgrip MVC force in hyperthermic subjects. PHYSICAL ACTIVITY IN TURKISH YOUNG ADULTS: ASSOCIATION WITH THE TOTAL AMOUNT AND TYPES OF BEVERAGE CONSUMPTION

Karabudak, E.1, Türközü, D.1, Kara, D.1, Terzioğlu, E.2, Şahin, A.2, Sevimli, K.2, Soydemir, G.2, Torosluoğlu, P.2, Parlak, M.2

1Gazi University, Faculty of Health Sciences, Nutrition and Dietetics Department 2Başkent University, Faculty of Health Sciences, Nutrition and Dietetics Department (Ankara, Turkey)

Introduction Previous studies of the relationship between physical activity and the total amount and types of beverages consumption yielded inconsistent results. So, the aim of the study was to determine relationship between physical activity and the total amount and types of beverages consumption in young adults. **Methods** The study was conducted on a total of 900 individuals, 626 of whom were women and 274 were men (21.6±1.38 years). Physical activity status of individuals assessed with a brief physical activity tool used by

family doctors. Individuals were classified as "sufficiently active" if they had total score of physical activity ≥ 4 points. If they had total score "0-3 points", they were classified as "insufficiently active". The questionnaire applied regarding the consumption situations of 19 different kinds of beverages including water (frequency, amount) to the individuals. Results: When the physical activity status is assessed, 25.9% of the male individuals and 17.6% of female individuals are sufficiently active. The daily beverage consumption of sufficiently and insufficiently active males respectively are as follows; tea types: 318.4 ± 228.84 , 362.7 ± 366.07 ml ($p > 0.05$); coffee types: 111.8 ± 171.89 , 98.1 ± 120.6 ml ($p > 0.05$); ayran/kephir: 139.8 ± 150.06 , 110.4 ± 106.54 ml ($p > 0.05$); milk: 116.3 ± 154.78 , 87.5 ± 125.83 ml ($p > 0.05$); carbonated drinks: 166.6 ± 159.59 , 176.2 ± 207.33 ml ($p > 0.05$); soft drinks: 76.1 ± 84.62 , 66.7 ± 107.16 ml ($p > 0.05$) and alcoholic drinks: 39.8 ± 81.81 , 48.0 ± 133.26 ml ($p > 0.05$). When the daily beverage consumption amounts of the females are evaluated, the following results were found; tea types: 368.8 ± 335.47 , 364.9 ± 337.01 ml ($p > 0.05$); ayran/kephir: 121.8 ± 97.27 , 105.3 ± 122.30 ml ($p > 0.05$); milk: 128.7 ± 122.02 , 108.7 ± 125.62 ml ($p > 0.05$); carbonated drinks: 75.7 ± 97.13 , 82.9 ± 121.29 ml ($p > 0.05$); soft drinks: 53.4 ± 70.66 , 58.9 ± 102.33 ml ($p > 0.05$) and alcoholic drinks: 16.2 ± 45.60 , 8.7 ± 47.40 ml ($p > 0.05$). The difference between the amounts found statistically significant for water (1395.6 ± 609.80 , 1200.7 ± 603.04 ml) and coffee types (136.6 ± 156.21 , 100.5 ± 128.67 ml) consumption of sufficiently and insufficiently active females ($p < 0.05$). The differences between the total fluid intake amounts found statistically significant of sufficiently and insufficiently active males and females ($p < 0.05$). Discussion As the result of this study, it was found out that the total amount and types of beverages consumption may be related with physical activity status. EFFECT OF ANSERINE-CONTAINING FISH-SAUSAGE SUPPLEMENTATION ON HIGH-INTENSITY EXERCISE

Kato, S.1, Ogata, H.2, Tsukahara, H.1, Aoshima, Y.1, Kobayashi, Y.3, Muneda, H.4, Shiina, Y.4, Omi, N.2

1: Undergraduate, University of Tsukuba 2: Faculty of Health and Sport Sciences, University of Tsukuba 3: Maruha Nichiro Food, Inc., Utsunomiya Plant 4: Maruha Nichiro Holdings, Inc., Central Research

Introduction A large amount of the histidine-containing dipeptide carnosine and anserine has been to be present within the skeletal muscle of most vertebrate species. It has been reported (1) that carnosine and anserine are effect of blood lactate buffering, remove of reactive oxygen species and reduction of muscle fatigue. Maemura (2) was reported carnosine concentration in skeletal muscle increase by carnosine and anserine high-containing drink supplementation. And also performance of high-intensity intermittent exercise was improved by the carnosine and anserine high-containing drink supplementation. Anserine is can't be existence in human skeletal muscle (3), however, anserine and those constitution amino acids was temporary detected in blood by carnosine or/and anserine supplementation (2). The purpose of this study was to examine the effects of anserine-containing fish-sausage supplementation after exhaustion exercise on high-intensity exercise performance. **Methods** Twenty four male students (body weight: 67.7 ± 9.48 kg) as subjects in the present study. The subjects randomly selected and divided into three groups (High-anserine, Low-anserine, 0-anserine). Subjects was performed drop-jump and 30-s maximal sprinting exercise for exhaustion exercise. Two hours after completing the exhaustion exercise, the subjects performed the high-intensity intermittent exercise (EX). Intermittent exercise consisted of ten 5-s maximal sprints with 25-s of recovery between each sprint. Also, subjects was took the test sample for fish-sausage (20g) after the exhaustion exercise during 10-15 minutes. Fish-sausage anserine-containing quantity was determined according to previous study (4), each at High-group 400mg, Low-group 50mg, 0-group 0mg. Mean power was measured each sprint for an assessment of the EX performance. The data was expressed division by subject weight. Results In the mean power, it was not statistically significant, but it was suggested that possibility have a tendency to keep anserine concentration-dependent in the final set. (0.05)

EFFECT OF INORGANIC NITRATE INGESTION WITH BEETROOT JUICE ON SKIN-GAS NITRIC OXIDE CONCENTRATIONS

Itoh, H., Matsuura, K., Yamaguchi, A., Sugiura, S., Nakano, S., Li, S., Ohkuwa, T., Tsuda, T.

Nagoya Institute of Technology

Introduction Nitric oxide (NO) is one of the most important endothelium-derived relaxing factor (EDRF), which plays a pivotal role in modulating smooth muscle tone in the human conductance and resistance vessels (Moncada S. and Higgs E., 2006). Interestingly, inorganic nitrate (NO₃⁻) ingestion with beetroot juice (BR) has been shown to increase plasma [NO₃⁻], nitrite (NO₂⁻) concentrations, and reduce blood pressure due to the production of NO-like bioactivity (Wylie et al. 2013). Although we (Ohkuwa et al. 2006) have been detected NO emanating from human skin (skin-gas), no one has confirmed the effect of inorganic NO₃⁻ ingestion on skin-gas NO concentrations. Therefore, the purpose of the present study was to investigate the effect of BR ingestion on skin-gas NO concentrations. **Methods** Nine healthy male students (22.6 ± 1.0 years; mean \pm SD) ingested 280 ml BR (containing 16.8 mmol NO₃⁻; Beet It; James White Drinks, Ipswich, UK) or 280 ml water (placebo (PI)). The skin-gas samples were obtained by the covering left hand for 30 sec with a polyfluorovinyl bag (Tedlar bag; GLScience, Tokyo, Japan) in which pure nitrogen gas was introduced, and collected in a sampling bag at rest, and 1, 2, 3, 4 h after P or BR ingestion. The skin-gas NO concentration was measured by a chemiluminescence analyzer (Pico-Device Co., Ltd., Nagoya, Japan). Forearm blood pressure was also measured with a Vascular Screening System (VaSera VS-1000, Fukuda Denshi Co., Ltd., Tokyo, Japan). **Results** At resting baseline, the skin-gas NO concentration was not significantly different between P and BR. BR ingestion tended to increase the skin-gas NO concentration, and the peak values above baseline in skin-gas NO concentration occurred 1 h post BR ingestion. Thus, there was a significant interaction effect for the skin-gas NO concentration between ingestion and time ($p < 0.05$). On the other hand, no significant difference was found in blood pressure between P and BR ingestion at rest and after ingestion. **Discussion** The beneficial hemodynamic of NO₃⁻ supplementation are thought to be due to the reduction of NO₃⁻ to NO₂⁻ and then to NO within the blood vessel (Feelisch et al. 2008), resulting in arterial dilatation and a reduced peripheral resistance (Webb AJ et al. 2008). Our results in the skin-gas NO concentration were similar to the results of Wylie et al. (2013) which has reported increased plasma [NO₃⁻], and reached the peak values in plasma [NO₃⁻] above baseline 1 h post BR ingestion. Although the reason for increased the skin-gas NO concentration in this study was unclear, changes in the skin-gas NO concentration might reflect plasma [NO₃⁻]. **References** Moncada S and Higgs E (2006) Br J Pharmacol, 147: S193-201. EFFECT OF ENERGY DRINK CONSUMPTION ON AUTONOMIC CARDIOVASCULAR CONTROL DURING MENTAL AND PHYSICAL STRESS IN YOUNG

Lima, F.R., Nascimento, J.C.F., Guaraldo, E., Braggion, G.F., Brito, C.A.F., Alonso, D.O.

The Municipal University of São Caetano do Sul – USCS

In recent years, energy drinks consumption has grown significantly, especially for young people, who aims to increase physical endurance, get faster reactions and higher concentration, increase mental alertness, prevent sleep, feel wellness and stimulate metabolism. The energy drink is a soft drink, basically composed of caffeine, taurine and guaranine. Although several studies have shown the effects of energy drinks at rest and during exercise, its effect on the autonomic control has been less discussed. The assessment of heart rate variability (HRV) during mental stress can bring about the effects of autonomic control without influence of metabolic changes caused by exercise. The aim of this study was to evaluate autonomic control after intake of energy drink by HRV in young subjects at rest, during mental and physical stress (exercise). Ten young subjects were evaluated on three sessions, 30 minutes after ingestion of energy drink or placebo: Session 1 (energy drink): rest, mental stress, recovery; Session 2 (placebo): rest, exercise, recovery; Session 3 (energy drink): rest, exercise, recovery. Exercise was performed by 30 minutes with intensity set at 50-70% of heart rate (HR) reserve. HR (R-R interval) and HRV was measured by Polar® RS800CX and analyzed on time and frequency domains by Polar Pro Trainer and Cardio Series softwares. Statistical analysis was made using Friedman test, with Bonferroni correction, and T test, considering $P < 0.05$. HR and HRV variability showed no differences between sessions 1, 2 and 3, at rest (R-R: 734.9 ± 95.7 vs. 742.3 ± 110.0 vs. 762.3 ± 122.5 ; LF: 1207.2 ± 562.1 vs. 1332.3 ± 796.8 vs. 1860.8 ± 1277.2 ; HF: 1147.1 ± 949.5 vs. 491.2 ± 234.1 vs. 890.2 ± 789.3). Mental stress diminished R-R (734.8 ± 95.7 vs. 629.1 ± 33.6) and standard deviation (SD: 79.1 ± 33.0 vs. 56.8 ± 13.7) of HR. SD returned to rest values at mental stress recovery (79.1 ± 33.0 vs. 73.9 ± 26.2), which was not observed after sessions 2 (73.6 ± 26.2 vs. 36.8 ± 18.3) and 3 (77.0 ± 25.4 vs. 52.2 ± 21.9). There were no differences in HR (415.0 ± 39.0 vs. 422.1 ± 60.3) or HRV (SD: 21.2 ± 12.7 vs. 15.4 ± 6.2 ; LF/HF: 7.4 ± 3.2 vs. 7.2 ± 4.0) between sessions 2 and 3 at exercise, but, studying SD1 of seven participants, we noted that this variable was lower in session 2 (2.6 ± 1.2 vs. 3.6 ± 2.9), suggesting that exercise after placebo ingestion elicited more intensity than after caffeine ingestion. Recovery data also support this possibility, because parasympathetic activity was augmented faster after caffeine ingestion. Caffeine ingestion seems to facilitate exercise and recovery. This effect can be beneficial for athletes or individuals who practice physical activity for health promotion.

THE EFFECT OF ACUTE VS CHRONIC MAGNESIUM SUPPLEMENTATION ON RESISTANCE EXERCISE AND VASCULAR RESPONSE.

Kass, L.S., Poeira, J.F.

University of Hertfordshire

Introduction Magnesium (Mg2+) supplementation has shown reduction in blood pressure in previous studies varying from 0 to 12 mmHg. Previous research has also shown a positive relationship between Mg2+ supplementation and performance gains in resistance exercise. However, no previous studies have investigated loading strategies for Mg2+ to optimise response. The aim of this study was to assess the effect of oral Mg2+ supplementation on resistance exercise and vascular response for an acute (A) and chronic (Chr) loading strategy. Methods The study was a randomised, double-blind, cross-over controlled 2 day repeat design (n=20). Bench press at 80% 1RM to exhaustion was completed, with blood pressure and total peripheral resistance (TPR) recorded after. 300mg/d elemental Mg2+ was supplemented for either a 1 (A) or 4 (Chr) week loading strategy. Food diaries were recorded to ensure participants met the RNI for Mg2+. Results Dietary Mg2+ intake was 368mg and 375mg for A and Chr respectively, both above the RNI. Bench press showed a significant increase of 17.7% ($p=0.031$) for A on day 1 with no significance shown for the Chr ($p=0.281$). On day 2 A showed no decrease in performance compared to day 1 with Chr showing a 32.1% decrease, not showing significance. On day 2 post-exercise systolic blood pressure (SBP) was significantly lower in both A ($p=0.047$) and Chr ($p=0.016$) compared to placebo. Diastolic blood pressure (DBP) also showed no changes with intervention on day 1 but again on day 2 there were significant decreases with the intervention compared to baseline for A ($p=0.047$) but no changes in the Chr. TPR reduced for A on days 1 and 2 ($p=0.031$) with Chr showing an increase on day 1 ($p=0.008$) and no change on day 2. Discussion This study found that Chr did not have a cumulative effect on A. Acute Mg2+ loading showed a significant improvement for bench press of 5.5kg concurring with previous research (Matias et al 2010) which was not seen in Chr. On day 2 Chr showed a 32.1% decrease whereas A showed a small non-significant increase but not a decrement as would be expected. SBP showed no reduction with either intervention. DBP showed reductions in both Chr and A at various time points, agreeing with previous literature (Kass et al 2013) but showing no difference between the two loading strategies, suggestive of a different mechanism for BP reduction than for muscular contraction. TPR showed greater reductions with A than Chr, which would not be expected as both interventions had reductions in BP, which is associated with TPR. References Matias, C. N., Santos, D. A., Monteiro, C. P., Silva, A. M., Raposo, M. D. F., Martins, F., Laires, M. J. (2010). *Mag Res.* 23(3), 138–41 Kass, L. S., Skinner, P., & Poeira, F. (2013). *J Sports Sci Med.* 144–150.

MICROBIOLOGICAL QUALITY AND SAFETY OF DIETARY SUPPLEMENTS IN SAUDI ARABIA

Aljaloud, S.

KING SAUD UNIVERSITY

Abstract The global market for dietary supplements has advanced in recent years capitalizing on the growing awareness of healthy living worldwide. Supplements provide enhanced nutritional levels for daily competitive performance. However, there is a need to explore the quality of dietary supplements as there are few studies related to this area. Therefore, the objective of this study was to determine the microbiological quality of dietary supplements in the local markets of Saudi Arabia. The total bacterial count, coliform, *Escherichia coli*, *Salmonella*, and *Staphylococcus aureus* were included in this analysis. The 60 most popular supplements were tested in this study. Our results showed that microbial contamination was present in only six products. The microbial level ranged from 1.66–8.62 Log CFU/mL. The higher level of total count (8.62 Log CFU/mL) and *S. aureus* (8.43 Log CFU/mL) were found in supplement glutamine. Amino acids, dynamisan, creatine monohydrate, and whey protein, also showed the presence of bacterial contamination. Our findings suggested that improvements are needed in these supplements which were tested for microbiological contamination. These findings highlight the fact that a review of product safety and quality is becoming increasingly important for consumer health. This will help to ensure safe products available for today's savvy, health-conscious consumer.

NITRIC OXIDE EMANATING FROM HUMAN SKIN FOLLOWING SUBMAXIMAL BICYCLE EXERCISE

Matsuura, K., Yamaguchi, A., Sugiura, S., Nakano, S., Li, S., Ohkuwa, T., Tsuda, T., Itoh, H.

Nagoya Institute of Technology

Introduction It is well known that an increase in blood flow stimulates vascular endothelial cells and advances the production of nitric oxide (NO) (Matsumoto et al. 1994; Jungersten et al. 1997). Previously, we (Itoh H, et al. 2007) have demonstrated that the repetitive wrist flexion-extension exercise increases regional blood flow and skin-gas NO concentration of the exercising hand. However, very little data concerning the changes in skin-gas NO concentration during whole body exercise has reported. Therefore, the purpose of the present study was to investigate the changes in skin-gas NO concentration of non-exercising hand during submaximal bicycle exercise. **Methods** Six healthy male students (22.5 ± 1.1 years; mean \pm SD) performed submaximal (50% HRmax) cycle exercise for 30 min. The skin-gas samples were obtained by covering the left hand for 30 sec with a polyfluorovinyl bag (Tedlar bag; GLScience, Tokyo, Japan) in which pure nitrogen gas was introduced, and collected in a sampling bag at rest and after exercise (0, 10, 20, 30 min). The skin-gas NO concentration was measured by a chemiluminescence analyzer (Pico-Device Co., Ltd., Nagoya, Japan). Results HR of the subject increased during exercise (from 76.2 ± 11.0 to 139.8 ± 12.3 beats/min). The skin-gas NO concentration significantly increased immediately after the exercise compared to the resting values ($p < 0.05$), then returned to resting values until 20 min after the exercise. Thus the peak skin-gas NO concentration was observed immediately after the exercise. **Discussion** NO is the most important endothelium-derived relaxing factor, which plays a pivotal role in modulating smooth muscle tone in the human conductance and resistance vessels (Moncada S. and Higgs E., 2006). Increased NO concentrations in non-exercised hand observed in this study have suggest that NO production was facilitated with increased cyclic wall stress associated with increasing pulsatile blood flow during whole body exercise (Matsumoto et al. 1994; Jungersten et al. 1997). Furthermore, sympathetic nervous activity, circulating hormones, exercised muscle-derived metabolites might also affect the production of NO during and after the exercise. **References** Matsumoto A, et al. Introduction In the last few years, rodents fed on a fructose-rich diet (F) have been used as a Metabolic Syndrome (MS) model. Among the forms of treatment of the MS and/or its components are medication, diet and physical exercise. Thus, the purpose of this research was to determine whether the administration of a balanced diet in an experimental model is able to reverse some MS markers triggered by F. **Methods:** Immediately after birth, the male offspring were split into three groups according to the administered diet. Balanced diet (B): fed on a B during the whole experimental period; Fructose (Fructose-rich diet 60%): fed on F during whole experimental period, and Fructose/Balanced (FB): F diet from birth to 60 days and B diet from 60 to 90 days. **Results:** A F imposed from birth to 60 days reduced weight gain, as well as the weight of adipose tissue (mg/100mg) in all regions analyzed (Epididymal – B: 0.22 ± 0.05 ; F: $0.14 \pm 0.07^*$), Mesenteric – B: 0.43 ± 0.07 F: $0.22 \pm 0.16^*$, Retroperitoneal – B: 0.23 ± 0.08 ; F: $0.10 \pm 0.11^*$ and Posterior Subcutaneous – B: 0.38 ± 0.07 ; F: $0.18 \pm 0.10^*$, and it altered the lipid profile (mg/dL) – * Significant difference, Student's t-test's, $p < 0.05$ (Triglycerides – B: 84 ± 24 ; F: $133 \pm 30^*$, Total-Cholesterol – B: 71 ± 12 ; F: $90 \pm 15^*$, LDL-Cholesterol – B: 50 ± 6 ; F: $63 \pm 7^*$). When a B was administered after the F, it was able to partially reverse changes to lipid levels (mg/dL): total cholesterol (B: $100 \pm 11a$; F: $136 \pm 9b$; FB: $119 \pm 16c$), LDL-Cholesterol (B: 55 ± 6 ; F: 59 ± 6 ; FB: 54 ± 5) and Triglycerides (B: $76 \pm 17a$; F: $128 \pm 19b$; FB: $103 \pm 27c$). Different letters indicate significant difference, Two-Way ANOVA and Newman-Keuls' Post-Hoc, $p < 0.05$. **Discussion:** This reduced weight in the adipose tissue and the consequent reduction in the rate of weight gain may be due to a fructose intolerance due to the excessive intake of this nutrient from the neonatal period (Cambri et al., 2010). The lipogenic characteristic of fructose (Sanchez-Lozada et al. 2007; Cambri et al., 2010) led to increased levels of plasma lipids as presented by the groups fed on this diet (F and FB). Concluding, in this study, a fructose rich diet triggered some signs of metabolic syndrome, and the short-time administration of a balanced diet partially reversed these changed parameters. These results suggest that a combination of diet and physical exercise seems to be essential for obtaining substantial changes in certain parameters. **References** Cambri LT, Ghezzi AC, Ribeiro C, Dalia RA, Mello MAR (2010). *Nut Res*, 30(2), 156-162. LEUCINE SUPPLEMENTATION DOES NOT CHANGE EXPRESSION OF PROTEINS INVOLVED IN THE SIGNALING PATHWAYS FOR PROTEIN SYNTHESIS IN DETRAINED RATS UNDER CALORIC RESTRICTION

Nishimura, L.1, Pedrosa, J.A.B.1, Matos Neto, E.M.1, Cruz, C.G.1, Pires, I.S.O.1, Tirapegui, J.1

1-University of São Paulo

Introduction Physical detraining (PD) is associated with increased fat mass and changes in protein metabolism, accelerating muscle catabolism. One of the nutritional strategies used to minimize the increase in adipose mass is caloric restriction (CR). However, this strategy may potentiate the loss of muscle mass, as observed in PD. Supplementation with essential amino acids, particularly leucine, might mitigate these effects. This seems to act effectively to promote protein balance and body fat reduction. Therefore, this study aims to assess the influence of chronic leucine supplementation in the signaling pathway of protein synthesis in skeletal muscle of detrained rats undergoing caloric restriction. **Methods** 48 adult male Sprague-Dawley rats were distributed into 2 groups: Sedentary (SED, n=8) and Trained (TRAIN, n=40); the animals of the latter group underwent training on a treadmill for 8 weeks. TRAIN animals were then re-distributed into four groups: Trained (TRAIN, n=8): which continued following the physical training protocol; Detrained (DT, n=8): consisting of animals who stopped training and had access to food ad libitum; Detrained + Caloric restriction (CR+DT): consisting of animals who stopped training and had 70% of DT caloric intake; Detrained + Leucine + Caloric restriction (CR+DT+LEU): composed of animals who stopped training and had 70% of DT caloric intake, and had 5% leucine supplementation. After 14 weeks, animals were euthanized and the expression of proteins involved in the signaling pathway for protein synthesis in skeletal muscle tissue was assessed ANOVA was used for comparison between groups, along with Scheffé test, considering a 5% significance level. **Results** Regarding expression of proteins involved in signaling pathway of protein synthesis in the muscle, no statistically significant difference was detected between groups for proteins mTOR (Ser2448), P-4EBP1 (Thr70), P-s6K1 (Thr389) and eIF4E (Ser209). **Discussion** Studies indicate that branched-chain amino acids stimulate synthesis and mitigate protein degradation, thus maintaining lean body mass (CROZIER et al, 2005). Specifically

leucine exerts its effects at post-transcriptional level during the initiation phase of messenger RNA translation into protein (ANTHONY et al, 2000). However, this study shows that in detrained rats undergoing caloric restriction, leucine supplementation was not effective to change the expression of proteins involved in the signaling pathway of protein synthesis. THE PROTEIN INTAKE FROM DIETARY AND SUPPLEMENTS IN MEN BODYBUILDER

Çoşkun, M.N.1, Karabudak, E.2

1Başkent University, Faculty of Health Science, Nutrition and Dietetic Department (Ankara, Turkey) 2Gazi University, Faculty of Health Science, Nutrition and Dietetic Department (Ankara, Turkey)

Introduction Bodybuilders habitually consumed excessive dietary protein over the amounts recommended for them to promote muscle mass accretion. This study investigated the protein intake from dietary source and nutritional supplements of individuals interested in body building sport. **Methods** Thirty amateur bodybuilders (mean age 26.9±3.9 years) who attended five different sports clubs and a control group of age, sex and cultural features matched which do not make physical activity regularly were recruited. Bodybuilders trained over two years. To determine dietary intake, three-day food records were used to assess the amount of consumed foods and number of daily meals. Bodybuilders also recorded all of the protein supplements they were taking. For 2-group comparisons, independent t test were used to identify evidence of a significant difference. **Results** Nearly half (43.3%) of the individuals engaged in body building were interested in this sport to improve the physical self appearance. Reported that; 60% of the bodybuilders and 30% of the control group are satisfied with self body weights and 56.7% of bodybuilders and 26.7% of control group are satisfied with the current muscle size. Nearly 47% of bodybuilders and 23.3% of control group individuals are using nutritional supplements. A daily intake of dietary protein was 1.7±0.5 g/kg per body weight for bodybuilders and 1.1±0.3 g/kg per body weight for control groups. Protein amount which also consist of nutritional protein supplements which is taken by bodybuilders increased from 1.7±0.5 g/kg per body weight to 1.8±0.6 g/kg per body weight and it was found to be statistically significant ($p<0.05$). **Discussion** It has been suggested that the consumption of 1.2-1.7g protein/kg body weight is recommended for bodybuilders to maintain muscle mass. This study provides preliminary information amount of protein intake in Turkish amateur bodybuilders who engaged in high-intensity resistance exercise. References Lowery LM, Devia L. RELATIONSHIP BETWEEN UNDESIRABLE EATING HABITS AND HEALTH-RELATED COMPLAINTS OF ELITE HIGH SCHOOL TRACK AND FIELD ATHLETES

Sugiura, K.1, Sakai, K.2, Takenami, E.3, Ishii, K.4, Torii, S.5, Sugita, M.6

1: Rikkyo (St. Paul) Univ., 2: Josai International Univ., 3: Univ of Tokyo., 4: Doshisha Univ., 5: Waseda Univ., 6: Mie Univ.

Introduction It is universally accepted that prudent nutrient intake and desirable eating behaviour improve physical performance and/or maintain physical condition in athletes. Many reports suggest that some adolescents have not established a well-balanced diet, such as low fruit and vegetable intake, frequent consumption of high-fat snacks, skipping breakfast, and other poor nutritional choices. Therefore, in this study, we examine the relationship between undesirable eating habits and health-related complaints of elite high school track and field athletes. **Methods** Seven hundred and twenty two elite high school track and field athletes, who had got a place in Inter-high school Championship during 2004 to 2012 have completed self-administered questionnaire. Athletic events were divided into 7 categories; sprints, middle/long distances, jumps, throws, hurdles, combined events, and race walks. Questionnaire was consisted of scales for measuring two constructs of undesirable eating habits (junk foods and high fat foods) and health-related complaints. Comparison of the total score of each variable was carried out using 2-way ANOVA. The relationship between each total score was analysed using Pearson's product-moment correlation coefficient. Differences were considered significant at $p<0.05$. **Results** Analysis with 2-way ANOVA showed all the variables measured had significant differences in the main annual effect, but showed significant differences in 2-way interactions. The score of junk foods, represent one of undesirable eating habits of throwers was higher than that of middle/long distance runners. Another score of high fat foods of throwers was higher than that of sprinters, middle/long distance runners and race walkers. On the other hand, the score of health-related complaints of middle/long distance runners was higher compared to that of race walkers. There was significant correlation between the score of high fat foods and the score of health-related complaints regardless of categories. Only in sprinters and jumpers, the scores of junk foods correlated with the scores of health-related complaints. **Discussion** These results suggested that undesirable eating habits affect the health-related complaints of elite high school track and field athletes. Especially habitual eating of high fat foods might impair their physical condition. Middle/long distance runners were intent not to be undesirable eating, but they felt health-related complaints, so they might be overtrained. Further study would be needed to elucidate the relationship between dietary behaviour and physical condition to prevent the occurrence of sports injury. Contact ksugiura@rikkyo.ac.jp

EXCESS DIETARY MAGNESIUM INCREASES EXPRESSION OF TRPM7, BUT DOES NOT IMPROVE THE AMOUNT OF MAGNESIUM IN RAT SKELETAL MUSCLE OF SWIMMING EXERCISED RATS

Sakai, K., Shibata, R., Sugo, T., Shuto, E., Ohta, A.

JOSAI International University

Introduction Magnesium (Mg) is an abundant mineral in the human body, and plays a role as a co-factor to activate various enzymes, particularly gluco-regulated kinases. We have observed that swimming exercise increased the apparent absorption of Mg, expression of TRPM7 and amount of Mg content in rat skeletal muscle, revealing significant positive correlations between these variables. These results suggested that swimming exercise would enhance Mg requirements in rats. Therefore, the aim of this study is to examine whether the increase in dietary Mg content improves the nutritional Mg-status measuring these variables in swimming rats. **Methods** Forty-four 6-week-old male Wistar-Hannover rats were randomly assigned to two equal groups. Rats in one group ($n=22$) were housed under sedentary conditions during the experimental period, and rats in another swam continuously for 2 h without a load (6 days/week). Rats in each group divided into two subgroup and one-half of the rats were fed a purified diet of AIN-93G composition (Mg; 530 ppm) and the remaining half were fed high Mg diet (Mg; 1194 ppm) according to AIN-93G for 15 days (17.5 g/day). On day 15, rats were sacrificed and their blood and gastrocnemius muscle were quickly removed. Mg levels in serum and muscle were determined using a sequential plasma spectrometer. Amount of TRPM7 expression in muscle was detected with Western blotting analysis. Apparent Mg absorption was

calculated from amounts of Mg intake and fecal excretion. Results Activities of citrate synthase were higher in the swimming rats than in the sedentary rats. Apparent Mg absorption in swimming rats was also higher than in sedentary rats, but not significantly. Serum Mg level in sedentary rats with high Mg diet was higher compared to rats fed normal diet. Mg levels in skeletal muscle were not affected by both amount of dietary Mg and swimming exertion. The expression of TRPM7 in skeletal muscle was improved the effect of dietary Mg contents and swimming exertion. Discussion The present investigation demonstrated that excess dietary Mg did not improve the amount of Mg in rat skeletal muscle regardless of swimming exercise. However, expression of TRPM7 was elevated with increasing dietary Mg content. In the previous study, we observed that the elevation of TRPM7 expression and amounts of Mg contents in swimming rats skeletal muscle. Therefore, exercise-derived stimulation and high Mg concentration in blood might be enhanced the expression of TRPM7 independently. Also, it might be existed some efflux system to regulate intramuscular Mg concentration. Further study would be needed to elucidate the mechanism of Mg influx into skeletal muscle derived from exercise stimulation in rats. Contact: ksakai@jiu.ac.jp

CONCERN FOR WEIGHT CONTROL AND DIETARY SELF EFFICACY OF UNDERGRADUATES

Oladipo, I.O., Konwea, P.E.

University of Ibadan; Ibadan Nigeria

Introduction The study examined undergraduates concern for weight-control and their dietary self-efficacy to determine the level of confidence they have in their ability to reduce the amount of fat in the food they consumed by engaging in fat restrictive actions, based on their weight control status. **Methods** The descriptive survey research design of the ex-post facto was used for this study. One thousand nine hundred and fifty undergraduates were included in the study. The instrument used was a self developed validated questionnaire (Concern for Weight and Dietary Self Efficacy Questionnaire). The questions allowed respondents to determine the category they belonged to in terms of issues of weight and how often they have had such concerns with five points options. The data collected was analysed using percentages and Pearson Product Moment Correlation. **Results** A higher percentage of the respondents 35.5% were trying to avoid gaining weight constituting more males than females. There is an inverse relationship between dietary self-efficacy and concern for weight control ($r = -.094$, $N = 1950$, $p < 0.05$). This means that while concern for weight control increased, dietary self-efficacy scores reduced. In all the categories of weight control status, more than half of the respondents had moderate dietary self efficacy. For those "considering losing weight" "trying to avoid gaining weight" and those "actively trying to lose weight", only 19.9%, 26.4% and 31.7% respectively had high dietary self efficacy. **Discussion** The findings of this study revealed that undergraduates have varying concern for weight control and that majority of them have moderate dietary self efficacy irrespective of their weight control status. This indicates that attempt to control weight may not depend on altering food content or on fat restriction for these respondents. This could be because there are other conditions that the respondents cannot control. Money et al (1994) however stated that personal choice of food causes thinness or obesity. Though researchers (Liou, 2004;) have shown that high dietary efficacy predict increased ability to lose weight and decreased attrition from weight loss programmes. **References** Hawks, S.R. LEUCINE IS REQUIRED FOR MAXIMAL AMINO ACID INDUCED S6K1 ACTIVITY IN HUMAN SKELETAL MUSCLE AFTER RESISTANCE EXERCISE

Apró, W.1,2, Moberg, M.2, Ekblom, B.2, Holmberg, H.C.3, Blomstrand, E.2

1:CLINTEC, Karolinska Institutet (Stockholm, Sweden), 2:The Swedish School of Sport and Health Sciences (Stockholm, Sweden),

3:Department of Health Sciences, Mid Sweden University (Östersund, Sweden)

1Dept. of Clinical Sciences, Intervention and Technology, Karolinska Institutet, 2Åstrand Laboratory, Swedish School of Sport and Health Sciences and 3Dept. of Health Sciences, Mid Sweden University, Sweden **Introduction** Muscle hypertrophy is mainly regulated by the mechanistic target of rapamycin complex 1 (mTORC1) which phosphorylates ribosomal protein S6 kinase 1 (S6K1) at T389, thus increasing the activity of this kinase [1]. Amino acids induce robust elevations in S6K1 phosphorylation when combined with resistance exercise [2] and it has been suggested that leucine (Leu) mediates this response. Indeed, when Leu is removed from an essential amino acid (EAA) supplement, T389 phosphorylation is dramatically reduced [2], thus highlighting the importance of Leu. However, to date, no direct comparisons have been made between the effects of Leu and EAA. Therefore, the aim of this study was to examine the role of Leu in the amino acid induced phosphorylation of S6K1 and the resulting increase in kinase activity. **Methods** Nine male subjects performed four sessions of resistance exercise and were randomly supplemented with one of four drinks: Pla, Leu or essential amino acids with (EAA) and without Leu (EAA-Leu). Muscle biopsies were taken before and 1 hour after exercise and analyzed for S6K1 phosphorylation and activity using western blot and radiolabeled technique, respectively. **Results** After exercise, phosphorylation of S6K1 at T389 was significantly higher with Leu (170%) and EAA (280%) vs. the two supplements without leucine. Moreover, the increase with EAA was 40% larger ($P < 0.05$) than with Leu. Accordingly, the maximal activity of S6K1 tended to be higher (28%, $P = 0.075$) with EAA vs. Leu and both Leu and EAA induced a larger ($P < 0.05$) increase in S6K1 activity (54 and 97%) vs. Pla. Additionally, there was a significant correlation between T389 phosphorylation and S6K1 activity ($r = 0.72$, $P < 0.05$). **Discussion** In this study we show that Leu plays a critical role in the regulation of mTORC1 and its downstream target S6K1. However, our data also indicate that Leu alone may not be sufficient to maximally activate the pathway as evidenced by higher phosphorylation and a trend towards a higher S6K1 activity with EAA intake. In addition, we show a strong relationship between T389 phosphorylation and S6K1 activity. Contact E-mail: william.apro@gjh.se **References** 1. EFFECTS OF OIL SUPPLEMENTATION IN TRAINED AND SEDENTARY ANIMALS

Candido, J.P., Costa, K.G., Brenzikofer, R., Macedo, D.V.

State University of Campinas-UNICAMP

EFFECTS OF OIL SUPPLEMENTATION IN TRAINED AND SEDENTARY ANIMALS Introduction Plant and animal oils have been linked to weight loss and gain of lean body mass. Rice bran oil looks interesting as an exercise supplement due to the high content of polyunsaturated fatty acids ($\omega 9$ 40%, $\omega 6$ 34.5%, $\omega 3$ 1.8%) and antioxidants. Also contains gamma oryzanol, an sterol with possible anabolic effects. Our goal was to analyze the effects of different doses of rice bran oil ingestion in sedentary (protocol A) and in rats submitted to strength training (protocol B) on body composition, food intake and serum leptin and adipokine concentrations. Methods Protocol A: Forty Wistar male rats were divided into 4 experimental groups: control (water - GW) and supplemented during 8 weeks with different doses of rice bran oil by gavage (1, 2, and 6 mL - G1, G2 and G3, respectively). Protocol B: Twenty Wistar male rats trained for eight weeks with three sessions per week, four climbing for session, and overload in grams (g) adjusted every week by a performance test were divided into 3 groups: Control trained (Tr) and trained supplemented with 0.75 and 1.5mL of oil (Tr-0.75 and Tr-1.5). Food intake and animals weight were evaluated weekly. The amount of gonadal fat and serum leptin and adipokine concentrations was also evaluated. Results Protocol A: Food intake did not change in G1 (86.19 ± 12.56) and G2 (74.32 ± 4.73) when compared to GW (85.03 ± 8.37 g). However, it was significantly lower in G3 (40.45 ± 7.77 g). The weight of animals did not change significantly in any group. However, gonadal fat in G2 (9.91 ± 1.71 g) and G3 (11.08 ± 2.53 g) significantly increased compared to GW (7.01 ± 0.98 g) and G1 (8.59 ± 1.84 g). Also serum leptin were significantly increased in G2 (1393 ± 682 pg/mL) and G3 (1977 ± 652 pg/mL) relative to GW (259.2 ± 179.7 pg/mL) and G1 (1018 ± 465 pg/mL). There were no significant changes in serum adipokine concentrations between groups. Protocol B: The performance of Tr (596.8 ± 33.53), Tr-0.75 (575.0 ± 57.7) and Tr-1.5 group (527.5 ± 54.4) significantly increased compared to non-trained group (402.5 ± 27.9). It was not observed significant differences in weight, food consumption, gonadal fat and muscle cross-sectional area of trained animals supplemented or without supplementation. Discussion Although the rice bran oil contains components with potential effect for lean mass gains, the data presented here did not confirm that. Contrarily, we have showed increased fat mass, especially when were consumed larger amounts of oil without physical activity. On the other hand, rice bran oil supplementation produced no additional ergogenic effect on strength performance and body composition of animals induced by strength training. Overall our data suggest caution when using oil as a supplement.

PHYSICAL ACTIVITY LEVELS AND NUTRITIONAL KNOWLEDGE'S AMONG CHILDREN AND ADOLESCENTS

Ribeiro, J.I, Ramos, H.I, Ferro Lebres, V.I,3, Aires, L.I, Mota, J.I, Guimarães, N.I, Esteves, R.I, Moreira, P.I,2, Marçal, G.I

1: Sports Faculty, University of Porto; 2:Faculty of Nutrition and Food Sciences, University of Porto; 3:School of Health Sciences - Polytechnic Institute of Braganza

Introduction Childhood obesity is a consequence of environments that disrupt the balance of energy intake and energy expenditure. Obesogenic environments consist of social norms and environmental factors that facilitate unhealthy behaviors around diet and physical activity. Nutritional knowledge and physical activity are cornerstones of every obesity treatment. The aims are to understand and compare how nutritional knowledge and physical activity patterns occur in children and adolescents, and if there's any differences by gender. **Methods** Sample comprised 467 children and adolescents, 237 boys. PA was measured using Actigraph accelerometers (GT3Xs). Participants were instructed to use the accelerometer, according to standard procedures, and data analyzed using the recommended guidelines (Evenson et al, 2008). Nutritional Knowledge (NK) was assessed using the General Nutrition Questionnaire for Portuguese Adolescent, and results presented as a Final Nutritional Score, in accordance with standard procedures (Ferro-Lebres, V, Ribeiro, J, Moreira, P, 2014). Height, weight, body mass index were also assessed. Univariate Analysis of Variance-GLM was used to compare genders adjusted to different school levels of the students, using SPSS. Results Our results present higher ($p < 0.05$) nutritional scores for girls (67,1) than boys (63,6 score). Opposed to these results boys (as expected) significantly present higher amounts of moderate to vigorous PA compared to girls (71,6 min./day vs 42,3 min./day; $p < 0.01$). Additionally, we have 14,7% overweight/obese girls and 17,4% overweight/obese boys. **Discussion** Other studies have observed similar results regarding MVPA in boys and girls, but the NK about diet and nutrition is also crucial for the treatment and prevention of obesity in children. Therefore it's important to understand if higher scores in NK would lead to better nutritional practices; would it be possible that increasing student's NK about food contents regarding different nutrients could improve their daily practices. Do children and adolescents that have better NK behave differently regarding PA practices? **References:** Evenson, K. R., et al (2008). Journal of Sports Sciences, 26(14), 1557-1565. EFFECTS OF ISOLATED AND COMBINED CARBOHYDRATE AND CAFFEINE SUPPLEMENTATION DURING A SHORT-PERIOD RECOVERY ON SOCCER PERFORMANCE

Andrade Souza, V.I, Bertuzzi, R.2, Bishop, D.3, Lima Silva, A.I

1: UFPE (Vitória Sto Antão, Brazil), 2: USP (São Paulo, Brazil), 3: ISEAL (Melbourne, Australia)

Introduction Considering the lack of published data around the isolated and combined effects of CHO and CAF supplementation on physical and technical performance of soccer players, this study was drafted to investigate whether isolated and combined CHO and CAF supplementation administrated during a 4-h recovery period would have effect on subsequent soccer performance parameters. **Methods** In the morning, participants performed a 90-min Loughborough Intermittent Shuttle Test (LIST). Then, participants ingested: 1) 1.2 g • kg⁻¹ body mass (BM) • h⁻¹ CHO of a 20% CHO solution immediately after and 1, 2, and 3 h post LIST; 2) a dose of CAF (6 mg • kg⁻¹ BM) 3 h post LIST; 3) the same amount of CHO combined with CAF (CHO + CAF); 4) distilled water combined with cellulose capsule (PLA). After a 4-h recovery period the participants performed in sequence (5 min between each test) a countermovement jump test (CMJ), an agility test, a Loughborough Soccer Passing test (LSPT) and a repeated sprint test (5 x 30 m). Results CAF tended to improve CMJ height compared to baseline (34.9 ± 4.4 vs. 32.9 ± 3.5 cm, $p = .07$), and significantly improved LSPT performance (40.9 ± 13.0 vs. baseline 45.8 ± 11.6 s, $p = .05$). Both CHO and CHO + CAF ingestion promoted negative effects on RPE and pleasure-displeasure. **Discussion** The main finding of this study was that the isolated ingestion of a moderate dose of CAF (6 mg • kg⁻¹ BM), but not when associated with CHO, improved CMJ height and passing accuracy on subsequent training session. These results are consistent with Foskett et al. (2009), who reported using similar dose of CAF an improvement on CMJ and passing performance after a LIST protocol. However, in the present study, the co-ingestion of CHO and CAF did not promote positive effects on passing skills, corroborating with Gant et al. (2010) who also observed that

soccer passing accuracy was not improved with CHO + CAF. On the other hand, isolated CHO and combined CHO + CAF ingestion promoted an increase in RPE and a decrease in pleasure before the tests, when compared to baseline. Although, this adverse effect was not observed after the four tests. Furthermore, the positive effects of CAF alone suggest that any effect of CHO + CAF is not derived from a potentiation of these two supplements, but might be an isolated effect of CAF. References Foskett A, Ali A, Gant N. (2009). *Int J Sport Nutr Exerc Metab*, 19(4), 410–423. Gant N, Ali A, Foskett A. (2010). *Int J Sport Nutr Exerc Metab*, 20, 191-197.

EXERCISE TRAINING, BUT NOT CREATINE SUPPLEMENTATION, PROMOTES BENEFICIAL EFFECTS ON BONE TISSUE IN OVARECTOMIZED RATS.

Murai, I.H., Pabis, L.V.S., Roschel, H., Takayama, L., Pereira, R.M., Ballester, R.Y., Gualano, B.

University of Sao Paulo

Introduction Exercise training has been recognized as a potential therapeutic strategy to counteract postmenopausal-mediated bone loss. Moreover, it has been showed positive effects of creatine supplementation on bone tissue in animals and human. The aim of this study was to assess the effects of physical training associated or not with creatine supplementation on bone mass and biomechanical parameters in ovariectomized rats (OVX). **Methods** Fourteen-week-old female Wistar rats were randomly assigned into five groups: i) sham-operated (SHAM, n=12), ii) OVX supplemented with placebo (OVX+PL, n=12), iii) OVX supplemented with creatine (OVX+CR, n=12), iv) OVX supplemented with placebo and trained (OVX+PL+TR, n=12) and v) OVX supplemented with creatine and trained (OVX+CR+TR, n=13). All the groups were pair-fed to the SHAM group. One week after ovariectomy surgery, the trained groups were submitted to a 12-week 20° downhill running on a treadmill, 5 days a week, 30 min per session. The animals were treated either with creatine (300 mg/kg/day) or placebo (water) at the same dosage. Body weight was measured daily and bone mineral density and body composition were assessed using a dual-energy x-ray absorptiometry (DXA) scanner before (PRE) and after the experimental protocol (POST). Biomechanical parameters were assessed by a three-point bending test using an universal testing machine. **Results** There were no significant differences between groups at PRE for any variable. Food intake and body weight did not differ within and between groups throughout the experimental protocol ($p>0.05$). Both trained groups (OVX+PL+TR and OVX+CR+TR) showed greater femoral maximal load when compared to SHAM ($p=0.024$ and $p=0.020$, respectively), OVX+PL ($p<0.001$ and $p<0.001$) and OVX+CR ($p=0.002$ and $p=0.002$). No significant differences were observed between OVX+PL and OVX+CR ($p>0.05$), or between OVX+PL+TR and OVX+CR+TR ($p>0.999$). Additional OVX+PL+TR had greater vertebral BMC and BMD when compared to OVX+PL ($p=0.004$ and $p=0.020$, respectively), and OVX+CR+TR showed greater vertebral BMC and BMD when compared to OVX+CR ($p=0.011$ and $p=0.050$). Interestingly, only the trained groups had comparable bone mass parameters when compared to SHAM. **Conclusion** Exercise training, irrespective of creatine supplementation, improved bone mass and biomechanical parameters in ovariectomized rats. These data reinforce the therapeutic role of exercise in offsetting bone mass loss and refute the benefits of creatine on bone tissue.

CONJUGATED LINOLEIC ACID AS AN ERGOGENIC AID IN ENDURANCE PERFORMANCE IN TRAINED CYCLISTS/TRIATHLETES

Mushtaq, S., Morris, M., Benn, J.

University of Chester

Introduction Fatty acid supplements, such as conjugated linoleic acid (CLA), are increasingly being used as ergogenic supplements by endurance athletes. The aim of this study was to assess the efficacy of CLA supplementation as an ergogenic aid in endurance performance among trained cyclists/triathletes. Endurance performance, respiratory exchange ratio, body composition and other exercise parameters were assessed. **Methods** A double-blind, parallel, randomised, placebo controlled trial was carried out in 22 participants (17 men and 5 women) from local triathlon/cycling clubs. A dose of 3000mg/day of CLA (50:50 ratio of cis-9,trans-11 and trans-10,cis-12 isomers) was taken orally for four weeks. A 30-minute steady state cycling test and a 20 kilometre (km) time-trial were performed on a cycle ergometer before and after supplementation to measure the time to finish, as well as heart rate, oxygen consumption (VO₂), respiratory exchange ratio (RER), rating of perceived exertion (RPE) and blood lactate concentrations. Body composition was measured via skin-fold calliper and used to calculate body density and body fat percentage. Diet diaries were provided to ensure that participants' nutrition intake remained consistent. **Results** There were no significant differences between placebo or CLA supplementation groups at baseline or post-supplement in any of the variables measured. There was no significant difference (mean \pm SD) in the time to finish 20km cycling trial between placebo (1513 \pm 145 seconds) and CLA (1619 \pm 169 seconds) groups ($p=0.163$). **Discussion** The results of this study suggest that CLA supplementation for four weeks does not improve endurance performance or alter body composition in trained cyclists/triathletes. The use of CLA as an endurance performance enhancing supplement is relatively new, with very limited evidence to date. However, the findings of the present study are largely consistent with the observations of Colakoglu et al. (2006), who also reported no additional ergogenic effects with ingestion of CLA, although participants in that study were not specifically trained in a particular sport. **References** Colakoglu, S., Colakoglu, M., Taneli, F., Cetinoz, F. & Turkmen, M. (2006). Cumulative effects of conjugated linoleic acid and exercise on endurance development, body composition, serum leptin and insulin levels. *Journal of Sports Medicine and Physical Fitness*, 46(4), 570–577

THE EFFECT OF ACUTE RHODIOLA ROSEA INGESTION ON SUBSTRATE UTILISATION, MOOD STATE, AND PERCEPTIONS OF EXERTION, AROUSAL AND PLEASURE/DISPLEASURE IN ACTIVE MEN

Clarke, N.D., Duncan, M.J.

Coventry University

Introduction The effect of Rhodiola Rosea (R.Rosea) ingestion on exercise performance in time trial and time to exhaustion tasks is equivocal, although studies of the efficacy of R.Rosea ingestion are sparse. However, Noreen et al (2013) suggested that R.Rosea acts to acutely increase endogenous opioid production or receptor sensitivity, which subsequently impacts on brain dopamine and serotonin, cardiac activity and attenuates the perception of effort at a given workload. Therefore, the aim of this study was to examine the effect of acute R.Rosea ingestion containing on substrate utilisation, mood state, RPE, perceptions of arousal and pleasure/displeasure. **Methods** In a double-blind counterbalanced design, ten active males (mean age \pm SD: 26 \pm 6 yr), completed two 30 min cycling trials at an intensity of 70% VO₂max preceded by ingestion of either 3 mg•kg⁻¹ body mass of R.Rosea or placebo. During exercise, heart rate and RPE (6-20 scale) were recorded at 10 min interval. Participants also completed measures of mood state and perceptions of arousal and pleasure/displeasure pre- and post-exercise. Expired air samples were taken pre-exercise and at the mid and endpoint of exercise from

which energy expenditure and substrate utilisation were determined according to the Weir (1949) and Frayn (1983) equations respectively. Repeated measures analysis of variance was used to assess differences in all variables and across time and treatments. Results Results indicate that RPE was lower at 30 min into the exercise bout compared to placebo ($P = 0.003$). Perceptions of arousal were higher in the presence of R.Rosea ($P = 0.05$) and perceptions of pleasure were higher post exercise in the R.Rosea condition compared to placebo ($P = 0.003$). Mood state scores for vigor were also higher in R.Rosea condition compared to placebo ($P = 0.008$). Exercise heart rates were not significantly different and there were no significant differences in energy expenditure, carbohydrate or fat oxidation between conditions ($P > 0.05$). Conclusion Ingestion of R.Rosea favourably influenced RPE and exercise affect without changes in energy expenditure or substrate utilization during 30 minutes submaximal cycling performance at moderate intensity in regularly active men. These changes support the efficacy of acute R.Rosea ingestion in positively enhancing psychophysiological responses to submaximal exercise performance. References Frayn, KN. THE EFFECT OF MILK ON THE ATTENUATION OF EXERCISE-INDUCED MUSCLE DAMAGE IN MALES AND FEMALES.

Rankin, P.1, Stevenson, E.2, Cockburn, E.3

(1)Institute of Technology Carlow, (2)Northumbria University, (3)Middlesex University

Introduction Unaccustomed eccentric muscle contractions have been associated with microdamage in muscle fibres, which is manifested by a decrease in muscle function, and increased muscle soreness. Research has demonstrated that the consumption of milk after muscle damaging exercise can attenuate decreases in muscle functional capacity in males (Cockburn et al., 2010, 2012). There has been no similar research in female participants. Therefore, the aim of this study was to investigate the effects of milk consumption on exercise-induced muscle damage (EIMD) in males and females. Methods Four independent groups (2 male, 2 female) of 8 team sport participants consumed either 500ml milk or 500ml of an energy-matched carbohydrate drink immediately post completion of an eccentrically biased exercise protocol designed to induce muscle damage in the hamstring muscles. Peak torque at 60 and 180°/s, vertical jump height, 20m sprint time and passive and active soreness were assessed immediately before and 24, 48 and 72h post EIMD. Data was analysed by making probabilistic magnitude based inferences about the true values of outcomes (Batterham and Hopkins, 2006). Results Results showed a very likely benefit of milk in females for limiting losses in peak torque at 60°/s, a likely benefit for peak torque at 180°/s, 20m sprint time, passive and active soreness, and a possible benefit for vertical jump, across the 72h. Results for males showed a likely benefit of milk in attenuating passive soreness from baseline-24h, and a very likely benefit for active soreness from baseline-72h. No other benefits for male participants were noted. Gender comparisons provide an indication that females experienced greater muscle damage than males. Discussion The results of this study demonstrate that the consumption of milk is beneficial for females in attenuating the effects of EIMD. In contrast to previous research, there is limited evidence of milk being beneficial for males. However, females experienced greater levels of muscle damage which may have impacted the results. RESPONSIVENESS OF SKELETAL MUSCLE TO TIMING AND DISTRIBUTION OF PROTEIN INTAKE IN OLDER ADULTS: A SYSTEMATIC REVIEW

Thomas, D.K., Greig, C.A.

University of Birmingham

Introduction Ageing is associated with a loss of muscle mass and function, and older muscle demonstrates a 'blunted' anabolic response to protein feeding compared with that of younger adults (Cuthbertson et al., 2005). There is evidence to suggest that responsiveness may be improved by altering the timing and distribution pattern of protein intake (Bollwein et al., 2013, el-Khoury et al., 1995), however chronic intervention studies in older people are sparse. The aim of this systematic review, conforming to the PRISMA statement (Moher et al., 2009), was to determine whether chronic manipulation of protein intake pattern influences muscle mass and function in older men and women. Methods We searched a number of databases (MEDLINE, EBSCO, CINAHL Plus and SPORTDiscus) to include controlled trials in adults aged 65 years and over, comparing the effects of two or more protein intake patterns differing in either timing or distribution. Outcome measures included muscle strength and size, body composition, nitrogen balance, protein turnover and functional measures. Results Five studies were eligible, including 106 participants (34 male, 72 female) with a mean age of 78 years. 2/5 studies investigated distribution and 3/5 the timing of protein intake. Distribution was investigated by comparing an even spread of total daily protein intake with one large pulse dose given at the noon-time meal. With this pulse regimen, greater improvements were seen in body composition (FFM 0.10 versus -0.33 kg, $p < 0.05$; LBM 0.91 versus -0.41 kg, $p = 0.01$), nitrogen balance (54 versus 27 mg.kg FFM⁻¹.d⁻¹, $p < 0.05$) and protein turnover rate (5.6 versus 5.0 g.kg FFM⁻¹.d⁻¹, $p < 0.05$) compared with the spread distribution. Studies comparing the timing of protein supplementation (relative to exercise) showed greatest improvement when administered immediately post-exercise in terms of muscle size (CSA 7.0 versus 0.2 %, $p < 0.01$), body composition (LBM 1.8 versus -1.5 %, $p < 0.05$) and nitrogen balance (1.2 versus 0.8 g, $p < 0.05$; 1.7 versus 1.0 g, $p = 0.09$). Discussion Particular patterns of timing and distribution of protein intake appear to improve muscle mass and function. Thus, protein consumption could potentially be optimized to combat sarcopenia, and merits further investigation. EFFECTS OF A 4 DAY ALKALINIZING VERSUS ACIDIZING DIET ON 400M RACE TIME, CAPILLARY BLOOD LACTATE CONCENTRATION, BLOOD PH AND URINARY PH IN HEALTHY SPORTS STUDENTS

Eibl, A., Platen, P.

Ruhr University Bochum

Introduction: Ingestion of blood buffer modifying agents like sodium bicarbonate, sodium citrates or ammonium chloride can enhance high-intensity exercise performance. This topic has often been addressed in sport scientific studies (Carr et al. 2011). The effect of a specif-

ic diet containing alkalinizing or acidizing nutrients, however, has not been examined sufficiently, even though nutrition is known to strongly influence acid base balance (Remer 2001, Heil 2010). We supposed that an alkalinizing diet enhances buffer capacity and therefore improves high intensity exercise performance, represented by 400m race time. Whereas blood pH is regulated to stay within a narrow range, urinary pH ranges between very acidic (4.8) and very basic (8.0) and is strongly influenced by an alkalinizing or acidizing diet. Methods: 16 healthy sports students (12 men, 4 women) aged 27 \pm 3 years, volunteered to participate in this double crossed randomized study. They performed three 400m-runs at intervals of one week. The first run was performed under an unmodified diet (unmodified). 4 days before the second and 4 days before the third run, an acidizing (acid) or alkalinizing (base) diet was followed in a randomized order. Besides the race time, blood pH, urinary pH and capillary blood lactate concentration were measured at fixed times before and after the run. Statistical analysis included ANOVA and paired T-test. Results: Mean \pm SD: 400m race time was 66,8s \pm 7,8 (unmodified), 67,2s \pm 7,3 (acid), 65,9s \pm 7,4 (base); $p < 0,05$ for unmodified vs. base and acid vs. base. Urinary pH was 6,0 \pm 0,8 (unmodified), 5,6 \pm 0,7 (acid), 7,0 \pm 0,9 (base); $p < 0,05$ for unmodified vs. base and acid vs. base. Blood pH was 7,46 \pm 0,04 pre-run and 7,22 \pm 0,05 post-run (unmodified), 7,46 \pm 0,06 pre-run and 7,24 \pm 0,06 post-run (acid) and 7,48 \pm 0,09 pre-run and 7,23 \pm 0,08 post-run (base). Blood lactate post-run (max. value) was 13,45 mmol/l \pm 1,51 (unmodified), 15,08 mmol/l \pm 2,52 (acid), 16,65 mmol/l \pm 2,76 (base), $p < 0,05$ for unmodified vs. acid and vs. base and for acid vs. base. Discussion: The results confirmed the hypothesis: a short-term alkalinizing diet improves the 400m race time. People tolerated higher blood lactate concentrations under the alkalinizing diet, suggesting an enhanced blood buffer capacity. References: Carr AJ, Hopkins WG, Gore CJ (2011). POST-EXERCISE PROTEIN INGESTION ATTENUATES LAT1/SLC7A5 MRNA EXPRESSION DURING OVERNIGHT RECOVERY IN HUMAN SKELETAL MUSCLE

Franssen, R., Wall, B.T., Burd, N.A., Gorissen, S.H., Snijders, T., Zorenc, A.H., van-Loon, L.J.C.

Maastricht University

Introduction A single bout of resistance-type exercise increases muscle protein synthesis rates for up to 24 h. Increased muscle protein synthesis rates are accompanied by an increase in intramuscular transport of amino acids, a process facilitated by amino acid transporters. Little data is available that assessed the impact of post-exercise nutrition on mRNA expression of these amino acid transporters in skeletal muscle tissue. In the present study, we assessed whether protein ingestion following exercise modulates basal and post-prandial mRNA expression of skeletal muscle amino acid transporters following overnight recovery. Methods At 7.00 pm, in a fed state, 16 recreationally active, young (24 \pm 1 y) men performed a single bout of unilateral resistance-type exercise (consisting of four sets of 10–15 repetitions at 70% of 1-RM on leg press and leg extension machines). After cessation of exercise, subjects were randomly allocated to ingest a bolus of either 20 g protein (PRO group; n=8) or an isocaloric placebo control (CON group; n=8), and a further bolus of 60 g protein (PRO) or placebo (CON) prior to sleep. The following day muscle samples were collected in the fasted state and 3 h following ingestion of 20 g whey protein. Muscle mRNA expression of L-type amino acid transporters (LAT1/SLC7A5 and CD98/SLC3A2), sodium-coupled neutral amino acid transporter 2 (SNAT2/SLC38A2) and proton-assisted amino acid transporter 1 (PAT1/SLC36A1) were assessed by real-time PCR. Results In the fasted state, muscle mRNA expression of LAT1/SLC7A5 was 61% greater in the CON compared with the PRO group (relative expression: 0.83 \pm 0.09 vs 0.51 \pm 0.08, respectively; $P < 0.05$), whereas CD98/SLC3A2, SNAT2/SLC38A2, and PAT1/SLC36A1 did not differ between groups. In response to dietary protein ingestion, LAT1/SLC7A5 increased by 359 \pm 134% ($P < 0.05$) and 268 \pm 78% ($P < 0.05$) in PRO and CON groups, respectively, with no differences observed between groups. Following protein ingestion, SNAT2/SLC38A2 ($P < 0.05$) and PAT1/SLC36A1 ($P < 0.05$) decreased significantly and to a similar extent in both groups, whilst CD98/SLC3A2 did not respond to protein ingestion in either group. Discussion Protein ingestion immediately after a single bout of resistance-type exercise reduces fasting skeletal muscle LAT1/SLC7A5 mRNA expression but not CD98/SLC3A2, PAT1/SLC36A1 and SNAT2/SLC38A2 expression, assessed following overnight recovery. In contrast, the amino acid transporter mRNA expression response to dietary protein ingestion during subsequent protein intake is not modulated. We conclude that post-exercise protein ingestion attenuates a rise in LAT1/SLC7A5 mRNA expression, but does not modulate the mRNA expression of amino acid transporters following subsequent protein ingestion in skeletal muscle tissue. ACUTE ORAL L-GLUTAMINE SUPPLEMENTATION DOES NOT IMPROVE ROWING PERFORMANCE

Volianitis, S., Biegel, A., Nielsen, K.B., Pedersen, C.B.

Aalborg University

Introduction Acute glutamine supplementation has been shown to increase alkaline reserves (plasma bicarbonate concentration) and, therefore, may contribute to acid-base homeostasis during high-intensity exercise that generates an acid load. Maximal rowing is eliciting high metabolic acidosis and, thus, this study investigated the effect of acute L-glutamine supplementation on maximal ergometer rowing performance. Methods Ten experienced rowers (4 males, 6 females; mean \pm SD; age 17.8 \pm 3.4 y; body mass 67.0 \pm 5.8 kg; height 179 \pm 8 cm) performed 2,000 m maximal ergometer rowing with, or without, oral L-glutamine ingestion (0.03 \pm 0.00 g/kg) in a cross-over, randomized, double-blinded, controlled experimental design. The day to day variability of the rowing trial was evaluated with the coefficient of variation between two control rowing trials. Results The test-retest coefficient of variation (CV) of the power during the maximal ergometer trial was 0.7 \pm 0.5 %. There was no improvement in time (448 \pm 42 vs. 447 \pm 41 s, $P = 0.777$), or power (262 \pm 69 vs. 263 \pm 70 W, $P = 0.599$), between the two experimental trials (L-glutamine vs. control). Discussion In the present study, the dose of L-glutamine was similar to a previous study that has shown elevated alkaline reserves (Welbourne 1995). Even though L-glutamine ingestion has been shown not to prevent the development of metabolic acidosis and, hence, improve maximal cycling (Haub, et al 1998) it may be that a possible ergogenic effect can only be manifested if the acid-base homeostasis during exercise is improved (Volianitis et al. 2011). In conclusion, these data indicate that acute ingestion of L-glutamine does not improve 2,000m maximal ergometer rowing. References Welbourne TC. (1995). Am J Clin Nutr. 61(5), 1058-1061. CREATINE SUPPLEMENTATION IN WALKER 256 TUMOR-BEARING HAS NO EFFECT ON TUMOR GROWTH IN A TIME COURSE STUDY.

Campos Ferraz, P.L.1,3, das Neves, W.I, Andrade, I.I.3, Signorini, I.H.1, Alves, C.R.R.1, Pereira, R.T.S.1, Seelaender, M.2, Lancha, A.H.1

University of Sao Paulo/ State University of Campinas

1. University of Sao Paulo - School of Physical Education and Sport, Sao Paulo, Brazil 2. University of Sao Paulo - Institute of Biomedical Sciences, Sao Paulo, Brazil 3. State University of Campinas - Faculty of Applied Sciences, Limeira, Brazil Introduction: Creatine supplementation is a very effective sport supplement to increase muscle mass and performance in intense exercise. More recently, the therapeutic potential of this amine has been investigated in diseases such diabetes, muscle disorders and cancer. There is a growing body of evidence indicating that creatine administration in experimental models of cancer can reduce tumor growth when associated to other compounds like ciclocreatine, methylglyoxal or vitamin C, all of them being performed during short periods of time (15 days average). However, to date, no studies showed if creatine alone can reduce tumor growth in a longer period after tumor implantation (35 days). Aim of the study: To evaluate the effects of creatine supplementation upon tumor growth in rats after 40 days of tumor implantation. Methods and Animals: 40 male Wistar rats (average weight 285g) were allocated into three experimental groups: control placebo (n=6), cancer placebo (n=17) and cancer creatine (n=17). Walker 256 cells were implanted in the right flank of each rat of both cancer groups (4x10⁷ cells). Body weight, food intake and tumor growth were measured every two days during 40 days. Survival period was also evaluated. Creatine supplementation via intragastric gavage (300mg/kg body weight/day) started at the seventh day of experiment to assure adequate tumor growth before intervention and filtered water was administered as placebo. Results: Tumor growth among experimental groups was plotted in days 4 (before supplementation), 14, 21, 28 and 35 (after supplementation). No significant differences were detected at these points. Discussion: This is a preliminary study on creatine supplementation on tumor growth. No differences were detected among experimental groups in this time course evaluation. This result may be attributed to variations in tumor evolution and lifetime among animals of the same group, or to a lack of effect of creatine alone, as it might be used as energy fuel for both healthy and tumoral cells. Conclusion: Creatine did not feature any effect on tumor growth in a 35-day time course study compared to placebo. More studies are necessary to understand the variations over time between creatine and placebo cancer group. References: Patra S et al. Amino Acids 2012, 42: 2319-2330; Gualano B et al. L-GLUTAMINE AND L-ALANINE IMPROVES GLUTAMINE STORES IN RATS SUBMITTED TO HIGH INTENSITY RESISTANCE TRAINING.

Raizel, R.I, Leite, J.S.M.1, Hypólito, T.I, Dias, B.P.1, Motarelli, J.H.1, Cruzat, V.F.2, Tirapegui, J.1

1: Faculty of Pharmaceutical Sciences, University of São Paulo (São Paulo, Brazil) 2: School of Biomedical Sciences, Curtin University, Western Australia.

Introduction The availability of the body's most abundant amino acid, glutamine can be compromised under exhaustive endurance training, which may impair cell's function and recovery. Conversely, less is known about glutamine metabolism and supplementation in resistance training. Hence, the aim of this study was to determine the effects of chronic oral supplementation with L-glutamine and L-alanine, both in its free form or as a dipeptide on plasma and tissue glutamine concentration in rats subjected to resistance training. Methods Adult male Wistar rats were subjected to high intensity resistance training for 6 weeks and supplemented with L-glutamine and L-alanine as a dipeptide or in its free form (DIP, GLN+ALA and ALA groups, respectively) or water (CTRL, group). Resistance training consisted to climb a ladder from 3 to 6 sets with progressive loads (25% to 100% of body weight). In the last 21 days of training supplements were given in a 4% solution dissolved in a drinking water. Glutamine was determined in plasma, liver and two skeletal muscles (Extensor digitorum longus - EDL and tibialis). Results High intensity resistance training reduced glutamine availability in EDL muscle, when compared to the sedentary group (p<0.05), however GLN+ALA and ALA supplementations reverted this scenario, promoting higher levels of glutamine, when compared the CTRL group (p<0.05). DIP and GLN+ALA supplementation increased glutamine levels in tibialis muscle, whereas higher levels of glutamine were found in liver in the GLN+ALA group (p<0.05). Discussion High intensity resistance training decrease muscle glutamine availability, fact that may compromise recovery. Nonetheless, the supplementations were able to restore glutamine concentration in the liver, and skeletal muscles predominantly composed by type II fibers. The presence of L-alanine may spare glutamine metabolism and utilization, since both amino acids are important gluconeogenic substrates, which may alleviate glutamine oxidation (Cruzat et al. 2014; Petry et al., 2014). In conclusion, chronic oral supplementations with L-glutamine and L-alanine, both in its free form or as a dipeptide are effective nutritional methods to increase tissue glutamine availability in rats submitted to high intensity resistance training. EFFECT OF DIETARY PROTEIN DISTRIBUTION ON LEAN MASS DURING ENERGY RESTRICTION WITH AND WITHOUT RESISTANCE TRAINING IN OVERWEIGHT OLDER MEN

Murphy, C.H., Churchward Venne, T.A., Mitchell, C.J., Kolar, N.M., Devries, M.C., Phillips, S.M.

McMaster University

INTRODUCTION Ageing is associated with a lower skeletal muscle protein synthesis (MPS) response to lower quantities (<20 g) of dietary protein, whereas moderate servings of ~30-40 g have been shown to maximally stimulate MPS under resting conditions (Symons et al., 2009; Yang et al., 2012). Thus, it has been suggested that a 'balanced' distribution of protein intake throughout the day, with the ingestion of ~30g of high quality protein at each meal, may represent an effective strategy to slow the loss of muscle mass with aging, particularly during energy restriction when the rate of muscle loss is accelerated. This study aimed to assess the effect of dietary protein distribution on lean mass changes during a period of mild energy restriction, with and without resistance training (RT). METHODS Twenty overweight/obese older men (65.9 ± 3.5 yr, 31.4 ± 4.6 kg/m²) were provided with a hypocaloric (-300 kcal/d), higher protein (1.3 g/kg/d) diet for 4 weeks. In weeks 1 and 2 (phase 1) participants continued their habitual physical activity and in weeks 3 and 4 (phase 2) participants performed whole body progressive RT (3 d/week). Participants were randomized to 2 groups (n=10/group): balanced (BAL) or skewed (SKEW). In BAL, dietary protein was spread evenly over the four daily meals such that ~25% of total protein intake was consumed at each meal. In SKEW ~72% of protein was consumed in the evening meal. Body composition was measured by DEXA at 0, 2, and 4 weeks. RESULTS Overall, participants lost 3.8 ± 1.6 kg body mass (p<0.01) and this was greater during phase 1 (2.46 ± 1.13 kg) than phase 2 (1.38

± 0.89 kg) ($p < 0.01$), with no difference between groups. Participants lost 2.42 ± 1.04 kg fat mass in total ($p < 0.01$) with no difference between groups or phases. Participants lost 1.1 ± 2.2 kg lean mass ($p < 0.01$) during phase 1, however lean mass was unchanged during phase 2, with no difference between groups. **DISCUSSION** The distribution of dietary protein did not affect lean mass loss during short-term, mild energy restriction and higher protein intake in older men. However, longer-term interventions may be required to observe an effect. RT appeared to attenuate lean mass loss during energy restriction although given that lean mass loss is greatest early in a period of energy restriction, an effect of timing cannot be ruled out. **REFERENCES** Symons, T. BEEF AND MILK DO NOT DIFFER IN THEIR CAPACITY TO STIMULATE POST-EXERCISE MYOFIBRILLAR PROTEIN SYNTHESIS IN YOUNG MALES

Gorissen, S.H.M., Burd, N.A., van Kranenburg, J., Snijders, T., van Loon, L.J.C.

Maastricht University Medical Centre+, Maastricht, the Netherlands

Introduction The type of protein consumed after resistance exercise can differentially modulate the muscle protein synthetic response. To date, a great amount of work has been carried out to study the effects of ingesting milk proteins on muscle protein synthesis. However, little is known about the effect of ingesting beef on post-exercise muscle protein synthesis rates. The present study compared dietary protein digestion and absorption kinetics and the muscle protein synthetic response following ingestion of minced beef versus an isonitrogenous amount of milk during post-exercise recovery in healthy young men. **Methods** Twelve young men (age 22 ± 1 y; BMI 22.1 ± 0.4 kg•m⁻²) performed leg press and leg extension exercise at 80% of one-repetition maximum. In separate trials, the participants ingested 30 g of intrinsically L-[1-¹³C]-phenylalanine-labeled beef or milk immediately after exercise. Blood samples and muscle biopsies were collected at rest and after exercise during primed continuous infusions of L-[2H5]-phenylalanine and L-[2H2]-tyrosine to assess protein digestion and absorption kinetics as well as postprandial muscle protein synthesis rates. **Results** Plasma insulin concentrations increased following milk ingestion and remained at baseline values after beef ingestion. Plasma leucine concentrations and exogenous phenylalanine appearance rates increased to a greater extent in the beef when compared with the milk condition. Post-exercise beef and milk ingestion increased myofibrillar protein fractional synthesis rates over the entire 5 h postprandial period ($P < 0.01$), with no differences between conditions (0.062 ± 0.004 and 0.070 ± 0.005 %•h⁻¹ in the meat and milk condition, respectively; $P = 0.22$). During the early postprandial phase (0-2 h), milk ingestion resulted in higher myofibrillar protein fractional synthesis rates when compared with beef ingestion (0.058 ± 0.005 and 0.091 ± 0.013 %•h⁻¹ in the meat and milk condition, respectively; $P = 0.03$). **Discussion** Both insulin and leucine are believed to be anabolic stimuli for muscle protein synthesis. We observed that milk ingestion after resistance exercise resulted in a significant increase in plasma insulin levels. On the other hand, beef ingestion after resistance exercise resulted in a greater increase in plasma leucine concentrations and exogenous phenylalanine appearance rates when compared with milk ingestion. Post-exercise myofibrillar protein synthesis rates did not differ following ingestion of an isonitrogenous amount of beef or milk. We conclude that beef and milk are as effective to facilitate the post-exercise rise in muscle protein synthesis.

PATTERNS OF HERBAL SUPPLEMENT USE AMONG IRANIAN NATIONAL LEVEL ATHLETES

Golshanraz, F.

Sports Medicine Federation of Iran

Introduction In the ceaseless demand for increased athletic performance, athletes are eager to use any new idea that promises to give easier access to sport success. Athletes need expert advice to take appropriate supplements, otherwise they will be threatened by misuse, compromised health and performance, and even doping violation. The aim of this study was to evaluate variety of herbal supplement use, and the difference in consumption patterns between female and male national level athletes. Based on the collected data we can offer them best practice advice. **Methods** After a literature survey and questionnaire design, its reliability and validity were assessed and distributed among 350 athletes of national squad. This study was cross sectional and used cluster sampling. The data collected were analyzed via SPSS 18.1. **Results** 350 national level athletes (55.7% male, 44.3% female) with mean age of 21.87 years from 26 sports fields entered the study. The most common herbal supplement used by male athletes was ginseng (12.82%), however, green tea was used most frequently by female athletes (12.25%). 40.2 % of athletes reported improved performance and 11.4 % of them reported side effects. **Discussion** According to the observed tendency to use herbal supplements especially ginseng and green tea by national level athletes and the need to replace the lost water and electrolytes through sweating during exercise and to supply necessary energy sources to increase and maintain sports efficiency, formulation of sports drinks with combination of carbohydrates, salt, water and addition of green tea and ginseng can be proposed. It should be noted that in addition to antioxidant effects of green tea, it reduces total and cardiovascular mortality (Kuriyama et al., 2006). Some studies have found a significant decrease in heart rate and an increase in maximal oxygen uptake compared to placebo, and improved mental tests following ginseng use. However, its efficacy on performance and safety need further evaluation. (Vogler et al., 1999) Taste preferences differ in various countries and affects sports drink acceptability. It should be focused that there are fundamental differences between sport and energy drink formulations. Sport drinks contain optimal amounts of electrolytes and carbohydrates, on the contrary, it has been shown that energy drink consumption is associated with a problem behavior syndrome and substance abuse. (Miller, 2008) **References** Kuriyama Sh, Shimazu T, Ohmori K, Kikuchi N, Nakaya N, Nishino Y, Tsubono Y, Tsuji I. (2006). *JAMA*, 296(10), 1255-65. Vogler BK, Pittler MH, Ernst E. Philosophy and Ethics

A STUDY ON THE SLOWNESS OF TAI CHI CHUAN FROM THE SOMATIC PERSPECTIVE

Kwon, O.1, Kim, H.2, Shin, S.2, Park, H.3, Kim, S.1, Jang, J.1, Kim, C.1, Han, D.1, Lee, S.1

1: Pusan National University (Busan, Korea), 2: Kyungnam University (Masan, South Korea), 3: Chon Nam National University (Gwangju, Korea)

Introduction This paper is intended to study the slowness of Tai Chi Chuan(or Tai Chi) from the Somatic Perspective. The slow-practice method of Tai Chi Chuan is different not only from any other Chinese Martial Art, but from any sports in the world, which mostly concentrate on outward strength, muscle force and speed. It is not easy to divide it into these two points, but we focused on slowness in this study. **Methods** We studied basing on the Somatic Perspective of Hanna's or Kleinman's in America. Kleinman said in his sixth visit to

Korea, The body, for Plato and other dualists such as Descartes, is seen as something which prevents us from achieving truth. Based on this somatic viewpoint, we focused on the slowness of Tai Chi Chuan including the concept of Yin-Yang originated from the book of I-Ching. Results This concept of slowness in Tai Chi Chuan does not mean slowness relatively in the fast and slow activity. Its slowness is based on Qi, the inner energy of body which was an essential concept in ancient East Asian culture including China, Korea and Japan. This intended-exercise based on Qi is to control and raise a sense of feeling oneself and detecting someone else's moving, considering body and mind as "a holistic being" in Somatic language. "By reflecting outer calm, one's inner self will become quiet and still like the water in an old well (Jou. T. H., 1991)." "The slower the movements, the better one can concentrate on their details. In addition, through practicing the forms as slowly as possible, one develops a more acute sense of balance (Jou Tsung Hwa, 1991: 202)". This way of knowing oneself first and then reading the other's move is the reason that Tai chi Chuan is good for health and one of famous martial arts. Slow and soft moving involves the saying 'Softness wins Strength'. This is connected with the law of nature, 'Every flow has its ebb', as Chinese people represented it as 'Ying and Yang' movement from the book I-Ching. Discussion In conclusion, what Somatics has paid attention to can be identified through the slowness practice of Tai Chi Chuan. Firstly, the slowness during practicing the Chuan is based on Qi with the accumulation of days and months, the internal energy will be penetrated and refined, and its subtlety will arise on its own. Secondly, you can enhance the sense of balance and accuracy in moving with the parts of body; the head, the body, the shoulders, legs should be aligned with the Chuan rules. Thirdly, you can improve your sense to feel yourself better internally and externally. With slow motions relaxing all the joints of the entire body, you can control your body and mind effectively and see things more clearly and precisely. By developing the sense of response to the others (this is called Push-hands), Tai Chi Chuan can be used as a useful Martial art. Finally, with these facts together in harmony, it could be called 'Zen through slow moving', leading to your experience of satisfaction and inner peace in mind and body like meditation's effect.

MEANINGS AND RELEVANCE OF THE CREATIVITY IN THE SPORT AND PHYSICAL EDUCATION

Park, H.1, Na, Y.2, Kim, D.1, Hwang, Y.3, Kwon, O.3

1:Chonnam National University (Gwangju, South Korea), 2:Dong Shin Girl High School (Gwangju, South Korea), 3:Pusan National University (Busan, South Korea)

Traditionally creativity is considered as the divergent thinking or convergent thinking. Guilford(1950) suggested creativity of divergent thinking in only cognitive domain. In the recent have studied Hopsicker(2011), Lacerda(2010), Mumford(2010), and Campos(2008) creativity in the domain of sport. We have identified creative behavior from abilities of sports heroes such as Michael Jordan, Diego Maradona, Tiger Woods, David Beckham, Roger Federer, Wayne Gretzky. They have performed wonderful, beautiful, and successful performance in various sports. Their achievement has opened new paradigm of their disciplines of sports. Nowadays creativity has been admitted as the most important value in the world of sport because winning and loss rely upon creative skills, strategies, and equipment. The school has emphasized enhancement of creativity as the aim of education in Korea. Especially in mathematics and natural sciences has tried the educational policy to enlarge creativity through creative discovery learning. On the other hand the improvement of creativity through participation of the activity of sport and physical education has been less paid attention. The academic research on creativity in sport and physical education was initiated in the domain of dance and play education in Korea (Bae & Kim, 2000; Kim & Kim, 2004; Cho, 2005; Shin & Lee, 2006; Ahn, 2008). The aim of this study were to try 1) to investigate practicing domains of creativity, 2) to structure characteristics of the creativity in the world of sport and physical education, and 3) to identify effects of participation of sport and physical education on improvement of the cognitive creativity. As a result, the creativity in the world of sport and physical education includes cognitive, physical, psychological, behavioral, cultural and environmental characteristics. Especially creative achievement in the physical domain resulted from long training and preparation. Second, the creativity of the sport and physical education has affected the development of the new disciplines, skill, strategic, equipment, management of team, and artistically expression. Third, the participants of this experiment were 30 middle school male students and were divided into 3 groups in soccer group, basketball group. After 3 months practice the soccer group showed significantly increased fluency and elaboration. The basketball group demonstrated significantly increased originality and fluency. No significant difference was found in the control group. The difference among groups was significant increase in fluency and originality of two groups than control group.

Physical Education and Pedagogics

SEGUNDO TEMPO PROGRAM: SPORT EDUCATION FOR THE BRAZILIAN YOUTH – THE PEDAGOGICAL AND ADMINISTRATIVE SUPPORT.

Stanganelli, L.C.R.1, Daros, L.B.1, Dourado, A.C.1, Oliveira, A.A.B.2, Bernardo, C.3

1: UEL (Londrina, PR), 2: UEM (Maringá, PR), 3: Ministry of Sport (Brazil)

Introduction The Segundo Tempo Program (PST), sponsored by the Ministry of Sport-Brazil (ME), has already employed about 17.000 physical education (PE) teachers. To achieve the objectives of the PST all involved personnel must, at first, to attend special classes related to the technical, pedagogical and administrative contents. After this phase these human resources are regularly monitored either personally or online by a 16 Teams work(TW) distributed regionally and composed of 110 PE teachers from 45 different Brazilian universities led by the Federal University of Rio Grande do Sul, State Universities of Londrina and Maringa, both the main partners of the ME to monitor the PST. The aim of this study is to present the strategies applied by ME to monitor the partner institutions and their personnel while running the PST. Methods The state and government PST partners of the ME are visited locally by the TW at least twice while it is being developed and if necessary a third visit is determined. The partner's size ranges from 01 to 466 nuclei composed of a hundred youth (from 7 to 17 years old) each one. It was established that partners from 1 to 5 nuclei are totally visited; partners from 6 to 10 nuclei are 50% visited while partners with 11 or more nuclei is 20% visited. Before being visited the nuclei are sampled according to their location and their regional characteristics. After each visit a specific report (SR) is produced including the technical, pedagogical and administrative issues related to how the PST is being developed by the partners. Results The PST has being developed for 10 years and so far with more than 9 million youth enrolled. Considering only 2013 there were 787 nuclei visited from 136 partners leading to a 342 SR which information was analyzed in detail in order to provide recommendations that could lead to an improvement and to an upgrade of the pedagogical activities as well as the administration issues of the partnership. Discussion This process highlights the importance to monitor how the public fundings are being applied by the partners. Also, the expertise of the 16 TW (33% PhD; 37% Masters; 30% graduate students) to monitor the PST seemed to be positive. It was demonstrated that this is an important tool to achievement the PST objectives such as the development of social values, the improvement of physical capacities and motor skills, the enhancement of life quality and the reduction of social risks in order to aim to an awareness of sport practice and to ensure the exercise of citizenship. ANALYSIS OF THE PEDAGOGIC PURPOSE INCORPORATION IN SEGUNDO TEMPO PROGRAM

Oliveira, A.A.B.1, Rinaldi, I.P.B.1, Pizani, J.1, Kravchychyn, C.1, Stanganelli, L.C.R.2, Bernardo, C.3

Universidade Estadual de Maringá - UEM e Ministério do Esporte - Brasil

Introduction The objective of the Segundo Tempo Program (PST) is to provide the practice of educational sport for youth at social risk (from 7 to 17 years) after school hours. This is a 10 years long program with more than 9 million youth enrolled. In 2008 it was established a partnership between the Ministry of Sport (ME) and the Federal University of Rio Grande do Sul in order to implement a new model for monitoring the PST pedagogic purpose and its management issues. Besides, a Team Work composed of physical education teachers from 45 different universities was set to visit each partner aiming to verify locally the application of the pedagogic aspects of the program. All the monitoring process is described into a specific report (SR) which results are stored at ME database for immediate feedback to the partners of the PST. The aim of this study was to analyze the SR content mainly on how the new pedagogic purpose was being applied from 2008 to 2012. A possible evolution and the type feedback provided by the Team Work about the new purpose were also assessed. **Methods** A documentary research method was used to analyze 262 SR from the ME partners (state, regional government and non-profitable institutions) that developed the PST from 2007 to 2012. The analysis was focused on two main aspects of the monitoring process: the planning and the development of the activities applied to the youth. After all, each partner received recommendations based on the SR in order to improve the development of the PST. **Results** The results demonstrated that planning and developing the activities of the PST were improved. The partners accepted 69,9% and 66,7% for planning and development, respectively. During the investigated period the need of recommendations was reduced from 100 to 61% for planning and from 100 to 50% for development of the activities of the PST. **Discussion** The professionals involved in the PST were gradually increasing the use of the pedagogic purpose leading to an autonomy related to planning and the execution of the activities. Among the evaluated indicators it was found an improvement in the effective participation in planning organization, an increased knowledge about the PST policies, a better choice of the activities applied to youth considering their interest and complexity and the application of the evaluation processes. Since the PST has approximately 1,5 million youth enrolled nowadays, these results brought a very significant information regarding to the qualification of the Brazilian policy established for educational sport. **References** OLIVEIRA, A. THE RELATIONSHIP AMONG PARTICIPATION MOTIVATION OF AFTER-SCHOOL PHYSICAL ACTIVITIES, ADAPTION TO SCHOOL LIFE AND EDUCATIONAL ACHIEVEMENTS FOR THE MIDDLE SCHOOL STUDENT.

Kim, D.I, Kim, Y.2

Korea National University of Education

Introduction This study aims to enhance educational achievements by analyzing the relations among after-school physical education participation motivation, school life adjustment and educational achievement for the middle school student and provides policy related to education and the basic resource for the educator who teach the teenager by illuminating the value and effect of the physical activity. **Methods** Questionnaire was used for the data. 66 survey questions, the participation motivation (Yang, H, 2000) 22 items, school adjustment (Im, H, 2002) 19 items, educational attainment (Kang, S, 2005) 17 items, are modified to suit the purpose of the study. collected data was used SPSS WIN 17.0. 658 middle school students of after-school sports were analyzed through Way ANOVA, multiple regression, multiple regression analysis. **Results** The results are as follows. First, there is a significant difference in the educational achievement according to personal character. Second, there is a significant different in educational achievement according to the sport experience character. Third, the participation motivation has an effect on school life adjustment. Fourth, participation motives has an effect on the educational achievement. Fifth, the school life adjustment has an effect on the educational achievement. There is the causal relations among the participation motivation, school life adjustment and educational achievement. **Discussion** According to the results of the study with the results of several previous studies (Kang, S, 2005; Yang, H, 2000; Im, H, 2002), the participation motivation and school life adjustment provides a positive effect on educational achievements. The positive participation motivation and the efforts to improve school life adjustment are needed to improve the educational achievement, and the active effort of the physical educator is also needed. **References** Kang, S. CHINESE MARTIAL ARTS' PROGRAM AT THE BRAZILIAN UNIVERSITY

Correia, W.R.

University of Sao Paulo

Introduction The Ving Tsun is a Chinese system of strategic intelligence (Kung Fu/ Chinese martial arts). The founder of this Kung Fu style was Yim Ving Tsun. The Ving Tsun is considered as a intangible cultural heritage of the humanity (UNESCO). The University of São Paulo offers a undergraduate subject named as Chinese Martial Arts: culture and movement, which aims to introduce and promote the Ving Tsun system. The aim of the present study was to verify the effect of a Ving Tsun/Kung Fu program on the declarative knowledge of undergraduate students from the School of Physical Education and Sport, University of São Paulo, Brazil. **Methods** Forty undergraduate students participated in a 16-week Ving Tsun/Kung Fu program conducted at the University of São Paulo, Brazil. The declarative knowledge of the students was measured by means of questionnaires and interviews. The content analysis was adopted and based on Bardin's method. **Results** Due to the content analysis it was possible to identify that the martial art experience lead to changes in three main initial concepts of the students when their declarative knowledge was compared from pre-to-post program: 1) the understanding about the means of Ving Tsun/Kung Fu shifted from fight skills learning to the development of strategic intelligence focused on their daily life activities; 2) the students reported that the specific - Ving Tsun/Kung Fu movements should be recognizing not only as a technical related skills but also and mainly as a form of integration with the fight environment; 3) the tutoring became an important concept rather than just teaching Ving Tsun/Kung Fu movements and its related skills. **Discussion** The present results suggest that a 16-week Ving

Tsun/Kung Fu program may provide changes in previous concepts of undergraduate students regard their view about the use of Ving Tsun/Kung Fu technical skills shifting from the perception of using them just for fighting purposes to their use as a tool for the human development. MOTOR RHYTHMIC ABILITY IN GREEK PRESCHOOLERS: A STUDY ON THE INFLUENCE OF AGE AND GENDER

Venetsanou, F., Koutsouba, M., Donti, O.

UNIVERSITY OF ATHENS

Introduction Rhythm is present in any human activity and it affects the development, performance and learning of motor skills. The aim of the present study was to investigate the effect of age and gender on the motor rhythmic ability of Greek preschool aged children. Methods Four hundred and twenty three Greek children (223 boys), aged 48-71 months participated in the study. Children were divided in four age groups [48-53 months (n=91), 54-59 months (n= 104), 60-65 months (n= 122), and 66-71 months (n= 106)] and their motor rhythmic ability was assessed with the subtest "Jumps on the rhythm" of the Democritus-Psychomotor Assessment Tool for Preschool Children constructed by Kambas, Aggeloussis and Gavriliadou (Stalikas, Triliva & Roussi, 2012), whose technical adequacy is sufficiently supported (Venetsanou, 2007). Results The two- way analysis of variance (ANOVA) that was applied revealed that age had a significant effect on children's scores ($F_{3,415} = 42.25$, $p < .001$, $\eta^2 = .23$). According to the post hoc comparisons using Sidak test, each age group had higher performance than the younger ones. Gender differences were also statistically significant ($F_{1,415} = 25.97$, $p < .001$, $\eta^2 = .059$), with girls outperforming boys. However, the low values of the η^2 associated with gender indicated that those differences were not of practical importance. Moreover, the interaction of the aforementioned factors was insignificant. Discussion As far as age is concerned, the present findings are in close agreement with previous studies and can be interpreted by the biological processes of development occurring between four and eight years old. Regarding gender, it is worth noticing that interpreting the results under the prism of factors' effect size, it was disclosed that the identified differences were not practically significant. Taking into consideration (a) the importance of motor rhythmic ability for motor skills development, (b) the above findings and (c) that motor performance differences in preschool years are culturally and environmentally provoked (Thomas, 2000), it seems of critical importance, teachers' and parents' expectations and practice encouragements to be identical for both genders. EVALUATION OF AGILITY, SPATIAL ORGANIZATION, LANGUAGE AND TEMPORAL ORGANIZATION IN PRACTICING THE KODOMO METHOD

Ires, C.R.I.3, Silva, I.L.I.3, Silva, F.T.I.3, Gomes, I.L.V.2

1: University Center of Estácio-Ceará – Brazil, 2: University State of Ceará – Brazil, 3: ASKACE - Escola de Karate-Do Shotokan – Brazil

Introduction: In sport in general has its beginning around 5 or 6 years, is called the sport initiation also in martial arts this is the standard. The proposed Kodomo methodology in the martial arts addresses even smaller children 3-5 years old, those who were neglected in terms of sports, can experience a rich psychomotor experience. Between birth and adulthood are produced in the human body, profound changes. The motor possibilities of the child evolve broadly in line with their age and come to be increasingly varied, complete and complex (1). In this study some psychomotor aspects were compared by practitioners Kodomo Method of kindergarten children in a school of Fortaleza. Methods: The sample consisted 15 children of 3-5 years old in the Kodomo Method and others 15 in a school with the same age group. The research instrument used the Motor Development Scale (MDS) proposed by Rosa Neto where three components were evaluated: Balance, Spatial Organization, Language and Temporal organization. In Temporal Organization perceive the passage of time from the changes that occur during a given period and its succession that progressively transforms the future in the present, then in the past. The temporal organization includes a logical dimension, a conventional size and an aspect of experience that appears before the other two (1). For Piaget, the time is not perceived as such ever. As opposed to space or speed, it does not enter the realm of the senses, since only perceive the events, movements and actions, their speed and their results (2). Discussion: The individual is always undergoing changes related to age and to constantly alter the interaction with the environment and the task. The movement features and enhances this interaction. There are some quantitative changes, such as increases in height, body weight, which usually termed physical growth. And there are qualitative changes in order to acquire and improve functions, called development (3). The Kodomo Method martial arts created and developed by Silva (4), has continued in his studies offered to its development, it brings out-group permanent study presentations in the academic environment for undergraduate and postgraduate courses such content, monographs, articles and lectures. Conclusion: It is concluded that students who practice the Kodomo Method showed higher values for the components like Agility, Spatial Organization and Language / Temporal Organization under school children. We can state that the Kodomo Method is a great way to aid in infant motor development at this age. References: 1 - Rosa F. Desenvolvimento Motor. RELATIONSHIP BETWEEN DAILY PHYSICAL ACTIVITY AND MOVEMENT ABILITY IN PRESCHOOLERS

Ishizawa, J.I, Sasaki, R.2, Yoshitake, Y.3

1: Soai Univ. (Osaka, Japan), 2: Keio Univ. (Yokohama, Japan), 3: Nat Inst Fitness Sports in Kanoya (Kanoya, Japan)

Introduction Infancy is an important developmental stage with regard to movement ability, which has been associated with physical activity (PA) in preschool children (Fisher, 2005; Leah, 2012). Thus, this study examined the intensity of PA and classifications of movement (locomotive, non-locomotive) in relation to movement ability in preschoolers. Methods Participants were 214 nursery school children (mean age, 5.7 ± 0.6 years) who performed 6 activities measuring movement ability (a 25m round-trip run, standing broad jump, "jump over and crawl" test, duration of sustaining their own body weight, ball catching, and overhand ball throws). Measures of PA, including step counts and time spent in moderate to vigorous physical activity (MVPA), were recorded for 7 consecutive days using a triaxial accel-

erometer, which was also used to measure locomotive and non-locomotive activities during MVPA. The relationship between PA and movement ability were evaluated by partial correlation analysis controlling for age, gender, and body mass index (BMI). Results Each type of movement ability was greater in older than younger children. Step counts and time spent in MVPA were longer among boys than girls. Step counts and time spent in MVPA were significantly correlated with total scores (z-scores) of all six movement abilities. However, the relationship between PA and each movement ability differed. Step counts were correlated with a 25m round-trip run, standing broad jumps, and overhand ball throws. Time spent in MVPA was correlated with a 25m round-trip run, standing broad jumps, ball catching, and overhand ball throws. When we analyzed classifications of movement, the time of locomotive activity during MVPA was correlated with five movement abilities except the "jump over and crawl" test. However, the time of non-locomotive activity was not correlated with any of the movement abilities. Discussion These results suggest that total ability of these fundamental movements is associated with PA indicated by step counts and time spent in MVPA (Fisher, 2005; Williams, 2008). In particular, locomotive activity during MVPA was correlated with many movement abilities. Therefore, vigorous locomotive activity during various plays is especially important for preschool children. However, we found that there was different relationship between PA and movement ability; because of the motor elements. References Fisher et al. (2005). *Med Sci Sports*, 37(4), 684-688 Leah et al. WHO IS THE TEACHER COURSE OF PHYSICAL EDUCATION AT THE UNIVERSITY DISTANCE OF BRAZILIA?

Silva, A.R.1, Oliveira, P.F.A.1, Carvalho C.R.F.1, Barros, J.F.2, Alves, E.D.1

1: UNB (Brasília, Brazil), 2: UFRN (Natal, Brazil)

The expansion of college education in Brazil, due to its territorial extension, is a challenge for the government (Nunes et al., 2010). The proposal of distance degree course in Physical Education teacher has as principle a broad and deep training on the area as a curricular component in schools, the development of citizenship and life quality and promoting health. Besides political and ethical questions that are relevant to the teaching profession in Brazil. According to the method chosen for the course, with the use of computational resources and other technological tools, such as video and multimedia ones, students will have during the course the mastery of information and communication, digital and analogic technologies that are essential to education (Physical Education, 2012). Supervisor teachers are responsible for developing the discipline, and also conducting pedagogical meetings with distance tutors and coordinating the course, planning activities aimed to presence required meetings, participating in the training of classroom and distance tutor teachers, guiding the dynamics of mentoring as well as making monitoring and evaluation reports (Vieira, 2008). The supervisor teacher should be preferentially a permanent teacher at UNB, which often does not even have experience and interest in Distance Education (EAD in Portuguese). The tutor has the function of assisting a students class, individually, mediating their behavior and studies, always on the coordination of the supervisor teacher. This must necessarily be a physical education teacher, who often already has a high weekly workload in order to perform the duties of tutor. In a study (Soares et al., 2013) students said tutors have a little proactive behavior in finding solutions and solving problems. This fact shows the need to conduct more consistent training, directed to the development and unity of academic and operational skills in managing various situations and conflicts that permeate the scenario where the proposal of distance teacher training is inserted and expands the tutor teacher training for coherent acting with the demands of EAD. MOTIVATION FOR SPORTS ACTIVITIES IN BASIC SCHOOL ADOLESCENTS: INFLUENCE OF GENDER

Costa, M., Oliveira, T., Mota, J., Santos, M., Ribeiro, J.

Sports Faculty, University of Porto, Portugal

Introduction: School is the ideal place for promoting learning and knowledge, and likewise should be a setting for promotion and stimulation of the access to organized sports practice, to guide and create healthy life styles. Understanding behavior patterns implies knowing the reasons that drives adolescents to participate in sports activities. The aim of this study was to identify student's motivations for sport involvement, specifically taking into account the gender differences. Methods: Sample comprised 218 adolescents, 94 boys aged 11,60±1,63 and 124 girls aged 12,06±1,60, enrolled at public schools in Porto, Portugal. We used a five points Likert scale questionnaire with 30 items, Participation Motivation Questionnaire developed by Gill et al. (1983), translated and validated for the Portuguese version by Frias and Serpa (1991). Results: Normality of the results was checked, and we used non-parametric tests for data analysis. The results showed that the most emphasized motives for sports participation were the related with Physical Form (4,28±0,62), Development of Competencies (4,12±0,69), and the less designated reason was Emotions (3,38±0,66). Boys attribute higher relevancy for the motivational factor Status (3,86±0,63), Competition (3,89±0,91), Development of Competencies (4,21±0,77), General Affiliation (3,95±0,79), and Specific Affiliation (3,97±0,68) than girls (3,71±0,85, 3,54±0,81, 4,06±0,63, 3,81±1,73 and 3,87±0,66, respectively) (p<0,05). Discussion: Adolescents pointed Physical Form (4,28±0,62) and Development of Competencies (4,12±0,69) with the most relevant motivational factors. These results are similar to those that were found by Fonseca and Soares (2001), which referred that the values to motivational dimensions are gender dependent. Fonseca (1995) corroborates the conclusions of our study stating that the girls give less importance to motives relating to Competition and Status, while Kilpatrick et al., (2005) verified that the boys attach greater importance to intrinsic reasons related with ego and performance. TEACHING STYLES IN PHYSICAL EDUCATION AND TOTAL DAILY PHYSICAL ACTIVITY: AN SCHOOL-BASED RANDOMIZED INTERVENTION IN ADOLESCENTS.

Martín, N.T., López, I., Torres, G., Chinchilla, J.L., Carnero, E.

Universidad de Málaga. Biodynamic and Composition Laboratory.

Physical education (PE) classes are an excellent way to improve moderate and vigorous physical activity (MVPA). However, a wide variability is commonly attributed to typed of activities performed during PE classes, which in turn must be related with the teaching style (TS) used by teachers. It was our aim to observe the differences between reproducing (RK) and producing knowledge (PK) TSs on total daily PA of adolescents during a complete academic year. METHODS: Valid data of 23 adolescents (12 girls and 11 boys) from the same high school accepted to wear an accelerometer to record one week total daily PA at the beginning and at the end of the academic year. Groups of PE classes were randomized to be taught according with two different strategies: RK and PK following the classical Spectrum of Mosston. The contents and PE teacher were the same for all students. Differences after and before academic year were calculated for patterns and total daily PA; these were compared between RK and PK by independent sample T-test. RESULTS: No significant differences were found between RK and PK for MVPA (-4.54 ± 22.44 min vs. 4.87 ± 18.04 min, respectively; $P > 0.05$) or sedentary time (-65.65 ± 69.90 min vs. 10.73 ± 71.73 min, respectively; $P = 0.09$). The largest change for total sample was observed in sedentary time, but it was not significant (-29.83 ± 74.21 min, $P = 0.067$). CONCLUSIONS: Our preliminary results seem to inform that the TS used during one year of PE classes had not influence to modify significantly the MVPA or sedentary time in adolescents. However, the small sample could be an important reason, which did not allow us to find significant differences between PK and RK, or for total group. So, our hypothesis must be confirmed in larger sample, different high schools and more teachers.

SCHOOL OF SPORT: PROGRESS AND PROSPECTS FOR A PARTNERSHIP BETWEEN THE SECOND TIME PROGRAM AND MORE EDUCATION PROGRAM

Bisconsini, C., Anversa, A.L.B., Oliveira, A.A.B., Bernardo, C., Petersen, R.D.

MARINGÁ STATE UNIVERSITY

Introduction The partnership between the More Education Program (Ministry of Education) and the Second Time Program (Ministry of Sports) exists since 2010, and today is called Sports School. The aim of the partnership is to ensure access to the sport by offering multiple sports experiences from the perspective of sports education in order to contribute to structuring of full-time education in Brazil. Methods This work is an account of government actions developed by the Sports Ministry and its departments purposes in intersectional action between the Sport and Education Ministries designed to consolidate the process of holistic education in our country. Data were obtained through analysis of the official documents of these ministries. Results The evolution of Sports School took place as follows: a) in 2010 were attended 1.149 schools and 329,809 students, b) in 2011 were 4.620 schools and 996.672 students, c) for 2012 attended 5.172 schools and 1.073.562 students. In 2013 the program has advanced significantly since directors opted in 20.758 schools offer the School of Sport, being scheduled for 2014 attendance to 3.448.856 students in 2.965 municipalities of all Federative Units of Brazil. To meet this number of students, the partnership between the Ministries will feature the participation of 31.270 teachers/instructors. This evolution of care is resulting public policy of expanding supply and future service to all Brazilian student community, still in the early design phase. However, since its inception has increased the attendance at 401% with an estimate of universal offer for Brazilian schools in the year 2016, when he did the Olympics in our country. Discussion Thinking and structuring public policy that meets the fullness of our country with dimensions and specific characteristics of each region stands as a huge challenge. Brazilian education has sought alternatives and ways to advance and enhance the development, adopting the sport education as an essential partner in this full-time education proposal. Within this inclusive and evaluative policy, sport has been an important partner, because the pedagogical proposal advocated by the Ministry of Sports and Second Time Program, meets the existing challenges and greatly expands the membership of students in integrated schools projects. It was achieved great adhesion and bonding of students to training and information purposes targeted by the integral education. References BRAZIL. Ministry of Education. DISTANCE EDUCATIONAL TECHNOLOGIES IN SYSTEM OF PREPARATION OF SPECIALISTS IN SPHERE OF PHYSICAL EDUCATION AND SPORTS

Fyodorov, A., Sivokhin, I.

Ural State University of Physical Education

Introduction In conditions of development of processes of information of education, it is especial in connection with necessity of creation of uniform educational space, the high urgency is got with a problem of creation and an effective utilization of information educational resources. Last years within the framework of traditional ways of the organization of educational process in higher educational institutions the big distribution was received with learning and methodical complexes (LMC). The purpose of research – studying of methodical features of application of network learning and methodical complexes in educational process in high school of physical education. Methods During research such methods, as the analysis of the scientific, methodical and technical literature, pedagogical modeling and designing, pedagogical experiment, methods of mathematical statistics were used. During research technological features of designing of network learning and methodical complexes are revealed, the structure and model LMC is developed, are created LMC on several subject matters, methodical features of application LMC in educational process are investigated. Results The important feature of designing LMC is application of the modular approach. The modular approach of LMC provides an openness of structure, an opportunity of addition and the further expansion of his contents, and also big “flexibility” and variability of educational process. The modular principle was used by development of structure and model LMC. Discussion / Conclusion Thus, network learning and methodical complexes represent modern means of education which allows to open educational potential of information and communication technologies. At designing LMC alongside with didactic principles it is necessary to take into account principles of interactivity, potential redundancy of the educational information, nonlinearity of information structures and the processes, the combined application of various forms of training, complex use of diverse computer means and technologies. PARENTS' OPINIONS ABOUT EFFECTS OF PHYSICAL EDUCATION ON MENTALLY DISABLED CHILDREN

Çeliksou, M.A., Çeliksou, S.

ANADOLU UNIVERSITY

Introduction It is known that Physical Education and Sport has a significant importance on mentally disabled individuals as it helps them to challenge, contribute to society, and independent living (Cavkaytar,2005). Physical Education programs should be prepared in accordance with individuals' needs. Hence, physical education programs have to be applied gradually. Firstly, physical movements for adaptation secondly, therapeutic activities and the last step is physical education programs to develop individuals' physical movements. Disabled individuals will be able to share, communicate, learn and develop their social behaviors by joining group activities (Vuran,2005). In this research, parents' opinions about effects of Physical Education on mentally disabled children have been evaluated. Method A survey has applied to 20 mentally disabled individuals' parents. It has personal information and totally 20 questions but three questions require interview method. SPSS 21 program has been used. Arithmetic average, frequency and percentage analyzes have been used in evaluation process. Results The responses to the questions in the interview are as follows; How do your children spend their time? % 20 drawing pictures, % 40 watching TV,% 10 playing computer games, % 30 doing all these activities. What effects does Physical Education have? %30 social, %30 health-wise % 40 psychological. Does your child do physical activity at home or outdoor? %30 yes, %70 no. Discussion The research reveals that parents do not spend much time with their mentally disabled children, they do not have enough knowledge about physical education and they do not support their children to join an activity. They should help their children's physical development by spending more time and doing physical activity with their children. References Cavkaytar,A. SECOND TIME PROGRAM AND INTANGIBLE LEGACIES: SOME INDICATIVES

Anversa, A.L.B., Bisconsini, C.R., Silva Junior, A.P., Oliveira, A.A.B.

MARINGÁ STATE UNIVERSITY

Introduction The Second Time Program (PST) is linked to the National Department of Sports, Education, Leisure and Social Inclusion (SNELIS) as a social policy directed to the educational sport. Currently meets a million and half of beneficiaries. The operational strategy is by consolidating agreements, aiming nuclei that offer afterschool, two collective modalities and one individual of sport, three times a week and 2-4 hours per day, plus complementary activities. Actions are developed by Physical Education teachers from the conceptual, procedural and attitudinal dimensions, emphasizing citizenship principles; sports autonomy; equality; overcoming adversity; coeducation and emancipation, positioning the benefited as their learning agent. Therefore, the aim of the present search is trace indicative of how the sport education can be a fundamental part of the intangible legacy. Methods This study consists in a descriptive type of documentary that, according Lehfeld and Barros (2000), allows us to observe, analyze and correlate facts or variables phenomena without manipulating them. Results In a survey developed by Sousa et al. (2010), under the guidance of the Ministry of Sports/SNELIS, with 1.961 beneficiaries linked to PST, it was found that the average age is 12 years and 42,3% are in the program over a year. 72,5% likes the proposed activities, and this is reflected in the fact that 86% of the beneficiaries already have indicated the PST to someone. Most part is present at the activity 3 to 4 times per week, 2 to 3 hours per day. According the beneficiaries the activities proposed improvement social interaction, communication skills, academic performance, self-esteem and reduce exposure to social risks, once the free time is destined for activities instead of hours in front of the TV or on the street. Discussion Considering the aspects presented, the educational sport avoids the hyper competitiveness contributes to the integral development of the subject and his training for citizenship and practice of leisure, democratizing access to sport. From this approach, can get to the precepts of intangible legacies, since it breaks with the antagonisms, incorporating the culture of sports practice, stimulating the formal and non-formal practices, through creative and active lifestyle, contributing to the detachment of the beneficiaries of the social risks and the quest for improved quality of life. THE EFFECT ON PHYSICAL FITNESS OF CHANGING PITCH AREA PER PLAYER IN SMALL-SIDED SOCCER GAMES IN PE CLASSES

Tsuda, R., Inoue, A., Suzuki, K., Saito, K.

Kanazawa Medical University

Introduction It has been suggested that small-sided games in football enable players to improve their physical fitness if conditions for the games, such as the court area per player and player number, are adjusted appropriately (Hill-Hass et al., 2011). However, few studies based on this knowledge have been conducted in physical education (PE) classes. The purpose of this study was to examine the effect on physical fitness of changing the pitch area per player in small-sided soccer games in PE classes. Methods Two types of small-sided games, "pitch area per player was smaller", and "pitch area per player was larger", were played by two first year junior high school PE classes. Twenty students participated in the game with a small pitch area per player (S group), and 20 students participated in the game with a large pitch area per player (L group). Before and after classes, a skill test (figure eight dribble), a fitness test (150m sprint with changing direction ; 25m×6times, rest interval 30s), and a test game were conducted. Results and Discussion The results of the figure eight dribble test improved significantly after classes in both groups. This result suggests that improvement of technique could be obtained regardless of whether they played the game with a smaller or larger pitch area per player. On the other hand, the mean time for the 6 sprints improved significantly after classes in the L group. This result suggests that improvement of aerobic capacity could be obtained in the use of small-sided games, with a larger pitch area per player. There were no significant differences before and after classes in both groups in the distance covered and heart rate during the game. Conclusion These results suggest that improvement of energy-related physical fitness could be obtained in the game with a large pitch area per player, although improvement of technique could be obtained regardless of the size of the pitch area in small-sided games. THE ROLE OF PHYSICAL EDUCATION IN YOUTH AND ADULT SPORT PARTICIPATION: A REVIEW

Van Deventer, K.

Stellenbosch University

Introduction This review article sets out to assess the views of three academics on the outcomes of school physical education and school sport (PESS). In the second part of the article a counterplea is made. Green (2012) believes that it is wrong for PE specialists to attach themselves to a claim that appears weak and at worst unachievable and impossible to show. Bailey et al. (2009) believe that the claims for the outcomes is made in such insistent tones that bystanders might believe it and that nothing more is to be said. Bailey et al. (2009) focus on four domains: physical, social, affective and cognitive, but they and Hardman (2010) claim that research has not yet proven that PESS contributes to the holistic development of the child. **Methods** The aim of this review was to focus on the benefits of school PESS to prove its educational worth. The research was conducted by means of a literature study (mainly primary and secondary sources) in the field of PE. The methodology applied can be typified as qualitative research within the interpretative science paradigm. **Results** Clout should begin with what a subject means, not with what it claims it does or can do. Rivalry will always exist, regardless of whether PESS are studied from within a philosophical, sociological, pedagogical or historical background. On top of all the research an educational rationale for PE's inclusion in curricula is provided by the justification of the Arnoldian dimensions. **Discussion** The arguments surrounding PESS offered by Bailey and co-workers, Hardman and Green are to a great extent rejected. In line with most of the viewpoints offered in this paper and the Arnoldian dimensions, an educational rationale for the inclusion of PE in curricula was presented by Van Deventer (2002). The rationale for any subject to be included in curricula relates to the envisaged values related to unique content and aims (What!), learning programmes (How!), and the merit of the outcomes (Why). What should be taught in PE relates to the motor and physical domains, while the affective, social and cognitive domains are essential to ensure an educational and holistic approach to learning (Van Deventer 2002). **References** BAILEY, R.; ARMOUR, K.; KIRK, D.; JESS, M.; PICKUP, I.; SANDFORD, R. & the BERA PE and Sport Pedagogy Special Interest Group. ATTITUDES IN PRE-SERVICE PHYSICAL EDUCATION TEACHERS TOWARD IMMIGRANTS IN SPAIN

Pastor Vicedo, J.C., González Villora, S., Contreras Jordán, O.

University of Castilla-La Mancha

Introduction Spain has transformed from an emigration country to an immigration country (Zapata-Barredo, 2010). Almost 47 million people live in Spain, and a small part of those people is from a foreign country. They represent 10.10% of the total population. This multicultural diversity has soon become evident in schools, shaping a reality that is reflected in the last ten years, when in Spain we have gone from 307,151 immigrant students registered in non-university education in the 2002 school year, to 781,446 in the 2011 school year (MECD 2012). Therefore, the aim of this study was to find out which attitudes prevail in future Physical Education teachers when asked about immigrant population. **Methods** A sample of 2,524 volunteer pre-service Physical Education teachers was used to participate in this study. We used a semantic differential and an Immigrant scale, where some contextual variables were employed for understand better this situation. Descriptive and univariate statistics were used to analyse the information gathered. **Results** The data showed Pre-service Physical Education Teachers with an indifferent attitude toward the immigrants and these attitudes reflected were influenced by contextual variables. **Discussion** We have found that a big part of PPET reveal an indifferent attitude toward immigrant, but this opinion could be cover other rejected attitudes. However, as reflected in the work of Pettigrew and Meertens (1995), Cea (2005), and Fernández and Fernández (2006), people may not be aware of that feeling of rejection towards immigrants or they may simple refuse to acknowledge or show it. This is because, they tend to show typical traits of indirect, subtle and many times unconscious prejudice, believing that feelings of rejection are socially frowned upon and penalized by their peers (Beilock and McConnell 2004). And this opinion is affected by contextual variables (Van Dijk, 2003; Zapata-Barrero, 2010). **References** Zapata-Barredo, R., (2010). Dynamics of diversity in Spain. Old questions, new challenges. THE RELATIONSHIP BETWEEN ATTITUDES TOWARD PROBLEM-BASED LEARNING AND MOTIVATED STRATEGIES FOR LEARNING: A STUDY IN SCHOOL OF PHYSICAL EDUCATION AND SPORT

Senel, E., Ulucan, H., Adilogullari, İ.

MUGLA SITKI KOCMAN UNIVERSITY, KAYSERİ ERCİYES UNIVERSITY, CANAKKALE ONSEKİZ MART UNIVERSITY

Purpose: The aim of this study is to examine the relationship between attitudes toward problem-based learning and motivated strategies for learning of students studying in school of physical education and sport. **Method:** 333 of students in school of physical education and sport at Kayseri Erciyes University participated in this study. Students were selected in departments of physical education and sport teacher, coaching education, sport management and recreation. Turkish form of motivated strategies for learning scale (MSLQ) was used to determine the motivational learning strategies. Pintrich and De Groot (1990) developed the scale and Üredi (2005) adapted to Turkish language. The attitude scale towards problem based learning developed by Turan and Demirel (2009) was used to determine students' attitude toward problem-based learning. Collected data was analyzed in SPSS 22.0. Two different models were hypothesized and models' fit indices were analyzed in AMOS. **Results:** 143 female, 190 male students participated in this study. There was significant difference found between female and male students in terms of test anxiety, cognitive strategy use and self-regulation ($p < 0.05$). Positive correlations were found between positive attitude and sub-dimensions of intrinsic value, self-efficacy, cognitive strategy use and self-regulation. Negative correlations were found between negative attitude and sub-dimensions of intrinsic value, self-efficacy, cognitive strategy use and self-regulation. Two models were hypothesized in this study. In the first model, it was hypothesized that attitudes toward problem-based learning predicted motivated strategies for learning. Fit indices of first model were found to be acceptable fit. In the second model,

it was hypothesized that motivated strategies for learning predicted attitudes toward problem-based learning. Fit indices of second model were found to be good fit. Conclusion: Consequently, it can be said that students having positive attitudes toward problem-based learning have high self-efficacy, intrinsic value, and self-regulation level. Furthermore, students having positive attitude can better use cognitive strategies. References Pintrich, P. R., De Groot, E. V. (1990). INVESTIGATION INTO THE PHYSICAL FITNESS OF THE ELEMENTARY AND JUNIOR HIGH SCHOOL STUDENTS IN ISOLATED ISLAND AREA

Iida, T., Honda, S., Edamatsu, C., Onodera, S., Kawakami, M.
Shujitsu University

Introduction A living environment and educational environment affects the physical fitness of children. These environments differ between isolated island area and inland. Therefore, it is possible that the physical strength at the children of isolated island area may be different from that of inland. The purpose of this study was to show clearly the physical fitness of the elementary and junior high school students in isolated island area. **Methods** 7 schools (Elementary schools are 4, Junior high schools are 3.) in isolated island area and 21 schools (Elementary schools are 14, Junior high schools are 7.) in interior of Okayama Prefecture in Japan volunteered for this study. The total numbers of the subjects were 1,416 children. The measurement contents were grip strength, sit-ups, sit-and-reach distance, side steps, multistage 20-m shuttle run test, 50-m sprint, standing long jump and softball/handball throw. In addition, the total point of these eight contents was calculated by utilizing scorecard of Ministry of Education, Culture, Sports, Science and Technology in Japan. We performed comparison as a result of the physical fitness test of interior and isolated island area. **Results and Discussion** We obtained the following views. The physical fitness level of the children of an isolated island area shows a high tendency compared with an interior. Especially, the multistage 20-m shuttle run test and the softball/handball throw of the children at an isolated island area was a high level. One reason for this is an isolated island area has more environment for playing at outside than an interior. On the other hand, there is no difference between inland and isolated island area of physical fitness, until the junior high school from the higher grades at elementary school, although the physical fitness level of the children in the lower grades at school of an isolated island area is high. Some grades take lessons in physical education together because the number of children of school in isolated island area is small. Therefore, exercise intensity in a physical education of the higher grades is low. Because of this reason, we thought that is difficult to improve physical fitness of higher grades. **Conclusion** The result of this study suggests that educational and life environment of an isolated island affects physical fitness level of children. (The Ministry of Education, Culture, Sports, Science and Technology, Grant-in-Aid for Young Scientists (B))

PHYSICAL EDUCATION PROFESSORS' ENJOYMENT AS A FACTOR FOR INCLUDING CONTENTS FOR THEIR CLASSES

Cocca, M., Cocca, A., Tristán Rodríguez, J., Pérez García, J., Frömel, K.
Autonomous University of Nuevo León

Introduction Physical Education (PE), when taking into account students' profile and including innovation, can represent an effective means for increasing participation in exercise (McKenzie and Lounsbury, 2013). Nonetheless, the majority of PE teachers in Mexico use traditional approaches, overlooking students' real needs. This could entail lower students' motivation towards PE (Woods et al., 2012). The aim of this study was to assess PE professors' knowledge of non-traditional approaches towards PE and to analyse their enjoyment in practical sessions. **Methods** PE professors (n = 61) from primary and secondary schools in Monterrey (Mexico) were presented practical sessions using traditional (football games) and non-traditional approach (Spark, beach-volleyball games, handball games). Prior to the intervention and after that, they underwent a short interview about non-traditional approaches. In addition, after each session, they were asked to fill in PACES questionnaire (Moreno et al., 2008). **Results** 91% of participants affirmed they did not know any non-traditional approach. That was also the main reason they do not use them in their classes. Participants knowing these approaches stated that they do not use them because they do not have enough knowledge about them (68%), consider them too complex (18%), and consider themselves not enough experienced in them (14%). After the practice, 82% of professors expressed the intention to include these non-traditional approaches in their PE classes because they considered them enjoyable (65%) and motivating for pupils (23%). 18% of professors considered these approaches still too complex to be executed. High levels of enjoyment were found for all the sessions, but no significant differences between them. **Discussion** Professors' main reasons for not using non-traditional approaches were lack of knowledge and perceived non-suitability for pupils. In line with previous studies, knowledge, experience and bias are important factors while designing PE programs (Jung, 2012). The high enjoyment they experienced while practicing non-traditional approaches seemed to represent an agent for changing their opinion and willing to implement them in their activities program. In the future, academic and on-going training should focus on practical, enjoyable experiences in order to avoid bias and provide professors with wider and deeper knowledge. **References** Jung J. (2012). *Phys Educ Sport Pedagog*, 17 (2), 157-175. McKenzie T, Lounsbury M. (2013). *Res Q Exerc Sport*, 84(4), 419-430. Moreno J, González-Cutre D, Martínez C, Alonso N, López M. (2008). *Estud Psicol*, 29(2), 173-180. Woods C, Tannehill D, Walsh J. (2012). *Irish Educ Studies*, 31(3), 263-280.

RELATION BETWEEN PHYSICAL ACTIVITY AND MOTOR SKILLS IN YOUNG CHILDREN

Watanabe, M.1, Hikiyara, Y.2, Wakabayashi, H.2, Hanawa, S.3, Aoyama, Y.4, Hoang, T.N.5, Tsurumi, T.1, Omi, N.5, Tanaka, S.6

1:Ibaraki Univ., 2:Chiba Institute of Technology, 3:Ritsumeikan Univ., 4:Research Fellowship of Japan Society for the Promotion of Science, 5:Univ. of Tsukuba, 6:National Institute of Health

Introduction Physical activity (PA) by young children is necessary for development of physical fitness and for acquisition of motor skills. Nevertheless, because of inaccurate estimation for PA in children, no report in the relevant literature describes a study showing strong correlation of PA parameters (i.e., amount or intensity) with motor skills (i.e., locomotor or object control). This study was designed to elucidate the relation between motor skills and PA using a tri-axial accelerometer. **Methods** Subjects were 248 Japanese children (boys, 152; girls, 96) in the first grade of elementary school. Motor skills were tested using the Test of Gross Motor Development second edition

(TGMD-2), which comprises six locomotor tests (run, gallop, hop, leap, horizontal jump, and slide) and six object control tests (striking, dribble, catch, kick, overhand throw, and underhand roll). Each motor skill was assessed according to checklists of skill criteria, and was respectively converted into total scores as locomotor and object control ability. PA was assessed using a tri-axial accelerometer (HJA-350IT; Omron Corp.), which the children wore for 2 weeks. Data were screened through the criteria (more than 10 hours a day and more than 7 days including 2 weekends). Average step count per day, physical activity level (PAL; total energy expenditure /basal metabolic rate), time spent doing moderate to vigorous PA and time spent doing vigorous PA were calculated. Results This study showed significant correlation between total object control scores and four PA parameters ($r=0.26-0.39$). However, significant correlation was found between total locomotor scores and PAL only ($r=0.21$). Results show that the intensity and amount of PA correlated especially with object control skills. Furthermore, total object control significantly correlated respectively with six object controls ($r=0.33-0.74$). Discussion If a subject's physical activity was influenced by the particular sports club activity (e.g., soccer, baseball), then particular object control skills would be expected to correlate with PA parameters, not the total. Although no causal association between motor skills and PA was proved, children who have high total object control tend to have high PA, which might reflect that they ordinarily participate in many activities using objects, especially balls. Acquiring many object control skills might play an important role in promoting total PA each day for primary school children. Reference Wrotniak BH, et al. (2006). *Pediatrics*. 118:e1758-65. THE ELEMENTARY TEACHERS' CONCEPTUAL KNOWLEDGES ABOUT THE GAME IN PHYSICAL EDUCATION: BACKGROUND OF FORMATION & REALITIES

Shin, K.

Jeonju National University of Education

Introduction The Teachers' teaching performance is reliant on their knowledge and belief in what they are teaching. Thus, their knowledge and beliefs are more dynamic that is affected by the teaching content, teaching method, learners and teaching contexts. This study focuses on the conceptual knowledge formed subjectively, relatively and changeably by elementary school teachers. The purpose of this study was to analyze the elements which affected conceptual knowledge of games, and the realities of the aforementioned conceptual knowledge. **Methods** To complete this study, four elementary school teachers were chosen after having taken into consideration their accessibility, rapport and teaching expertise. The data was collected through the use of in-depth interviews and descriptive observation. This data was then analyzed using case studies and inductive categorized analysis. The accuracy of the data was obtained through peer briefing, member-checking, and triangulation. **Results & Discussion** The results showed that the teachers' innate traits affected their own conceptual knowledge about games and, in particular their own experiences in a game activity, environment prior to becoming a teacher. However, the teachers were able to transform and adjust the games according to the students' ability and the school environment. These alternations were possible due to the teachers' understanding of major skills, rules and equipments. The teachers wanted to apply the Teaching Games for Understanding model and paid special attention to managing the students' activities on the playground. The teachers recognized that game activities should be a nexus to lifetime involvement in physical activity and as a result planned to pursue the concept of exciting PE classes.

A PRIMARY SCHOOL-BASED EDUCATIONAL PROGRAM TO IMPROVE FALL SKILLS; PROCESS EVALUATION ALONGSIDE A CLUSTER RANDOMIZED CONTROLLED TRIAL.

Nauta, J.

VU University Medical Center

Objective To describe, alongside a cluster randomized controlled trial, the process evaluation of an educational program to improve fall skills in primary school age children using the RE-AIM framework (Glasgow et al., 1999). In this framework five dimensions of intervention quality are described; 1) Reach of the target population, 2) Effectiveness of the intervention, 3) Adoption of the program by target settings, 4) Implementation and 5) Maintenance of behaviour change. **Methods** Thirty-three schools participated in a cluster-randomized controlled trial. Seventeen schools were randomly allocated to the intervention group. Injuries were registered during a school year. Fall skills were assessed using self-reports and a fall skills test. Lastly, questionnaires were used to evaluate experiences of both children and teachers with the educational program. **Results** All children participating in physical education lessons were reached. The program was effective in increasing self-perceived fall-skills and the score on a fall-skills test (0.94 points), but the change in fall-related injury rates did not reach significance. Fourteen percent of invited schools were willing to Adopt the educational program. And although participating teachers were positive about the educational program, 89% failed to implement the exercises as intended. Last of all, 54% of the teachers intended to maintain the educational program in their regular teaching routine. **Conclusions** Results of the process evaluation are promising: even though many teachers failed to implement the intervention as intended, fall skills in children did show improvements. Adjusting the educational program to better fit the needs of teachers will potentially increase adherence to the program. This could potentially result in a significant decrease in fall-related injury risk. **References** Glasgow RE, Vogt TM, Boles SM. Physiology

THE EFFECT OF WHOLE BODY CRYOTHERAPY ON THE REGENERATIVE CAPACITY FOLLOWING AN ECCENTRIC JUMP PROTOCOL ON BIOCHEMICAL MARKERS

Wechsler, K., Jedlicka, D., De Marees, M., Mester, J.

German Sport University Cologne

Introduction Enhanced recovery following competition and physical activity is an ongoing target in sports medicine. Since whole body cryotherapy (WBC) after a defined endurance exercise protocol is already partly examined, the purpose of this study was to test the efficacy of WBC on biochemical markers following an intensive eccentric exercise protocol. **Methods** 5 male subjects in a cross-over trial completed 50 drop jumps of 50 cm height before they randomly went in a cryo chamber (-110 degrees Celsius) for 3 mins or received no intervention. The effect on biochemical markers (creatine kinase (CK), myoglobin, C-reactive protein (CRP), hematocrit, white blood cells) was measured via blood samples taken pre and post exercise, post cryo- or control-intervention and 24 h post exercise. **Results** CRP stayed on resting levels in both groups. There were no significant differences between intervention and control group concerning CK. Myoglobin levels had a stronger incline and didn't reach baseline values after 24 h in the control group. Hematocrit and white blood cell

sampling didn't show any difference between the two groups. Discussion The purpose of this investigation was to examine the effects on biochemical markers in males performing eccentric exercise. Our main findings were that only myoglobin showed a significant difference between the examined groups. Until now, several other studies on WBC showed a tendency for an increase in anti-inflammatory interleukins, whereas a reduction in pro inflammatory interleukins and muscle damage markers was noticed (Krueger et al. (in preparation 2014); Pournot et al., 2011; Hausswirth et al., 2011; Costello et al., 2012). Other investigations found an improvement in muscle activation and cardiovascular activity as well as a reduction of overload symptoms (Banfi et al., 2010). Even though our own results showed some beneficial effects, due to low number of subjects, we lack the statistical significance to give clear recommendations of the use of cryotherapy in practice. Nevertheless, the differences in myoglobin values between the groups indicate a tendency for measurable effects of WBC after eccentric performance. INTERACTIVE EFFECT GALANIN-LIKE PEPTIDE AND SPONTANEOUS EXERCISE ON ENERGY METABOLISM

Takenoya, F.1,2, Ito, K.1, Kageyama, H.3, Hirako, T.2, Ota, E.2, Wada, N.2, Yamamoto, N.4, Ryushi, T.5, Shioda, S.2

1:Hashi University School of Pharmacy and Pharmaceutical Science, 2:Showa University School of Medicine, 3: Kiryu University, 4: Japanese Red Cross Hokkaido College of Nursin, 5: Daito Bunka Univ.

Introduction Galanin-like peptide (GALP) is a 60 amino-acid neuropeptide that plays an important role in the regulation of feeding, body weight and energy metabolism. The aim of this study was to determine if energy metabolism in spontaneously exercising mice could be promoted by intracerebroventricular (ICV) GALP administration. Changes in respiratory exchange ratio in response to GALP Methods The exercising and non-exercising group mice were assigned to either a vehicle- or a GALP treated group. Oxygen consumption (VO₂) and carbon dioxide production (VCO₂) were monitored using an indirect calorimeter for the 24 h. Body weight, and food and water intakes were measured after, the ICV administration. Results Changes in respiratory exchange ratio in response to GALP ICV administration indicated that lipids were primarily consumed followed by a continuous consumption of glucose throughout the dark period in non-exercising mice. In mice permitted to spontaneously exercise on a running-wheel, GALP ICV administration increased the consumed oxygen volume and heat production. The interaction between GALP ICV and spontaneous exercise decreased body weight. Energy metabolism-related enzymes were assessed in liver and skeletal muscle samples, with a significant interaction on mRNA expression between GALP ICV administration and spontaneous exercise observed in phosphoenolpyruvate carboxykinase that regulates gluconeogenesis and glucose transporter-4. Discussion These results indicate the GALP ICV administration can further promote energy metabolism when administered to spontaneously exercising mice. COGNITIVE PERFORMANCE IN YOUNG ADULTS RELATING THEIR LEVEL OF PHYSICAL ACTIVITY

Pluncevic Gligoroska, J., Mancevska, S., Dejanova, B., Todorovska, L., Petrovska, S., Antevska, V.

Medical Faculty University Ss Cyril and Methody

Do not insert authors hereIntroduction: Physical activity has been promotes as factor which affect cognitive functioning besides well-known positive effects on somatic health. Electrophysiological and psychological evaluation of cognitive processes: attention, concentration and learning were assessed in healthy young adult population relating to their level of physical activity. Material: 90 participants were divided into three groups, (each group consisted of 30 subjects, mean age 20.9 years): sedentary group (low level of PA), recreational group (moderate level of PA) and athlete's group (high level of PA). Methods: We used classic paper and pencil psychological test Trial Making Test to evaluate the psychomotor processing and original electrophysiological method EXG – electroexpectogram's paradigm to evaluate capability to response to cognitive challenging of investigational milieu. Results: The participants from physically active group had significantly better electrophysiological parameters of cognitive processes during EXG paradigm. They generated oscillatory EXG curves with certain features of successful cognitive adaptation. Results from TMT- A testing showed that sedentary individuals finished the task in 31.98 ± 10.14 seconds; the group with moderate level of PA average total time was 26.37±9.45 sec.; in the athletes it was 25.30±5.12 sec. The second part of TMT, part B is more challenging and sedentary individuals solved it for average 79.7±22.33 sec; recreational participants needed 68.23±22.39 sec and athletes was the fastest with 60.67 ±14.24 sec. Conclusion: Young adults who participated in moderate and intensive physical activity showed better cognitive performance on electrophysiological and TMT testing than their sedentary siblings. These results maintained the hypothesis that regular physical activity might be beneficial on cognitive functions in young adults. References: 1. Lambourne K. WALKING ECONOMY IN PERIPHERAL ARTERIAL DISEASE: THE FASTER THE BETTER?

Figueiredo, P.1,2, Bona, R.L.1,2, Bonezi, A.1,3, Sanseveriano, M.1,2, Moraes, R.1,2,4, Peyre Tartaruga, L.A.1,3, Umpierre, D.1,2

Federal University of Rio Grande do Sul

Introduction Patients with peripheral arterial disease (PAD) present marked circulatory impairments, reduced muscle blood flow, and usually experience decreases in walking capacity. Thus, the present study aims to evaluate the walking economy at different walking speeds in patients with PAD. Methods PAD patients and healthy control individuals underwent a maximal incremental test to determine peak oxygen uptake (VO₂ peak). On a different day, a walking transport cost (C) protocol was performed on the treadmill to evaluate walking economy. In this protocol, subjects exercised in 5 different walking velocities, in randomized order: self selected walking speed (SSWS), two speeds below the SSWS (-40% and -20%), and two speeds above the SSWS (+20% and +40%). The study is ongoing, therefore, the present abstract reflects a preliminary analysis. Results Six PAD patients (age 62±3, VO₂ peak 18.3 ±0.7 ml.kg⁻¹.min⁻¹, SSWS 0.80 ±0.05 m.s⁻¹, C at SSWS 2.94 ±0.16 J.Kg⁻¹.m⁻¹) and six controls (age 64 ±3, VO₂ peak 26.1 ±2.6 ml.kg⁻¹.min⁻¹, SSWS 0.96 ±0.05 m.s⁻¹, C at SSWS 2.66 ±0.5 J.Kg⁻¹.m⁻¹) participated in the study. In the PAD group, a walking economy difference was found at all the speeds

(ANOVA $p < 0.05$), showing that SSWS was less economical than the higher speeds ($C 2.16 \text{ J} \cdot \text{Kg}^{-1} \cdot \text{m}^{-1}$ and $2.24 \text{ J} \cdot \text{Kg}^{-1} \cdot \text{m}^{-1} + 20\%$ and $+40\%$ respectively, $p < 0.05$). No walking economy difference was found among the five speeds in the control group. Discussion Our preliminary findings indicate that PAD patients seem to choose a SSWS in which they are less economical. Such pattern partially conflicts with the metabolic cost, however, it may reflect additional sources of walking impairment in this population, such as biomechanical, neuromuscular or ventilatory parameters. This kind of walking economy alterations have already been found in heart failure patients (Figueiredo et al., 2013). Although healthy subjects present lower energy cost at the SSWS (Saibene and Minetti, 2003; Figueiredo et al., 2013), we were still unable to observe that behavior in our control group, probably due to the small sample size. THE EFFECTS OF THREE DIFFERENT WARM UP PROTOCOLS ON MAXIMAL POWER OUTPUT DURING CYCLING.

Farrell, J., Spendiff, O.

Kingston University

Introduction In sprint cycling, the ability to generate and maintain high power output is of paramount importance. However, performance could be unknowingly compromised by fatigue accumulated during traditionally accepted Warm Up (WU) protocols. Much is still to be understood about the mechanisms of WU and how muscle temperature, duration and intensity affect sprint performance. The aim of this study was to compare the effects of different WU protocols on power output in sprint cycling. **Methods** Nine male cyclists (age 21 ± 1 years, stature 182.1 ± 3.9 cm, body mass 77.2 ± 6.2 kg; mean \pm S.D) undertook a 30-s Wingate test preceded by either passive warm up (PWU) (25 min) using heated blankets, short active warm up (SAWU) (8 min) or long active warm up (LAWU) (17 min) protocol. The active warm up protocols comprised of increasing intensity from 60%HRmax to 70%HRmax incorporated with a 6 second maximal sprint. Performance measures of peak (PPo) and mean power output (MPo) (W) were recorded. Skin temperature ($^{\circ}\text{C}$) was recorded on the mid-point of the vastus lateralis. The thermometer placement and neoprene insulation was assumed to give an indication of changes in muscle temperature during warm up (Brajkovic et al. 2006). **Results** MPo was higher following the SAWU and LAWU protocols when compared to PWU (PWU 646 ± 65 , SAWU 679 ± 68 , LAWU 679 ± 83 W, $p < 0.05$). PPo was not different between conditions (PWU 924 ± 137 , SAWU 970 ± 171 , LAWU 928 ± 160 W, $p < 0.05$). Skin temperature increased in all WU conditions and was not different between conditions immediately prior to the performance test (PWU 34.2 ± 0.8 , SAWU 34 ± 0.9 , LAWU 34.3 ± 0.9 $^{\circ}\text{C}$, $p < 0.05$). **Discussion** The lower MPo ($p < 0.05$) observed after PWU indicates that an active component of a warm up elicits changes that improve maximal cycling performance. As skin temperature was not different between passive and active WU conditions this indicates that non-temperature related mechanisms have a greater effect on maximal cycling performance. Possible performance enhancing mechanisms associated with active warm up include postactivation potentiation of the muscle (Sale 2004) and accelerated oxygen uptake kinetics (Gerbino et al. 1996). The finding that no differences in MPo following the SAWU and LAWU protocols is persuadable evidence that a duration longer than 8 minutes is unnecessary for sprint cycling. Furthermore, although not reaching statistical significance the PPo after SAWU was 4.6% higher compared with LAWU indicating that extending the warm up could possibly contribute to fatigue and have a negative effect on performance. Future research should refine WU and rest periods to determine which conditions yield the most benefit. **Reference** Brajkovic D, Ducharme M., Webb P, Reardon F, Kenny G (2006). Eur J Appl Physiol 97: 761-765. Gerbino A, Ward SA, Whipp BJ (1996). J Appl Physiol 80: 99-107. Sale D (2004). J Sports Med 38: 386-387.

EFFECTS OF THE PERCENTAGE OF SKELETAL MUSCLE AND BODY FAT ON PHYSIOLOGICAL CHANGES AFTER A JUDO MATCH

Takashina, T., Kushi, H., Yoshida, A., Fukada, K., Onuma, N.

Nihon University

[Introduction] Competitive Judo is divided into 7 classes according to weight, with men divided into the following classes: <60 kg, 66 kg, 73 kg, 81 kg, 90 kg, 100 kg, and >100 kg. Body fat percentage increases with increasing weight class, with a particularly rapid increase in the >90 kg classes. The purpose of this study was to compare physiological changes before and after a Judo match between men <90 kg group and >90 kg group. **[Subjects and Methods]** This study included 15 men with >10 years of Judo experience who were divided into 2 groups: one is "<90 kg ($n = 7$)" and ">90 kg ($n = 8$)". Body composition (body fat percentage, skeletal muscle percentage, and extracellular water) was measured before the match, while heart rate, blood lactate concentration, tympanic temperature, and skin temperature (thigh, Tsurite, and Hikite temperatures) were measured before and 1, 10, and 20 min after the match. **[Results]** Body fat percentage was significantly higher in the >90 kg group ($20.8 \pm 2.3\%$) than in the <90 kg group ($11.6 \pm 1.4\%$) ($p < 0.01$). Skeletal muscle percentage was significantly higher in the <90 kg group ($50.1 \pm 1.3\%$) than in the >90 kg group ($43.7 \pm 1.6\%$) ($p < 0.01$), and extracellular water was significantly higher in the <90 kg group ($0.20 \pm 0.0031/\text{kg}$) than in the >90 kg group ($0.17 \pm 0.0071/\text{kg}$) ($p < 0.05$). Blood lactate concentrations measured at 1, and 10 min after the match were $5.8 \pm 0.9 \text{ mmol/l}$ and $3.3 \pm 0.5 \text{ mmol/l}$, respectively, in the <90 kg group and $9.5 \pm 0.5 \text{ mmol/l}$ and $5.7 \pm 0.7 \text{ mmol/l}$, respectively, in the >90 kg group. These differences at both time points were significant ($p < 0.05$). Thigh, Tsurite, and Hikite temperatures measured 10 min after the match were 34.3 ± 0.3 degrees Celsius ($^{\circ}\text{C}$), 34.4 ± 0.3 degrees C and 34.3 ± 0.2 degrees C, respectively, in the <90 kg group and 35.0 ± 0.1 degrees C, 35.1 ± 0.2 degrees C and 34.9 ± 0.2 degrees C, respectively, in the >90 kg group. These values were higher in the >90 kg group than in the <90 kg significantly ($p < 0.05$). **[Conclusions]** The present study revealed that Judo athletes with lower skeletal muscle and higher body fat percentages accumulated more blood lactate and experienced greater increases in skin temperature after the Judo match. Judo athletes with lower percentage of skeletal muscle may have fewer muscle capillaries compared to those in athletes with a higher percentage of muscle. Therefore, blood lactate accumulates owing to a lack of oxygen supply for the working muscles. Moreover, increased body fat may result in increased skin temperature because of inefficient heat diffusion from the skin. The results of this study demonstrate that body composition, specifically the percentage of skeletal muscle and body fat affects physiological changes after a Judo match.

PRELIMINARY EVIDENCE ON THE ACUTE EFFECTS OF MODERATE INTENSITY EXERCISE ON SMOKING DELAY

Georgakouli, K., Manthou, E., Tsiami, A., Tzatzaki, T., Zourbanos, N., Goudas, M., Jamurtas, A.Z., Hatzigeorgiadis, A., Theodorakis, Y.

University of Thessaly

Introduction Exercise has been proposed as a strategy to help individuals reduce or quit smoking, while at the same time reduces morbidity linked to cigarette smoking. This study is part of an ongoing project aiming at the development of an intervention involving exercise and self-regulation strategies for smoking cessation. The purpose of the present study was to examine the acute effects of moderate intensity physical exercise on smoking delay. **Methods** Twelve healthy non-systematically exercising heavy smokers (7 males, 5 females) with the following characteristics (mean \pm SD): age, 30.7 ± 7.0 years; body mass index, 25.8 ± 5.9 ; smoking cigarettes/day, 28.7 ± 10.0 ; nicotine dependence, 7.2 ± 1.9 , participated in the study. They underwent two trials after overnight smoking abstinence, one control and one exercise, in a balanced design separated by at least six days. The exercise trial involved cycling at 50-60% of the Heart Rate Reserve ($122-138$ beats \cdot min $^{-1}$) for 30 min, while in the control trial participants rested quietly for the same duration. Physiological and psychological measurements were assessed before each trial, while time till the first cigarette smoking was strictly monitored after the end of each trial. Results Blood pressure, heart rate at rest, carbon monoxide (CO) and carboxyhemoglobin (COHb) in breath were not different between the two trials ($p > 0.05$). Mean exercise heart rate was 132.2 ± 5.2 beats \cdot min $^{-1}$ and mean exercise workload was 82.4 ± 17.0 W. Perceived rate of exertion at exercise was 13.1 ± 1.9 . Smoking the first cigarette was significantly delayed after the exercise trial (15.3 ± 15.2 min) in comparison to the control trial (4.0 ± 2.7 min), ($p = 0.02$). **Conclusion** The results from the present study indicate that smoking is likely delayed after a session of moderate intensity exercise in heavy smokers. **Author Note** This research has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program ‘Education and Lifelong Learning’ of the National Strategic Reference Framework (NSRF) - Research Funding Program: THALES. Investing in knowledge society through the European Social Fund.

SYSTEMIC CYTOKINE RESPONSES FOLLOWING EXERCISE-INDUCED MUSCLE DAMAGE IN HUMANS

Philippou, A.I, Giannopoulos, A.I, Thodou, A.I, Psarros, C.I, Maridaki, M.I, Koutsilieris, M.I

University of Athens

Introduction Muscle adaptation which occurs following exercise-induced muscle damage has been associated with an inflammatory response before the completion of muscle repair or regeneration. The final outcome of this response is influenced by a crucial balance between pro-inflammatory and anti-inflammatory cytokines (Philippou et al., 2012). The purpose of this study was to investigate systemic cytokine responses for several days after eccentric exercise-induced muscle damage in humans. **Material & Methods** Ten healthy men volunteers (age: 25 ± 5 yr, height: 180 ± 5 cm, mass: 77 ± 8 kg; mean \pm SD) performed 50 maximal eccentric muscle actions using the knee extensor muscles of both legs. Blood samples were withdrawn before and at 6 h, 2 days and 5 days post-exercise. Serum levels of interleukin (IL)-1 α , IL-2 and IL-10 were measured by ELISA using commercially available kits. One-way ANOVA was used for statistics and the level of statistical significance was set at $p < 0.05$. **Results** Circulating levels of the pro-inflammatory cytokine IL-1 α did not change over time compared with the pre-exercise levels, while IL-2 increased slightly 48 h following eccentric exercise, but without reaching significance ($p > 0.05$). Serum levels of the anti-inflammatory cytokine IL-10 exhibited a nearly two-fold increase 6 hours post exercise and remained elevated throughout the experimental period. However, IL-10 changes following exercise failed to be statistically significant ($p > 0.05$) due to a large variability shown between the subjects. **Discussion** The findings of the present study suggest that eccentric exercise might trigger a systemic cytokine response as part of the adaptation process to muscle damage, where the anti-inflammatory cytokine IL-10 may be especially involved (Hirose et al., 2004). **References** Hirose L, Nosaka K, Newton M, Laveder A, Kano M, Peake J, Suzuki K. *Exerc Immunol Rev.* 2004;10:75-90. SINGLE BOUT OF SWIMMING EXERCISE CHANGES AUTOPHAGY IN CARDIAC MUSCLE

Hong, G.E.I, Kim, S.H.I, Kim, D.H.I, Yang, M.H.I, Lee, H.Y.I, Kang, H.S.I, Ju, J.S.I, You, Y.S.I

1: Chonnam Nat'l Univ.(Gwangju, Korea), 2: Kwangju Women's Univ.(Gwangju, Korea), 3: The Univ. of Suwon(Hwaseong, Korea)

Introduction Autophagy is the process of forming vesicle structure by response to nutritional deficiency or outside stress and then surrounding and decomposing cell organelles to make energy. Autophagy, which is activated by being given diverse stimuli of stress including exercise, plays an important role in generating and maintaining energy in diverse muscles as well as skeletal muscle. However, there are very few studies on the physiological mechanism to explain the effects of such autophagy on cardiac muscle both at home and abroad. Thus, this experiment was conducted through acute swimming exercise to learn what effect autophagy makes on cardiac muscle. **Methods** For lab animal, 24 experimental rats were bred in groups of 6 mice (control+saline, control+colchicines, exercise+saline, exercise+colchicines) using plastic cages, with temperature of 24-25°C, 70-80% humidity and light control in 12-hour cycle for breeding room. The selected animals were supplied with pellet and sufficient water for the whole period of experiment. Before the exercise, all the subject mice were given training for adaptation for two days, 10 min. for each, while at this exercise, 12 rats in exercise group were given exercise in the water of 35 to 36°C in two divided sessions (1-hour swimming + 15-minute rest + 1-hour swimming). For colchicine and saline, three times of treatment in total were given including the two days right after adaption training and right after the main training. Samples of cardiac muscle were abstracted 24 hours after exercise while conducting Western blot by use of LC3 and p62 as antibodies. **Results** Group in treatment with colchicine showed a clearer difference in change compared to group in treatment with saline, while results were drawn among groups in treatment with colchicine. Compared to control group, change in LC3-II showed a significant difference for the whole group of ‘exercise+colchicine’ with a significant difference in Gel-2 and Gel-3, except Gel-1. However, visible increase was also found in Gel-1. As to p62, compared to control group, the whole group of exercise+colchicine showed significant difference. As with LC3-II, however, there was no significant difference found in Gel-1, but with significant difference in Gel-2 and Gel-3. **Discussion** Through this, it was found that acute swimming exercise makes significant effect on autophagy of cardiac muscle, meaning the effect of stimuli like exercise on cardiac muscle. Furthermore, supposing autophagy as apoptosis or energy source, it is considered possible to help in solving the problems of modern society by applying it to aging, sarcopenia, discontinuance in training, long-term exercise, etc. **References** Combaret, L., Dardevet, D., Bechet, D., Taillandier, D., Mosoni, L., & Attaix, D. THE INFLUENCE OF CROSS-FIT TRAINING ON BDNF AND IRISIN CONCENTRATIONS IN YOUNG MEN'S BLOOD

Murawska Cialowicz, E.

University of Physical Education

Introduction BDNF (brain derived neurotrophic factor) is a protein stimulating processes of neurogenesis in the nervous system, which help to support the survival of neurons and microglia, stimulate neuroplasticity, and take part in differentiation of cells developed in the hippocampus. An increase in the production of BDNF in response to a contraction of skeletal muscles and its ability to stimulate neurogenesis are proof that regular physical effort can facilitate communication between the nervous and muscular systems. BDNF also takes part in an organism's energy expenditure, stimulating the conversion of white adipocytes into brown ones. BDNF also stimulates the secretion of irisin – an effort hormone, which is involved in body mass reduction through its influence on oxidation processes of energy substrates. It is a vital issue from the point of view of prophylaxis and treatment through physical effort of age-related (eg senile dementia) or obesity-related conditions, eg type-2 diabetes or cancer. **Methods** The aim of the study was to assess changes in concentrations of BDNF and irisin in young men subjected to a 3-month cross-fit training. Before and after the training, the subjects had their blood taken and concentrations of BDNF and irisin were assayed. The subjects also took part in Wingate and progressive tests to check if the applied training affected their physical performance. Their body mass and composition were also analyzed. Results Anaerobic and aerobic capacity of the subjects, which was analyzed on the basis of Wingate and progressive test results, improved after cross-fit training. An increase in VO₂max, reduction in adipose tissue percentage, and increase in LBM were noted. BDNF concentration in the serum increased significantly. No important changes in irisin concentration were observed. **Discussion** A beneficial influence of cross-fit training on subjects' body composition parameters, anaerobic capacity and cardiovascular fitness as well as an increase in BDNF concentration that was observed in the study makes it possible to assume that this type of training could have a very high application value, especially in a therapeutic process leading to improving a patient's wellbeing or when counteracting diseases included in the group belonging to the so-called diseasesome, which are age-related but, at the same time, a result of low level of physical activity (Pedersen 2009). **References** 1. RECTAL TEMPERATURE DYNAMICS DURING GRADED EXERCISE TESTING

Rakovac, M., Sentija, D., Babic, V., Marsic, T.

University of Zagreb, Faculty of Kinesiology

Introduction Different physiological variables show distinct trends of increase during incremental exercise. The increase trend reflects the underlying changes in skeletal muscle metabolism related to increasing exercise intensity, and is often used to describe different intensity zones. The aim of this study was to determine the pattern of increase in body core temperature during incremental treadmill exercise test. **Methods** The sample consisted of 32 physically active males (age (mean±SD) 26.5±6.6 years; height 179.2±5.0 cm; body mass 76.8±8.1 kg). They performed a graded treadmill exercise test until volitional exhaustion (speed increments of 0.5 km/h each 30 seconds) in controlled thermoneutral conditions. Rectal temperature (measured at 8 cm from the anal sphincter) was registered throughout the test. Three independent evaluators performed computer-assisted fitting of temperature curves. Results Three models of temperature increase during graded exercise test were identified. Each was described by three distinct segments of temperature rise (an additional fourth segment was identifiable in several cases), delimited by threshold-like changes in trend of increase. The first model was described by three segments of progressive linear increase. The second model was described by an initial segment of linear increase, followed by a curvilinear increase (best fitted by a 2nd-degree polynomial model), and a third segment of linear increase. The third identified model consisted of an initial curvilinear increase (2nd-degree polynomial model), followed by two segments of linear increase. The slope of temperature rise increased between subsequent zones in all models. **Discussion** The rectal temperature, as a measure of body core temperature, showed three distinct patterns of increase during graded treadmill exercise test. A phasic increase identified in all models, characterized by distinct segments of increasing slope of temperature rise, arguably reflects thermodynamic changes imposed by metabolic effects of increasing intensity of exercise. **References** González-Alonso (2012). *Exp Physiol*;97(3):340-6. ANTHROPOMETRICAL PREDICTORS OF PERFORMANCE IN ELITE AGE GROUP SWIMMERS

Mitchell, L.J., Rattray, B., Saunders, P.U., Pyne, D.B.

Australian Institute of Sport

Introduction A swimmer's anthropometry is an important factor for performance. For junior swimmers many anthropometric measures have been related to freestyle and butterfly performance, with different combinations of these metrics differentiating successful males and females from their competitors [1, 2]. However these factors have not been investigated across all strokes for competition performances. **Methods** Junior national-level swimmers (n=21 female, 15.4±1.2 y, 16 male, 16.7±1.1 y) were measured for height, body mass, sitting height, sum of 7 skinfolds, foot length, biliocrystal breadth, anterior-posterior chest depth, and femur breadth using standardised methods [3]. Competition performances in all strokes within 3 months prior to measurements were compiled and expressed as the swimmer's time divided by the world record for that event. Swimmers' stroke and distance preferences were determined by the event for which they were closest to the world record. The sprint and distance subgroups had best events of 200 m or less and 400 m or more respectively. Alpha level = 0.05. Results Predictors of performance in 100 m events for males were femur breadth (r = -0.50, -0.80 to 0.00; r value, 95 % confidence limits), biacromial breadth (r = -0.58, -0.84 to -0.12) and weight (r = -0.55, -0.82 to -0.08). Male sprinters had larger anterior-posterior chest depths (19.4 ± 0.9 cm; mean ± SD, 17.7 ± 1.1 cm) and were heavier (76.6 ± 7.4 kg, 69.1 ± 3.9 kg) than the distance specialists. For female swimmers height (r = -0.46, -0.74 to -0.03) and sitting height (r = -0.50, -0.76 to -0.08) were predictors of 100 m performance. Female sprinters were taller (172.9 ± 5.4 cm, 167.4 ± 3.5 cm), had a larger arm span (176.4 ± 5.8 cm, 171.4 ± 0.5 cm) and larger feet (25.2 ± 0.9 cm, 23.9 ± 0.9 cm) than distance specialists. **Discussion** Males appear to be differentiated by measures related to mesomorphy for 100 m performance. This is intuitive as muscle mass is important for short duration high-intensity performance. For females the predictors of sprint performance was related to overall stature rather than muscularity, indicating they rely less on explosive strength as a differentiating factor for 100 m performance. **References** 1. THE EFFECTS OF SWIMMING TRAINING ON CONTRACTILITY OF AN ISOLATED RAT HEART

Djordjevic, D.1, Stojanovic Tosic, J.1, Zivkovic, V.1, Srejovic, I.1, Radovanovic, D.2, Djuric, D.3, Jakovljevic, V.1

1Faculty of Medical Sciences, Kragujevac, Serbia, 2Faculty of Sports and Physical Education, Nis, Serbia, 3School of Medicine (Belgrade, Serbia)

Introduction Swimming is a proven way of a valid application of the training load to induce physiological cardiac hypertrophy in rats (Wang et al, 2010). The aim of this research was to assess the changes in cardiac contractility of isolated rat hearts after 8 and 12 weeks of swimming. Methods Eight weeks old Wistar albino female rats were subjected to swimming (1hour a day, 5 days a week) in a specially constructed rat swimming pool for 8 or 12 weeks. Control groups were put in water for 3 minutes a day, in order to achieve the same water-induced stress effects on rats. After sacrificing animals, their hearts were isolated and perfused on a Langendorff apparatus. Coronary perfusion pressure was gradually increased (from 40 to 120 mmHg) in order to establish coronary autoregulation. Parameters of cardiac contractility (maximum and minimum rate of change of pressure in the left ventricle: dp/dt max and dp/dt min) were recorded. Results Values of dp/dt max were significantly lower in rats trained for 8 weeks than in initially sacrificed group of control rats during all perfusion pressures, while after 4 more training weeks this difference was noticed only during perfusion with the lowest and the highest value of perfusion pressure. However, the difference was not observed between trained rats and controls of the same age. On the other side, the only significant difference in dp/dt min values was seen between the 8 weeks trained rats and controls of their age, especially during higher perfusion pressures. Discussion Although several experimental studies from isolated heart, papillary muscle and isolated cardiomyocytes have extensively demonstrated the positive effects of exercise training on myocardial function, some reports found no effects or even impairment on cardiac and myocardial function (Bocallini et al, 2010). The results of our study may suggest that the most commonly reported swimming protocol in available literature (60min for 5 times a week during 8 weeks) was not long enough to induce positive changes in cardiac contractility of rats. Since the difference between controls and trained rats almost disappeared after 12 weeks of training, it may be concluded that observed decrease of cardiac contractility after 8 weeks of training was just a transitory phase after which, with extension of training process, adaptation occurs and positive effects of exercise start to be visible. ACUTE EFFECT OF STRENGTH TRAINING WITH BLOOD FLOW OCCLUSION IN PARAMETER RELATED TO MUSCLE DAMAGE

Letieri, R.V., Figueiredo, A.J.B., Furtado, G.E., Letieri, M., Silva, F.B., Alves Junior, T.A., Sousa, F.C.S.

Faculdade Católica Rainha do Serão - FCRS

Introduction: Japanese researchers have developed a technique that combines strength training performed at intensities reduced (20-50% 1RM) with occlusion of blood flow also called 'KAATSU training.' Studies have shown that the changes caused in gaining strength and muscle mass after a period of training with this technique are similar to those caused by strength training of high intensity ($\geq 80\%$ 1RM) (Karabulut, Abe, Sato & Bemben, 2010 ; Kubo et al ., 2006; Takarada et al., 2000). Methods: The study included 18 male volunteers and the groups were defined as high intensity without vascular occlusion (HI, n = 6), low intensity without vascular occlusion (LI, n = 6) and low-intensity with vascular occlusion (LIVO, n = 6). The groups and LIVO and LI performed strength training at an intensity corresponding to 20% of 1RM and the group HI performed at 80% of 1RM (ACSM, 2009). Blood samples were collected before, immediately after, 24 hours and 48 hours after the training session. The volunteers remained seated and the cuff was placed on the proximal arm and inflated to a pressure of 130% occlusion of Systolic Blood Pressure (Loenneke et al., 2011). Results: There was no statistical difference in CK before and immediately after training between groups, statistical difference after 24 hours ($p < 0.05$) and 48 hours ($p < 0.05$) in favor of the group HI toward the group LI. The perception of muscle pain and discomfort was also checked and showed that individuals who had higher CK were also those with greater muscle pain. Conclusion: In the present study it was evident that the high intensity produces higher levels of CK, especially in the exercise without occlusion, but occlusion produces relatively high intensity workout with less muscle damage. However, it is clear that it is extremely important to analyze the behavior of more variables in an attempt to express conclusive data on the muscle damage induced by strength training. CHANGES IN COMPLIANCE OF SUPERFICIAL AND DEEP VEINS IN RESTING LIMB DURING PROLONGED EXERCISE UNDER DIFFERENT ENVIRONMENTS

Oue, A., Sato, K., Yoneya, M., Sadamoto, T.

Toyo University

Introduction The venous compliance in a resting forearm was decreased during prolonged cycling exercise under a hot environment (Fortney et al. 1983), indicating the increase in venous blood return to the heart and the preservation of central venous blood volume. However, there are two unanswered questions. First, it is not clear which venous vascular response of skin or muscle contribute to the decrease in venous compliance during prolonged exercise. Second, it is not clear whether the ambient temperature influence the decrease in venous compliance during prolonged exercise. Thus, we investigated the changes in compliance of superficial (skin) and deep (muscle) veins in a resting limb during prolonged cycling exercise under hot and normal environments. Methods Nine young males carried out cycling exercise at 60% of peak oxygen uptake until a rectal temperature elevated 1.2 °C under hot (35°C) and normal (25°C) environments. Venous compliance was determined using the first derivation of the cuff pressure-venous cross-sectional area (CSA) relation obtained during cuff deflation protocol (Halliwill et al. 1999). To assess the venous compliance of skin and muscle separately, we measured CSA in a superficial basilic vein and a deep brachial vein by ultrasound technique. Results During prolonged exercise, stroke

volume was lower and heart rate was higher at hot rather than normal condition. Mean arterial pressure was not different between environments. Under a hot condition, deep venous compliance decreased but superficial venous compliance did not change during prolonged exercise compared with pre-exercise. However, under a normal condition, both deep and superficial venous compliance decreased during prolonged exercise. Discussion Our results indicate that the decrease in venous compliance of a resting limb during prolonged exercise might be due to the venous vascular response of not skin but muscle under a hot condition, and might be caused by that of both muscle and skin under a normal condition. The decrease in venous compliance of a resting limb during prolonged exercise might be caused by the increase in sympathetic nerve activity via an unloading of cardiopulmonary receptors, because the increase in skin blood flow and sweating induced the decrease in central volume. On the other hand, the superficial venous compliance under a hot condition did not alter during exercise, which might be the one of factors which induced the significant cardiovascular drift under a hot environment. WHOLE BODY CRYOTHERAPY AND MAGNITUDE OF COOLING ON ANTHROPOMETRIC CHARACTERISTICS

Cuttell, S.I, Meyler, J.I, Nunley, P.I, Hammond, L.I

Moulton College

Institutions: 1 Moulton College, Moulton, NN3 7RR, UK. 2 University of Bedfordshire, Luton, Bedfordshire LU1 3JU. Introduction: Whole body cryotherapy (WBC) involves a short exposure (1-4 minutes) to very cold air (-110 to -140°C). It has been used in both clinical and sporting populations for treatment of a wide variety of conditions. Differences in magnitude of cooling resulting from WBC have been observed in individuals with a high BMI compared to low BMI (Cholewka et al., 2012). The difference may suggest a relationship with anthropometric factors where WBC is used. The aim of this study was to investigate whether a range of anthropometric measures influence on the magnitude of cooling. Methods: Thirty-two recreationally active participants (males: n=18, mean age 29.5 ± 4.4 years; females n=14, mean age 28.3 ± 6.4 years) gave informed consent to participate in the study. Height, weight and body composition were measured (body fat percentage and lean mass), enabling calculation of body surface area and body surface area to mass ratio (Du Bois & Du Bois, 1916). A WBC protocol of 30 seconds at -60°C followed by 2 minutes at -110°C was used. Thermal images were captured pre- and post-WBC, with skin temperature measured at the chest, posterior arm, thigh and calf. Mean skin temperature (Tsk) for pre- and post-WBC and change in mean skin temperature ΔTsk were calculated. Results: The lowest temperatures reached were in the calf (19.54±3.28 and 15.05±2.04°C for males and females respectively). ΔTsk was significantly greater in females (12.07±1.55°C) than males (10.12±1.86°C; t(30)=-3.09, P=.004). A highly significant moderate relationship was observed between body fat percentage and ΔTsk for combined male and female data (P=.002, r=.516). A significant relationship was observed between BSA:mass and ΔTsk for males (P=.030, r=-.512). Discussion: The response of individuals to WBC appears to depend upon anthropometric variables, with body fat percentage demonstrating a significant positive correlation with ΔTsk in a combined dataset of males and females. These findings could specifically have an impact on athletic performance as recovery time may be attenuated where WBC is used. Currently a wide range of elite teams and athletes use WBC for this purpose, with little known about the anthropometric effects. Our results suggest anthropometric variables can predict the magnitude of skin cooling and therefore individualised treatment protocols could be used for optimal effectiveness in elite team sports and individual athletes for optimal recovery. ASSOCIATION OF VITAMIN D STATUS WITH SERUM ANDROGEN LEVELS IN YOUNG ATHLETES FROM THE MIDDLE EAST

Cardinale, M., Nikolovski, Z., Varamenti, E., Elzain Elgingo, M., Douglas, A.R., Cable, N.T.

Aspire Academy, Doha, Qatar

Introduction Studies in rodents indicate a role of vitamin D in male reproduction, but the relationship between vitamin D and androgen levels in young athletes is largely unexplored. Recently, (Wehr, Pilz, Boehm, Mārz, & Obermayer-Pietsch, 2009) observed a positive, cross-sectional association between testosterone (T) and 25-hydroxyvitamin D [25(OH)D] together with a concordant pattern of seasonal variation for both hormones. The authors suggested that serum vitamin D levels likely impact directly on gonadal function, due to the presence of vitamin D receptor (VDR) in the testis, hypothalamus and pituitary gland. Due to the paucity of data on the interaction between Vitamin D and androgens in young and healthy individuals, we aimed to investigate the association of 25(OH)D levels with testosterone, free androgen index (FAI) and SHBG in a cohort of young athletes from the middle east. Methods 52 elite male youth athletes (Age 12 to 18) were assessed for Vitamin D and androgen status as a part of their routine medical screenings in September (end of summer), January (winter) and May (end of spring). After an overnight fast, a blood sample was drawn from the antecubital vein, with the subject seated in BD serum vacutainer tubes (BD Diagnostics, Plymouth, UK). Samples were spun to separate serum and stored at -80 °C until assayed. Serum Vitamin D, Testosterone, and SHBG were determined using ELISA kits (25-OH Vitamin D ELISA, Euroimmun, Luebeck, Germany; Testosterone parameter Assay Kit, and Human SHBG Quantikine ELISA Kit were from R&D Systems, Inc. (Minneapolis, MN, USA)). Anthropometric measures were also performed for the determination of peak height velocity (PHV; Mirwald et al., 2002). Results Mean PHV of the subjects was 14.1 ± 0.8 years. There was no relationship between Vitamin D and T, FAI and SHBG at any time point. Values were then grouped for athletes in the pre PHV (30) and post PHV (22) status at the time of the September screening. Post PHV athletes, as expected, showed higher T, lower SHBG, higher FAI and higher Vitamin D levels (P<0.05) than those athletes still to attain PHV. A small correlation coefficient was identified between years from PHV and Vitamin D (r=0.276; P<0.05). Large Correlation coefficients were identified between years from PHV and T and FAI (respectively r=0.514 and r=0.568; P<0.005). A moderate negative relationship was identified between years from PHV and SHBG (r=-0.359; P<0.005). Discussion Our data show no relationship between Vitamin D levels and T, FAI and SHBG, but imply an association between maturation status and Vitamin D metabolism. Future studies should further investigate the link between Vitamin D metabolism, androgens and bone health in growing athletes. References Wehr, E., Pilz, S., Boehm, B. THE EFFECT OF SUPRASYSTOLIC WRIST-CUFFING ON FOREARM MUSCLE HAEMODYNAMICS DETERMINED BY NEAR-INFRARED SPECTROSCOPY

Sabapathy, S., van Beekvelt, M., Constantini, K., Cross, T.

Griffith University (Queensland, Australia), Norwegian University of Science and Technology (Trondheim, Norway)

Introduction Near-infrared spectroscopy (NIRS), coupled with the venous occlusion technique (NIRS-VOT), has been used to quantify limb muscle blood flow (DeBlasi et al., 1997; van Beekvelt et al., 2001). However, it is difficult to compare results between studies using NIRS-VOT because of the inconsistent application of distal (e.g., hand or foot) circulatory occlusion during measurements. The aim of this study was to examine the influence of hand circulatory occlusion, via suprasystolic wrist-cuffing, on resting forearm muscle blood flow and indices of muscle metabolism as determined by NIRS-VOT. Methods Twenty-five healthy adults (18 males, 7 females; 28 ± 4 yr; 71 ± 7 kg) completed, in random order, a series of five venous occlusion trials with suprasystolic wrist-cuffing and a series of five venous occlusion trials without wrist cuff inflation, all performed on the dominant arm. Arterial oxygen saturation and blood pressure measurements were obtained from the non-dominant arm. NIRS data were obtained from the flexor digitorum superficialis (FDS) muscle of the dominant arm, using an interoptode distance of 35 mm, with a fixed differential path-length factor of 4.0, and sampled at 100 Hz. NIRS-derived parameters included tissue blood flow, vascular conductance, oxygen consumption, venous oxygen saturation, and fraction of oxygen extracted from arterialised blood (FOE). Results Heart rate and mean arterial pressure during wrist cuff inflation trials were similar to that observed without cuffing at the wrist. In contrast, wrist-cuffing resulted in a significant ($P < 0.05$) reduction in FDS blood flow ($-36 \pm 23\%$), vascular conductance ($-37 \pm 23\%$), oxygen uptake ($-14 \pm 31\%$) and venous oxygen saturation ($-14 \pm 12\%$). Conversely, FOE was significantly higher during wrist-cuffing trials ($+14 \pm 13\%$; $P < 0.05$). The coefficient of variation for the NIRS-derived parameters was similar between the trials performed with and without suprasystolic wrist-cuffing. Conclusion Hand circulatory occlusion using a suprasystolic wrist cuff reduces arterial inflow and oxygen consumption of the FDS muscle – as assessed by NIRS-VOT – but does not affect the reproducibility of NIRS-derived hemodynamic and metabolic parameters. These findings highlight the need for investigators to be cognisant of the influence that suprasystolic wrist-cuffing bears on the resting forearm when using NIRS-VOT to quantify muscle haemodynamics and metabolism. THE EFFECTS OF A 30 MIN DOWNHILL RUN ON SUBSEQUENT PERFORMANCE DURING A MAXIMAL INCREMENTAL EXERCISE TEST

Christmas, B.C.R.1, Taylor, L.1, Carroll, S.2, Smith, A.3, Pemberton, P.3, Siegler, J.C.4, Midgley, A.W.5

1 University of Bedfordshire; 2 The University of Hull; 3 Central Manchester Foundation Trust; 4 University of Western Sydney; 5 Edge Hill University

Maximal incremental exercise testing is ubiquitous in the field of exercise physiology, and it is critical that the results obtained from this test are an accurate representation of an individual's aerobic capacity. Asking individuals to adhere to a set of pre-test procedures is one way to endeavour to ensure this. Subsequently any exercise (particularly high-intensity or unaccustomed) is to be avoided 24 – 48 h prior to the test (Garrett and Kirkendall 1999) due to evidence that certain forms of exercise can initiate a cascade of signs and symptoms manifesting as exercise induced muscle damage (Hough 1902, Newham, McPhail et al. 1983), which may persist for several days. Consequently, these symptoms (e.g. muscle soreness) may negatively impact on subsequent performance in the maximal incremental exercise test, which could ultimately invalidate the results obtained. PURPOSE: To investigate the effects of a bout of muscle damaging exercise on the results obtained during a treadmill maximal incremental exercise test. METHODS: Fifty (36 male, 14 female), apparently healthy participants were randomly allocated into a control group ($n = 10$), or experimental group ($n = 40$). Participants visited the laboratory a total of six times (familiarisation, pre-trial 1, pre-trial 2, intervention, post-trial 1 and post-trial 2). Identical testing was performed during all visits, except during the intervention trial, where the experimental group performed a 30 min downhill run (-12.5% gradient, $70\% V_{max}$) and the control group performed no exercise. RESULTS: There were no significant differences ($p \geq 0.32$) between trials for any of the measures obtained during the maximal incremental exercise tests for the control group. In the experimental group there was a significant group x trial interaction effect for TTE ($F = 7.9$, $p = 0.007$), BLA_{max} ($F = 5.0$, $p = 0.03$), and HR_{max} ($F = 3.8$, $p = 0.04$). Additionally, there was a significant group x trial interaction effect for creatine kinase ($F = 4.5$, $p < 0.01$) and muscle soreness ($F = 34.8$, $p < 0.001$). Furthermore, there was a significant group x trial interaction effect for MVC in the dominant leg ($F = 9.5$, $p < 0.001$), and non-dominant leg ($F = 7.5$, $p = 0.001$), and voluntary activation in the dominant leg ($F = 3.9$, $p = 0.02$), and non-dominant leg ($F = 4.8$, $p = 0.03$). CONCLUSION: Delayed onset muscle soreness may increase an individual's perception of effort during the incremental exercise test, and ultimately result in premature termination of the test. However, there is currently no direct evidence to support this theory, and therefore these findings must be interpreted with caution. Contact: bryna.christmas@beds.ac.uk Garrett, W. E. and D. T. THE EFFECTS OF A 30 MIN DOWNHILL RUN ON SUBSEQUENT SUB-MAXIMAL RUNNING PERFORMANCE

Taylor, L.1, Carroll, S.2, Smith, A.3, Pemberton, P.3, Siegler, J.C.4, Midgley, A.W.5, Christmas, B.C.R.1

1 The University of Bedfordshire; 2 The University of Hull; 3 Central Manchester Foundation Trust; 4 University of Western Sydney; 5 Edge Hill University

The intrinsic nature of an athletic training schedule dictates that training regularly occurs on consecutive days (Gee et al. 2011). Furthermore, an individual's training regime typically incorporates a resistance exercise component characterised by eccentric contractions (Gee et al. 2011, Howatson et al. 2012). Despite eccentric contractions providing a greater stimulus for neuromuscular adaptation, they can also initiate a cascade of signs and symptoms manifesting as exercise induced muscle damage (Hough 1902, Newham et al. 1983). Consequently, the delayed presence of these signs and symptoms may negatively impact on an individual's ability to achieve optimal performance in a subsequent training session. PURPOSE: To investigate the effects of a bout of muscle damaging exercise on sub-maximal running performance. METHODS: Fifty (36 male, 14 female), apparently healthy participants were randomly allocated into a control group ($n = 10$), or experimental group ($n = 40$). Participants visited the laboratory a total of six times (familiarisation, pre-trial 1, pre-trial 2, intervention, post-trial 1 and post-trial 2). Identical testing was performed during all visits, except during the intervention trial, where the experimental group performed a 30 min downhill run (-12.5% gradient, $70\% V_{max}$) and the control group performed no exercise. RESULTS: There were no significant differences ($p \geq 0.19$) between trials for any of the measures obtained during the sub-maximal running tests for

the control group. In the experimental group, there was a significant group \times trial interaction effect for RPE ($F = 9.8$, $p < 0.01$), and perceived pain ($F = 20.3$, $p < 0.001$). Post hoc comparisons showed a mean increase of 10% for RPE ($p < 0.001$), and 200% for perceived pain ($p < 0.001$) 48 h post downhill run. CONCLUSION: The results from the present study showed that a 30 min downhill run had no effect on running economy. However, an increase in RPE during sub-maximal running may have implications for individuals returning to training with the signs and symptoms associated with exercise induced muscle damage still present. For example, perception of effort has been shown to be related to motivation (Marcora et al. 2009). If an individual perceives the exercise as being more difficult they may reach a less than optimal physiological intensity, and may be less motivated to continue to engage in the exercise task. MANIPULATION EFFECTS OF EXPECTED PERCEIVED EXERTION FEEDBACK ON PERCEIVED EXERTION AND PERFORMANCE IN WALKING EXERCISE

Serafim, T., Smirmaul, B., Nakamura, P., Kokubun, E.

UNESP (Rio Claro, Brazil)

Introduction Studies have been showing strong relationship between perceived exertion (PE) and performance. Among other factors, the psychological ones can influence PE. Thus, the aim of this study was to verify the manipulation effects of expected PE feedback on PE and performance in walking exercise. **Methods** Ten men (24 ± 3 years) participated in five sessions of treadmill walking exercise. The first session was an incremental test to determine the ventilatory threshold (VT) of the subjects. The other four sessions (reference, deflation, control and inflation) consisted of a constant load test (VT intensity) during 30 minutes (min) followed by an incremental load (rectangular) until exhaustion. In the reference session subjects reported their PE (reference PE) in the Borg Scale (6-20) every three min (constant load) and every min (incremental load). The remaining sessions were divided into deflation, control and inflation of PE in a randomized order. In these sessions, the PE of the subjects was reported by the researcher every three min during the 30 min. The reported PE was two values below, equivalent or two values above in relation to the reference PE for the deflation, control and inflation sessions, respectively. Subjects were asked to agree to the reported value or report another value of PE. After the 30 min subjects reported their own PE every min. Two-way repeated measures (RM) ANOVA (condition \times moment; 3: deflation, control and inflation \times 11: 3°, 6°, 9°, 12°, 15°, 18°, 21°, 24°, 27°, 30° min and exhaustion point) was used to analyze PE. One-way RM ANOVA (deflation, control and inflation) was used to analyze performance (exercise time). Significance was set at $p < 0.05$ (SPSS 17.0). **Results** PE mean values in deflation and inflation sessions were lower and higher than the control session, respectively. Two-way ANOVA revealed a significant main effect of condition ($F(2,18) = 157.8$, $p < 0.001$), moment ($F(10,90) = 65.8$, $p < 0.001$) and interaction ($F(20,180) = 8.4$, $p < 0.001$). Mean exercise times were: deflation 35.4 ± 1.1 min, control 34.9 ± 1.1 min and inflation 34.2 ± 0.9 min. One-way ANOVA revealed statistical difference in exercise times among conditions ($F(2,18) = 5.2$, $p = 0.017$, Partial Eta Squared = 0.4, Power = 0.8). **Discussion** The manipulation influenced PE of the subjects by decreasing or increasing it according to the feedback given, highlighting the psychological effects on PE (Borg, 1998). Exercise times were statistically different among conditions, suggesting that PE influences performance. This is in agreement with the Psychobiological Model of intensity regulation and tolerance in endurance exercise (Marcora, 2010). **References** Borg G. (1998). *Human Kinetics*, Champaign. RESISTANCE TRAINING ATTENUATES THE DECREASE IN MUSCLE PROTEIN SYNTHESIS AND LOSS OF MUSCLE MASS INDUCED WITH SEDENTARY ACTIVITY IN OLDER MEN.

Devries, M.C., Breen, L., Von Allmen, M., Mitchell, C.J., Churchward Venne, T.A., Phillips, S.M.

McMaster University

Introduction Aging results in a progressive loss of muscle mass and function, termed sarcopenia, which begins in the 5th decade of life and progresses at $\sim 0.8\%$ muscle mass loss annually. Short-term periods of muscle disuse occur with increasing frequency with age due to a variety of circumstances. These disuse periods accelerate the rate of muscle mass loss. We have previously shown that 14 d of reduced ambulation in older adults reduced muscle mass, which was underpinned by reductions in postprandial muscle protein synthesis (MPS) [1]. The purpose of this trial was to determine if the decrease in muscle protein synthesis and loss of muscle mass induced by 14 days of reduced ambulation could be attenuated by low-load, higher-volume resistance training (RT). **Methods** Healthy, older men (70 ± 1 yr) underwent 14 d of reduced daily step-count (< 1500 steps/d). In addition, subjects reported to the laboratory for thrice weekly unilateral RT (leg press, knee extension, 30 reps at 30% 1-RM, 3 sets, last set to failure). Prior to commencing the trial subjects underwent body composition analysis (DXA) and strength testing (maximal voluntary contraction [MVC], 1 RM). Upon completion of the intervention subjects repeated the body composition and strength measures. Primed constant infusion of L-[ring- $^{13}C_6$]phenylalanine with serial muscle biopsies from the step-reduced (IMM) and exercised (EX) legs was performed in the postabsorptive and postprandial states to determine rates of MPS. **Results** Steps were reduced by 79% to 1378 ± 135 steps/d throughout the intervention ($P < 0.0001$). Lean mass and calculated skeletal muscle mass were increased in the EX leg (125 ± 68 g and 100 ± 50 g, $P = 0.06$ and $P = 0.045$, respectively) and tended to decrease in the IMM leg (125 ± 61 g and 73 ± 45 g, $P = 0.07$ and $P = 0.11$, respectively) as compared with baseline. The differential response in the EX and IMM legs were significant for both lean mass and skeletal muscle mass (both $P = 0.03$). Isometric knee extension MVC was lower following the step-reduction in the IMM leg (-12.7 ± 5.2 Nm, $p = 0.02$) whereas it was unchanged in the EX leg (-0.3 ± 5.3 Nm). Rates of MPS were lower in the IMM as compared to EX leg in both the postabsorptive ($0.026 \pm 0.001\%/hr$ vs $0.045 \pm 0.001\%/hr$, $P < 0.0001$) and postprandial ($0.055 \pm 0.002\%/hr$ vs $0.115 \pm 0.0035\%/hr$, $P < 0.0001$) states. **Discussion:** Two weeks of step-reduction decreased isometric strength and tended to decrease lean and skeletal muscle mass whereas isometric strength was maintained and lean and skeletal muscle mass increased with concurrent low-load, higher-volume RT. These phenotypic changes align with lower rates of postabsorptive and postprandial MPS in the IMM vs EX leg. These findings suggest that low-load, high-volume RT can attenuate the deleterious effects of reduced activity that occur with increasing frequency with age. 1. Breen L, et al., JCEM, 2013

UNLOADING INDUCES HIGHER EXPRESSION OF UBIQUITIN LIGASE NEDD4 AND AUTOPHAGY-RELATED PROTEINS IN PLANTARIS MUSCLE OF AGED RATS INDEPENDENTLY OF INTERMITTENT RELOADING

Yamauchi, H., Nakahara, N., Takemori, S.

Jikei University School of Medicine

Introduction It is well documented that two muscle specific ubiquitin ligases, atrogin-1/MAFbx and MuRF1, are involved prominently in the skeletal muscle atrophy. Recent studies have suggested that other ubiquitin ligase, Nedd4 (neural precursor cell expressed developmentally down-regulated protein 4) plays a more encompassing role in denervation-induced muscle atrophy (Nagpal P et al., 2012). These ubiquitin-ligases are considered to act coordinately with autophagy-lysosome systems, which are responsible for the normal bulk degradation of long-lived and damaged proteins and organelles (Mammucari C et al., 2007). For instance, in denervation induced muscle atrophy, the autophagy-lysosome systems are reported to play a significant role (Wang X et al., 2005). In the present study, we investigated the involvement of Nedd4 and autophagy related proteins in unloading-induced muscle atrophy with a specific focus on age dependency. **Methods** F344 female rats (4-, 10-, and 20-month) were randomly assigned to three groups of each age; caged control, hindlimb-unloaded, hindlimb-unloaded and intermittently reloaded groups. Rats of the reloaded group were exercised on resistance exercise device with a load of 30% of body mass for 3 weeks (30 min/day, 6 days/week). At the end of the experimental treatment, plantaris muscles were analyzed. Maximum isometric force was measured in situ as an index of muscle atrophy. The expression levels of Nedd4 and autophagy proteins were determined with immuno-blotting. **Results** Maximum force in caged control group increased from 4-month to 10-month and decreased from 10-month to 20-month. The hindlimb-unloading decreased the maximum force of any age, but most prominently in 20-month rats. Significant increase in the expression of Nedd4 was found only in 20-month rats with hindlimb unloading. The expression of Beclin-1 of the class III PI3K, which is essential for autophagosome formation, increased only in 20-month hindlimb-unloaded rats. Intermittent reloading during hindlimb-unloading period inhibited muscle force deficit independent of age. However, the effect of reloading was not significantly observed on the expressions of Nedd4 and Beclin-1 even in 20-month rats. **Conclusion** Unloading induced higher expression of ubiquitin ligase Nedd4 and autophagy especially in aged rats independently of intermittent reloading sufficient for the prevention of atrophy. Reloading may have induced some anabolic process that overwhelms the catabolic process of the ubiquitin-autophagy system. **References** Nagpal P et al. (2012). PLOS ONE, 7, e46427. INFLUENCE OF DAILY EXERCISE AND CALORIC RESTRICTION ON THE MORPHOLOGY OF SKELETAL MUSCLE IN OBESE ZUCKER RATS.

Shiroya, Y.1, Yamauchi, H.2, Kurosaka, Y.1, Kitamura, H.3, Minato, K.1

1: Wayo Women's University (Chiba, Japan), 2: Jikei University School of Medicine (Tokyo, Japan), 3: University of Marketing and Distribution Science (Kobe, Japan)

Introduction: Daily physical exercise and caloric restriction have been used to improve obese, especially daily exercise has been shown to have beneficial effects on lipid metabolism. The aim of the present study was to elucidate the effects of daily exercise and/or caloric restriction on the morphology of skeletal muscle and its relationship to insulin resistance in genetically obese rats. **Methods :** Obese Zucker rats were randomly assigned to obese (OB), caloric restriction (CR), or daily exercise plus caloric restriction (CR+EX) groups. Lean littermates served as a control (LC) group. The LC and OB rats had free access to food. The CR and CR+EX rats had food intake restricted to 69% and 74% of the OB group level, respectively. The CR+EX rats were exercised voluntarily on the wheel ergometer with a load of 30% on their body weight every day. After 6 weeks, all rats were prepared for the experiment. The soleus muscle was excised and weighed. The muscle tissues were prepared for transmission electron microscopy. **Results :** The body weights, food intake and fat pad weights of the OB rats were significantly greater than the LC, CR and CR+EX rats. Daily exercise combined with caloric restriction attenuated weight gain, increased the soleus muscle weight and significantly reduced serum insulin, triglyceride and total-cholesterol concentrations compared with the OB and CR rats. Electron micrographs of the skeletal muscle in both the OB and CR rats revealed lipid accumulation and mitochondrial swelling within the myofibril. In contrast, the skeletal muscle from CR+EX rats showed marked reduction of intramyocellular lipid accumulation. **Discussion :** A combined intervention of daily exercise and caloric restriction induced decrease in intramyocellular lipid content and amelioration of the mitochondrial ultrastructure within the skeletal muscle. These findings correlated with improvements in insulin resistance, may contribute to the amelioration of lipid metabolism. **Contact :** shiroya@wayo.ac.jp

PEAK OXYGEN UPTAKE DIFFERENTIATES COMPETITIVE FROM RECREATIONAL MALE SURFBOARD RIDERS

Almeida, N.1, Reis, J.2, Beckert, J.3, Alves, F.2

Faculty of Human Kinetics - University of Lisbon

Introduction Surfboard riding at elite level has been shown to depend on aerobic performance capacity. OBLA and VO₂peak were reported to discriminate between surfers of different competitive levels (Mendez-Villanueva et al., 2005; Farley et al., 2011). The purpose of this study was to verify if competitive performance status was associated to different levels of specific aerobic fitness in Portuguese surfboard riders. **Methods** 12 male surfers were assigned to two groups, one comprising 6 elite competitive international level athletes (ES: mean age: 32.3±3.1; mass: 73.2±7.8; height: 175.2cm±4.9) and the other composed by 6 recreational surfers (RS: mean age: 25±8.4; mass: 68.5±3.8; height: 173.7±4.7). All subjects performed a maximal continuous incremental paddling test consisting of two-minute steps starting at 20W, with increments of 10 W, on a VASA trainer ergometer, for determination of VO₂ peak, and maximal aerobic power (MAP). Ventilatory threshold (VT) and respiratory compensation point (RCP) with corresponding heart rate and power output were estimated. Respiratory data were collected breath by breath (Metamax 3B, Cortex, Biophysik, Leipzig, Germany). **Results** VO₂peak showed significant differences between ES (43.67±7.94 ml.kg⁻¹.min⁻¹) and RS (31.17±7.44 ml.kg⁻¹.min⁻¹) but there were no differences between RS and ES for MAP (ES: 76.67±18.62W; RS: 76.67±16.63W) nor for the power output at which VT (ES: 50.3±12.85W; RS: 46.32±8.99W) and RCP (ES: 79.73±14.37W; RS: 75.48±11.42W) occurred. VO₂ at VT was higher (p<0.05) in ES group (22.5±5.89 ml.kg⁻¹.min⁻¹) than in the RS group (16±3.74 ml.kg⁻¹.min⁻¹). The same tendency could be seen regarding oxygen consumption at RCP (ES: 33.83±10.38ml.kg⁻¹.min⁻¹; RS: 23.67±6.37ml.kg⁻¹.min⁻¹). However, these parameters occurred at a similar %VO₂ peak, 51.5 and 51.3 % for VT, and 77.5 and 77.9 for RCP. **Discussion** Research on the physiological profile of surfers is still scarce. These findings suggest that ES developed physiological adaptations. ES have higher values of VO₂max than RS which suggests a higher aerobic adaptation that may be related to the different amount of exercise volume undertaken. However, the absence of differences between the groups regarding power output may indicate that this test protocol is not specific enough to account for muscular performance changes, moreover when paddling is a secondary skill

in surfing competitive performance outcome. Further studies should be conducted in more ecological situation, preferentially involving actual water board paddling. SYSTEMIC CYTOKINE RESPONSES FOLLOWING PROLONGED EXERCISE IN HEALTHY HUMANS

Giannopoulos, A.1, Spanoudaki, S.2, Philippou, A.1, Thodou, A.1, Psarros, C.1, Koutsilieris, M.1, Maridaki, M.2

National and Kapodistrian University of Athens

Introduction Exercise has been associated with beneficial or detrimental effects on the immune system function depending on its intensity and duration (Gleeson, 2007). Pro-inflammatory and anti-inflammatory cytokines regulate the immune responses and have been shown to be modified by exercise (Pedersen & Toft, 2000). The purpose of the present study was to examine systemic cytokine responses following prolonged exercise in healthy humans. **Methods** Nine males (age: 25 ± 5 years, body mass: 79 ± 9 kg, height: 181 ± 6 cm, body fat: $9 \pm 3\%$) participated in the study. Participants avoided any type of exercise 2 days prior to the study measurements. They underwent a one-hour cycling exercise bout at constant intensity of $70 \pm 5\%$ $\dot{V}O_{2\max}$. Blood samples were collected before (T0), at the end (T1) and one hour after the end (T2) of the cycling exercise. Serum concentrations of interleukin (IL)-1a, IL-2 and IL-10 were measured by ELISA using commercially available kits. One-way ANOVA was used for statistics and the level of statistical significance was set at $p < 0.05$. **Results** No statistically significant changes ($p > 0.05$) were observed in circulating levels of the pro-inflammatory cytokines IL-1a (T0: 2.95 ± 0.07 , T1: 2.95 ± 0.08 , T2: 2.95 ± 0.11 , pg/ml) and IL-2 (T0: 2.42 ± 0.3 , T1: 2.37 ± 0.36 , T2: 2.29 ± 0.22 , pg/ml) following the prolonged exercise compared with the pre-exercise levels. Serum levels of the anti-inflammatory IL-10 increased post exercise (T0: 2.45 ± 0.67 , T1: 6.33 ± 2.85 , T2: 9.49 ± 3.94 , U/ml), however they did not reach statistical significance due to a large variability in the IL-10 responses between the participants post exercise. **Discussion** The findings of the present study suggest that the prolonged exercise bout used may promote an acute anti-inflammatory response, as it was reflected by the rapidly increased levels of IL-10 post exercise. The variance in exercise-induced inflammation and innate immunity in response to prolonged cycling exercise is associated with exercise intensity (Nieman et al., 2012) and could explain the large variability in post-exercise IL-10 responses observed in the present study. **References** Gleeson M. THE EFFECT OF HABITUAL WALKING IN MINIMALIST FOOTWEAR ON DYNAMIC BALANCE AND LOWER LIMB STRENGTH.

Griffiths, L., Eastough, D., Gravestock, H., Thomas, G., Mizen, R., Horne, S.

University of Worcester

Introduction Recent evidence suggests that habitual walking in minimalist shoes (> 6 wk regular wear) leads to reductions in knee loading (Shakoor et al. 2013), and increased muscular strength and flexion in the metatarsophalangeal joints (Potthast et al. 2005) compared to traditional shoes. Further understanding of the benefits of habitual walking in minimalist footwear may lead to clinical applications of this type of footwear in the general population. Hence, the aim of this research is to examine the chronic effect of minimalist footwear on measures of dynamic balance and strength of lower limb musculature. **Methods** Fifteen healthy adult males voluntarily participated in the study (age 30.4 ± 9.4) and were assigned into an intervention (IG; $n = 7$) or control group (CG; $n = 8$). The IG performed an 8 wk accommodation period of wearing minimalist footwear (2.5 mm sole thickness; Feelmax Osma 2, Feelmax®) for at least six hours per day; CG were instructed to wear traditional footwear during the intervention period. Bilateral assessment of dynamic balance was assessed using the Star Excursion Balance Test (SEBT) in 3 directions (anterior, medial and lateral). Maximal strength assessments of the lower limb were performed utilising the Humac Norm Isokinetic dynamometer; outcome measures included muscle strength assessments (concentric and eccentric) for ankle dorsiflexion and plantarflexion. **Results and Discussion** The results indicated that both leg length and height were significantly correlated to reach distance in the anterior direction in the SEBT test ($p > 0.05$). As leg length was highly correlated to height ($r = 0.81$; $p = 0.000$), excursion distances were normalised to participant's leg length (Gribble & Hertel, 2003). Post-test analysis revealed an increase in the SEBT in all directions for both groups; however only the anterior excursion distance in the left leg for the IG ($p = 0.003$) and the right leg for the CG ($p = 0.007$) were significant. The IG had an increase in strength during the eccentric movement of plantar flexion in the left foot (18%; $p = 0.021$); there was also a non-significant increase in the concentric movement of plantar flexion in both the right (45.8%, $p = 0.146$) and left foot (21.6%, $p = 0.116$). No improvement in lower limb strength was observed in the CG. An inverse relationship was observed between the percentage change for the IG in left foot anterior excursion distance and right dorsal flexion concentric strength ($r = -0.87$; $p = 0.025$). The findings suggest that habitual walking in minimalist footwear resulted in an increase in lower limb strength, however this did not translate into an improvement in dynamic balance. **References** Gribble P and Hertel J (2003). *Meas Phys Educ Sci*, 72(2) 89-100. THE EFFECT OF WHOLE-BODY CRYOSTIMULATION ON LYMPHOCYTE SUBPOPULATIONS IN PERIPHERAL BLOOD IN TRAINED AND UNTRAINED PEOPLE

Szygula, Z.1, Szpotowicz Czech, B.1,2, Wiecek, M.1, Szymura, J.3, Maciejczyk, M.1

University School of Physical Education

Introduction Whole-body cryostimulation (WBC) has now become widely used both in patients and in the sporting world. There are however, only a few studies conducted to answer the question of how the application of cold affects the immune system. Therefore the aim of the study was to estimate the influence of a single and repeated WBC on chosen lymphocyte subpopulations in blood of trained and untrained people. **Methods** The study was carried out on twenty healthy men (10 non-athletes aged 22 ± 1.65 yrs., BMI 22.91 ± 2.39 kg/m² and 10 athletes aged 22 ± 1.52 yrs. and BMI 20.52 ± 1.92 kg/m²). Participants were subjected to 12 whole-body cryostimulation treatments (at -130°C) in a cryogenic chamber for 3 minutes, 3 times a week. Blood samples were collected four times, before the 1st and 12th WBC and 30 minutes after the 1st and 12th WBC. Participants were asked not to perform any physical exercise during the 48 hours before blood sampling. Determination of surface markers of lymphocytes in peripheral blood (leukocytes, lymphocytes, CD3+, CD4+, CD8+, CD19+, CD56+) was performed using the flow cytometry method (FCM). **Results** A significant increase of the number and percentage of CD19+ cells in both groups of subjects; an increase of percentage of CD4+ cells; and a drop in the number and percentage of CD56 in

the non-athlete group ($p < 0.05$) – all were observed after a single WBC. A significant increase in the number of leukocytes was observed in athletes and a drop in the percentage of CD56+ cells were noted in the group of non-athletes, while an increase of the number and percentage of CD19+ cells in both groups of participants were observed post the 12th WBC treatment compared to values prior to the final WBC. After 12 treatments a significant increase in the number of CD19+ was found in both groups and a significant increase in the percentage of CD4+ in the athlete group, while an increase in the number and percentage of CD4+ cell were noted in the non-athlete group (no./%) compared to the baseline values. After the whole series of WBC, a further decline of CD56+ cells was observed in both groups. There were no differences in the levels of the examined indicators between both groups of subjects. The number of lymphocytes, CD3+ and CD8+ remained unchanged in both groups. Conclusion Both single and repeated whole-body cryostimulation treatments have a modifying effect on the immunological system in both athletes and non-athletes. INTENSITY-DEPENDENT EFFECTS ON LEG VASCULAR CONDUCTANCE KINETICS IN TYPE 2 DIABETES

Egaña, M., O'Connor, E., Kiely, C., Green, S., O'Shea, D.

Trinity College Dublin

In this study we tested the hypotheses that type 2 diabetes (T2D) impairs the dynamic response of leg vascular conductance (LVC) at light and heavy contractile forces [30% and 70% maximum voluntary contractions (MVC), respectively] but that these impairments are not sex-specific. Forty-four middle-aged individuals with T2D (30 male, 14 female), and 34 age- and BMI-matched healthy individuals (16 male, 18 female) were tested. After establishing each participant's MVC, participants performed three 6-minute bouts of low intensity (30% MVC) calf plantar-flexion exercise (6s duty cycle: 2 s contraction, 4 s relaxation); and a subgroup of participants also performed two 6-minute bouts of high intensity (70% MVC) plantar-flexion exercise. All tests were performed in the supine posture. Leg blood flow (LBF) was measured between each contraction using venous occlusion plethysmography. LVC (LBF/MAP) responses were fitted using a tri-exponential (two growth / one decay phases) or quad-exponential (two growth / two decay phases) function. Ethical approval was obtained from the Trinity College Dublin Faculty Research Ethics Committee. At heavy contractile forces (70% MVC) the time constant of the second growth phase of LVC was significantly longer ($P < 0.05$) in men and women with T2D compared with their respective non-diabetic counterparts (men, 29.7 ± 31.6 vs. 13.6 ± 11.1 s; women, 44.3 ± 21.6 vs. 17.9 ± 10.1 s), and the amplitude of the first growth phase was significantly smaller ($P < 0.05$) in men and women with T2D compared with controls (men, 3.3 ± 1.4 vs. 5.0 ± 1.0 ml/min/mmHg; women, 2.5 ± 1.0 vs. 5.1 ± 3.5 ml/min/mmHg). At 30% MVC, T2D did not affect any of the kinetic parameters of LVC. The magnitude of any of the impairments at 70% MVC was not different between men and women. The results do not support the first hypothesis and suggest that the T2D-induced slowed leg hyperaemic response is manifest at high forces but it does not occur at low forces. On the other hand, in agreement with the second hypothesis, the magnitude of the leg hyperaemic impairments at high forces is not affected by sex in middle-aged participants.

A NEW PRACTICAL PRE-COOLING METHOD RETARDING EXERCISE – INDUCED HYPERTHERMIA

Zavvos, A., Nassis, G., Gkrilias, P., Manolaki, N., Cherouveim, E., Geladas, N.

national kapodistrian university of athens

Introduction: Exercising in a hot environment (>30 °C) results in a rapid increase of body core temperature (T_c) up to ~ 40 °C (Gonzalez – Alonso et al. 1999). This temperature is considered to be critical to the health of the athletes, because of the high risk for developing hyperthermia, a life threatening situation (Gonzalez –Alonso et al. 1999). Pre-cooling by means of cold water immersion, ice cubes or ice vest applications have been proven to be effective in forestalling exercise induced hyperthermia. Although effective, none of the existing pre-cooling methods is nifty and practical. The purpose of this study was to investigate the effectiveness of a novel, inexpensive and practical method of pre-cooling human body when subjects perform a prolonged, high-intensity intermittent exercise in the heat. Method: After providing a consent form, seven healthy subjects (25 ± 4.1 yrs) participated in this study. The experimental design entailed two conditions: the intervention (pre-cooling) one and the control condition (without pre-cooling). In the intervention condition subjects, while seated at rest for 20 minutes in a thermo – neutral environment (24 ± 1 °C and $40 \pm 10\%$ rh), wore a wet bathrobe and had their feet wrapped with a wet towel. Both pieces of garment were previously soaked into water of 15 ± 1 °C. Upon termination of the resting period subjects performed a 46 minutes intermittent protocol, which was structured by multiple 2 minutes exercise bouts. Each bout was comprised by 5 seconds sprinting on a cycle ergometer against a resistance equal to 7.5% of each subject's body weight, and 105 seconds energetic rehabilitation at 35% VO_{2max} , followed by a 10 sec passive recovery period. When the 46 min exercise protocol completed a 15 minutes break was allowed in which all individuals, being at rest, were subjected to another 10 minutes pre-cooling maneuver, similar to the initial one. Subsequently, another intermittent exercise period was executed lasting for 10 minutes (5 times a 2 min bout) Results: Upon completion of the 46 minutes exercise period, T_c increased to a lower level ($p = 0.001$) after the initial pre-cooling maneuver (Prec; 37.83 ± 0.23 °C) compared to the control condition (Con; 38.81 ± 0.02 °C). On the contrary, final T_c (afterwards, 10 min post break exercise period) did not differ between the two conditions (Prec; 38.34 ± 0.08 and Con; 38.36 ± 0.09 °C, $p = 0.85$). Heart rate (HR) increase was also lower ($p = 0.00$) in Prec (116 ± 2.8 pulses/min and 124 ± 1.7 pulses/min) compared to Con (167 ± 0.87 pulses/min, and 154 ± 1.6 pulses/min) after the 46 and 10 minutes exercise periods, respectively. Conclusion: Wearing a wet bathrobe prior and in the break of two exercise periods appears to be an effective way of pre-cooling since this technique retards the ensued hyperthermia and lowers heart rate increase. THE LEGACY EFFECTS OF HIGH FAT DIET AND RUNNING EXERCISE IN CHILDHOOD ON GENE EXPRESSION PROFILES OF ADIPOSE TISSUE IN ADULT MICE

KIMURA, M., WHITEHEAD, J.P., SAITO, Y., SAITO, H.

Keio University, Faculty of Pharmacy

INTRODUCTION and PURPOSE There is little evidence that the effects of overweight and physical activity in childhood on adipose tissue conditions in adulthood. The purpose of this study was to investigate the legacy effects of high fat diet and running exercise in childhood on gene expression profiles of epididymal fat tissue in adult mice. MATERIALS and METHODS Male ICR mice were used in this study. At 4 weeks of age, the mice were randomly assigned to a normal (4.8% fat) diet (ND-ND) group, a 10-week high fat (13.8% fat) diet (HFD-ND) group, or a 10-week voluntary wheel running exercise (EX-ND) group. After 10 weeks of each intervention, at 14 weeks of age, all of these 3 groups of mice were provided normal diet and sedentary condition for 10 weeks. Additionally, other 4-week-old mice were randomly

assigned to a 20-week high fat diet (HFD-HFD) group or a 20-week running exercise (EX-EX) group. At 24 weeks of age, epididymal fat tissue was collected from all groups of mice and mRNA expression profiles were analyzed using DNA chip microarray method. RESULT and DISCUSSION At 14 weeks of age, body weights were higher in the HFD-HFD and HFD-ND groups and were lower in the EX-EX and EX-ND groups than in the ND-ND group (HFD-HFD, 62.0 ± 5.9 ; HFD-ND, 61.8 ± 8.5 ; ND-ND, 49.7 ± 1.8 ; EX-ND, 43.8 ± 3.4 ; EX-EX, 43.8 ± 3.2 g). At 24 weeks of age, body weights were decreased in the HFD-ND group and increased in the EX-ND group compared to those of 14 weeks of age, and no significant difference was found among 3 groups (ND-ND, 59.6 ± 6.3 ; HFD-ND, 61.5 ± 9.9 ; EX-ND, 57.5 ± 2.6 g). Body weights were significantly higher in the HFD-HFD group and were significantly lower in the EX-EX group than in the ND-ND group (HFD-HFD, 76.3 ± 9.7 ; EX-EX, 46.1 ± 4.1 g). Results of the genome-wide 30,000 gene expression analysis using representative samples from each group demonstrated that, compared to the ND-ND group, 1,330 genes were increased more than two-fold and 1,689 genes were decreased by more than half in the HFD-ND group, and then 633 genes were increased and 730 genes were decreased in the EX-ND group. Results of the hierarchical clustering analysis demonstrated that gene expression profiles of HFD-ND group were similar to those of EX-EX group rather than those of HFD-HFD group, and those of EX-ND group were similar to those of HFD-HFD group rather than those of EX-EX group. These findings suggest that overweight and physical activity in childhood produce the legacy effects on adipose tissue mRNA expression profiles in adulthood and several candidate genes related to these legacy effects were suggested in the present study.

THE EFFECT OF CARDIO TENNIS PROGRAM ON THE CARDIOPULMONARY FUNCTION, OVARIAN SENESCENCE INDEX AND INFLAMMATORY MARKERS IN MENOPAUSE TRANSITION FEMALES

Park, H.1, Kim, S.H.1, Kim, D.H.1, Yang, M.H.2, Lee, H.Y.1, Na, C.I.1, Hwang, Y.H.1, Kwon, S.Y.1

1: Chonnam Nat'l Univ.(Gwangju, Korea), 2: Kwangju Women's Univ.(Gwangju, Korea)

Introduction Women undergoing menopause transition show various symptoms of estrogen deficiency, including fatigue and ovarian senescence. To alleviate these symptoms, typically dietary intake, therapeutic exercise and biofeedback therapy have been applied. Especially a modified form of conventional sports started to receive attention for the therapeutic purpose. This study was conducted to investigate the effect of 8-week cardio tennis program on cardiopulmonary function, ovarian senescence indexes and inflammatory markers. **Methods** Twenty women over age 45 in menopausal transition had been recruited and divided into two groups: EG(n=10) and CG(n=10). They performed a cardio tennis program 5 times/week and 60 minutes/day for 8 weeks, with the intensity of 50-60% of HRmax during 1-4 weeks and 61-70% of HRmax during 5-8 weeks. Cardiopulmonary function (VO2max, HRpeak, ventilation, exercise duration), ovarian senescence indexes (anti-müllerian hormone; AMH, inhibin B, estradiol; E2, follicle stimulating hormone; FSH) and inflammatory markers (monocyte chemoattractant protein 1; MCP-1, C-reactive protein; hs-CRP) were measured three times: immediately before exercise program, 4 weeks and 8 weeks after exercise program. One-way ANOVA and independent t-test were used for data analysis with the significant level .05. **Results** HRpeak was higher in EG than CG 4 weeks after exercise (p<.05). Ventilation and exercise duration were higher in EG than CG 4 weeks and 8 weeks after exercise (p<.01). While AMH, inhibin B and E2 showed an increasing tendency with no significance, FSH significantly decreased in EG (p<.05). Inhibin B and E2 were higher in EG than CG 8 weeks after exercise (p<.01). FSH, however, was lower in EG than CG 8 weeks after exercise (p<.001). hs-CRP was lower in EG than CG 4 weeks (p<.05) and 8 weeks (p<.01) after exercise. **Discussion** The result showed that the cardio tennis program could prevent and delay physical health caused by menopause. Thus, this program can be used for women in menopausal transition for improving cardiopulmonary function, alleviating inflammatory status and delaying ovarian senescence. However, since this study is limited to women over the age of 45 in menopausal transition, further studies which take account of the progression phase of menopause, number of subjects, nutrition status, exercise type, duration and intensity will be necessary. **References** Kelishadi, R., Sharifi, M., Khosravi, A., & Adeli, K. THE INFLUENCE OF LOWER BODY NEGATIVE PRESSURE ON ARM BLOOD FLOW DURING WRIST FLEXION EXERCISE

Askew, C.1, Abeln, V.2, Steegmanns, A.2, Drescher, U.2, Hoffmann, U.2, Foitschik, T.2, Klein, T.1, Schneider, S.2

1: University of the Sunshine Coast, Australia; 2: German Sport University, Germany.

Introduction Understanding the relationship between blood flow and muscle function has implication for conditions such heart failure and peripheral arterial disease. As lower body negative pressure (LBNP) induces peripheral (upper limb) vasoconstriction, it is possible that this technique provides a suitable non-invasive means of manipulating blood flow during investigations of arm muscle function. The aim of this study was to determine the effect of LBNP on brachial artery blood flow at rest and during wrist flexion exercise. **Methods** Participants (13 male and 6 female; age: 26 ± 5 y) were positioned in a supine position with their lower body within the LBNP chamber. Blood flow and exercise assessments were conducted using the right arm, which was abducted 90 degrees and supported in a supine position. Resting blood flow and post-occlusion reactive hyperaemia at the brachial artery were measured using duplex ultrasound. Maximal force of the wrist flexors was then determined from five isometric wrist-flexion maximal voluntary contractions (MVC). Participants then performed a 5-min bout of intermittent isometric wrist-flexion contractions at a target intensity equal to 30% MVC (6.1 ± 2.8 N.m), where each contraction was 2 s and separated by 3 s. Brachial artery blood flow was measured prior to exercise and during the final 10 s period of each minute throughout exercise. All procedures were conducted with -50mmHg LBNP, and without (CON), in a random order separated by 20 min supine rest. **Results** Resting brachial artery blood flow tended to be lower during LBNP, although not significantly. Reactive hyperaemia was reduced in the LBNP condition at 0s (LBNP 380 ± 12 ; CON 434 ± 12 ml/min) and 60s (LBNP 147 ± 13 ; CON 204 ± 12 ml/min, $P<0.05$) after cuff occlusion. Pre-exercise blood flow was not different between conditions. After the first minute of exercise there tended to be a reduction in blood flow with LBNP (LBNP 298 ± 14 ; CON 340 ± 14 ml/min, $P=0.08$, NS), and this difference peaked and became significant in the second and third minutes of exercise (LBNP 321 ± 14 ; CON 423 ± 14 ml/min, $P<0.05$). Thereafter, brachial blood flow in the LBNP condition continued to rise and there was no difference between conditions by the fifth minute of exercise (LBNP 360 ± 14 ; CON 396 ± 14 ml/min, $P=0.12$). **Discussion** LBNP resulted in a slowing of the rise in blood flow during the initial three minutes of exercise. That blood flow was not different between the conditions after five minutes of exercise indicates that there may have been a gradual attenuation of sympathetic vasoconstrictor activity that is time or fatigue dependent.

ASSESSMENT OF SPONTANEOUS BODY SWAY DURING STATIC UPRIGHT STANCE IN SOCCER PLAYERS

Bachev, V., Stambolieva, K.

National Sports Academy, Institute of Neurobiology

Introduction The system of postural control is particularly complex and involves the integration of various sensory and motor components. The integration of information from the three sensory systems (visual, vestibular and proprioceptive) is of great importance for standing balance. Sport training has significant effect on motor skills of athletes and has a considerable role for maintenance of their stable equilibrium during upright stance. The aim of this study was to evaluate the standing balance during quiet upright stance of soccer players compared with healthy untrained subjects. **Methods** The postural stability of 15 soccer players and 15 age-matched untrained healthy controls was investigated. Four conditions were tested: upright stance on firm and foam supports with open and closed eyes. The postural sway was measured by a static posturographic system made at the Institute of Neurobiology, Sofia. The equilibrium was evaluated by changes of following parameters: mean velocity and mean amplitude of displacements of center of foot pressure in medial-lateral (ML) and anterior-posterior (AP) planes. **Results & Discussion** No significant differences in anthropometric data (weight, height, length of soles) between groups were found. The sway amplitude and mean velocity were lower in the group of soccer players than in the group of untrained subjects in four conditions: open and closed eyes, stance on firm and soft supports. The stance on soft support led to significantly increased lateral postural sway for the untrained subjects only. The reduction of vision (eyes closed) did not significantly change the mean amplitude and velocity of postural sways of the athletes. The untrained subjects showed slight increase in the amplitude in both planes during stance with eyes closed. In the ML plane, we found greater differences in balance performance between both groups than in the AP plane. The football is a sport characterized with small sprints, acceleration and deceleration of movements and body turnings. We suggest that prolonged specific training programs of soccer players may change the strategy of the postural control in quiet upright stance and may improve the static postural maintenance.

INFLUENCE OF TRAINING AND A MAXIMAL EXERCISE TEST IN ANALYTICAL VARIABILITY OF MUSCULAR, HEPATIC, AND CARDIOVASCULAR BIOCHEMICAL VARIABLES

Alvarez Martínez, M.1, Alis, R.1, Primo Carrau, C.1, Verdejo, P.2, Basterra, J.1, Villar, J.2, Sanchis Gomar, F.1,3, Lippi, G.4, Romagnoli, M.1

Introduction It is well known all the benefits associated with moderate physical exercise. However, above certain intensity and duration, there could be muscular, cardiovascular or hepatic damage [1]. Thus, the aim of the present study was to assess the effect of a maximal incremental test on the circulating concentrations of muscular, hepatic, and cardiovascular makers taking into account the training status subjects. **Methods** Thirteen physically active (trained group, >12 h/week of physical activity) and ten inactive male (sedentary group, <1 h/week of physical activity), performed a maximal incremental test on a motorized treadmill until exhaustion. The test velocity remained constant while the slope was increased by a 1% each minute. Venous blood samples were taken before, immediately after and after a 30' recovery period. We measured serum concentrations of C reactive protein (CRP), procalcitonin (PCT), gamma glutamyltransferase (GGT), CK-MB isoenzyme, Hs-TnT, NT-proBNP, CK, LDH, AST, and ALT in both groups. **Results** Maximal oxygen consumption was higher for trained than for sedentary subjects (55.93 ± 4.34 and 46.84 ± 4.28 mL/kg/min, $p < 0.001$, respectively). The age of both groups was similar (30 ± 6 and 34 ± 7 , $p = 0.238$). At baseline, trained subjects showed higher levels of CK, CK-MB, ALT and LDH and lower CRP compared to sedentary subjects ($p = 0.006$, $p = 0.005$, $p = 0.006$, $p = 0.026$ and $p = 0.049$, respectively). Intense exercise induced an increase levels of NT-proBNP only in sedentary subjects ($p < 0.05$). **Discussion** Our results show that trained subjects tend to have significantly raised rest concentrations of muscular damage biomarkers compared to sedentary individuals, probably due to a mild injury of skeletal muscle induced by periodic training. However, after single maximal exercise test there was not an increase on the cardiovascular damage markers, which means that cardiac involvement is mostly benign in nature in this exercise protocol. Other biomarkers were also not altered probably due to the duration of the exercise test. **References** 1. Kratz, A., Lewandowski, K. B., Siegel, A. J., Chun, K. Y., Flood, J. G., Van Cott, E. IMPAIRED CARDIORESPIRATORY EFFICIENCY IN TYPE 2 DIABETES DURING INCREMENTAL TEST

Sousa, N.F.M., Bertucci, D.R., Baldissera, V.

1: FESV, (Vitória, Brazil), 2: UFSCar (São Carlos, Brazil), 3: UNESP (Rio Claro, Brazil)

Do not insert authors here INTRODUCTION Untrained people with type 2 diabetes have been shown to have a reduced maximal oxygen uptake (VO₂max) and impaired VO₂ kinetics (Brandenburg et al, 1999). The aim was to compare cardiorespiratory efficiency and running economy between diabetics and nondiabetics during incremental test (IT). **METHODS** Eight men with type 2 diabetes (DG) (mean \pm SD age 55.4 ± 7.0 years, BMI 32.2 ± 3.2 kg/m²) and 13 overweight nondiabetic men (NDG) (mean \pm SD age 51.5 ± 5.8 years, BMI 27.2 ± 3.2 kg/m²) performed an IT on treadmill, which consisted in stages begun in 3km/h with increasing speed of 1km/h every two minutes. Respiratory parameters were analyzed using a gas analyzer (VO2000®). At rest and at the end of the IT, blood lactate concentration (BLC) was analyzed (YSI 1500S). The comparison between groups in each stage was performed until 9 km/h (maximal running velocity that all the DG presented voluntary exhaustion). The independent-samples t-test was used to compare the differences between groups. **RESULTS** The DG had the lowest VO₂max (22.7 ± 5.7 mL.(kg.min)⁻¹ for DG and 30.8 ± 5.4 mL.(kg.min)⁻¹ for NDG, $p \leq 0.05$) and running velocity that elicited VO₂max (vVO₂max) (8.2 ± 0.7 km/h for DG and 11.6 ± 1.5 km/h for NDG, $p \leq 0.05$). The DG also had lowest VO₂ at rest and in the first stage of the IT. Although there was no difference in maximal VE (63.2 ± 16.2 L/min for DG and 63.1 ± 16.2 L/min for NDG, $p > 0.05$), the VE remained higher ($p \leq 0.05$) for DG from 5 km/h stage until the end of IT (at 9 km/h the difference was approximately 25 L/min). The ventilatory equivalent for oxygen (VE/VO₂) also remained higher ($p \leq 0.05$) for DG from 5 km/h stage until the end of IT, however, the maximal VE/VO₂ was not different (31.6 ± 3.8 for DG and 31.9 ± 6.2 for NDG). The BLC was higher for DG at rest (2.19 ± 0.65 mmol/L for DG and 1.41 ± 0.61 mmol/L for NDG, $p \leq 0.05$) and no differences were found at the end of the IT (7.07 ± 1.46 mmol/L for DG and 7.16 ± 2.07 for NDG, $p > 0.05$). **DISCUSSION** In type 2 diabetes, the metabolic dysfunction could lead to different physiological responses during an IT test that may influence muscle metabolic profile and contribute to lower maximal aerobic power (Simoneau and Kelley, 1997). It is clear in this study that the DG presented a lower cardiorespiratory efficiency due to the highest values of VE and VE/VO₂ than NDG when compared at the same stage of the IT. The similar BLC at maximal exercise would also show the effort of the DG to reduce the acidosis in

early stages of the IT. It seems that the running economy was not impaired in type 2 diabetes (similar VO₂ values to nondiabetics), however it is supposed that the DG had a higher oxygen deficit (Regensteiner et al, 1998) because presented a lowest VO₂ in the first stage of the IT. ASSOCIATION AMONG SARCOPENIA, PHYSICAL ACTIVITY AND QUALITY OF LIFE IN HEALTHY ELDERLY

Cereda, F.1, Vago, P.1, Casolo, F.1, Gatti, F.M.2, Colombo, L.2, Narici, M.V.3

1Milan, Università Cattolica del Sacro Cuore, Italy, 2Derby, University of Nottingham, United Kingdom

Background: loss of skeletal muscle mass (sarcopenia) is one of the most profound changes affecting the human body with ageing (Narici & Maffulli 2010) as it reduces strength, mobility and ability to dispose of circulating blood-sugar, eventually reducing quality of life of individuals. However there is paucity of data on the prevalence of sarcopenia in non-clinical populations and in particular how this affects mobility and quality of life. Aim: to investigate the association between sarcopenia and variables related to quality of life in a population of medically stable, community-dwelling elderly men and women. Method: 88 participants (40 male and 48 female), age range 64-83 years (mean 72.3 ± 4.6 years), body mass index (BMI) men: 26.5 ± 3.7 and women: 24.7 ± 3.5 , were recruited for this study and underwent the following measurements: a) Body Composition analysis (by bioelectrical impedance, BIA), b) Gait speed, measured over 4 m, c) Quality of Life (QoL) measured using the Medical Outcomes Survey Short-form General Health Survey (SF-36) translated and validated in Italian (Apolone and Mosconi, 1998) and, d) Physical Activity level, measured with the IPAQ-short version, (Mannocci et al. 2010). The data were analyzed with descriptive statistics and strength of monotonic relationship between paired data was tested with the Spearman correlation coefficient. Results: BIA Skeletal Muscle Index (SMI) was 34.3 ± 3.2 for men and 30.8 ± 4.9 for women; 45 participants (51%) were classified as sarcopenic and 43 (49%) as non-sarcopenic according to Janssen et al. (2002). SMI significantly correlated with musculoskeletal pain ($Rho = -0.245$; $p < 0.05$), in particular sarcopenic people reported a more intensive musculoskeletal pain. Instead, no correlation between SMI and physical activity level was found. IPAQ categorical score was low 10% ($n=9$), moderate 42% ($n=37$), high 40% ($n=16$) for the men and low 13% ($n=6$), moderate 33% ($n=16$), high 54% ($n=26$) for the women and IPAQ score was positively correlated with social activities ($Rho = 0.301$; $p < 0.01$). Conclusions: Our findings show that sarcopenia is widespread (prevalence $>50\%$) even amongst moderately to highly physically active older individuals. Although sarcopenia is associated with an increased perception of musculoskeletal pain, some compensatory mechanisms seem to be in place since mobility was found to be preserved. References 1. VARIABILITY OF HEART RATE OF ELITE ATHLETES AT DEEP BREATHING TEST

Sukhov, S.

National Anti-Doping Centre

Introduction Vegetative nervous system (VNS) plays important role in regulation of adaptation to intensive physical load. One of the informative noninvasive methods of study of VNS is analysis of variability of heart rate at deep breathing test (VHR at DBT). This test allows assessing the reaction to stimulation of the parasympathetic part of VNS. Goal of the study was to compare VHR at DBT of elite athletes and young male non-athletes. Methods Twenty-five elite judoists (experimental group) and fifteen healthy young male non-athletes (control group) have been examined. VHR at DBT was conducted with use of hard- and software complex VNS-Spectrum. ECG was recorded in supine position during the performance of VHR at DBT (breath intake during 5 seconds and expiration for next 5 seconds, with total 6 breathing cycles a minute). Such breath rate causes a maximal stimulation of nervus vagus. Results Respiratory coefficient (RC), that is, the ratio of maximum and minimum heart rates during the breathing cycle, was determined at analyzing the rhythmograms. Tachycardia at rest and reduction of this coefficient is symptomatic of deterioration of parasympathetic function. According to our findings, normally the RC should be above 1.35, and decrease of the coefficient down to 1.2 can be considered as the lower limit of normal. Athletes had the RC on level of 1.43 ± 0.03 while in the control group it was 1.23 ± 0.05 which evidences to the better functional status of athletes as compared to the control group. As a rule, at rest the athletes demonstrated prevalence of the parasympathetic part of VNS (background at rest vagotonia). In this case the equilibrium of different parts of VNS should be considered as an eutonia (balanced type). At long and draining exercises and decrease of fitness, the athletes demonstrate shift from the prevalence of parasympathetic part of VNS to the predominance of its sympathetic part. The notable maladjustment is accompanied with desynchronization of respiratory and vasomotor centers. Conclusion DBT is an objective indicator of the status of parasympathetic part of vegetative nervous system and it allows getting the information on current functional status of athletes.

EFFECTS OF EXERCISE ON INTERMITTENT HYPOXIA-INDUCED LC3-II EXPRESSION IN RAT LEFT VENTRICLE

Yang, K.T., Huang, S.F., Tu, W.C., Lin, H.Y., Chen, T.I.

Tzu Chi University

Purpose: Investigating the effects of different time intervals after exercise on intermittent hypoxia (IH)-induced autophagy in rat left ventricle. Methods: Eight-week-old male Sprague-Dawley rats were randomly assigned to control (CON), exercise (EXE), IH, room air exposure (RA), post-exercise 1 and 3 h combined with RA (PE1h + RA and PE3h + RA) and IH (PE1h + IH and PE3h + IH) groups. Rats were exposed to a single IH bout (2%–6% O₂ for 1–2 sec/75 sec) for 8 h and a single exercise bout on treadmill (24 m/min, 2% grade) for 60 min. Myocardial glycogen, autophagy-related proteins and mitochondrial-related mRNAs were determined after euthanasia. Results: Immediately after exercise, microtubule-associated protein 1 light chain 3-II (LC3-II)/LC3-I protein levels decreased ($p < 0.05$) but p62 levels did not alter ($p > 0.05$). IH did not alter p62 levels but did increase LC3-II/LC3-I protein and nuclear respiratory factor 1 and 2 (NRF-1 and NRF-2) mRNA levels ($p < 0.05$). Compared with IH, significantly lower LC3-II/LC3-I protein and NRF-1 and NRF2 mRNA levels were found with PE1h + RA, PE3h + RA and PE3h + IH ($p < 0.05$). With PE1h + IH, NRF-1 and NRF-2 mRNA levels were lower than with IH ($p < 0.05$), although LC3-II/LC3-I levels did not differ between these groups ($p > 0.05$). Conclusion: Exercise at 3 h before IH exposure could prevent IH-induced increased myocardial LC3-II/LC3-I levels.

A 16-WEEK EXERCISE INTERVENTION ON MICROSCOPIC T-WAVE ALTERNANS COUPLING WITH HEART-RATE VARIABILITY IN HEALTHY POSTMENOPAUSAL WOMEN

Wen, H.J.1, Shen, T.W.2, Li, T.L.3

1: TCU (Hualien, Taiwan), 2: TCU (Hualien, Taiwan), 3: NTSU (Taoyuan, Taiwan)

Introduction The purpose of this study was to inspect the effects of a 16-week high-intermediate exercise intervention on heart rate variability/microscopic T-wave alternans (HRV/MTWA) in postmenopausal women (PMW) and to examine the association between exercise-induced change and noninvasive cardiac indices of HRV/MTWA. **Methods** Twenty-two healthy PMW (age 60.77 ± 2.02 yr, BMI 22.52 ± 2.21) were recruited and divided into an exercise group (EG, $n = 11$) or a control group (CG, $n = 11$). The EG took part in a progressively high-intermediate intensity (75%-85% heart rate reserve, HRR) group-based step aerobic exercise program 2 days a week and resistance training once a week for 16 weeks, whereas the CG did not receive any intervention. HRV/MTWA and physical function-related indices were measured before and within 24-h, 48-h and 72-h following the 16-week exercise program. **Results** Following a 16-week exercise intervention, the EG had significant percent change when compared to CG in HF (ms²; 65.33% vs 50.46%, $p=0.026$), LF (n.u.; 5.71% vs -18.16%, $p=0.038$), and LF/HF (16.89% vs -31.16%, $p=0.039$) within 24-h. The EG showed a significant increase in SDNN baseline vs 72-hr sig. (-4.72%, $p=.042$), CV baseline vs 72-hr (-4.76%, $p=.05$), SDSD baseline vs 48 hr (-20.08%, $p=0.016$), RMSSD baseline vs 48 hr (-20.84%, $p=0.016$), HF (m.s.) baseline vs 48 hr (-38.47%, $p=0.010$), whereas no significant finding was evidenced on HRV and TWA variables in the CG. **Discussion** The coupling effect of MTWA and HRV after intervention suggests that exercise intervention definitely affects regulation changes of the autonomic nervous system synchronically in PMW. The rebound effect of biomarkers has proven to be a considerable factor on HRV/MTWA measurements. **References** Shen TW, Wen HJ (2013). *Int J Sports Med.* 2013 Dec; 34(12):1099-105.

ADDING RESISTANCE TO ENDURANCE TRAINING DOES NOT ENHANCE AEROBIC CAPACITY IN MODERATELY TRAINED CYCLISTS

Psilander, N., Frank, P., Flockhart, M., Sahlin, K.

The Swedish School of Sport and Health Science and Karolinska Institutet

Introduction We have previously shown that resistance exercise enhances the molecular signalling of mitochondrial biogenesis (mRNA of PGC-1 α) induced by endurance exercise in recreationally active subjects (Wang et al 2011). The purpose of the present study was to examine if this enhanced signalling response will be translated into increased mitochondrial content and improved endurance performance after eight weeks of training in cyclists. **Methods** Twenty moderately trained cyclists (VO₂max 56 ± 1 mL kg⁻¹ min⁻¹) were assigned to two groups. One group (E) performed endurance training only (60 min cycling at approx. 80% of VO₂max) and the other group (ER) performed endurance training followed by resistance training (60 min cycling + 6-set of leg press at 70-80% of 1 RM). Both groups trained two times per week for eight weeks while maintaining their regular training routine. Muscle biopsies were obtained approx. 48 h before and after the first and last training session. **Results** Strength (1 RM in the leg press) increased to a greater extent in ER (19%) compared with E (4%), $p<0.01$. VO₂max, lactate threshold, cycling economy, 40 min time trial and 30 s Wingate sprints did not differ between groups. There was also no difference between groups in the activity or content of mitochondrial enzymes (citrate synthase and 3-hydroxyacyl-CoA dehydrogenase). **Discussion** Eight weeks of concurrent resistance and endurance training did not enhance markers of mitochondrial content or endurance performance compared with endurance training alone in moderately trained cyclists. This demonstrates that the improved signalling response observed after acute concurrent exercise does not translate into training-induced improvements in muscular aerobic capacity. One possible explanation for this might be that the amplified PGC-1 α expression was attributed to a splice variant (PGC-1 α 4), which is not related to mitochondrial biogenesis. An alternative explanation could be that we used subjects with different training background and status in the two studies (recreationally active students vs. moderately trained cyclists). **References** Wang L, Mascher H, Psilander N, Blomstrand E, Sahlin K. Resistance exercise enhances the molecular signaling of mitochondrial biogenesis induced by endurance exercise in human skeletal muscle. *J Appl Physiol* (1985). 2011 Nov;111(5):1335-44. EXPERIMENTAL TEST OF THE BACK-EXTRAPOLATION METHOD AS AN ESTIMATE OF GROSS EFFICIENCY

ten Haaf, T., de Koning, J.J., Foster, C.

MOVE Research Institute Amsterdam, VU University Amsterdam

Introduction Recently, De Koning et al. (2013) introduced a new method to estimate the change in the gross efficiency [GE] during high intensity exercise. By means of back-extrapolation of the GE over several minutes following the high intensity bout, the change in the GE can be estimated. However, using this approach the excess post-exercise oxygen consumption [EPOC] might be a disturbing factor. Carbon dioxide [CO₂] removal after high intensity exercise might also distort the method. The purpose was to study the possible bias of the back-extrapolation method of estimating changes in GE during high intensity exercise. **Methods** Sixteen male cyclists performed, in random order, 2 exercise tests in which they cycled successively at 50% PPO (10min); 90% PPO (4 min); recovery at 25 W (1min); and a second bout at 50% PPO (10min). The subjects breathed either a normobaric, hypoxic (mean FIO₂: 12.6%, FICO₂: 0.03%) gas mixture during the 1 minute recovery period in 1 of the trials and room-air during the other. **Results** Overall, the gross efficiency was higher at the start than at the end of the HI (mean difference 1.8, 95% CI: 1.5, 2.1). This illustrated that, regardless of the calculation method, the GE was different from the traditionally assumed constant GE. After hypoxic recovery, the VO₂ was higher in the first minute compared to the normoxic trial, but no difference was observed in the remaining 9 minutes of the last 50% PPO bout. The estimated GE at the end of the high intensity bout between trials did not differ (18.07% and 18.10%). In addition, the GE was estimated using a constant respiratory exchange ratio [RER]. This method resulted in a higher ($p<.001$) estimated GE at the end of the high intensity bout (18.34%), which corresponds to a 10.5% smaller decrease of the GE across the high intensity exercise. **Discussion** The differences between all of the back-extrapolation measurements used in this study are very large compared to the constant GE assumption that has been traditionally used. Furthermore, the back-extrapolation method is not disturbed by excess post-exercise oxygen consumption. Buffered CO₂ may distort the calculation, but the higher RER at the start of the sub maximal exercise bout might also originate from a change in substrate utilisation. As long as the cause of the changing RER remains unclear, the original back-extrapolation method is preferred. **References** de Koning JJ, Noordhof DA, Uitslag TP, Galiart RE, Dodge C, Foster C. An approach to estimating gross efficiency during high intensity exercise. *Int J Sports Physiol Perform.* 2013;8(6):682-684 Contact t.p.g.ten.haaf@student.vu.nl

LOSS OF ALPHA-ACTININ-3 INFLUENCES MUSCLE FIBER PROPERTIES IN YOUNG MEN

Broos, S., Malisoux, L., Theisen, D., Francaux, M., Van Leemputte, M., Deldicque, L., Thomis, M.

KU Leuven

Introduction Recently, the ACTN3 gene has received much attention as a performance-determining factor. A common stopcodon (R577X) polymorphism results in α -actinin-3 deficiency in fast fibers of XX carriers. This genotype is underrepresented in power athletes and has been associated with reduced muscle strength and sprint performance in non-athletes, which suggests a reduction in the function of type II fibers when α -actinin-3 is absent. The Actn3-/- KO mouse shows a lower grip strength, smaller type IIb fiber diameter, enhanced recovery from fatigue and higher oxidative enzyme levels which indicates a shift in fast muscle fiber characteristics towards a slow, oxidative phenotype. However, mechanistic properties in human α -actinin-3 deficiency are less well studied. **Methods** Therefore, we explored the effect of the ACTN3 R577X polymorphism on contractile and morphological properties of skinned single muscle fibers of the m. vastus lateralis in eight non-athletic young men (n=4 RR, n=4 XX, age 20.7 \pm 1.7yrs). Individual fibers were mounted between an isometric force transducer (model 400A, Aurora Scientific, Ontario, Canada) and the arm of a high-speed motor (model 312B, Aurora Scientific) by means of two connectors. The motor was operated either in length (slack tests and passive stretch tests) or in force mode (isotonic contractions) via a high speed digital controller (model 600A, Aurora Scientific). A digital camera (Camedia 720 Z, Olympus) was connected to the microscope, allowing picture capture of the fiber to determine fiber diameter and fiber length. A slack test was performed to register Fmax, power and V0. The force-velocity relationship was calculated using the Hill equation. Young's modulus and hysteresis were defined as parameters assessing fiber elasticity. We hypothesized that P0, V0, force/velocity relationship and power in IIX and IIA fibers of R-allele carriers would be higher compared to 577XX subjects. Also, a greater stiffness is expected in fast fibers of RR and RX individuals compared to α -actinin-3 deficient fast fibers. No differences are expected in the properties of type I fibers between groups as α -actinin-3 is not expressed in these fibers. **Results** No differences were found in type I and IIA fiber diameter, length, Fmax or in power between RR and XX homozygotes. In contrast, the maximal unloaded velocity of type IIA fibers was higher in RR carriers compared to the XX group (RR=4.18 \pm 1.2 FL/s; XX=3.00 \pm 1.41 FL/s; P=0.0007). Fiber stiffness was similar in both groups. **Discussion** This is the first study in healthy humans to study the effect of the ACTN3 R577X polymorphism on individual muscle fiber contractile properties. Although several studies show a greater force in RR individuals, no differences were observed in Fmax between the RR and XX group. The increased velocity of type IIA fibers in RR carriers could explain (in part) the advantage of the R allele in activities such as sprinting. Contact Sia-cia.broos@faber.kuleuven.be

THE EFFECT OF ACUTE L-ARGININE INGESTION ON THE PHYSIOLOGICAL RESPONSES TO ACTIVE AND PASSIVE HEAT STRESS

Tyler, C., Coffey, T.

University of Roehampton

Introduction: During heat stress, elevated core and skin temperatures increase skin blood flow and nitric oxide concentrations (Kellogg, Jr. et al., 2003). Inhibiting nitric oxide synthase reduces peripheral vasodilation in humans (Kellogg, Jr. et al., 1998) and animals (Mills et al., 1997) but L-arginine (LA) supplementation can attenuate this reduction (Mills et al., 1997). During heat stress the body redirects blood to the periphery to lose heat and pharmacological inhibition of this peripheral vasodilation (using aspirin and clopidogrel) elevates core temperature during passive hyperthermia (Bruning et al., 2013). Although the proposed mechanisms of action differ, it would be prudent to suggest that if LA supplementation improved the vasodilatory response it could be of benefit in heat stress situations. The aim of this study was to investigate the physiological responses to an acute oral dose of LA during active and passive heat stress. **Methods:** In a double-blind, crossover study, nine healthy men (27 \pm 6 y; 176 \pm 6 cm; 76 \pm 4 kg; 238 \pm 39 Wmax) completed 30 min of supine rest followed by 30 min 60% Wmax cycling and 30 min of passive recovery in the heat (35°C, 50% rh) on two occasions having consumed 500ml of a blackcurrant cordial beverage 30 min prior. On one occasion the drink contained 10g of dissolved LA whereas on the other it did not (CON). Rectal, skin and forearm temperatures, heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP) and oxygen consumption were measured at regular intervals throughout. Sweat loss was estimated from pre- and post-nude body mass. Blood was drawn at 0, 15, 30, 45, 60, 75 and 90 min. **Results:** LA had no effect on any physiological variable at rest, during exercise or recovery (P > 0.05). Mean rectal, skin and forearm temperatures were comparable during the rest (~37; ~34; ~34°C), exercise (~38; ~36; ~36°C) and recovery periods (~38; ~36; ~36°C) between trials. Mean oxygen uptake and HR were also comparable during the rest (~0.4 l/m; ~72 bpm), exercise (~3.6 l/m; 156bpm) and recovery periods (~0.6 l/m; 95bpm) between trials. Mean SBP, DBP and MAP were similar between trials at rest (~122; ~76; ~92 mmHg) and recovery (~126; ~70; ~89 mmHg). Blood data are pending. **Conclusion:** Acute LA supplementation had no effect on the measured physiological responses to active or passive heat stress. This may be due to LA concentrations already exceeding that required to saturate endothelial nitric oxide synthase (Alvares et al., 2011). **References** Alvares et al. 2011. *Sports Med.*, 41, (3) 233-248 Bruning et al. 2013. *Med.Sci.Sports Exerc.*, 45, (4) 674-682 Kellogg, Jr. et al. 1998. *J.Appl.Physiol*, 85, (3) 824-829 Kellogg, Jr. et al. 2003. *J.Appl.Physiol*, 94, (5) 1971-1977 Mills et al. 1997. *J.Appl.Physiol*, 82, (4) 1035-1039

LIPID PEROXIDATION IS EXACERBATED BY ACUTE STRENUOUS EXERCISE IN MEN WITH A HIGH BODY MASS INDEX

Fukada, K., Kushi, H., Yoshida, A., Takanshina, T., Onuma, N.

Nihon University

[Introduction] The release of reactive oxygen species (ROS) by mitochondria increases during strenuous exercise due to an increase in oxygen consumption. Moreover, autooxidation of catecholamines and ischemia-reperfusion are also associated with an increase in ROS production during strenuous exercise. Oxidative stress is capable of inducing various diseases, such as arteriosclerosis (a lifestyle-related diseases). Therefore, the relationships between oxidative stress and obesity needs to be examined. The aim of this study was to evaluate whether body mass index (BMI), also known as the simple index of the degree of obesity, affects the generation of oxidative stress during strenuous exercise. **[Subjects and Methods]** Thirteen healthy men aged 19 - 23 years participated in the study. Seven of these men were categorized in the BMI < 23 group (mean \pm SE, 20.7 \pm 0.5), and six were in the BMI \geq 23 group (mean \pm SE, 31.4 \pm 2.3). Venous blood samples were collected from the subjects before and after they performed the Cooper 12-min test (running as far as possible within 12 min), and the 8-isoprostane (a marker for lipid peroxidation, pg/ml) and, 8-hydroxy-2'-deoxyguanosine (a marker for of DNA oxidation, 8-OHdG, ng/ml) levels were measured. **[Results]** The 8-isoprostane levels before and after exercise were 11.8 \pm 0.5 pg/ml and 11.6 \pm 0.5 pg/ml in the BMI < 23 group, 12.1 \pm 0.6 pg/ml and 14.0 \pm 0.4 pg/ml in the BMI \geq 23 group, respectively. The 8-OHdG levels before and after exercise were 0.15 \pm 0.02 ng/ml and 0.19 \pm 0.02 ng/ml in the BMI < 23 group, 0.16 \pm 0.01 ng/ml and 0.18 \pm 0.01 ng/ml in the BMI \geq

23 group, respectively. Two-way analysis of variance revealed significant interaction between the groups for the 8-isoprostane levels, with an increase in the levels after exercise in the BMI ≥ 23 group ($P > 0.05$). With regards to the 8-OHdG, there was no significant interaction between the groups ($P > 0.05$). However, a significant main effect (time) was found, with the 8-OHdG levels increasing after exercise in both groups ($P > 0.05$). [Conclusions]The 8-isoprostane levels increased significantly after acute strenuous exercise in men with high BMI. Consequently, the present study revealed that obesity is associated with an increase in lipid peroxidation during acute strenuous exercise.

ACUTE AEROBIC EXERCISE DOES IMPROVE VISUAL PERCEPTUAL LEARNING

Perini, R.1, Capogrosso, M.1, Bortoletto, M.2, Miniussi, C.1,2

1 University of Brescia 2 IRCCS San Giovanni di Dio Fatebenefratelli (Brescia)

Introduction Regular participation in physical activity has been demonstrated to be associated with improved cognitive functions across the lifespan. Aerobic exercise of moderate intensity has been shown to elicit increment in concentration of brain-derived neurotrophic factor. Brain plasticity could be enhanced and executive functions, learning and memory processes could result improved. We evaluated, therefore, the effect of a single bout of aerobic exercise on visual perceptual learning, that is considered to reflect brain plasticity. **Methods** Thirty-two healthy males (age: 23 ± 2 yrs, mean \pm SD) were randomly assigned to an exercise-group (exe-group; $n=16$) or a control group (ctrl-group; $n=16$). All subjects exercised on a cycle-ergometer for 30 min: exe-group pedaled at an intensity eliciting 70% of individual maximal heart rate (HR), ctrl-group pedaled at 20 W, i.e. an almost unloaded task. The subjects were administered an orientation discrimination task (ODT), in which they had to decide whether the presented stimulus was tilted clockwise or counter-clockwise relative to the previously presented stimulus. ODT lasted about 5 min and was performed before (block-pre) and six times after the exercise (block1, 2, ..., 6). The orientation sensitivity was calculated as d' value for each subject and for each block. HR was continuously recorded throughout the experiment. **Results** At the end of cycle task, HR was 82 ± 21 b/min and 8 ± 8 b/min above resting value in exe-group and in ctrl-group, respectively. In exe-group, HR dropped by about 50 b/min in the initial 2 min of recovery and then further slowly decreased. An improved performance in ODT was found at block1 compared to block-pre in both exe- and ctrl-group ($d' +160\%$ in both groups). In exe-group, the orientation sensitivity showed a continuous increase in the successive blocks, being d' value at block6 more than doubled compared to block1. In contrast, in ctrl-group no modification in d' value occurred from block1 to block6. Performance in all blocks was significantly lower in ctrl-group than in exe-group. **Discussion** Performance in "orientation discrimination task" progressively improved during recovery after dynamic exercise. This would indicate that a single bout of aerobic muscular work does enhance visual perception learning. Thus, suggestion can be made that acute exercise, at least of moderate intensity, can have an influence on brain plasticity. renza.perini@med.unibs.it

CAUSES FOR THE DECREASE IN HAEMOGLOBIN MASS AFTER RAPID WEIGHT LOSS IN COMBAT ATHLETES: IMPAIRED ERYTHROPOIESIS AND INCREASED HAEMOLYSIS

Reljic, D.1,2, Feist, J.1, Jost, J.2, Kieser, M.3, Friedmann Bette, B.1

1:Medical Clinic, University of Heidelberg 2:Olympic Training Centre Heidelberg 3: Institute of Biomedical Biometry, University of Heidelberg (Germany)

Introduction Recently, we found a significantly decreased total haemoglobin mass (tHb) after rapid weight loss (RWL) before competition in elite boxers (Reljic et al., 2013). The aim of this study was to investigate the underlying mechanisms of this surprising observation. **Methods** Twenty-eight trained combat athletes participated in this study. Fourteen athletes (weight loss group, WL; 22.6 ± 4.0 years; 176 ± 8 cm; 77.0 ± 12.9 kg; VO_{2max} : 57.9 ± 5.2 mL/min/kg; tHb: 909 ± 144 g) reduced their body weight (BW) within a few days by individual methods in a real-life setting. Fourteen athletes did not reduce BW (control group, CON; 23.8 ± 4.8 years; 178 ± 8 cm; 78.3 ± 11.6 kg; VO_{2max} : 56.8 ± 6.8 mL/min/kg; tHb: 939 ± 112 g). During an ordinary training period (t-1), 1-2 days before competition (after RWL in WL, t-2) and ~1 week after competition (t-3), tHb was determined by the CO-rebreathing method and venous blood was drawn for measurement of red blood cell count parameters (RBC), reticulocytes (RET), erythropoietin (EPO), lactate dehydrogenase (LDH), bilirubin, haptoglobin, iron, transferrin, ferritin and free androgen index (FAI = total testosterone/SHBG). **Results** In WL, BW and tHb were significantly ($P < 0.001$) reduced by $5.5 \pm 0.9\%$ and $4.1 \pm 2.6\%$, respectively, from t-1 to t-2 and were still decreased by $1.6 \pm 2.3\%$ ($P < 0.01$) and $2.6 \pm 2.0\%$ ($P < 0.001$) at t-3 compared to t-1. After RWL a decrease was observed in RET (10.7 ± 3.7 vs. 12.9 ± 3.9 [t-1] and $12.8 \pm 4.8\%$ [t-3, $P < 0.05$]), EPO (5.50 ± 2.25 vs. 6.61 ± 2.46 [t-1] and 8.94 ± 5.70 mU/ml [t-3, $P < 0.05$]), haptoglobin (0.50 ± 0.44 vs. 0.58 ± 0.39 [t-1] and 0.66 ± 0.45 g/L [t-3, $P < 0.01$]) and FAI (47 ± 21 vs. 64 ± 20 [t-1, $P < 0.01$] and 62 ± 14 [t-3, $P < 0.01$]). An increase occurred in ferritin (99 ± 46 vs. 77 ± 46 [t-1, $P < 0.01$] and 68 ± 38 μ g/L [t-3, $P < 0.001$]) and in bilirubin (0.94 ± 0.51 vs. 0.62 ± 0.30 [t-1] and 0.51 ± 0.15 mg/dL [t-3, $P < 0.001$]). Iron, transferrin, RBC, and LDH did not change significantly. In CON, there were no significant changes in any parameter. **Discussion** The decrease in RET and EPO indicate impaired erythropoiesis during RWL which may be related to changes in FAI. However, the changes in ferritin, haptoglobin and bilirubin levels suggest that also haemolysis might be a cause for the significant decrease in tHb during RWL in combat athletes. **References** Reljic D, Hässler E, Jost J & Friedmann-Bette B. EXCITABILITY AND EXCITATION DURING EXERCISE OF HIGH INTENSITY

Finkel, A., Maassen, M., Eigendorf, J., Maassen, N., Shushakov, V.

Institute of Sports Science

Introduction Various mechanisms and processes which are responsible for the generation of the action potential are linked to the pH and the potassium concentration [K⁺] (Allen et al., 2008; Juel, 2008). Therefore it was supposed, that the acid base status and the elevation of the extracellular [K⁺] could have an influence on the excitability. The aim of this study was to investigate the effect of a severe acidosis and extracellular [K⁺] during and after a repeated high intensive exercise on the excitability. **Methods** 16 healthy male athletes performed two 30-second Wingate tests (WT) separated by a break of 1 minute. Changes of the acid base status and [lactate] in arterialised blood and [K⁺] in venous plasma were measured. Blood samples were collected at rest, end of 10min warming up (WP), before the first WT, end of the first WT, end of the second WT and during recovery period (RP; 3, 7, 11, 15 min). Acid base status and [K⁺] were measured by an ABL 825 Flex (RADIOMETER, Copenhagen). M-Wave and voluntary EMG were recorded throughout cycling from the vastus medialis and the vastus lateralis via surface electrodes. Root-mean square value of EMG (RMS) and median frequency of EMG (MF) were calculated from

raw EMG (BIOPAC SYSTEMS INC., Santa Barbara, USA). Results The pH reached 7.125 (± 0.047), the [lactate] 15.8 (± 1.32) in RP. Extracellular [K⁺] rose to 5.5 – 6.0 during WT and dropped in RP under the resting values. The propagation velocity of the action potential showed an almost identical course in both muscles with an increase during WP, a decrease during WT and an increase after 3 min in RP ($p < 0.001$). In both muscles we found a significant enlargement in the area of the M-Wave in RP ($p < 0.001$) but no changes during WT. There was a significant correlation between the area of the M-Wave and the [K⁺] during the whole test (working period + RP) ($p < 0.025$). MF decreased in both muscles during WT ($p < 0.001$). No changes could be found in the EMGRMS. MF correlated with the changes of the pH ($p < 0.01$), the [K⁺] ($p < 0.001$) and the [lactate] ($p < 0.01$) during the WT in both muscles. Discussion A severe acidosis seems not to reduce the area of the M-Wave and does not have an influence on the excitability. A decrease of the [K⁺] in RP is a sign of the impact of an increased activity of the Na⁺-K⁺-pump. Both factors might cause the rise in the area of the M-Wave. The decreased MF during WT accords with the decreased velocity of the action potential of the M-Wave. References Allen, D.G., Lamb, G.D. & Westerblad, H. EXERCISE-INDUCED DIAPHRAGM FATIGUE IN AN ELITE ADAPTIVE ROWER WITH SPINAL CORD INJURY

Romer, L.M., Tiller, N.B., Aggar, T.R., West, C.R.

Brunel University

Introduction: Exercise requiring heavy use of the arms forces the respiratory muscles to generate pulmonary airflow while providing postural stability to the thorax. The dual role for respiratory muscles during upper-body exercise likely impacts on respiratory mechanics and may induce fatigue of the associated musculature. Although diaphragm fatigue has been shown to occur in response to predominantly lower-body exercise, it is not yet known whether this phenomenon occurs with upper-body exercise. Aims: To characterise mechanical ventilatory responses and exercise-induced diaphragm fatigue in an elite arms-only rower with spinal cord injury. Methods: A Paralympic, World and European Champion oarsman (category: 1xAS, age: 28 y, stature: 1.89 m, mass: 90.4 kg) with motor-complete spinal cord injury (T12) performed a 1000 m time-trial on an adapted Concept II rowing ergometer. Measurements included pulmonary function (spirometry, plethysmography, lung diffusion), ventilation and pulmonary gas exchange, central respiratory drive via diaphragm EMG (multi-pair oesophageal electrode catheter) and pressure-derived indices of respiratory mechanics. Diaphragm fatigue was assessed by measuring the twitch transdiaphragmatic pressure (P_{di,tw}) response to anterolateral magnetic stimulation of the phrenic nerves before and up to 30 min after exercise. Results: Baseline pulmonary function exceeded the upper-limit-of-normal (FEV₁: 5.5 L [114% predicted], VC: 7.6 L [130%], TLC: 10.1 L [126%], MVV: 262 L/min [141%]; DL_{CO}: 17.2 mmol/min/kPa [131%]). The 1000 m time-trial was completed in 3.9 min (248 \pm 25 W) and induced peak values for minute ventilation and O₂ uptake of 154 and 3.57 L/min, respectively. The breath-to-stroke ratio was 1:1 during the first 400 m and 2:1 thereafter (tidal volume: 2.67 \pm 0.06 vs. 1.63 \pm 0.82 L). Diaphragm EMG root-mean-square amplitude during inspiration was higher in the second half of the time-trial, yet inspiratory transdiaphragmatic pressure and tidal volume were lower. Relative to baseline, potentiated P_{di,tw} was reduced by 33% at 15 min after exercise (40 vs. 59 cmH₂O) and by 16% at 30 min (50 vs. 59 cmH₂O). Conclusions: The results of this case-study indicate that exercise-induced diaphragm fatigue can occur in response to high-intensity upper-body exercise. The uncoupling of central respiratory drive and thoracic volume displacement suggests that diaphragm fatigue may be attributable, at least in part, to factors other than ventilation (e.g., postural drive).

ARE POST-EXERCISE SALIVARY CORTISOL VALUES AFFECTED BY HYDRATION STATE?

Sánchez Martos, M.A., Aracil, A., Pastor, D., Sarabia, J.M., Moya, M.

Miguel Hernandez University of Elche

Introduction Biochemical monitoring of training is an effective tool to control the impact of external load of exercise (Crewther, 2012). One of the most commonly used molecule is cortisol, a catabolic hormone secreted by the pituitary adrenal axis under physical and psychological stress. However, there is no evidence about the effect of the subject's hydration state on salivary cortisol concentrations after exercise. Therefore, the aim of this study was to describe if the salivary cortisol levels are affected by the subject's hydration state. Methods Ten healthy male, recreational athletes (26.5 \pm 2.5 years, 179.6 \pm 6.4 cm, 74.1 \pm 6.5 kg, 19.8 \pm 3.6% body fat) took part in this study, after informed consent. Subjects arrived to the laboratory at 8 am for an anthropometry. Afterwards, they had to run in a treadmill at the corresponding pace to maintain their 60% of heart rate reserve, until: a) losing 1.8% of their initial weight; or b) reaching 90 minutes of exercise. Subjects were weighed at 30, 60, 75 and 90 minutes of exercise. Saliva samples were obtained pre- and post-exercise, and frozen at -20°C until assayed for cortisol by ELISA. Participants performed this protocol in two different days, with seven days in between. During the first day participants were not allowed to drink anything during the test (dehydration state, DEH), whereas during the second day, participants drank the same volume lost during the different weighing of the first day (euhydration state, EUH). Results In comparison with EUH, at the DEH: a) a decrease in the performance was observed (7.05 \pm 0.90 vs 7.73 \pm 1.02 km/h, $p=0.002$, paired t test); and b) an increase of the dispersion of cortisol levels by 53,7% was noted. In both days a decrease in cortisol concentration was noted post-exercise, but only in EUH this decrease was significant (Pre=0.32 \pm 0.21 μ g/dL, post=0.12 \pm 0.06 μ g/dL, $p=0.032$, paired t test). Discussion and conclusion A small change in the participants' hydration state involves a significant decrease in performance measured as submaximal running speed. An intensity corresponding of 60% of heart rate reserve seems insufficient to generate an increase in salivary cortisol concentration. However, as in previous publications (Maresh et al., 2006) the hydration state increased the variability of this hormone in saliva. In conclusion, for using salivary cortisol concentrations as a tool of measure acute training impact, we should control the athletes' hydration state. RELATION BETWEEN NOX CONCENTRATION IN PLASMA AND RED CELLS DURING ACUTE HYPOXIA

Maassen, M., Nacke, M., Tsikas, D., Maassen, N.

Leibniz University Hannover

Introduction Gladwin et al. (2008) have shown that hemoglobin has a nitrite reductase activity. This activity is highest when half of the hemoglobin is desaturated (P50). During high intense exercise the oxygen saturation in the working muscle is lower than P50. In recent investigations we could show a significant decrease in NO3 (Sutmöller et al. unpublished) and in NO2 (Dreißigacker et al. 2010) during/after high intense exercise. The cause for the decreasing NOX could be the change in acid base status and oxygen content. In the present investigation we tried to evaluate the effect of decreasing SO₂/PO₂ by applying systemic hypoxia in vivo at rest. Methods To vary

the SO₂ 12 subjects were connected to the „Hypoxicator GO2Altitude®“ (BIOMEDTECH, Melbourne, Australia). The relative oxygen concentration in the inspired gas was stepwise reduced from 21% to 9%. In parallel blood samples were taken from a cubital vein. Acid base status was measured by an ABL 520. In plasma and haemolysate [NO₂] and [NO₃] were determined by GC-mass-spectroscopy. The concentrations were related to liter H₂O. The results of the experiment are evaluated in two ways. The first comparison was between normoxia and the end of the experiment, the second was between the samples with maximum and minimum oxygen saturation. Statistics: To test significant differences between means a paired t-test was used. The level of significance was set to $p < 0.05$. Results The mean cubital venous PO₂ at the end of the hypoxia trial was 24.6 ± 4.5 mmHg and SO₂ was $45.8 \pm 12.7\%$. In plasma the decrease during the experiment in [NO₂-] is not significant ($p > 0.14$) but the decrease was significantly correlated to a decrease SO₂ ($p < 0.008$). [NO₃-] decreased significantly during the experiment ($p < 0.05$). The change in [NO₃] correlated to SO₂ ($p < 0.04$). [NO₃-] in red cells did not change during the experiments and was not related to SO₂. Intracellular [NO₃-] was significantly lower than in plasma ($p < 0.03$). [NO₂] in plasma is significant lower than in red cells. The concentration in red cells is by far higher than expected from the Donnan-Equilibrium. [NO₂] in red cells increased significantly ($p < 0.05$) with decreasing SO₂. Discussion In the range of the P₅₀ there seems to be a net shift of NO₂ from the plasma into the red cells. By that the Hb-reductase activity might be supported. Since the intracellular [NO₃] remains constant, the decrease in [NO₃] in plasma seems to be caused by extracellular effects. With this pathway an NOS-independent way to produce NO might function under hypoxic condition. Contact Mirja.Maassen@sportwiss.uni-hannover.de

ROLE OF SATELLITE CELLS IN HUMAN SKELETAL MUSCLE REMODELLING FOLLOWING VERY LOW-VOLUME HIGH-INTENSITY INTERVAL AND ENDURANCE TRAINING

Nederveen, J.P., Joanisse, S., Gillen, J.B., Gibala, M.J., McKay, B.R., Scribbans, T.D., Edgett, B.A., Gurd, B.J., Parise, G.
McMaster University

Introduction There is paucity of data regarding the influence of satellite cells (SC) on exercise-induced skeletal muscle adaptations/remodeling. Existing literature demonstrated an expansion of the SC pool following various modalities of exercise training (Kadi & Thornell, 2000). Therefore, we examined the impact of low volume high intensity training (LVHIT) and endurance exercise (END) on the SC pool in various populations since it is known that LVHIT is capable of inducing significant skeletal muscle remodeling (Gibala et al., 2012). **Methods** Fourteen overweight/obese adults (n=14; men (n=7): 29 ± 9 yr, BMI: 31 ± 3 kg/m²; women (n=7): 29 ± 20 yr, BMI: 29 ± 2 kg/m²) performed 18 sessions over 6 wk (LVHIT-O). Each session consisted of 3 x 20s all-out cycling sprints against 5.0% body weight followed by 2 min of recovery per bout. Nine active men (n=9; 21 ± 2 yr, BMI: 22.8 ± 2) performed 24 sessions over 6 wk (LVHIT). Each session consisted of 8 x 20s all-out cycling sprints at 170% WRpeak followed by 10s of recovery per bout. Nine active men (n=9; 20.7 ± 3.8 , BMI: 23.3 ± 3) performed 24 sessions over 6 wk (END). Each session consisted of 30 min continued cycling at 65% WRpeak. Pre- and post-training muscle biopsy samples were cut into cross-sections and stained using immunohistochemistry techniques. Results Across all three training groups, there was no expansion of the SC pool ($p > 0.05$). Following LVHIT-O, there were a greater ($p < 0.05$) number of centrally located nuclei/100 fiber post-training (11 ± 6) compared to pre-training (7 ± 5). In a comparison between END and LVHIT, neither program induced muscle hypertrophy as assessed via muscle cross sectional area. Furthermore, there was a main effect ($p < 0.05$) for training in the number of cells engaged in cell cycle activity (Pre LV-HIT: 3.0 ± 1.5 Pax7+/MyoD+/100MF, Pre END: 2.4 ± 1.6 Pax7+/MyoD+/100MF; Post LV-HIT: 6.9 ± 1.4 Pax7+/MyoD+/100MF, Post END: 6.7 ± 1.3 Pax7+/MyoD+/100MF). **Discussion** Following HIT in obese adults, there are increased centrally located nuclei suggesting active remodeling of skeletal muscle tissue despite a lack of expansion of the SC pool. Similarly, data from active men suggests training stimuli that neither causes hypertrophy nor causes an expansion of the SC pool still induces satellite cell activity presumably for the purpose of skeletal muscle remodeling. ACUTE CARDIOVASCULAR RESPONSES TO RESISTANCE EXERCISE IN ANABOLIC STEROIDS USERS: A PRELIMINARY INVESTIGATION

Angell, P.J., Green, D.J., Whyte, G., George, K.P.
Liverpool Hope University

Introduction With the increase in the prevalence of AS use for non-medical performance and image enhancement purposes, the impact of AS on cardiovascular health is a growing issue. AS use has long been associated with a number of CV outcomes as well as negatively impacting CV risk factors (Angell et al. 2012). It is worth noting that all of the available data has been in individuals at rest. Exercise increase cardiac workload and stress and it is more likely cardiac health problems may be “unmasked”. As a consequence, the focus of this study is the cardiovascular responses to exercise and recovery in AS users. **Methods** Strength trained individuals were recruited (AS n=7, age=29±5yr; NAS n=6, age=25±1 yr) with measurements of cardiac function (Vivid Q, GE Healthcare, Norway) and blood pressure (Dinamap; GE Pro 300V2, GE Healthcare) taken at rest and following a full body resistance exercise session (c.70mins). Each exercise was performed for 8-12 reps for 3 sets with one minute rest between each set (~70% 1RM). Data were analysed using ANCOVA's performed on the overall change controlling for pre-exercise values (SPSS v.20, IBM, USA). Results There was no significant difference in height or weight between groups but the AS group had a greater resting HR (AS=66±6; NAS=56±8, $p < 0.05$). Pre and post exercise E:A ratio's were not significantly reduced in the AS group (AS= Pre: 1.60 ± 0.23 , Post: 1.20 ± 0.33 ; NAS=Pre 1.61 ± 0.12 , Post: 1.32 ± 0.21). When comparing between groups there was no significant difference in standard echocardiographic parameters, however, some differences were observed when we controlled for pre exercise (ANCOVA). AS users had a significant reduction in mean change of ejection fraction following the exercise session (AS= -0.81 ± 5.5 , NAS= 5.69 ± 5.19 %, $p < 0.05$). No significant differences in the change in diastolic function following the exercise session were observed. Late atrial strain rate in the longitudinal plane was increased greater in the AS group following exercise (AS= 0.31 ± 0.20 , NAS= 0.01 ± 0.19 , $p < 0.05$). Peak rotation rate was significantly reduced in the AS group at the mitral (AS= -24.96 ± 34.86 ; NAS= 7.20 ± 16.16 $p < 0.05$) and basal (AS= -14.05 ± 41.15 ; NAS= -5.55 ± 27.08 $p < 0.05$) levels respectively. **Discussion** The key finding from this study is that the completion of a standard, full body, resistance exercise programme provides an increase in stress upon the cardiovascular system and that this may be mediated by AS use. The difference in change in mean ejection fraction in the AS group demonstrate a possible role of AS use in limiting the cardiac response to exercise. In addition, a general trend of a reduced diastolic function as well as the in the AS group might suggest a possible negative of AS use and therefore a possible increase in CV risk. Despite the limitations in this study due to its small numbers, some valuable information was garnered demonstrating the need for further investigation.

EFFECT OF ACUTE EXERCISE UNDER MODERATE HYPOXIA ON COGNITIVE FUNCTION

Komiyama, T.1, Ando, S.1, Sudo, M.2, Okuda, N.1, Kiyonaga, A.1, Tanaka, H.1, Higaki, Y.1

1: Fukuoka Univ. (Fukuoka, Japan), 2: Meiji Yasuda Life Foundation of Health and Welfare (Tokyo, Japan)

Introduction Acute hypoxia alters physiological function because of decreased available oxygen, which may impair cognitive function (Lemons et al., 2012). In contrast, acute moderate exercise improves cognitive function (Nanda et al., 2013). Hence, cognitive function during exercise under hypoxia may be determined by the balance between the beneficial and detrimental effects. However, little is known about how cognitive function is altered during exercise under hypoxia. The purpose of this study was to examine the effects of acute exercise under moderate hypoxia on cognitive function. **Methods** Sixteen subjects were recruited in this study. They completed cognitive tasks at rest and during exercise under either normoxia (FIO₂: 0.209) or moderate hypoxia (FIO₂: 0.15). Cognitive function was assessed by a combination of Delayed Response (DR) task (working memory) and GO/NOGO task (executive function). At the beginning of the experiment, the subjects performed the cognitive task at rest under normoxia or hypoxia. Then, they cycled ergometer for 30-min while keeping their heart rate (HR) at 140 beats/min. Cognitive tasks were performed 5 min and 23 min after their HR reached at 140 beats/min. Pulse oximetric saturation (SpO₂) and cerebral oxygenation were monitored throughout the experiment to assess oxygen availability. Blood lactate and RPE were recorded at rest and immediately after each cognitive task. **Results** SpO₂ and cerebral oxygenation were significantly lower under hypoxia than normoxia ($p < 0.01$, respectively). We observed no differences in blood lactate and RPE between normoxia and hypoxia. Accuracy of the cognitive task tended to be lower under hypoxia than normoxia ($p = 0.08$). Reaction time in the GO/NOGO task significantly decreased during exercise relative to rest under both conditions ($p < 0.01$). Exercise tended to improve accuracy of the cognitive task ($p = 0.052$). **Discussion** Moderate hypoxia decreased available oxygen relative to normoxia. However, the reaction time significantly decreased during exercise under both condition. Thus, acute exercise improves the speed of response, independent of oxygen availability. Moderate hypoxia tended to compromise accuracy of response. We did not observe significant differences, possibly caused by individual variability under moderate hypoxia on accuracy of response. We conclude that moderate hypoxia may impair accuracy of response. Nevertheless, acute moderate exercise improves cognitive function under moderate hypoxia. **References** de Aquino Lemos V, Antunes HK, dos Santos RV, Lira FS, Tufik S, de Mello MT. (2012). THE INDUCED DELETERIOUS EFFECTS OF HIGH FAT DIET AND SUCROSE CONSUMPTION ON ENDOCRINE PANCREAS IS ATTENUATED BY SIMULTANEOUS SHORT TERM EXERCISE TRAINING IN MICE

Veras, K., Lucena, C., Pires, F.O., Carpinelli, A., Carvalho, C.R.O.

University of São Paulo

Introduction High fat diet (HFD) consumption can induce impaired pancreatic beta cell function and β -cell damage and death, which are associated to enhance reactive oxygen species (ROS) production and oxidative stress. Despite the well know beneficial effects of the regular exercise training upon obesity and DM2, less is known about the impact of regular exercise training prevention of induced impaired insulin secretion due HFD. We investigated the effect of exercise training upon prevention of the deleterious effects induced by a hypercaloric diet on insulin secretion and β -cell damage from male mice. **Methods** Simultaneously to the beginning of a high-fat diet sucrose feeding (HFDS), 60 days C57BL/6 mice were submitted to a treadmill running with intensity set at 60% of the peak treadmill velocity by 30 minutes, five days per week, for 8 weeks (HFDS + TR group). Glucose and insulin tolerance tests were performed on food restriction mice. Glucose stimulated insulin secretion (GSIS) was determined by RIA and Cu,Zn-superoxide dismutase 1 (SOD1) content was also analyzed by Western blotting. **Results** HFDS feeding induced a higher corporal mass weight ($P < 0.001$) and gonadal adipose tissue ($P < 0.01$) as early as the first week of feed intervention. As expected Insulin resistance ($P < 0.01$) and glucose intolerance ($P < 0.001$) were observed associated to impaired GSIS on isolated pancreatic islets ($P < 0.05$). HFDS mice presented a lower proportion (62%) of viable pancreatic islets cells when compared to control group ($P < 0.01$). The exercise program improved the insulin sensitivity and the content of the SOD1 protein levels to similar pattern ($P < 0.05$). **Discussion** Studies have showed that exercise training increases peripheral and hepatic insulin sensitivity after installation of a disease state (Cao et al., 2012). Our findings demonstrated that 8 weeks short-term exercise training may prevent the progression of a HFDS-induced insulin resistance and impaired GSIS. Furthermore, cellular viability and endogenous antioxidant enzyme SOD1 content were enhanced on endocrine pancreatic cells with exercise training. Thus, considering that SOD1 proteins are important to maintain the cellular redox status, our data further suggest that regular exercise training may help to prevent the progression of obesity, DM2, and endocrine pancreas injury development. **References** Cao S, Li B, Yi X, Chang B, Zhu B, Lian Z, Zhang Z, Zhao G, Liu H, Zhang H. EFFECTS OF N-ACETYLCYSTEINE IN ISOLATED SKELETAL MUSCLE FUNCTION IN RATS SUBMITTED TO ACUTE AEROBIC EXERCISE

Jannig, P.R., Bechara, L.R.G., Voltarelli, V.A., Bozi, L.H.M., Alves, C.R.R., Brum, P.C.

University of Sao Paulo

Introduction Although oxidative stress has been related to skeletal muscle adaptive responses to exercise training, its exacerbation during an acute bout of aerobic exercise can impair skeletal muscle contractile properties, contributing to the fatigue phenomenon. However, it is still unclear whether this response is dependent of local or systemic oxidative stress. Therefore, the aim of this study was to evaluate the effects of the antioxidant N-acetylcysteine (NAC) in isolated skeletal muscle function in rats submitted to an acute bout of aerobic exercise. **Methods** Male Wistar rats (410 \pm 41g) were studied at rest (control group; C, n=7) or immediately after an acute bout of aerobic exercise in treadmill (60 min at 60% of maximal speed; EX, n= 7). Soleus and extensor digitorum longus (EDL) muscles were carefully removed and attached to an isometric force transducer within an in vitro organ bath system containing aerated (95% O₂, 5% CO₂) Krebs-Ringer solution (in mM: 137 NaCl, 5 KCl, 2 CaCl₂, 1 KH₂PO₄, 1 MgSO₄, 24 NaHCO₃, 11 C₆H₁₂O₆; 22 \pm 0.2; pH 7.4). Skeletal muscles were stabilized for 30 minutes, during which individual optimal lengths for isometric contraction were determined. Soleus and EDL muscles were then electrically stimulated (0.2ms, 80V, with 1200ms and 350ms, respectively) in a force-frequency protocol (stimuli frequencies of 1, 10, 20, 30, 50, 80 and 100Hz separated by 3min of recovery) to evaluate muscle's force generation capacity and in a fatigue protocol (100Hz stimuli every 5 seconds for 4min) to evaluate muscle's fatigability. The same analysis were performed in another set of exercised animals, but then the muscles were incubated for 10min with 20nM NAC prior to each protocol (EX+NAC, n=6). Data were analyzed by one-way ANOVA (Tukey's post hoc) and statistical significance was considered achieved when $p < 0.05$. **Results** Compared to C, EX soleus and EDL showed reduced specific maximum tetanic force (Po), which was partially prevented in EX+NAC group.

Pulse frequency for 50% of Po (F50%), time to peak (TPT) and one-half relaxation time (1/2RT) at 100Hz were similar among groups in soleus. In EDL, F50% was reduced in both EX and EX+NAC, TPT was reduced in EX but not in EX+NAC and 1/2RT increased in both EX and EX+NAC groups. Regarding to muscle fatigue, soleus time to 50% of initial Po (T50%) was reduced in EX but not in EX+NAC. EDL showed an increased T50% in both EX and EX+NAC groups. Discussion Exercised skeletal muscles shown several contractile properties alterations, which were more pronounced in EDL than in soleus. In addition, incubation of exercised muscles with the general antioxidant NAC was able to restore some alterations imposed by aerobic exercise. These results suggest that the local redox imbalance affects skeletal muscle function and that its attenuation could account for acute improvements in contractile properties. COMPARISON OF MUSCLE OXYGEN CONSUMPTION MEASURED DURING AND IMMEDIATELY FOLLOWING CYCLING EXERCISE BY NEAR-INFRARED SPECTROSCOPY

van Beekvelt, M., Furset, T., Skovereng, K.

Norwegian University of Science and Technology (NTNU)

Introduction Near-infrared spectroscopy (NIRS) has frequently been used to quantify muscle oxygen consumption (mVO₂) by application of the arterial occlusion method. This method has mostly been applied during rest, or immediately following exercise as an indication of mVO₂ during exercise. More recently, our group has applied mVO₂ during cycling, as a more direct measurement of mVO₂ under physical activity. The aim of this study was to examine whether the measurement of mVO₂ during exercise is comparable to that measured immediately following exercise. **Methods** Ten healthy male recreational cyclists participated in the study. Two 7-min cycling periods were done on an electro-magnetically braked cycle ergometer at 150 W and 200 W, respectively. A 20-sec arterial occlusion (280 mmHg) was applied at minute 5, and again immediately following the end of cycling at minute 7. NIRS data were obtained from the vastus lateralis (VL) muscle of the right leg using an interoptode distance of 40 mm and a differential path-length factor of 4.0. Data was sampled at 100 Hz. During cycling, NIRS, oxygen consumption (VO₂) and heart rate (HR) were measured continuously. NIRS-derived mVO₂ was calculated from the linear rate of decrease in oxyhemoglobin (van Beekvelt et al., 2001). **Results** Preliminary results show no difference between mVO₂ measured during cycling at 150 W and 200 W and that measured immediately following exercise ($P = 0.45$ and $P = 0.52$, respectively). During rest, mVO₂ was 0.05 ± 0.02 ml/min/100g and increased with a factor of 23% during exercise to 1.10 ± 0.45 ml/min/100g and 1.09 ± 0.35 ml/min/100g for 150W and 200W, respectively. **Conclusion** This study showed that the measurement of mVO₂ during cycling was comparable with the method of measuring mVO₂ immediately following exercise. Since the measurement following exercise is highly perceptible for errors based on the time course of the mVO₂ kinetics following exercise (van Beekvelt et al., 2001), this study showed a possible alternative approach to obtain mVO₂ more directly during exercise. **References** van Beekvelt MCP, Shoemaker K, Tschakovsky ME, Hopman MT, and Hughson RL. *Am J Physiol Regulatory Integrative Comp Physiol* 280: R1741–R1747, 2001. THE EFFECT OF TWO DIFFERENT EXERCISE PROTOCOLS ON INSULIN SENSITIVITY IN HEALTHY HUMANS

Thodou, A.1, Spanoudaki, S.2, Giannopoulos, A.1, Philippou, A.1, Psarros, C.1, Koutsilieris, M.1, Maridaki, M.2

National and Kapodistrian University of Athens

Introduction Insulin is a hormone that plays an important role in the regulation of carbohydrate and fat metabolism. It causes cells to take up glucose from blood and exercise can improve muscle insulin sensitivity enhancing glucose transport into the muscle cells (Holloszy, 2005). The purpose of this study was to examine the effect of two different exercise protocols, i.e., prolonged exercise of constant and alternative intensity, on the circulating levels of insulin in humans. **Methods** Ten healthy male volunteers (age: 24.7 ± 4.7 years, body mass: 78.5 ± 8.9 kg, height: 180.8 ± 6 cm, body fat: $9.1 \pm 3.1\%$) participated in the study. Participants were fasted overnight and on separate days they underwent two cycling exercise trials at the same overall power output, lasting one hour each. During the first trial, exercise intensity was constant at $70 \pm 5\%$ VO₂max, while during the second trial, exercise intensity was alternated between $47 \pm 2\%$ VO₂max and 120% VO₂max for 40 s and 20 s, respectively. Blood samples were withdrawn prior to test, during the last seconds of 30 and 60 minutes of exercise, and 1 hour after the end of exercise. The serum insulin levels were measured by ELISA. Two-way ANOVA was used for statistics. **Results** The insulin levels decreased significantly over time in both exercise protocols compared to the pre-exercise levels ($p < 0.05$ – 0.001), while no significant differences were found between the two protocols (main effect for protocol, $p > 0.05$). However, in the protocol of alternative exercise intensity, the insulin levels decreased significantly only at the end of exercise ($p < 0.05$), while in the constant intensity exercise, its levels were significantly decreased at all the time points compared with the pre-exercise levels ($p < 0.05$ – 0.001). **Discussion** The decreased circulating levels of insulin observed in the present study indicate an increase in the insulin sensitivity induced by exercise, confirming the positive association of physical activity with insulin sensitivity (Borghouts et al., 2000). Moreover, the exercise protocol of constant intensity was found to increase insulin sensitivity not only during exercise but also after its completion, which is important for rapid muscle glycogen accumulation after exercise. Thus, it could be assumed that this type of exercise may be more effective to decrease insulin levels and to play a key role in the treatment and/or prevention of insulin insensitivity (Holloszy, 2005). **References** Borghouts, L.B. and H.A. Keizer. (2000). *Int J Sports Med*, 21(1): p. 1-12. Holloszy J. *J Appl Physiol* 99: 338–343, 2005. Contact thodousissy@gmail.com

THE EFFECTS OF 21 DAYS OF BED REST ON MITOCHONDRIAL OXIDATIVE CAPACITY.

Kenny, H.C.1, Rudwill, F.2, Heer, M.3, Blanc, S.2, O'Gorman, D.J.1,

Dublin City University

Introduction: It has been recently reported that physical inactivity is the 10th leading contributor to the burden of chronic disease (Lim et al, 2013). Bed rest represents a unique model of physical inactivity by which we can investigate the mechanisms underlying the development of metabolic diseases. In particular, reduced skeletal muscle mitochondrial capacity and a reduction in intrinsic mitochondrial function in response to physical inactivity may have broad implications for human disease. **Purpose:** The aim of the present study was to test the hypothesis that oxidative phosphorylation and electron transport capacity are diminished in response to 21 days of -6° head down tilt bed rest. **Methods:** The O₂ flux capacity of permeabilized skeletal muscle fibres obtained by muscle biopsy from the vastus lateralis was measured using high resolution respirometry before and after 21 days of bed rest. Subjects were assigned to the resistive vibration exercise (RVE) group (n=11), nutrition and exercise (NEX) group (n=8) and the control group (n=11). We measured the capacity of the electron transport system with high-resolution respirometry by applying two substrate-uncoupler-inhibitor-titration (SUIT) protocols. Citrate synthase enzyme activity was also measured and was used to normalize for mitochondrial content. **Results:** O₂ flux expressed per mg of

wet weight of muscle tissue was lower during LEAK respiration following 21 days of BR ($P=0.024$). LEAK respiration was measured in the presence of pyruvate and malate and in the absence of ADP. OXPHOS and ETS capacity showed a moderate decline following BR. Citrate synthase activity was significantly reduced ($P=0.01$). Conclusion: A reduction in LEAK respiration is an indicator of reduced mitochondrial uncoupling which, independently of mitochondrial content, has been associated with an increase in reactive oxygen species (ROS) production and dysregulation of lipid metabolism in skeletal muscle. Such changes may lead to altered cellular metabolism, ectopic fat storage and insulin resistance. Physical inactivity-mediated reductions in oxidative metabolism may inhibit skeletal muscle function and metabolism. Lim, S. S., T. Vos, et al. (2013). 'A comparative risk assessment of burden of disease and injury attributable to 67 risk factors and risk factor clusters in 21 regions, 1990–2010: a systematic analysis for the Global Burden of Disease Study 2010.' *The Lancet* 380(9859): 2224–2260.

CRITICAL VELOCITY AND HIGH INTENSITY TRAINING FOR A RECREATIONALLY ACTIVE POPULATION

Hughes, B., Murphy, C., Collins, D.K.

Institute Of Technology Tallaght

Introduction The use of high intensity interval training has gained considerable attention in recent years due to lack of free time being a factor in low levels of physical activity (Trost et al. 2002). Critical velocity is defined as peak power output (watts), which can be maintained over a 3-minute period. The exercise prescription in this current study is based on participant's 170% critical velocity. The aim of the current study was to assess the effect of the exercise prescribed using the critical velocity model of high intensity interval training on a recreationally active population. **Methods** Six recreationally active men and three recreationally active women ($n=9$) volunteered to participate in the study. Participants undertook testing pre- and post-intervention including anthropometric and maximal oxygen uptake (graded exercise test GXT). Each participant undertook 6 sessions over a 2-week period no less than 24 hours apart. The protocol consisted of 5 bouts of 20 seconds at 170% of participants critical velocity (determined from GXT) interspersed with 100 seconds of low intensity exercise at 50 watts. A warm up and cool down were performed pre- and post-protocol, adding up to a total time commitment of 16 minutes. Workloads elicited 90–100% of maximum heart rate and 90–100% of maximal oxygen consumption. Data is communicated as mean \pm standard deviation. To evaluate systematic differences, a paired t-test on the test re-test data was performed. Results The results show no significant changes across anthropometric data; weight (76.8 ± 15 vs. 76.6 ± 14.7 kg), BMI (25.8 ± 4.4 vs. 26.1 ± 4.2), body fat percentage (22.8 ± 7.1 vs. 22.5 ± 6.7 %bf) or fat free mass (58.3 ± 9.6 vs. 58.4 ± 9.6 kg) pre and post-intervention. There was statistically significant change in both $\dot{V}O_{2\max}$ $-P=0.014$ (34 ± 6.6 vs. $37.25 \pm 6.8^*$ ml/kg/min) and $\dot{V}O_{2\text{peak}}$ $P=0.002$ (38.9 ± 7 vs. $41.4 \pm 7.2^*$ ml/kg/min). There was also a statistically significant increase in participant's time to exhaustion $P=0.001$ (24.6 ± 6.3 vs. $28.3 \pm 6.3^*$ mins). Although not statistically significant ($P=0.05$) there was a decrease in session RPE from session 1 to session 6 (14.5 ± 2.4 vs. 12.5 ± 2.5). **Discussion** These findings provide novel information regarding the potency of the critical velocity model to prescribe exercise, indicating that it may offer a time-efficient alternative to conventional cardiorespiratory exercise training for improving health. It also suggests that the critical velocity model may be a practical alternative to sprint interval training (Wingate training), as it doesn't require 'all out' efforts or specialized equipment, while providing similar benefits (Burgomaster et al. 2008). **References** Rakobowchuk M, et al. (2008) *Journal of physiology* 295; R236–242 Trost SG et al. (2002) *Med Sci Sports Exerc* 34: 1996–2001 Contact Brian.hughes@ittd.ie

SPEEDING OF $\dot{V}O_2$ KINETICS IN RESPONSE TO HIGH-INTENSITY-INTERVAL TRAINING IN OLDER, HEALTHY MEN

Capelli, C., Bruseghini, P., Calabria, E., Tam, E., Pogliaghi, S.

University of Verona (Italy)

Introduction Experimental evidence suggests that High Intensity Interval Training (HIT, high intensity - low volume exercise) may be effective in accelerating the dynamic response pulmonary $\dot{V}O_2$ in older subjects through an improvement of the matching between local O_2 delivery and uptake (Williams et al., 2013). This study explores the effect of HIT on $\dot{V}O_2$ kinetics and muscle deoxygenating during step transitions of moderate intensity, cycling exercise in older, healthy men. **Methods** 12 moderately active older adults ($68\text{-}77 \pm 4$) were exposed to 8 weeks of HIT training with 7 two-minute repetitions at 40 and 90% of $\dot{V}O_{2\max}$, 3 times a week. Before and after training we measured: i) $\dot{V}O_2$ peak ($\dot{V}O_{2p}$), gas exchange threshold (GET) and respiratory compensation point (RCP) during an incremental test up to exhaustion; ii) breath-by-breath $\dot{V}O_2$ and change of fractional muscle O_2 extraction (ΔHHb) of vastus lateralis by quantitative NIRS during three step-exercise transitions performed at a workload corresponding to 90% of GET. $\dot{V}O_2$ kinetics was modeled, after synchronization and overlapping of the three series, by means of a double - exponential function so that we estimated the time constant (τ) of the primary component of $\dot{V}O_2$ kinetics. Finally, the normalized ΔHHb to $\Delta \dot{V}O_2$ ratio was obtained as index of the matching between muscular O_2 delivery and uptake (De Roia et al., 2012; Murias et al., 2011). **Results** $\dot{V}O_{2\max}$ increased by 9% ($29.9 \text{ mL min}^{-1} \text{ kg}^{-1} \pm 4.3$ - $32.6 \text{ mL min}^{-1} \text{ kg}^{-1} \pm 6.0$, $p<0.01$, ES 0.51) after 8 weeks of HIT. RCP (respiratory compensation point, per cent of $\dot{V}O_{2\max}$) significantly improved by 10% ($76.4\% \pm 8.3$ - $82.9\% \pm 4.9$, $p<0.05$, ES 0.97); τ decreased by about 26% ($26.97 \text{ s} \pm 5.54$ - $19.63 \text{ s} \pm 4.31$, $p<0.001$, ES 1.48), suggesting a substantial acceleration of $\dot{V}O_2$ kinetics; peak value of ΔHHb to $\Delta \dot{V}O_2$ ratio was smaller after HIT ($\sim 29\%$) (1.83 ± 0.63 - 1.23 ± 0.37 , $p<0.01$, ES 1.17). **Discussion** This study shows that 8 weeks of HIT were sufficient to induce a significant acceleration of $\dot{V}O_2$ kinetics during moderate intensity exercise and to improve the matching between muscular O_2 delivery and uptake in older, healthy men. These results suggest that the acceleration of the dynamic response of aerobic metabolism was due to an improved matching of O_2 utilization to microvascular delivery. **References** Williams AM, Paterson DH, Kowalchuk JM. STRESS TOLERANCE DURING FIGHTING FLIGHTS IS MEDIATED BY AEROBIC FITNESS AND BODY COMPOSITION

Oliveira Silva, I.1,2, Boullosa, D.A.1

Universidade Católica de Brasília: 1; UniEVANGÉLICA: 2

STRESS TOLERANCE DURING FIGHTING FLIGHTS IS MEDIATED BY AEROBIC FITNESS AND BODY COMPOSITION UCB (Brasília, Brazil):1; UniEvangélica (Anápolis, Brazil):2 **Introduction** Fighting pilots are exposed to high levels of stress during combat missions. Change in gravitational forces (G-force), among other factors, is the main source of stress. Recently, Dussault et al. (2009) reported a relationship between flight duration and sympathovagal acute adaptations as measured by means of heart rate variability (HRV) before and after training missions. However, the factors that influence on autonomic responses during flights have not been explored yet. Meanwhile, the

effect of physical conditioning and physical fitness on G-force tolerance is poorly understood (Bateman et al., 2006). Therefore, the aim of this study was to evaluate the autonomic responses during a simulated short flight, and to explore the influence of physical fitness and body composition on these responses (Boullosa et al., 2012). Methods Eleven male pilots were evaluated for body composition (body fat, %BF), muscular strength (5 repetitions maximum in various exercises, 5RM), and aerobic fitness (estimated maximum aerobic consumption, VO₂max) before performing a simulated fighting flight of 1 hour. Continuous R-R intervals were recorded with a heart rate (HR) monitor (RS800, Polar Electro Oy, Finland) 1 hr before, during, and 1 hr after the flight. Heart rate recordings were repeated in a control day for comparisons. Short- and long-term components of HRV from Poincaré plots, and HR complexity (SampEn) were subsequently analysed and compared within moments and days via analysis of variance. Correlation analyses were performed for verifying the relationships between selected parameters ($p < 0.05$). Results Short- and long-term components of HRV and SampEn were significantly reduced during and after flights. Significant correlations were observed between %BF and: short-term HRV ($r = -0.745$; $p = 0.009$), long-term HRV ($r = -0.708$; $p = 0.015$), and SampEn ($r = -0.606$; $p = 0.047$) during flights. Estimated VO₂max also correlated with SampEn during flights ($r = 0.782$; $p = 0.004$). No correlations were detected between muscular strength and autonomic responses. Discussion The current results provide evidence for the first time on the influence of body composition and aerobic fitness on stress tolerance to fighting flights in combat pilots. However, muscular strength, a factor previously proposed to mediate G-force tolerance, has not exhibited any influence on autonomic adaptations. From the current results, it would be suggested the importance of regular aerobic training for maintaining appropriate aerobic fitness and body composition for stress tolerance during fighting flights. DIRECT QUANTIFICATION OF CELL-FREE DNA KINETICS IN ATHLETES DURING CONVENTIONAL TREADMILL EXERCISE TESTING

Sterzing, B., Breitbach, S., Magallanes, C., Tug, S., Simon, P.

Johannes Gutenberg-University Mainz

Introduction: Kinetics of circulating cell-free DNA (cfDNA) concentrations during different kinds of physical activity is of growing interest in exercise physiology. Some recent studies showed rapidly increasing cfDNA concentrations following acute exercise and return to baseline within 1-2 hours of recovery (for review see Breitbach et al.1). We established a direct real-time PCR for the measurement of cfDNA from unpurified capillary plasma, which facilitates the investigation of cfDNA accumulations due to exercise. Here we tested the procedure on samples taken at a conventional treadmill test. Methods: 13 male handball players mean age 23.0 (1.9) and 13 male triathletes mean age 26.4 (3.2) performed an incremental treadmill test. They underwent a spiroergometry with lactate measurement to detect individual anaerobic threshold (IAT), maximal oxygen consumption, and ventilatory threshold (AT). Capillary samples to detect cfDNA were collected from the fingertip, lactate samples from the hyperemic earlobe, pre, during and several times post exercise. cfDNA was measured by direct quantification from unpurified plasma using a real-time qPCR assay. Results: cfDNA concentrations increased 9.8-fold during incremental treadmill testing, and nearly paralleled the kinetics of lactate. Significant elevations of cfDNA and lactate were found following the 10 km/h and 12 km/h stage, respectively. cfDNA concentrations correlated well with lactate, heart frequencies, oxygen consumption, energy expenditure and Borg values ($0.710 \leq r \leq 0.808$). No significant differences were revealed between handball players and triathletes with regard to the concentrations or the kinetics of cfDNA. Interestingly, in contrast to lactate cfDNA levels already increased consistently at the lowest intensity levels. Discussion: cfDNA accumulations could be triggered by stress hormones that likewise already increase at intensities below the anaerobic threshold.2 DNase concentrations might play a role in the clearance of cfDNA, since a recent study suggested an exercise dependent regulation of DNase I activity.3 In contrast to lactate or other metabolites, analyses of cfDNA might allow physiologically relevant conclusions on aerobic or intermittent exercise. VITAMIN D SUPPLEMENTATION AND HUMAN SKELETAL MUSCLE CONTRACTILE PROPERTIES

Owens, D.J., Webber, D., Impey, S.G., Tang, J., Donovan, T.F., Fraser, W.D., Morton, J.P., Close, G.L.

Liverpool John Moores University

Purpose – Evidence suggests that vitamin D may be a regulator of skeletal muscle function with improvements in function reported following correction of deficiency (Stockton, Mengersen, Paratz, Kandiah, & Bennell, 2011). Human trials investigating this hypothesis are however limited to predominantly elderly and clinical populations. We aimed to assess the effect of oral vitamin D3 in healthy, physically active, vitamin D insufficient young males upon skeletal muscle function. Methods - Participants ($n = 29$) received an oral dose of 10,000 IU.day⁻¹ vitamin D3 (VITD) or a visually identical placebo (PLB) for three months. Serum 25(OH)D and intact parathyroid hormone (iPTH) were measured at baseline and at week 4, 8 and 12. Muscle function was assessed in $n = 22$ participants by isokinetic dynamometry and percutaneous isometric electromyostimulation at baseline and at week 6 and 12. Results - Baseline mean total serum 25(OH)D was 40 ± 17 nmol.L⁻¹ and 41 ± 20 nmol.L⁻¹ for PLB and VITD, respectively. VITD showed a significant improvement in total 25(OH)D at week 4 (150 ± 31 nmol.L⁻¹) that remained elevated throughout the trial ($P < 0.005$). Contrastingly, PLB showed a significant decrease in 25(OH)D at week 12 (25 ± 15 nmol.L⁻¹) compared with baseline. Despite marked increases in total serum 25(OH)D in VITD and a decrease in PLB, there were no significant changes in any of our chosen muscle function outcome measures at week 6 or 12 for either group ($P > 0.05$). Conclusions - Elevating total serum 25(OH)D to concentrations > 120 nmol.L⁻¹, previously postulated to be an optimal serum concentration, has no effect on skeletal muscle function. We suggest that skeletal muscle function may only be perturbed in conditions of severe deficiency (< 12.5 nmol.L⁻¹) and future trials should aim to isolate individuals in this category for investigation. EXERCISE TRAINING AMELIORATES THE ACUTE EFFECT OF EXERCISE ON ARTERIAL FUNCTION

Dawson, E.A., Cable, N.T., Green, D.J., Thijssen, D.H.J.

Liverpool John Moores University

Introduction: Exercise training enhances vascular function, but the acute impacts of exercise are less clear. Some studies have demonstrated an immediate decrease in flow mediated dilation (FMD) following acute exercise, whilst others have reported no change. In this study we examined the possibility that this disparity may relate to training status. The aim of this study was therefore to examine whether exercise training can alter the immediate impact of an exercise bout on FMD. **Methods:** Ten male subjects (age: 24 ± 7 yr, weight: 79 ± 13 kg, height 182 ± 11 cm) were assessed on the first and final exercise session of a 2-week cycle exercise training program (80% HRmax, 3 X 30-min per week). FMD was assessed before and immediately after the exercise bout. A mixed linear model was used to examine the effect of an acute bout of exercise on FMD, pre and post 2 weeks exercise training. Post hoc t-tests were used to identify significance. **Results:** We found no significant main effects for an acute bout of exercise training on FMD, but we found a significant interaction ($P=0.016$). Post hoc t-tests revealed that, before exercise training, acute exercise induced a near significant decrease in FMD immediately after exercise (5.09 ± 1.41 to $3.34 \pm 1.92\%$, $P=0.07$). After training, this impact of an acute exercise bout was absent (3.32 ± 1.37 to $3.86 \pm 0.36\%$; $P>0.05$). Consequently, exercise training resulted in a significant attenuation of the immediate reduction in FMD following acute exercise. **Conclusion:** These data support previous findings which indicate that an acute bout of exercise causes an immediate decrease in endothelial function, as assessed by FMD. A short training program was able to prevent the decrease in FMD in response to an acute bout of exercise. Potential mechanisms underpinning the acute decrease in FMD include changes in oxidative stress, substrate exhaustion related to high shear, high blood pressure, shifts in artery baseline diameter and/or high sympathetic nervous activity. The protective effect of exercise training may relate to impacts on anti-oxidant status and/or improved nitric oxide production.

EVALUATION OF EXERCISE 'FIELD' TESTS <6 MIN WALK; SHUTTLE TEST; STEP TEST> IS ASSESSING EXERCISE CAPACITY IN COPD AND HEART FAILURE POPULATIONS

Hadi, A., Maki, A., Hussain, A.

University of Kuffa

Purpose: To evaluate the reliability and validity of the six-minute walk field test (6MWT), the incremental shuttle field test, and fixed height step field test with respect to their ability to predict exercise capacity in patients with COPD and heart failure populations. **Methods:** A systematic review was performed via 6 databases to assess relevant English language full-text articles published from January 1, 1990 to November 30, 2013. Participant characteristics, interventions, reliability, validity, and predictive value for each article with respect to exercise capacity as defined by peak VO₂ levels were extracted and compared. Quality Assessment of Diagnostic Accuracy Studies (QUADAS) scores were determined for each study. **Results:** Fifteen studies met the selection criteria. Comparison of the studies investigating reliability shows that the 6MWT has good reproducibility. The 6MWT showed high correlation with peak VO₂ levels, in contrast shuttle test demonstrated moderate correlation with peak VO₂ levels, and ability to forecast VO₂ (exercise capacity) reliant on distance walked. Cut-off distances vary from 350 to 510 meters relying on the study; if total distance walked remains equal or less than these values, the 6MWT and SWT retain their strong predictive value, whereas fixed height step test established moderate correlation with Peak VO₂ levels, the duration is variable (90 s-10 min), but the step height (23.0-50.8 cm) and stepping rate (22.5-35.0 steps/min) remain constant throughout the test. **Conclusion:** The field tests (6MWT, SWT, and step test) have good reliability, high validity, and a significant ability to predict exercise capacity in patients with COPD and HF.

PRACTICAL PRECOOLING IMPROVES THERMAL COMFORT DURING EXERCISE AND BETTER MAINTAINS AMBULATORY CONTROL IN HEAT SENSITIVE INDIVIDUALS WITH MULTIPLE SCLEROSIS

Maxwell, N.S.1, Young, M.1, Renesto, L.1, Lowe, S.1, Hayes, M.1, Freeman, J.2

1:University of Brighton; 2: University of Plymouth

Introduction: Exercise has been used as a rehabilitation strategy for people with Multiple Sclerosis (MS), but the associated rise in body temperature can exacerbate MS-related symptoms, precluding participation that may impact health. The aim of this study was to evaluate the efficacy of wearing practical cooling garments prior to exercise on thermal strain and comfort during exercise and whether this allowed heat sensitive individuals with MS to maintain ambulatory control post exercise. **Methods:** Six heat sensitive ambulatory individuals with multiple sclerosis (4 females, 2 males, age 48.3 ± 9.3 years, expanded disability status scale, 4.3 ± 1.0) completed a 5 min self-paced warm up and 20 min fixed intensity cycling at 50% peak oxygen uptake on three occasions in an environmental chamber set to a typical British summer climate (24.9 ± 0.7 degrees C, $52.0 \pm 4.8\%$ relative humidity). Exercise was preceded by 20 min of no cooling (Control), precooling via an ice vest (Vest), or via custom-made cooling shorts (Shorts) in a randomized order. Tests of walk performance (timed up-and-go, two minute walk), visual acuity, contrast sensitivity and subjective fatigue were assessed pre cooling and post exercise. **Results:** Vest and Shorts precooling reduced skin temperature prior to exercise compared with Control and this continued throughout exercise (Control, 32.3 ± 0.5 degrees Celsius; Vest, 30.5 ± 0.3 degrees Celsius; Shorts, 30.8 ± 0.9 degrees Celsius, $P<0.05$), but mean exercising core temperature was not different between conditions. Perceptually, cooling improved thermal comfort during exercise compared with Control (Control, 2.5 ± 0.3 ; Vest, 1.9 ± 0.3 ; Shorts, 2.0 ± 0.4 , $P<0.05$) and reduced thermal sensation (Control, 5.8 ± 0.4 ; Vest, 5.5 ± 0.3 ; Shorts, 5.4 ± 0.4 , $P<0.05$). Precooling reduced the decrement in the timed up-and-go walk performance post exercise (Control, 2.68 ± 0.79 s; Vest, 1.97 ± 0.92 s; Shorts, 2.12 ± 0.33 s, $P<0.05$), but did not ameliorate the reduction on post exercise 2 min walk distance, nor alter visual acuity, contrast sensitivity, subjective fatigue, or sweat rate. **Discussion:** In the absence of reductions in core temperature, both cooling garments reduced skin temperature and perceptual markers of thermal strain during submaximal exercise under modest heat stress. Practical cooling improves thermal comfort and can maintain ambulatory control post cycling that may encourage heat sensitive individuals with MS to participate in exercise.

EFFECT OF TESTING MODALITY ON THE ASSESSMENT OF THE VELOCITY AT MAXIMUM AEROBIC POWER IN RUNNERS AND SOCCER PLAYERS

Riboli, A.1, Limonta, E.1, Rampichini, S.1, Cè, E.1, Veicsteinas, A.1,2, Esposito, F.1

University of Milan

Introduction: The velocity associated with the maximum aerobic power ($\dot{V}O_{2\max}$) is an important physiological parameter in both laboratory and field settings (Billat et al., 1996). The aim of the study was to compare two different testing modalities (incremental ramp vs square wave tests) for $\dot{V}O_{2\max}$ assessment in two groups of athletes, runners and soccer players. The hypothesis is that during ramp test, due to the faster increase in work rate compared to cardiorespiratory and metabolic adjustments, $\dot{V}O_{2\max}$ could be overestimated compared to square wave test, where a steady state condition could be reached. **Methods:** Eight runners (RUN) and nine soccer players (SOC) reported to the laboratory twice to perform two maximum incremental tests: a continuous ramp protocol (1 km/h per min) and a discontinuous square-wave (SW) protocol (six work loads of 4 min each, with 5 min of rest in between), in random order, on a motorised treadmill for $\dot{V}O_{2\max}$ and $\dot{V}O_{2\max}$ assessment. At rest and during exercise, cardiorespiratory and metabolic parameters were collected breath-by-breath. Blood lactate concentration [La-] was measured at rest and at peak exercise. **Results:** $\dot{V}O_{2\max}$ was significantly higher in R1 compared to SW (SOC: 16.1 ± 0.3 vs 19.4 ± 0.4 km/h, +21%; RUN: 19.5 ± 0.3 vs 22.1 ± 0.3 km/h, +13%, for SW and R1, respectively; $P < 0.05$). No significant differences between groups and protocols were found in $\dot{V}O_{2\max}$ (SOC: 3892 ± 104 vs 3922 ± 423 ml/min; RUN: 4159 ± 115 vs 4170 ± 116 , for SW and R1, respectively), as well as in VE, VCO₂, [La-]peak and HR. **Discussion:** Despite similar $\dot{V}O_{2\max}$ values, $\dot{V}O_{2\max}$ was overestimated during the incremental ramp test compared to the square-wave test in both groups. This protocol-induced difference must be taken into account for athletes' evaluation and training planning, especially for soccer players. **References:** Billat V. and Koralsztein J.P. Significance of the velocity at $\dot{V}O_{2\max}$ and time to exhaustion at this velocity. *Sports Med.* 1996; Aug. 22(2): 90-108. **Contact:** andrea.riboli@unimi.it

CARDIAC PARASYMPATHETIC ACTIVITY AND RACE PERFORMANCE: CASE STUDY OF A TRIATHLETE

Stanley, J., D'Auria, S., Buchheit, M.

The University of Queensland

Introduction Longitudinal monitoring heart rate (HR) variability (HRV) has potential for assessing individual adaptation to training. The aim of this study was to examine whether changes in HRV are able to track adaptation to training and race performance. **Methods** An elite male long-course triathlete (28 years) was monitored during a 32-week competitive season. Resting HR was measured each morning and vagal-related indices of HRV (natural logarithm of square-root of mean squared differences of successive R-R intervals; $\ln rMSSD$ and the ratio of $\ln rMSSD$ to R-R interval length; $\ln rMSSD:RR$) were assessed. Daily training load was quantified using a power meter and wrist-top GPS device. Trends in HRV indices and training load were examined by calculating standardised differences (ES) week-to-week and in comparison to the overall mean. **Results** Positive adaptation to a training block assessed via training logs (i.e., all programmed sessions were successfully completed) was accompanied by an elevated $\ln rMSSD$ ($ES = +0.21$ to $+1.94$). Conversely, when the athlete was not coping, inconsistent trends in $\ln rMSSD$ were observed ($ES = +0.33$ to -0.71). A successful taper culminating in an optimal performance (i.e., overall competition performance relative to winner) was indicated by moderate decreases in $\ln rMSSD$ ($ES = -0.80$ to -0.91) and $\ln rMSSD:RR$ ($ES = -0.67$ to -1.08) in the week prior to competition. Conversely, a poor competition performance was indicated by trivial decreases in $\ln rMSSD$ ($ES = -0.04$) and trivial to small increases in $\ln rMSSD:RR$ ($ES = +0.15$ to $+0.41$) in the week prior to competition. **Discussion** To conclude, an increase in the relative level of $\ln rMSSD$ compared with the overall mean appears most indicative of positive training adaptation during periods of increased training load. A simultaneous reduction in $\ln rMSSD$ and $\ln rMSSD:RR$ during the final week preceding an competition was indicative of optimal performance.

INFLUENCE OF OXYGEN KINETICS ON PHYSICAL PERFORMANCE IN YOUTH SOCCER

Doncaster, G.1, Marwood, S.2, Drust, B.3, Iga, J.3,4, Unnithan, V.1

1Staffordshire University (UK), 2Liverpool Hope University (UK), 3Liverpool John Moores University (UK), 4The FA (UK)

Introduction The ability to perform, maintain and repeat high intensity actions, as well as the capacity to transition from low to high intensity activity frequently and efficiently, to minimise fatigue is essential in elite youth soccer. Quantifying these transitions could provide valuable information for coaches. Measurements of oxygen uptake kinetics ($\dot{V}O_2$ kinetics) may provide a useful insight into the relationships between the efficacy of transitions between workloads and physical performance in youth soccer. The aim of the study was to examine the relationship between $\dot{V}O_2$ kinetics, during work-to-work transitions, and physical measures associated with soccer match-play, within a group of highly trained youth soccer players. **Methods** Seventeen highly trained youth soccer players (age: 13.3 ± 0.4 y, Tanner: 3 ± 1) volunteered for the study. Players initially completed an incremental treadmill protocol to exhaustion, to establish ventilatory threshold (VT) and $\dot{V}O_{2\max}$ (59.1 ± 5.4 mL.kg⁻¹.min⁻¹). On the two subsequent visits, players completed a work-to-work protocol for the assessment of $\dot{V}O_2$ kinetics (moderate: 95%VT, severe: 60%D). Physical soccer-based performance was measured by a maximal Yo-Yo Intermittent Recovery Test Level 1 (YoYo-IR1) and the monitoring of total distance covered (TDC), relative high speed running (HSR) and very high speed running (VHSR), high speed efforts (HSReff), and very high speed efforts (VHSReff) during three 2x20min, 10v10 matches, using 10Hz GPS (Catapult, Australia). Partial correlations between $\dot{V}O_2$ kinetics and physical soccer-based measures were performed on the whole sample. Following this, an intra-group comparison was conducted, with performance in the maximal YoYo-IR1 being used as the criterion variable (Below Average (BA) n=9, Above Average (AA) n=8). **Results** Partial correlations revealed significant inverse relationships for the unloaded to moderate transition time constants (τ): YoYo-IR1 performance ($r = -0.58$, $P = 0.02$) and GPS variables (TDC: $r = -0.64$, $P = 0.007$, HSR: $r = -0.64$, $P = 0.008$, HSReff: $r = -0.66$, $P = 0.005$). Intra-group analysis found no significant difference between τ . However, differences in unloaded to moderate τ revealed a large effect size (Cohen's $d = 0.86$) (AA: 18.4 ± 4.4 vs BA: 24.1 ± 8.7 s). **Conclusion** The present study demonstrates that measures of $\dot{V}O_2$ kinetics may be an indicator of physical measures associated with soccer match-play and subsequently used as a measure to distinguish between those of superior physical performance, within a group of youth soccer players. Based on these findings, the physiological capacity to transition rapidly between workloads is a potential determinant of superior physical performance in highly trained youth soccer players. d031348b@student.staffs.ac.uk

UNCONTROLLED MOVEMENT DURING A SMALL KNEE BEND TEST IN YOUNG FOOTBALLERS WITH FEMOROACETABULAR IMPINGEMENT : PILOT CASE STUDIES

Botha, N.C.L.1,4, Warner, M.1,4, Gimpel, M.2,4, Mottram, S.1,3,4, Comerford, M.1,3, Stokes, M.1,4

University of Southampton

(1): Faculty of Health Sciences, University of Southampton, Southampton, UK (2): Southampton Football Club, Southampton UK (3): Movement Performance Solutions, Chichester, UK (4): Arthritis Research UK Centre for Sport, Exercise and Osteoarthritis, UK

Introduction Femoroacetabular impingement (FAI) is very common in footballers and causes hip pain, which may arise from abnormal morphologic features involving the proximal femur and/or the acetabulum (Ganz et al. 2003). Early diagnosis and treatment are important to prevent the development of osteoarthritis (OA) (Beck et al. 2005). Despite extensive publications on FAI, little is known regarding hip movement patterns, hip kinematics and uncontrolled movement (UCM) patterns associated with FAI, which may indicate biomechanical mechanisms of dysfunction to inform development of effective interventions. Methods Six male academy footballers aged 9–18 years with hip or groin pain, diagnosed with FAI on magnetic resonance (MR) imaging, were studied. A small knee bend functional test was performed, to observe the hip and pelvis for UCM patterns (Mottram & Comerford, 2008). Results In all six cases, poor movement control was observed. Hip flexion control appeared poor with participants unable to prevent or resist excessive hip flexion; with consistent patterns observed of the trunk leaning forwards and the hips moving into excessive flexion. Discussion These preliminary findings suggest flexion UCM patterns exist in academy footballers with FAI. Identifying and classifying these movement faults in footballers with FAI is essential if we want to effectively prevent and manage symptoms by controlling movement adaptations. Further studies are warranted to validate these findings against motion analysis technology and muscle activity using electromyography, and to further understand the mechanisms of movement dysfunction. Research is also needed to develop large databases of normal reference values in footballers and to document UCM patterns in musculoskeletal pain presentations. Since FAI has been shown to be strongly related to the development of hip OA (Agricola et al. 2013), it is vital that strategies are developed to prevent FAI and its progression to OA. THE DERMAL SUCTION INCREASES RANGE OF MOTION OF VOLUNTARY MOVEMENTS

Tsuji, J.1, Nakao, T.2, Shibutani, T.3, Ueno, H.4, Kurita, K.5, Takemura, M.6, Yamashita, Y.7, Tsuchiya, M.7, Kano, Y.7

1;Hyogo College of Medicine(Nishinomiya,Japan), 2;Kansai University of Health Sciences, 3;MU Company, 4;J Craft, 5;PCP, 6;Icchashi Clinic, 7;Riseisha College of Medicine and Sport

Background: For any physical activities, it is important to secure smooth movement of joints and proper range of motion. One of the factors relating to the smoothness of joint movements is thought to be the dermal mobility. For years, techniques such as massaging and application of external pressure were used for the purpose of myofascial releasing. These techniques focus on the application of pressure to skin, yet the possibility of using suction as an alternative technique has not been investigated as much. Purpose: The investigation was conducted to determine the effectiveness of increasing range of motion of voluntary movements by applying the dermal suction. Methods: Changes in range of motion of shoulders, elbow and neck regions of 10 healthy adult males were investigated. 30 kilopascal of the dermal suction was applied by using a round suction probe with 1 cm diameter. The probe was glided across the targeted muscles for five times with five seconds interval. For each subject, the range of motions of before and after the dermal suction, were measured by using an analogue goniometer. Result: By applying the dermal suction onto infraspinatus and teres minor, the range of motion for external rotation at the glenohumeral joint significantly increased from 60 ± 14.6 degrees to 68 ± 13.5 degrees ($P < .05$). The application to the medial side of the elbow joint significantly increased the range of motion of elbow flexion from 144.3 ± 3.6 degrees to 149.1 ± 4.6 degrees ($P < .05$). The suction was also applied to the left supraclavicular triangle, and found that the range of left rotation at the cervical vertebrae was significantly increased from 49.3 ± 3.3 degrees to 59.6 ± 6.2 degrees ($P < .05$). The paired t-test was used for the statistical analysis. Discussion: It is evident that the dermal suction applied at the same side of the joint which was moving toward would increase the mobility of skin and subcutaneous tissue, and allows those tissues to glide smoothly by reducing resistance within. For these reasons, it is inferred that the dermal suction increases the range of motion. Conclusion: The dermal suction increases range of motion of voluntary movement and induces the smoothness of movement. The method of using suction to increase joint mobility is a unique approach, and further refinement of this approach is hoped for.

EFFECT OF FATIGUE OF HIP ABDUCTORS ON THE SINGLE LEG QUIET STANCE

Savic, M., Sarabon, N.

S2P, science to practice, Ltd., Laboratory for Motor Control and Motor Behaviour

Introduction Postural stability in sagittal and frontal plane is in the domain of ankle and hip muscles (Winter, 1995; Bission et al., 2011) where hip muscles dominate in case of a single legged support. Capacity of the muscle to develop force is one of the parameters that contribute to the stabilisation and postural balance. Therefore the aim of presented study was to analyse the effect of fatigue of the hip abductors on the centre-of-pressure (CoP) during single leg quiet stance. Methods Thirteen healthy young adults participated. Each subject repeated the single leg quiet stance task on four time points: (i) before the movement tasks, (ii) after the hip abduction movement task with no load, and (iii) after the fatiguing hip abduction movement task with load. Both movement tasks were performed with one leg only. The single leg balance tests were performed for the exercised and non-exercised leg (non-involved). Each time the subject stood quietly for 30 s by each leg. The following parameters were calculated from the acquired CoP curve: (i) velocity, (ii) amplitude and (iii) frequency (anterior-posterior (AP) and medio-lateral (ML) direction respectively). One-way RANOVA was used to test statistical differences among the three conditions (pre, post – load and post – no load (i.e. factor time). A second factor (factor leg) was used to access the interactions between different parameters. Alpha was set to 0.05. Results CoP velocity and amplitude were highly significant ($0.002 < p < 0.013$) for non-involved leg in both directions. CoP frequency was significant for involved leg in AP direction ($p = 0.048$). Other frequency parameters were non-significant ($0.115 < p < 0.560$). There was no significance for other parameters of the involved leg ($0.071 < p < 0.994$). There was a significant interaction between leg and time ($0.011 < p < 0.028$) for CoP amplitude and frequency in AP direction. There were no statistically significant differences ($p > 0.05$) in any of the CoP parameters as regards factor leg. However, there was a

significant within-subject effect for factor time for CoP velocity (AP, ML and total) and amplitude (ML) ($0.001 < p < 0.010$). Discussion Regardless the fact, that only one leg was fatigued our hypothesis on central effects (i.e. cross-effect to the other leg) was at least partly confirmed. Namely, except for the evident effect of hip abductors' fatigue on CoP measures, the fatigue was also mirrored in the decreased stability during the single leg stance performed by the non-exercised leg. INFLUENCE OF VARYING ABDOMINAL DRAW-IN POSTURES ON TRANSVERSUS ABDOMINIS AND LUMBAR MULTIFIDUS ACTIVITY

Masahiro, W.1, Hiroshi, K.2, Akihiko, M.3, Shun, K.3, Koji, K.4, Takashi, H.1, Yasushi, M.1, Shumpei, M.3

1: TIU (Tsuchiura, Japan), 2: TUT (Tsukuba, Japan), 3: UOT (Tsukuba, Japan), 4: WU (Tokorozawa, Japan)

Introduction Recently, improving trunk stability to improve athletic performance has attracted attention. Various exercises of the deeper muscles like the transversus abdominis (TrA) and lumbar multifidus (MF) are essential to improve trunk stability. Draw-in exercises are effective for the same (Brown and McGill 2010). However, to the best of our knowledge, only a few studies have reported the relationship between posture and maximum muscle activity during TrA draw-in exercises, with no studies on MF contraction. Methods Eleven adult males (mean age 23.6 ± 2.4 years) of average fitness levels performed 7 postures and subsequently performed draw-in exercises: sitting pelvic neutral (S-N); sitting-pelvic anterior tilt (S-A); sitting-pelvic posterior tilt (S-P); standing position; supine; and prone and supine knee flex90. TrA and MF muscle activities were measured with wire and surface electrodes. To normalize the muscle activities, the maximum voluntary contraction (MVC) level was measured for each muscle and the root mean square (RMS) was calculated to obtain muscle activities. One-way analysis of variance with repeated measures was used to compare different muscle activities. Results During draw-in exercises, TrA muscle activity in varying postures showed no significant difference. However, the MF muscle activities were highest in the S-A and standing position than in all other postures. Discussion Previous studies state that the sacroiliac joint is stabilized by the simultaneous contraction of the TrA and MF (Ward et al. 2009). It was suggested that the S-A and standing positions are effective for selectively training the TrA and MF, which are essential for trunk stability. References Brown SH, McGill SM. MUSCLE-SKELETAL INJURIES PREVENTION OF LUMBAR REGION IN FEMALE CLEANING STAFF OF THE UNIVERSIDAD DEL FUTBOL Y CIENCIAS DEL DEPORTE

Gutiérrez Reyes, D.

Universidad del Fútbol y Ciencias del Deporte

Introduction. Muscle-skeletal injuries (MSI) are recurring health problems in cleaning workers, affecting the worker's life quality and causing high rates of absenteeism. The purpose of this study is to measure the effect of specific physiotherapeutic exercises muscle-skeletal injuries prevention of lumbar region in female cleaning workers of the UFD. Methods. A prospective longitudinal quasi-experimental study was conducted, including a sample of 6 full time female cleaning staff of the UFD. Measurements of different variables were performed. 1) Measurement of goniometric range of lumbar spine motion (flexion, extension and left and right lateralization and rotations) 2) Lumbar spine muscle strength (by Daniel's scale). After the initial evaluation specific sessions of physiotherapy exercises were performed. Subsequently, a new range of motion and muscle strength measurements were performed to assess the benefits. Results. Six subjects of female cleaning staff were evaluated ($n=6$) with an age average of 34 years. In the measurement of goniometric range motion, changes were presented in flexion from 71.66° to 81.66° (15.25% improvement), extension from 32.5° to 35° (7.33% improvement), left lateralization from 40° to 44.16° (13.66% improvement), in right lateralization from 38.33° to 41.66° (11.66% improvement), in right rotation from 40.83° to 41.66° (2.33% improvement) and left rotation from 40° to 43.33° (improvement 9.66%). In muscle strength assessment, 2 subjects passed from level 2 to 3, 2 subjects from 3 to 4 and 2 subjects had no change in order to flexion, 1 subject went from level 2 to 3, 1 subject from 3 to 4 and 4 subjects had no change in order to extension, 2 subjects passed from 3 to 4, and the rest remained unchanged in order to left lateralization, right lateralization, left rotation and right rotation. Discussion. According to the results, the increment of range motion amplitude is directly proportional to the strength increment is demonstrated, due to the implementation of specific physiotherapeutic exercises, muscle strength increased 1 stadium in those UFD workers whose were presenting values below the average, simultaneously mobility ranges had significant improvements in increasing joint motion in each studied at least 2%, respectively. THE EFFECTS OF DIFFERENT EXERCISE TRAINING PROGRAMS ON COGNITIVE PERFORMANCE: A STROOP TEST STUDY

Chi, L., Chu, C., Song, T., Chang, Y.

Ta Hwa University of Science and Technology

Introduction A growing number of studies have shown that long-term exercise training, particularly cardiovascular fitness training, is positively associated with cognitive functions in older individuals, and is specifically sensitive the executive function aspect of cognitive processing. However, whether various types of exercise training affect multiple types of cognitive functions is still unknown. The purpose of the present study was attempted in order to investigate the possible difference between effects concerning two types of exercise training programs on multiple cognitive functions. Methods Twenty-six healthy community dwelling elders (age = 64.42 yrs, $SD = 4.92$ yrs) were recruited and assigned into either a multi-functional exercise fitness group (i.e., exercise involving muscle strength, coordination, balance, agility and flexibility) or a dancing group (i.e., Folkdance). Two exercise programs were involved in these specific exercise contexts, twice weekly, for three months, whereby Stroop Tests, featuring color, neutral, and incongruent conditions, were employed to assess multiple aspects of cognition. Results The results indicated that there were significant time effects in both the exercise training group, regardless of the three Stroop Test conditions. A marginally significant effect on the Stroop incongruent condition, with the dancing group showing shortened reactions, compared to the multi-functional exercise fitness group, was also observed. Discussion These findings implied that short-length exercise programs, regardless of the exercise modes, enhanced multiple aspects of cognitive func-

tions. Moreover, it is possible that the exercise involved more coordinative features and that their corresponding cognitive demands would lead to more beneficial cognitive effects, particularly regarding executive functions. Contact chilin1215@hotmail.com

THE EFFECTS OF ACUTE AEROBIC EXERCISE ON STROOP TEST IN VIEW OF NEUROBIOCHEMICAL APPROACHES

Wang, C., Song, T., Wu, C., Chang, Y.

National Taiwan Sport University

Introduction The positive effects of acute aerobic exercise on executive functions have been proved by substantial literatures, and recently the mechanism underlying cognitive change responses to acute exercise has received attention. The brain derived neurotrophic factor (BDNF) is a member of the neurotrophin family and has been proposed as being related to acute exercise and cognition in certain animal-based studies. The purpose of this study is to examine the effects of acute exercise on the Stroop Test and whether serum BDNF concentration plays a mediational role in the relationship between acute exercise and cognition in humans. **Methods** Using within-subjects design, twenty-one healthy young adults were recruited. A Stroop Test was implemented, and serum BDNF concentration was measured immediately following the cessation of both an acute aerobic exercise condition and a reading condition, based on a randomized order. **Results** The results reveal that reaction times were significantly shorter in both congruent and incongruent conditions of the Stroop Test after acute exercise, relative to control treatment, whereas serum BDNF concentration was not significantly influenced by acute exercise. **Discussion** These findings suggest that acute exercise facilitated both the basic speed of processing aspect and the inhibition aspect of cognitive processing. However, the BDNF might not be substantial enough to warrant interpreting its potential influence regarding the positive effects acute exercise on cognitive functions. It is plausible that the positive effects of acute exercise on executive functions may be affected by other exercise-related neurobiochemical variables in human.

MALMÖ YOUTH SPORT STUDY – A SPORT PSYCHOLOGY PERSPECTIVE ON ACHIEVEMENT MOTIVATION.

Ingrell, J.

Education and Society

Introduction More and more elementary schools start to specialize towards sport and two reasons for this are often to 1) generate elite athletes and 2) stimulate to a more physical active lifestyle. Is it possible to predict how successful you are going to be in sport or if you continue to be physically active in your adult life? This PhD-project is part of the Malmö Youth Sport Studies, an interdisciplinary research project, with the main objective to study what possible physiological, psychological and social factors influence adolescents to continue doing sports during adolescence. The purpose of this specific thesis is to investigate and track/trace adolescents achievement goals, perception of motivational climate, behaviors, cognitions, and affects regarding sport participation. In addition, the aim is also to investigate if / how this changes over time and whether there are differences between students at elementary sports school and the students who attend regular elementary schools. **Methods** Longitudinal (three years); participants will three times a year respond to a number of questionnaires assessing peer, parents and coach motivational climate, and affective and behavioral responses in youth sport. Participants will be (n210) students, age 13-15, from various team and individual sports, attending sport schools and regular elementary schools. The first quantitative studies form the basis for selecting informants for the fourth qualitative study, using interviews as methodological approach. This enables a stratified random sample, meaning that the variables relevant to the research question can be included. **Results** While the study is in the initial stage no results have yet emerged. However, some preliminary findings regarding the first year of the longitudinal study will be presented and discussed during the conference. **Discussion** Results will be analyzed and discussed according to the purpose and the theoretical framework based on achievement goal theories in sport originated from Nicholls' (1989) two conceptions of ability (task and ego), Dweck's (1999) implicit theories of ability (entity theory and incremental theory), Elliot's (1999) approach-avoidance goal framework and Ames' (1992) work on motivational climate. **References** Ames, C. HEALTH-RELATED QUALITY OF LIFE IS RELATED TO CARDIORESPIRATORY FITNESS IN WOMEN AT INCREASED RISK FOR GESTATIONAL DIABETES

Engberg, E.1, Pöyhönen Alho, M.2, Koponen, A.1, Häggglund, H.1, Kukkonen Harjula, K.3, Peltonen, J.E.1, Tiitinen, A.2, Tikkanen, H.O.1

1: University of Helsinki (Helsinki), 2: Helsinki University Central Hospital and University of Helsinki (Helsinki) 3:UKK Institute for Health Promotion Research (Tampere)

Introduction Self-reported physical activity and objectively-measured cardiorespiratory fitness (CRF) may be differentially related to subjective well-being. The purpose of this study was to examine associations of health-related quality of life (HRQoL) and depressive symptoms with leisure-time physical activity (LTPA) and CRF in women who are at increased risk for gestational diabetes (GDM). **Methods** Twenty-one women planning pregnancy (age 33 ± 4 [mean \pm SD], BMI 30 ± 6) with prior GDM or BMI ≥ 30 participated. HRQoL was assessed with RAND-36 (Hays et al., 1993), depressive symptoms with EPDS (Cox et al., 1987) and LTPA (min/week) by a questionnaire. CRF was assessed by measuring maximal oxygen consumption (VO₂max) in incremental cycle ergometer test. **Results** LTPA was not related to RAND-36 or EPDS scores. However, VO₂max was positively associated with both physical ($r = 0.637$, $p = 0.003$) and mental ($r = 0.484$, $p = 0.031$) health summary scores of RAND-36 and negatively associated with EPDS score ($r = -0.546$, $p = 0.019$). Even after controlling for BMI, correlations of VO₂max with physical health ($r = 0.549$, $p = 0.015$), mental health ($r = 0.512$, $p = 0.025$), and EPDS score ($r = -0.503$, $p = 0.04$) remained. **Discussion** Higher level of CRF, but not self-reported LTPA, was associated with better HRQoL and lower depression scale score. Exercise training which improves aerobic fitness could be effective in improving HRQoL and in decreasing depressive symptoms in women at increased risk for GDM. **References** Cox JL, Holden JM, Sagovsky R. ANALYSIS OF THE INDIRECT EFFECTS OF THE QUALITY OF MOTIVATION ON THE RELATION BETWEEN NEED SATISFACTION AND EMOTIONAL RESPONSE TO EXERCISE

Teixeira, D.1,2, Palmeira, A.L.1,3

1 - ULHT - Universidade Lusófona de Humanidades e Tecnologias; 2 - ISCE - Instituto Superior de Ciências Educativas; 3 - CIPER - Universidade de Lisboa

Introduction: The study of the factors that may affect exercise adherence is warranted by the known benefits of exercise on several facets of health. The self-determination theory presents a rationale for the study of the motivational factors, in which the satisfaction of the basic psychological needs will lead to autonomous types of motivation, resulting on better adherence and psychological well-being (PWB). Therefore, this study aimed at the analysis of the indirect effects of the quality of motivation on the relation between need satisfaction and emotional response to exercise. **Methods:** The sample of this study was comprised by 904 fitness club members (353 Male, 548 Women, average attendance $M=3.32$; $DP=0.03$). Participants fulfilled the PNSE, BREQ-2 and SEES for the analysis of the basic psychological need satisfaction, motivational regulations and emotional response to exercise, respectively. The indirect effect analysis followed the procedures set forward by Preacher and Hayes (1). **Results:** The autonomous types of motivation and the need satisfaction were positively associated with PWB and negatively with psychological distress (PD, all $p<.05$). No associations were found with fatigue. The multiple mediation models showed that PWB was predicted by the needs satisfaction (26.1 to 29.2%). In these models we found a positive indirect effect for intrinsic motivation (all models) and a negative indirect effect for external regulation (autonomy and competence models). Therefore, the needs satisfactions increased intrinsic motivation which in turn increased PWB, while the needs satisfaction decreased external regulation which in turn reduced PWB. The competence and autonomy models also predicted PD (21.4 to 20.8%). In these models a negative indirect effect was found for amotivation and external regulation, in which the needs satisfaction decreased amotivation and external regulation which in turn decreased PD. **Discussion:** The satisfaction of the basic psychological needs related to exercise in the context of gyms and health clubs predicts better exercise emotional experiences. This association is partially explained by the increase in autonomous and decrease in controlled motivational regulations that the exerciser develops. These results warrant the need to have exercise professionals that are knowledgeable of how to create need support contexts for the exerciser, in order to increase the adherence and psychological well-being in the exercise settings. **References:** (1). Preacher, K. J., & Hayes, A. F. (2008). Asymptotic and resampling strategies for assessing and comparing indirect effects in multiple mediator models. *Behav Res Methods*, 40(3), 879-891.

INTERFERENCE OF PRACTICING YOGA IN THE MOODS.

Gomes de Amorim Pinto, A.C., Deutsch, S., Grimaldi, G., Damasceno Santos, F., Gorgatto Fraiha, A.L.

UNESP RIO CLARO

Introduction Yoga is a psycho-physical practice that has been taking more and more space as an ally to deal with emotional issues, since it provides the integration of man in the broadest sense, developing values and interfering on their behavior. Working the physical body to achieve higher levels of consciousness, in other words, aims towards a healthy, strong, perfect, immortal body, to be the appropriate place of the spirit that resides in it, since the goal is always to achieve samadhi (PAULA; BINDO, 2002). Moods, members of the mental health spectrum, consisting of affective states can influence a large apparatus of affective, cognitive and behavioral responses to a wide variety of events and seem to be involved in the instigation of self-regulatory processes based on internal and external sources (DEUTSCH, 1997). The present study examines the possible effects of the practice of Yoga and the moods in adults. **Methods** The study was conducted at UNESP-Rio Claro, in the extension project of Yoga. The sample consisted of 57 participants, all of them adults, 42 females and 15 males with an average age of 25.5 years. Was applied the Moods list Reduced and Illustrated - LEA - RI (Volp, 2000) for evaluation of moods and it is composed for 14 adjectives, with Likert scale of four levels and graphics figures facial expressions for each of the adjectives. The group attended a Hatha Yoga class with duration of 60 minutes. The class consisted of 4 steps: heating the joints, following psychophysical postures, breathing exercises and final relaxation. The participants completed the instrument before and after practice. **Results** The data were analyzed using the binomial analysis. The analysis of the change factor identified which adjectives or had no significant changes from pre to post-test and direction indicates whether there was an increase or decrease in intensity. **Discussion** There was significant improvement in the following moods: decrease in Heavy / Tired / Upset / useless / apathetic and afraid, and increased in slight / gentle, energetic and calm / peaceful. Thus, it is clear the interference in the practice of Yoga in improving moods. This confirms studies, such as (Deutsch, 1997), which shows similar results as the practice of physical activity and its psychological benefits. DEUTSCH, S. PSYCHOPHYSIOLOGICAL STRESS IN WOMEN WITH FIBROMYALGIA

Facco Stefanello, J., Jenichen, M.H.S., Góes, S.M.

Federal University of Parana

Introduction Fibromyalgia (FM) presents changes in the nociceptive system and psychological factors. The purpose of this study was to compare psychophysiological stress among women with and without FM. In addition, it was determined the relationship between psychophysiological stress with general features and FM symptoms. **Methods** Sixty women (30 in each group – FM and Control) participated in the study. Pain intensity and threshold, body mass index (BMI), physical activity level (PA), socioeconomic status, stress perception and symptoms, physiological stress responses (hair, salivary and plasma cortisol levels), and depressive symptoms were assessed. **Results** The FM group showed lower salivary cortisol level (15 minutes after awakening), and higher stress perception and level of depressive symptoms than Control group. In the FM group, 47% of the participants were at the Quasi-Exhaustion/Exhaustion stress phases ($X^2=28.8$; $p=0.001$). Furthermore, stress perception was related to BMI ($r=-0.39$) and depressive symptoms ($r=0.45$). Depressive symptoms were correlated to socioeconomic status ($r=-0.40$) and pain intensity ($r=0.39$). Salivary cortisol was related to socioeconomic status ($r=-0.39$). **Discussion** The low salivary cortisol level in the present study may indicate an exhaustion of stress response systems in FM (Riva et al., 2010). Indeed, half of the participants were at the quasi exhaustion/exhaustion stress phase, which can deplete the energy reserves (Lyon et al., 2011). However, no significant difference was found between groups in the hair cortisol (chronic stress biomarker), which goes in disagreement with Van Uum et al. (2008) findings with a chronic pain population. These differences may be due to methods discrepancy. There was no significant correlation between cortisol levels with stress perception, which suggests that cortisol does not

adequately reflect the perception of stress in FM. Further investigations are necessary in order to better understand chronic stress in FM and its consequences in FM symptoms, which may be useful when designing intervention programs. RISK-SEEKING/AVERSE STRATEGY FOR PERFORMING A COINCIDENT TIMING TASK.

Ota, K., Shinya, M., Kudo, K.

Laboratory of Sports Sciences, Graduate school of Arts and Science, The University of Tokyo

Introduction The best performance comes with risk in many sports. For example, the probability of scoring a point would be highest if a tennis player succeeds to hit a ball on line but he/she loses a point if the ball is out of the line even by 1 mm. The players are engaged in making a decision where in the tennis court to aim for under risk. In this decision-making, the player must take into account his/her own movement variability. For example, beginners who have large variance of ball bounce should aim for inner side of the court. Experts who have small variance of ball bounce should aim for edge of the line. Thus, to take appropriate strategy, the player should consider risk as well as variability in their motor output. Here, we investigated whether people can take optimal strategy under the particular risk condition in which high gain got closer to zero gain. **Method** Ten participants were performed a coincident timing task in which participants were rewarded with the highest score if they pressed a button just at a target time (2300 ms) but they did not get a score if they responded after the target time. The participants were required to make a decision which timing to press a button. An experimental session consists of 50 trials. The participants performed a total of 45 sessions for 9 days, with 5 sessions for day. The participants were instructed to maximize the total score in each session. In this task, optimal, that is, risk-neutral response time that maximizes the total score was calculated depending on each participant's response variance. Once we got a distribution of response time, we simply shifted until the highest total score was obtained. We defined risk-neutral response time as the difference between the shift size and the observed response time. We then compared the theoretically calculated risk-neutral response time with the observed response time. **Result** There were a discrepancy between the risk-neutral response time and the observed response time. Only two out of ten participants took risk-neutral strategy in day 1. Four participants responded later than the risk-neutral timing, suggesting that they took risk-seeking strategy which causes large number of miss trials. Four participants responded earlier than risk-neutral timing, suggesting that they took risk-averse strategy which causes a smaller expected score. These eight participants took suboptimal strategy in terms of reducing the total score. Only one out of eight participants completely acquired the risk-neutral strategy in day 9. **Discussion** These findings were consistent with studies in behavioural economics which claims that human decision-making is not always rational, and suggested that optimal strategy under risk is difficult to learn even after thousands of practice trials. THE INTERFERENCE OF MUSIC IN BALLROOM DANCE CLASSES IN PEOPLE'S HEALTH

Oliveira, D., Deutsch, S., Pinto, A.C.G.A.

Universidade Estadual Paulista - UNESP

Introduction: With the industrial and technological progress, problems arising from noise are now often identified, becoming a matter of concern for experts. Some practices physical activities such as dancing, exposes people to the presence of music not always in the most appropriate way. The present study aims to assess the levels of intensity and sound pressure during lessons ballroom dancing. **Methods:** 43 people participated in this study with an average age of 32, the research was developed in a classroom setting for 6 classes. To measure the sound pressure levels was used a digital noise meter (portable decibelimeter) Instrutherm brand, model DEC-490, was also a 'Sound Level Meter' application on a mobile phone handset that uses the same microphone to measure in decibels sound intensity and shows a reference sound pressure level. Both methods were utilized to ensure the accuracy of the measures, and with this app installed, it served like a baseline to ensure reliability of the data collection. The sound pressure level is measured in decibels - dB (A), with slow responses circuit, the tackle of the noise meter was calibrated before any classes and placed in the center of the room at a distance of approximately 140 cm from the ground. The group attended a Ballroom dance classes with duration of 1 hour and 15 minutes. The data collected were done three times after ten seconds of stabilization, and considered as the final result, the average of three readings. To collect the sound pressure levels, certain times based on the method of teaching the teachers were stipulated. **Results:** The sound pressure level during the ballroom dance classes, mean noise level of 81 decibel in accordance with and 87.6 were found, according to the Sound Level Meter app. **Discussion:** According to Fusco (1989) such high levels can cause a lot of reactions, such as insomnia, irritability, fatigue, malaise, and hearing loss. Therefore it is important that teachers of ballroom dancing to be aware and be careful with the volume of the music of their classes, so the hearing health of their students are preserved. THE RELATIONSHIP BETWEEN PERFECTIONISM AND PERFORMANCE FAILURE AT NATIONAL TRACK AND FIELD ATHLETES

Erkan, M.1, Cepikkurt, F.2, Kale Kizildag, E.3

1:Anadolu University,2:Mersin University,3:Eskisehir Sport Club

Introduction: Perfectionism is considered to be personality characteristics that reflect an individual's obsessive pursuits of exceptionally high standards and overly critical appraisals of performance (Hewitt, Flett, 2001). In early researches perfectionism seemed as one-dimensional, but later, this psychological construct was developed into multidimensional model of conceptualizations (Frost, et al, 1990; Flett, Hewitt, 1991). The maladaptive perfectionism is the negative aspect of perfectionism and have a positive correlation with fear of failure, anxiety, burnout etc. Fear of failure and continuous search for success are other features of perfectionism. When perfectionist individuals perceive any kind of failure in their work, they begin to evaluate themselves negatively and this results in harsh self-criticism (Shafran et al, 2002). For perfectionists, performance is not only evaluated in the context of achieving a goal, but also evaluated in the context of striving. The purpose of this study was to determine the relations between perfectionism and fear of failure at national athletes. **Methods:** Volunteered 33 athletes (22 males, 11 females) from track and field national team, aged between 16 to 36 years

[Magelyear]=23.52±5.12] participated in the study. Multidimensional Perfectionism Scale for Athletes-MPS (Dunn et al, 2002) and Performance Failure Appraisal Inventory-PFAI (Conroy et al, 2002) were used. MPS consists of 30 items and has 4 subscales. In Turkish version of MPS, factor analysis has supported the Scale's 3 factor (concern over mistakes, perceived parental pressure, personal standards) and 19 items. PFAI consists of 25 items and has 5 subscales. Pearson Moment Correlation Coefficients was used to determine whether there was a relationship or not between perfectionism and fear of failure. Results: The positive correlations were found between subscales of perfectionism and fear of failure ($p < .001$). Personal standards subscales have no correlation with fear of experiencing shame and fear of devaluing one's self estimate. Discussion: Results show that negative perfectionism subscales have positive correlation between fear of failure and this findings supported by some of the previous findings (Flett, Hewitt, 2006; Frost et al, 1993). According to Atkinson (1964), desire to achieve perfection leads to fear of failure; and these negative thoughts leads to stress. Also, perfectionistic persons who live fear of failure in sport area, may have problems in academic and social area too. Consequently, it can be said that perfectionism have positive and negative aspects, and the negative aspect of perfectionism also associated with negative thoughts and feelings. INFLUENCE OF PACED BREATHING ON COMPETITIVE ANXIETY AND GYMNASTICS PERFORMANCE

Pizzera, A., Laborde, S., Dederer, V.

German Sport University Cologne

Introduction An essential skill necessary for optimal sports performance is the ability to regulate one's emotions during critical moments of competition (Zachowsky & Baltzell, 2001). Reactions due to anxiety often result in a high state of arousal. A study with basketball players showed that systematic training of paced breathing can reduce anxiety and therefore lead to positive performance (Paul & Garg, 2012). The aim of this pilot study was to examine the effectiveness of this method with younger athletes in gymnastics. **Methods** Six female squad gymnasts (all eight years old) took part in the study. In a pre- posttest design subjective (state anxiety) and objective (heart rate, HR and performance) parameters were assessed. One hour before competition start we measured HR and competitive anxiety with a questionnaire specifically designed for children in gymnastics. Between the two competitions we conducted a 5-week breathing training for two times per week (each lasting 5 minutes). In this training the gymnasts were asked to breathe according to a visually presented increasing (inhalation) and decreasing (exhalation) bar on a computer. **Results** Due to the small sample size, only descriptive statistics are presented. From pre- to posttest, all gymnasts except one showed reduced somatic and cognitive anxiety (17.33 to 11.17 and 14 to 9.5, respectively) and enhanced self confidence (22.67 to 24.67). HR was reduced for all gymnasts, on average by 7.74 beats/minute. Competition performance slightly decreased (56.47 to 54.75). **Discussion** Paced breathing as a form of psychological skills training can be implemented very well into the training of young athletes. The results of the current study provide preliminary indications of its effectiveness with regard to physiological and psychological parameters. However, there seems to be no influence of paced breathing on gymnastics competition performance in this sample. Further research should aim to investigate paced breathing effectiveness on different aspects of sports performance. **References** Paul, M. & Garg, K. (2012). A DYNAMIC NETWORK MODEL OF EXPERTISE AND EXCEPTIONAL PERFORMANCE IN SPORTS

Den Hartigh, R.J.R.1,2, Van Geert, P.L.C.1

1: University of Groningen (The Netherlands), 2: Montpellier 1 University (France)

Introduction The study of expertise and exceptional performance covers a range from "beginner" to world-class performance. While developing sport expertise a variety of interacting internal and external performance factors are involved, which may differ between athletes (Phillips et al., 2010). The productivity distribution of athletes who ultimately reach expertise is highly right skewed. For instance, 30 male tennis players won 1 or 2 grand slams since the 90's, and one exceptional player won 17 grand slams. We aim to propose a model that accounts for the multidimensionality and idiosyncratic developmental patterns of expert ability growth, as well as the highly skewed distribution of expert products at population level. **Methods** We departed from an existing dynamic model of ability growth (Van Geert, 1991), defining change based on three parameters: 1) stable resources (e.g., genetic constraints), 2) variable resources (e.g., coaching, motivation), and 3) proportion of change over time. However, given that the variable resources are also influenced by the ability growth and by each other, an athlete's ability growth is better conceptualized as emerging from a dynamic network of connected components, defined as a set of coupled logistic growth equations (Van Geert et al., 2014). With computer simulations we first tested properties of individual expert ability growth. Second, we combined the network model with a model of product generation to test whether we could also predict the highly right skewed distribution of expert productivity. **Results** Model predictions based on simulations of many athletes revealed a wide variety of trajectories to reach expertise. Related to this, we found a low correlation between early indicators and later exceptional performance. Moreover, combining the network model with a (e.g., Poisson) product model we found highly right skewed distributions of expert productivity among the simulated athletes. **Discussion** The dynamic network model provides accurate predictions of key properties of expertise and exceptional performance (Simonton, 2001). This means that expertise and exceptional performance in sports likely emerge from a dynamic network model, which has important implications. For instance, the idiosyncratic developmental patterns and the lack of early indicators for later performance cast doubt on current practices of early talent detection and the search for (isolated) variables explaining expert performance. **References** Phillips E, Davids K, Renshaw I, Portus M (2010). THE RELATION OF EXERCISE MODALITY AND COGNITIVE FUNCTION IN MIDDLE-OLD AGED ADULTS

Wu, C., Chen, C., Chi, L., Chang, Y.

National Taiwan Sport University (Taoyuan, Taiwan)

Introduction Aging has been recognized as a main risk factor for causing cognitive decline that impairs significantly the quality of life in older adults. Therefore, how to maintain and promote cognitive functions in the population has received much recent attention. Previous

studies have pointed out that exercise has positive effects on cognitive functions. Notably, a majority of studies have examined aerobic types of exercise; however, the effects of other types of exercise are as yet undetermined. The purpose of this study was to examine the relationship between two types of exercise and cognitive functions in middle-aged adults. Methods Sixty-six adults, ages 45 to 65 years, were recruited and categorized into an aerobic exercise group (e.g., running, swimming), a complex exercise group (e.g., martial arts, gymnastics), and an irregular exercise group, based upon their exercise habits. The cognitive function was assessed by a Stroop Test, including both congruent and incongruent conditions with block design. Results The results revealed that there were significant differences resulting from the Stroop congruent condition, with both exercise groups showing shortened reaction times relative to the control group. Additionally, the complex exercise group demonstrated a shortened reaction time on the Stroop incongruent condition, compared to the aerobic exercise and control groups. Discussion These findings replicated those of previous studies that found a positive relationship between exercise and cognition, and additionally suggested that exercise with more cognitive demands may be linked to better cognition, particularly that involving more attention control. EVALUATION AND TRAINING OF ATTENTION IN SPORTS AND MUSIC USING HEG-FEDBACK - A RESEARCH APPROACH

Stucke, C., Hamacher, D., Schmidt, A., Wolfgram, H.J., Stucke, S.

Otto-von-Guericke-University Magdeburg, MediTech GmbH, Manhattan School of Music

Introduction Peak performances in sports and in music are based on the ability to focus on relevant cues and ignore irrelevant information. If the situation changes rapidly, attention must also change rapidly. Currently there are hardly any studies that analyze the attentional focus during the movement. The aim of our study is to investigate if near infrared based hemoecephalography (Toomin, 2002) is an effective method to analyze the attention during various movements. Methods The non-invasive HEG measures hemodynamic changes in the prefrontal cortex (PFC) by detecting changes in blood oxygenation. This can be describing neuronal activity in PFC (Serra-Sala et al., 2012). The PFC is a particularly important part of the brain to control executive function such as attention. Four tests were designed to analyze attention during: start in sprint (test 1; n=5), contextual cueing task with handball player (test 2; n=31), diagnostic of trunk strength (test 3; pre-posttest, n=32), playing music of various difficulties by violin (test 4; comparison mental vs. practical performance, n=1). Results The HEG-ratio graphs showed task specific patterns which are individually reproducible. The HEGR value increased in athletes with a good start at the command "ready" and decreased rapidly during the running motion. In contextual cueing tasks the HEGR value and the standard deviation decrease too. Further we found a correlation between the HEGR graphs and the muscular load in trunk strength diagnostic. If the violinist played with high attention the HEGR value and the standard deviation increased. Discussion We assume, that movement which requires little or no attention (routine movement, flow) low HEG-ratio values and standard deviation occur. If attention resources are necessary (non-routine procedures) the HEG-ratio values and standard deviation increase. The results can be explained by a model of the control of action proposed by Norman and Shallice (1986). Depending on the degree of task difficulty willed or automatic actions are controlled at different levels: The contention scheduling mechanism regulates at a lower level action involves a well-learned, rehearsed or automatic response. The supervisory attentional system controls attention to the relevant stimuli, switches attention between different processes and analyzes contents of memory storage when the action is novel, complex or a non-routine procedure. Our aim is to develop specific biofeedback programs that support athletes / musicians in their attention control. References Norman D, Shallice T (1986). Plenum, 4, 1-18. FRONTAL MIDLINE THETA AND SENSORY MOTOR RHYTHM DIFFERENCES BETWEEN GOOD AND POOR GOLF PUTTING PERFORMANCE.

Yi Ting, C., Cheng, M.Y., Huang, C.J., Hung, T.M.

National Taiwan Normal University

Introduction Attention is very important for precision sports. Frontal midline Theta (Fm θ) and Sensory Motor Rhythm (SMR) have been associated with different attention processes. Specifically, Fm θ was found as an indicator of top-down process and stable sustained attention in previous studies whereas SMR was related to the automaticity process of attention. Although previous studies have shown the relevance of Fm θ and SMR to performance in precision sports, no studies have directly compared these two indices of attention during sport performance. Therefore, this study aims to compare Fm θ and SMR activity between best and worst putting performance in expert golfers. Methods 18 skilled golfers were recruited for this study. The participants were instructed to do their best during 40 self-paced putts. This study selected 12 best and worst putts to compare the difference in Fm θ and SMR fluctuation during the pre-shot period. Results Lower Fm θ power for best performance compared to worst performance at the -0.5s epoch was observed. Moreover, worst performance showed intensely increased Fm θ power from the -1.5s to -0.5s epoch. However, no significant differences were observed between best and worst performance in SMR power. Discussion This study found that fluctuation of Fm θ , not SMR, is more associated with golf putting performance. Skilled putting performance is associated with lower Fm θ power in this study. The finding is consistent with previous studies (Kao, Huang, & Hung, 2013). Lower Fm θ indicates less top-down attention engagement and may suggest higher automaticity process during putting processes. The finding of no SMR difference between the best and worst performance may suggest that SMR is the basic component in the skilled level. Future studies are warranted where a direct manipulation of the EEG components through neurofeedback trainings further examine a causal relationship. References Buschman, T.J., & Miller, E.K. (2007). Top-down versus bottom-up control of attention in the prefrontal and posterior parietal cortices. Science, 315, 1860-1862. PubMed doi:10.1126/science.1138071 Cheng, M., Lo, L., Huang, C., & Hung, T. EFFECTS OF TABLE TENNIS ON COGNITIVE FLEXIBILITY IN THE ELDERLY

Liu, J., Chuang, L., Hung, T.

National Taiwan Normal University

Introduction Previous studies have found that cognitive control declines with age and that exercise can slow the rate of cognitive deterioration. However, most of the investigations focused on aerobic physical activity while opened-skilled exercises such as table tennis,

which requires more strategic thinking process, are less studied. Therefore, the main purpose of this study was to examine the effect of table tennis exercise on cognitive flexibility in elders. Methods Twenty-four healthy people aged between 65 and 75 years old were recruited for this study. All participants were randomly assigned to either an experimental group (table tennis, N=12), or a control group (no exercise intervention, N=12). Participants in the experimental group accepted table tennis training two times a week for 12 weeks. Each bout of training lasted approximately 40 minutes. Cognitive tasks (Task switch) were administered before and after the intervention and EEG data was collected during the task. Behavioral data included global cost, local cost, accuracy, and intra-individual variability of RTs. All behavioral data was subjected to 2 * 2 (pretest and posttest * group) two-way ANOVAs and EEG data was assessed by 2 * 2 * 2 (pretest and posttest * group * context) ANOVA with mixed-design. Due to incompleteness of the experiment, only data from part of the participants (table tennis, N=12), or a control group (no exercise intervention, N=12) was reported. Results Although no any significant interaction or main effect was found, the experimental group demonstrated the trends of larger N2 (FCZ) and P3 (PZ) amplitude in post-test rather than pretest. No such trend was found in the control group. Discussion The preliminary analysis exhibited a trendly larger N2 and P3 amplitudes after the four months of table tennis exercise whereas no such trend was observed in the control. Higher N2 and P3 amplitude are suggestive of increased investment of cognitive control and more allocation of attentional resource, in the table tennis group. Nevertheless, such interpretations cannot be confirmed until data is obtained from all the participants. Contact [Hana781106@hotmail.com]

RAMBLING AND TREMBLING DECOMPOSITION OF SWAY REVEALS EFFECTS OF FOCUS INSTRUCTIONS IN QUIET STANDING

Wünnemann, M., Neuhaus, D.

University of Paderborn

Introduction The constrained-action-hypothesis (Wulf, McNeven & Shea, 2001) implies that focusing attention on aspects of the movement process disrupts automatic control processes and hence leads to worse performance. However, Wulf, Töllner & Shea (2007) and Neuhaus (under review) did not find focus effects in quiet standing. Maybe, the absence of focus effects results from the choice of dependent variables. Root mean square may not be sensitive for differences in automatic control processes. The rambling and trembling decomposition (Zatsiorsky & Duarte, 2000) might reveal effects that could not be detected by other measures of sway, because the trembling component is supposed to reflect more automatic processes. Here we present a post-hoc analysis of data (Neuhaus, under review) concerning the effects of different attentional focus instructions with or without additional instructions. **Methods** 19 subjects (12 f/7 m, mean age = 24.7 years, SD = 3.1 years) completed 4 test blocks (each 3 x 30 s) of bipedal standing on a force plate. The 4 test blocks differed in the instructions used. A 2-factorial design was applied, factor 1: focus instruction (FI) (internal (int)/external (ext)); factor 2: additional instruction (AI) (without/with). The FIs related to the feet (int) or to marks underfoot (ext). The AI was '...try to apply the same pressure on them'. Dependent variables are the standard deviations (SD) of the rambling and trembling components in medio-lateral (ml) and anterior-posterior (ap) direction. **Results** There are larger SDs for trembling in ap under the use of int FIs, $F(1, 18) = 10.4, p = .005$, part. $\eta^2 = .367$, larger SDs for rambling in ap with AI, $F(1, 18) = 6.1, p = .024$, part. $\eta^2 = .252$, and trembling in ml with AI, $F(1, 18) = 8.0, p = .011$, part. $\eta^2 = .308$. All other main effects and interactions fail to reach significance. **Discussion** The rambling and trembling decomposition revealed effects of focus instructions that were not detected by other methods. These effects correspond well to the constrained-action-hypothesis. So, the rambling and trembling decomposition might be suitable for the analysis of disrupted automatic control processes in quiet standing. **References** Neuhaus D (under review). EVALUATION OF THE MENTAL SKILLS OF JAPANESE ELITE ATHLETES

Murakami, K.1, Hiraki, T.2, Uto, M.3, Arai, H.4, Tachiya, Y.5

1:Tokyo University of Science, 2:Nihon University, 3:Toin University of Yokohama, 4:Hosei University, 5:Japan Institute of Sports Sciences

Introduction Psychological variables are very important for success in sports. Indeed for the same physical, technique and tactics characteristics, some athletes achieve excellent performance, while also fail to emerge. In Japan Institute of Sports Sciences (JISS), as a part of the medical and fitness checkup prior to the Olympic Games, mental skills of the athletes were assessed. One key factor in bringing an athlete's capability into full play is mental skills. Therefore, the purpose of this work is to study the mental skills of Olympians and compare them with those of less successful players. **Methods** In collaboration with the JISS, we recruited a sample of 1965 elite athletes, divided into Olympians (n=915) and national level (n=1050). Olympians representing 49 different Olympic sports served as participants. The instrument used was the Diagnostic Inventory of Psychological Competitive Ability for athletes (DIPCA.3, Tokunaga, 2001). The questionnaire includes 52 items and 12 mental skills scales grouped under 5 broader conceptual components. To evaluate the differences between the two sub-samples we conducted a multivariate analysis of variance (MANOVA) using level of competition and gender as independent variables, and the average scores of scale as dependent variables. **Results** Results of analysis revealed several differences between psychological characteristics of athletes as function of their performance level. Significant differences appeared in almost scales. Means comparisons revealed that Olympians exhibited superior mental skills than national players in patience, aggressiveness, volition for self-realization, self-control, ability to relax, concentration, confidence, decisiveness, predictive ability, and judgment. By contrast, Olympians scored slightly lower in volition for winning and cooperation. **Discussion** This study has shown that there are significant differences in mental abilities depending on the level of competition. Olympians were better than national athletes in patience, aggressiveness, volition for self-realization, self-control, ability to relax, concentration, confidence, decisiveness, predictive ability, and judgment. Findings corroborate the results of previous studies (Gould et al., 2002) comparing mental skills of elite and non-elite athletes. The knowledge of the features of elite athletes may be useful to provide mental training programs relevant to successful performance. **References** Gould D, Greenleaf C, Chung Y, and Guinan D 2002 A Survey of U.S. Atlanta and Nagano Olympians: Variables Perceived to influence Performance. A QUALITATIVE INVESTIGATION OF COACHING MENTAL MODEL OF EXPERT ROWING COACHES IN JAPAN

Kitamura, K., Suzuki, D.

Tohoku University

Introduction The exceptional levels of coaching require certain types of environmental support, special experiences, and appropriate motivational encouragement (Salmela, 1994). In this context, Salmela suggested that the most important role of the coach is to make the athletes center their efforts upon deliberate practice and to minimize the resource, effort and motivational constraints which impede the skill development of the athletes (Salmela, 1994). The purpose of this study was to explore the coaching mental model of expert rowing coaches in Japan. **Methods** Participant selection was limited to expert coaches who had the coaching experience of Japanese national rowing team. Six coaches served as participants for this study. Their average age was 36.3 years old, and they had an average of 9.7 years of coaching. In-depth, open-ended interviews were conducted with each coach. Interviews ranged between 60 to 90 minutes, were recorded with the permission of the participants. The interviews were systematically transcribed verbatim immediately after the completion of each interview, and total of 473 meaning units were extracted from the data set. The data was decontextualized using an inductive procedure for analyzing unstructured qualitative data (Côté, Salmela, Baria, & Russell, 1993). **Results** The inductive analysis process resulted in regrouping these interview transcripts into three categories (continuous self-change through a reflection, focus on a learning process, and orientation toward self-growth), and eight sub-categories (attaching meaning to awareness, self-accept, vision, rationalization, feedback, communication, self-determination, and self-coaching). **Discussion** All of the participants faced a lot of problems and built up their unsuccessful experiences throughout their coaching career. Consequently they realized the needs of continuous self-change to develop their coaching expertise. Evidence of the coaches' mental conflicts to the coaching activities with athletes also surfaced throughout the training and race. This study found significant agreement between the perceptions of the concepts on how coaches evaluated their coaching activities in relation to performance enhancement of athletes and how this support affected their development of coaching excellence. The strong relationship between three categories indicates that coaches construct the practice environment in a manner that maximizes athletes' commitment to daily effortful practice. **References** Côté, J., Salmela, J.H., Abderrahim, B., & Russell, S.J. PERCEIVED MOTIVATIONAL CLIMATE RELATED TO TYPE OF MOTIVATION IN MEXICAN ATHLETES

Cocca, A., Cocca, M., López Walle, J., Ceballos Gurrola, O.

Autonomous University of Nuevo León

Introduction Motivation is considered one of the main factors for enhancing sports performance (Gillet et al., 2010). As a consequence, creating a positive motivational climate during training and sports events should be a primary aim for coaches, in order to provide favourable conditions for athletes to perform at their best (Smith et al., 2007). The aim of this study is to assess and compare perceived sports climate among several teams at Universidad Autónoma de Nuevo León (UANL), Monterrey (Mexico). **Methods** 131 athletes (64 men, 67 women) belonging to representative teams of UANL from seven sports disciplines filled in the Spanish version of Sport Climate Questionnaire (Balaguer et al., 2009) with Likert scale 1-to-7. ANOVAs and Tamhane tests were carried out in order to assess differences by sports discipline and gender. **Results** Average perceived sports climate was medium-high for all disciplines. The lowest score was obtained by volleyball male players (4.04), whereas fencing male athletes reached the highest (5.76). No significant differences were found comparing by gender, discipline, or by the combination of both. **Discussion** All athletes obtained medium-to-high values of perceived sport climate, which could indicate that they enjoy training and competing for their respective teams. According to literature, positive climate in sports could lead to enhanced performance and reduced anxiety and stress during trainings and competitions (Smith et al., 2007). Our outcomes could partially explain the positive results these athletes obtained in the past competing season, culminating with UANL reaching the highest number of medals in 2013 Mexican University Olympics (36 golden, 12 silver and 40 bronze), with a difference of more than 50 medals compared to the second placed institution. Coaching training and style at UANL could represent a quality model for other Mexican sports clubs and institutions aiming to improve athletes' psychological condition and performance in training and competition. **References** Balaguer I, Castillo I, Duda J, Tomás I. DELIBERATE PRACTICE AND SPORT EXCELLENCE: A DIARY STUDY WITH PORTUGUESE ELITE ATHLETES

Matos, D.S.1, Ferreira, M.J.1, Cruz, J.F.1, Almeida, L.S.2

University of Minho

Introduction The engagement in intensive and extended deliberate practice is a major assumption of the expert-performance approach in studying elite athletes. The purpose of this study was to examine the quantity and quality of practice activities in a sample of Portuguese elite athletes. The main aims were to explore how a "typical work week" of these athletes is organized, how their daily activities are perceived in terms of the qualities demanded by the "10-year rule" of necessary preparation in order to attain expertise, testing for the association between retrospectively estimated amounts of practice and "actual" practice and assessing their perceptions and characteristics of deliberate practice. **Methods** 9 purposefully selected Portuguese top athletes, ranging from 18 to 35 years old ($M=24.7 \pm 5.4$), of both genders, competing at the highest international level, who excelled in several sports (individual vs. team) completed biographic data and maintained diaries over a 7-day period. **Results** The analysis of the time spent by athletes in different types of daily activities (in or out of sport context), indicated that, in average, athletes spend more time in sport-specific practice activities. Such activities are highly evaluated in terms of enjoyment, required physical effort, mental effort, relevance to performance, and general satisfaction. Additionally, data seem to support, for the most of participants, the so-called "10-year rule" of necessary preparation and also the consistency between athletes retrospectively estimated amounts of practice (biographic data) and "actual" practice (diary). These results were independent of gender, type of sport (individual vs team) or even international experience of the athletes. **Discussion** The findings of this investigation provides some support for previous assumptions of deliberate practice and expert performance research (Ericsson, et al., 1993; Ericsson & Lehmann, 1996; Hodges et al., 2004), confirming the importance of the intensity and characteristics of sport-specific practice activities as a crucial factor in the qualitative difference between levels of expertise (e.g., Baker et al., 2005; Ward et al., 2007). Limitations and implications arising from this study are discussed. **References** Ericsson, K. A., Krampe, R., & Tesch-Römer, C. (1993). *Psychological Review*, 100, 363-406. Ericsson, K. OBSERVING COMPLEX DANCE MOVEMENTS CAN ACTIVATE EXECUTIVE-COGNITIVE NETWORK IN THE ELDERLY

Kimura, K.

Tokyo Denki University

Introduction Recently, dance exercise for the elderly has been focused on as being a beneficial exercise for maintaining and improving cognitive function. These reports suggested that the unique aspects of task complexity with regard to dancing effectively facilitate neuronal networks responsible for cognitive behavior. However, it still remains unclear whether movement complexity of dance can directly affect on cognitive networks. The present study was conducted to demonstrate the correlation between dance complexity and prefrontal-parietal activation responsible for executive cognitive function while participants observed and mentally rehearsed a full-body dance performance. **Method** Functional magnetic resonance imaging (fMRI) was employed to identify the prefrontal-parietal activation while participants were observing a prerecorded movie of a dance performance. The movie presented full-body dance movements demonstrated by an expert dance instructor. Thirty-four elderly people aged 65-78 years old participated in this study. None of the participants had any dance experience prior to this experiment. The participants were randomly assigned into two groups: one group focused on full-body movements and this group's participants were asked to mentally perform the instructor's upper and lower body dance choreographs while watching the video. The second group was likewise instructed to mentally perform only the upper body choreographs while watching the same full-body dance performance in which the first group had also watched. All participants underwent fMRI scanning as they watched the dance movie. **Result** In the results of brain imaging analysis, overlapping activations for both groups were found in the primary motor and the somatosensory cortices. However, the group which focused on full-body movements showed significant activation in neural regions compared with the group which focused only on upper-body movements in the following areas: the premotor and supplementary motor cortices, the cingulate gyrus, and the inferior parietal cortices. **Discussion** The present study demonstrated a link between dance complexity and executive-cognitive network in the elderly. The results showed that observing dance performance activated executive-cognitive network associated with movement complexity of dance. Thus, this suggests that the unique aspects of task complexity with regard to dancing can contribute to actively elicit cognitive resources such as attentional ability and multi-task processing. **References** Coubar, O. SPORT-SPECIFIC TRAINING IMPROVES PERFORMANCE OF ATTENTION SHIFTING WITH LOWER EXTREMITIES RESPONDING FOR BASEBALL PLAYERS, NOT FOR TABLE TENNIS PLAYERS

Chiang, C., Chen, W.Y., Wu, S.K.

National Taiwan University of Physical Education and Sport

Background & Purpose: The ability of attention shifting between multiple locations might be developed by distinct specific nature of the sport discipline. An intensive sport-specific training for baseball (BA) and table tennis (TT) players might have different improvements on performance of attention shifting. This study was designed to examine these two hypotheses. **Methods:** Eighteen TT players and twenty-three BA outfielders and infielders in top national teams in Taiwan were recruited in this study. The ability of attention shifting was measured by two spatial cueing paradigms with distinct complexities (simple or complicated) and different extremities (upper or lower). All participants were examined at the before and after the sport-specific training for three months. Both paradigms were separately analysed with mixed designed repeated-measures ANOVAs to investigate the effect of sport-specific training and responding extremities on performance between two sporting groups. **Results:** Prior to the sport-specific training, performance of attention shifting was similar between BA and TT players in the simple cueing paradigm. When the complexity of the paradigm increases, BA players had a better performance with lower extremities responding than TT players. Testing with both simple and complicated paradigms, after the sport-specific training, only BA players improved their performance of attention shifting with lower extremities responding. In contrast, TT players slightly deteriorated their performance with both upper and lower extremities responding. **Conclusion:** The study provides an evidence to support that the sport-specific training for BA players enhance the ability of attention shifting from the misleading location to the target location and eye-foot motor response. EFFECT OF ACUTE EXERCISE AND CARDIOVASCULAR FITNESS ON COGNITIVE FUNCTION: AN EVENT-RELATED CORTICAL DESYNCHRONIZATION STUDY

Chang, Y.I, Chi, L.I, Wang, C.I, Chen, F.I

1: National Taiwan Sport University (Taoyuan, Taiwan), 2: Ta Hwa University of Science and Technology (Hsinchu, Taiwan)

Introduction This study aimed to clarify the effect of acute exercise and cardiovascular fitness on cognitive function. The effect was assessed by the Stroop Test, and cortical oscillations were analyzed by event-related desynchronization (ERD) in an aged population. **Methods** Participants were first assigned to either a higher or lower fitness group and then underwent acute exercise and a reading control treatment in a counterbalanced order. Alpha ERD was recorded during the Stroop Test administered following the both treatments. **Results** Acute exercise improved cognitive performance regardless of the level of cognition, and older adults with higher fitness received greater benefits from acute exercise. Additionally, acute exercise, rather than overall fitness, elicited greater lower and upper alpha ERDs relative to the control condition. **Dissuasion** These findings suggest that the beneficial effect of acute exercise on cognitive performance may result from the exercise-induced attentional control observed in frontal neural excitation. However, further investigation is needed to study the neural activity related mechanisms for the modulation role of fitness involved in the relationship between acute exercise and cognition. THE RELATION OF REGULAR EXERCISE ON STROOP TEST RELATED EVENT-RELATED POTENTIAL: AN PRELIMINARY STUDY

Song, T., Yang, K., Chen, C., Chang, Y.

National Taiwan Sport University

Introduction Research has indicated that cognitive functioning declines with aging. Under the circumstances of an increasing aging population, factors that are associated with, maintain, or that improve cognitive functions have become an important research issue. Recently, studies have shown that exercise not only benefits physical fitness and reduces the chance of chronic illness, but also improves cognitive functions in the neuroelectric levels, such as event-related potential (ERP). The positive effects on cognition derived from exercise are correspondent to the recent evidences of neuroscience that suggest an enriched environment could enhance cognitive brain functions. To date, ERP studies have extensively examined cognitive functions, with results assessed by a flanker task; however, the task is only one type of assessment used to measure cognition, particularly the inhibitory aspect of executive function. The aim of this study was to investigate the relation of regular exercise and Stroop Test related ERPs in middle-aged older adults. Methods Twenty participants (mean age = 58.95 ± 3.51 years) meeting the requisite criteria were recruited and categorized into two groups: exercise group ($n = 10$, i.e. those that jog on a regular basis), and the control group ($n = 10$, i.e., those that exercise irregularly). Each individual was instructed to complete event-related potentials while performing a Stroop Test, whereby the Stroop Test involved congruent and incongruent conditions. Results The results indicate that the regular-exercise group exhibited larger P3 amplitude than the irregular-exercise group in both Stroop Test conditions. Moreover, regular exercisers showed significantly shorter P3 latency compared to the irregular exercisers in Stroop incongruent conditions. Discussion These findings suggest that regular exercise leads to enhanced attentional resource allocation, regardless of the types of cognitive function. However, regular exercise is associated with increased speed of classification and evaluation of stimulus, particularly in tasks requiring more cognitive demand, implying that exercise has a disproportionately greater effect on the inhibitory aspect of executive functions. The present study provides the warrants for examining the relationship between exercise and ERPs, and future research is encouraged to replicate the finding by increasing sample size and applying other ERP components as evaluative factors. ACCEPTABILITY OF AN ONLINE INTERVENTION TO MOTIVATE ADULTS AGED 50 + TO BE MORE PHYSICALLY ACTIVE: A PILOT STUDY

Stolte, E., Aartsen, M.J., Van Tilburg, T.G.

VU University

Goal A six week online intervention program was developed for people aged 50 and over. The goal is to motivate participants to be more physically active (PA) and to study the effect and mechanisms of e-mail prompts and cognitive antecedents of PA. Aim of the pilot is to assess the acceptability of the program. Methods Participants are randomly assigned to two groups. The first group receives an online PA plan, a PA diary, two brochures sent by mail and PA tips in the form of texts and animated video's ($n = 19$). The second group receives the same information ($n = 14$), however the PA tips are supplied using prompts, i.e. short e-mail messages, sent three times a week during four weeks. Of the participants 73% are female, the mean age is 63 years. Nineteen (58%) participants filled out the post measurement questionnaire. Results Appreciation of the program is high. Most participants (74%) report that they got more active during the program and that the program helped them to achieve this (79%). Half or more of the PA tips were viewed by 75% of the first group and 57% of the prompting group. Discussion The program is acceptable for most users who completed the program. Some participants expect more personal feedback. Usage of PA tips is lower than expected. As a result PA tips and prompts were adjusted for a new version of the program that is currently being evaluated.

THE EFFECTS OF TYPES OF SELF-TALK AND VOLLEYBALL SPORT PERFORMANCE

Cheng Hui, C.I, Chih Han, W.I, Chien Heng, C.I, Yu Kai, C.I

National Taiwan Sport University

Introduction Self-talk has been recognized as a primary psychological skill in sports training and it is known to benefit sport performance. However, whether self-talk types affect different types of sport performance is still unknown. The purpose of this study was to examine the effects of self-talk types on two sport performances in a volleyball setting. Methods Ten average level college-aged volleyball players were recruited. Using a planned experimental design, the self-talk was categorized into five types: Positive Instructional Self-talk (PIS), Negative Instructional Self-talk (NIS), Positive Motivational Self-talk (PMS), Negative Motivational Self-talk (NMS), and Non-Related Self-talk (NRS). Participants were asked to execute three-by-three serves and vertical jumps during their sport performances after experiencing each of the five types of self-talk, in a randomized order. Results Regarding the three-by-three serve conditions, the results indicated that while none of these differences were found in terms of time effects (pre-test and post-test) among each of the self-talk conditions, there were significant differences observed between the results of the different self-talk types. Additionally, a marginally significant difference was observed in the interactions between time effects and self-talk types. In general, PIS and PMS had significant superior performances, compared to NIS, NMS, and NRS. Differences in sport performances were also found after the interventions of each PIS, NIS, and PMS. Regarding the vertical jump, the time effects of self-talk type and the interactions were not found to be significant, but the self-talk types did manifest significant effects. Additionally, PIS and PMS had significantly superior performances compared to the NIS, NMS, and NRS. Discussion These findings suggest that positive self-talk can be considered a useful type of self-talk for volleyball performance, regardless of instructional or motivational self-talk. Moreover, there is a larger impact from self-talk affecting fine motor performance, compared to gross mass muscular sport performance. The research provides a knowledge basis regarding the usage of self-talk types for athletes applying this practice during different types of sport performance. Contact uso0717@hotmail.com

EFFECTS OF ACUTE EXERCISE ON WORKING MEMORY IN CHILDREN WITH ATTENTION DEFICIT/HYPERACTIVITY DISORDER

Yu, C., Tsai, Y., Huang, C., Hung, T.

National Taiwan Normal University

Introduction Working memory (WM) plays an important role in cognitive activity, and a large deficit in WM has been reported in children with ADHD relative to typical children. Physical activity has been found to be beneficial to WM in developed children (cite?). Therefore, this

study examined the effect of acute exercise with moderate-intensity on working memory in children with ADHD. Methods A multiple-baseline across subject design, which included baseline, treatment and follow-up phases, was employed. Three children with ADHD were recruited, and all participants performed the moderate-intensity exercise for 30 minutes. Baddeley's WM model was used, which showed the large effect size on WM task in children with ADHD compared to typically developing children as the test task (Kasper et al., 2012). Results A comparison between the treatment and the follow-up phases showed an average decrease of 5 grades in working memory. However, the comparison between baseline and treatment phases showed an average improvement of 7 grades in working memory, which indicated that the effects of acute exercise on WM disappeared in children with ADHD after the exercise intervention ceased. This result indicated that acute exercise results in better WM performance among children with ADHD. Discussion During the administration of the WM task, all participants had difficulty with the task, which is consistent with previous studies that suggest a deficit of WM in children with ADHD. Importantly, these children improve in WM after an acute bout of moderate intensity exercise. This is consistent with the report that acute exercise can improve the inhibition part of executive function in children with ADHD (Pontifex et al., 2013). Nevertheless, the benefits of acute exercise decline after children stop exercise. This finding suggests that continued participation in exercise should be recommended to children with ADHD if improvement in WM is their goal. Further studies should explore the effect of chronic exercise on WM in the same population. References Kasper, L. J., Alderson, R. M., Hudec, K. L. (2012). THE EXAMINATION OF THE IMPACT OF SOCIAL SUPPORT; A QUALITATIVE ANALYSIS OF THE REACTION TO VERBAL MESSAGES

Katagami, E., Weston, N., Nakasuga, T., Tsuchiya, H., Yamada, H., Yamakoshi, Y.

Osaka University of Health and Sport Science

The examination of the impact of social support; a qualitative analysis of the reaction to verbal messages Introduction Social support has been discussed as a significant factor in athletes' psychological well-being. The recent social support studies in sport have discussed social support in relation to performance with the four dimensions of social support; emotional, esteem, informational, and tangible support (Rees, & Hardy, 2009). Recently, Rees and Freeman (2009) emphasised the need of further understanding of the effect of social support upon athletes' cognitive, emotional, and behavioural mechanisms in order to establish a theory in this area. Therefore, the aim of the study was to examine on what aspects athletes' cognition are influenced from the recorded data of reaction to verbal forms of social support. Methods Eleven university student-athletes who belong to a female lacrosse club were recruited as participants in this study. Participants ($M=20.55$ years, $SD=0.52$) were required to record their communication with others in sport setting onto a provided communication diary for four weeks in pre-season. A communication diary was designed to record the details of their communication in sport (i.e. when, with who, and how) and the content of the communication, which is consisted of two parts; 1) what the person said, and 2) what the recipient perceived to the message. All the recorded data of 11 participants were inductively categorised individually by two researchers who has experienced in practical sport psychology, then discussed to gain an agreement on the categorization of the athletes' reaction of the messages. Results The results showed that social support in the forms of verbal message had impact upon their perceptions regarding behaviour, cognition, and affection. Firstly, behavioural-changing reaction such as actions for performance improvement, effort, support others, and challenge was identified. Secondly, cognition changing including decision-making, acknowledging self-concept, reflecting performance, and perceiving received support was found as a reaction of social support. Finally, affective changing reaction was recognised. Discussion As the result of the study indicated that social support in forms of verbal message had impact upon athletes' perception of behaviour, cognition, and affection, social support might be a key to enhance athletes' cognitive and behavioural modification, which may lead to athletes' well-being. Moreover, social support may positively be able to influence athletes' affection. Further research is needed to establish a mechanism in social support. References Rees, T., & Hardy, L. (2000). THE USE OF CONTEXTUAL INFORMATION IN EXPERT TENNIS ANTICIPATION

Murphy, C., Jackson, R.C., Williams, A.M.

Brunel University

Introduction The ability to read and effectively adapt to upcoming events is commonly regarded as an important component of expert performance. The expert advantage in anticipation has been regularly demonstrated in sport and other domains, with particular focus on how experts extract and process information from the visual display more effectively than their less expert counterparts. However, research investigating how contextual information contributes to anticipation is scarce. Dittich's (1999) interactive encoding model proposes that in dynamic, multi-element situations, performers extract motion information and temporal relationships between features, mapping this information onto past or potential experiences. In this way the information presented becomes meaningful with respect to complex memory representations. The aim of the study was to assess expert tennis players' ability to anticipate ball bounce location relative to depth and direction in the absence of superficial kinematic information using a simulated laboratory-based anticipation task. Methods 16 expert and 20 recreational participants viewed footage of rallies from professional tennis matches in normal video (NV) and animation (ANI) display conditions. The ANI condition, which was created using player movement and ball trajectory data, showed the same points as the NV condition but without superficial player kinematics. The players and the ball were represented by two cylinders and a yellow dot respectively, while rackets were not visible. Participants viewed 90 experimental trials in both conditions, between 3 and 13 shots long, on a 4.05X2.29m projection screen from a distance of 5m. Participants anticipated ball bounce location when the final shot was occluded at the opponent's racket-ball contact. Response accuracy (RA) was recorded as the percentage of correct responses in relation to depth, direction and both depth and direction together. Results There were significant display and group effects for depth, direction and both ($p<.01$). Experts' mean RA scores were significantly better than recreational players for depth (NV: $84.58\pm3.14\%$ vs $80.28\pm4.79\%$; $p<.01$, ANI: $69.31\pm4.42\%$ vs $65.83\pm5.41\%$; $p<.05$) and both depth and direction together (NV: $62.01\pm4.45\%$ vs $52.94\pm5.99\%$; $p<.001$, ANI: $49.10\pm4.00\%$ vs $44.00\pm6.61\%$; $p<.01$). Discussion The findings imply that experts can still anticipate significantly better than recreational players in the absence of superficial player kinematic information. This is consistent with Dittich's (1999) model, as expert tennis players appear to utilise dynamic relational information from the visual display in the form of players' court positioning to anticipate more effectively.

tively than recreational players. References Dittrich, W.H.: In: Gesture-based communication in human-computer interaction, Berlin: Springer-Verlag; 1999: 3-22

THE INFLUENCE OF BELIEFS AND GOALS FOR EMOTION REGULATION ON SELF-REGULATION STRATEGIES: THEIR IMPACT ON COMPETITIVE ANGER

Cruz, J., Sofia, R., Osório, J.

University of Minho

Introduction Athletes can use an array of strategies to deal with the demands of sport competition, including coping, emotion regulation and self-control strategies. However, the specific strategies used can be influenced by multiple factors. The literature has recently suggested the influence of individuals' beliefs about the malleability of their emotions (Tamir et al., 2007), their core self-evaluations (reflecting the most central evaluation individuals can make about themselves) (Kammeyer-Mueller et al., 2009) and the goals for emotion regulation (Rusk et al., 2007) on how they deal with the demands of sport competition. The main goal of this study is to understand how these beliefs and goals influence coping, emotion regulation and self-control strategies, as well as their ultimate impact on one of the most experienced emotion in sport: anger. **Method** 269 athletes from different types of collective and individual sports completed self-report measures of competitive anger, coping, emotion regulation, self-control, implicit theories of emotion, core self-evaluations and goals for emotion. **Results** Besides Pearson correlations between the variables in study, multiple regression analyses were performed for each strategy in study considering implicit theories, core self-evaluations and goals for emotion regulation as predictors. Generally, it was found that incremental implicit theories, high core self-evaluations and learning goals for emotion regulation (reflecting the desire to learn as much as possible) were associated to more adaptive strategies, such as importance reappraisal, and less adaptive strategies, such as self-blame. Additionally, to understand their influence on anger, multiple mediation analyses were performed, demonstrating the relationship between performance-avoidance goals for emotion regulation (avoid showing a bad performance) and anger was fully mediated by self-blame and anger rumination. **Discussion** This study highlighted the importance of deeply rooted implicit beliefs and goals for emotion regulation on how athletes deal with sport competition, and provides evidence for their influence on competitive anger, demonstrating that individuals holding performance-avoidance goals are more likely to use self-blame and anger rumination, which can increase their anger. These findings suggest not only the need for future studies further exploring these variables, but also the development of cognitive-based interventions to help athletes deal with the pressure of competition. **References** Rusk, N., Tamir, M., Rothbaum, F. THE RELATIONSHIP BETWEEN EXERCISE MODALITY AND THE STROOP TASK IN OLDER ADULTS

Yang, K.T.1, Kong, H.F.1, Ho, Y.M.2, Chang, Y.K.1

1: National Taiwan Sport University (Taoyuan, Taiwan), 2: Hsiuping University of Science and Technology (Taichung, Taiwan)

Introduction A growing body of literature has demonstrated that there is a decline in cognitive functions as people age. The issue of cognitive decline is of importance to ongoing research and investigation because according to the World Health Organization, cognitive function has been recognized as a primary component of health-related quality of life. Fortunately, previous research has shown that exercise is linked positively to cognitive function in older populations, in which case many studies have shown that enhanced cognitive function is accompanied by an improvement of cardiovascular fitness induced by regularly participating in exercise. The purpose of the study was an attempt to extend the current positive findings by examining whether different types of exercise participation would impact cognition differently. **Methods** Sixty-six adults were recruited and separated into either a continuous skill-related exercise group, a serial skill-related exercise group, or a control group. The cognitive function as measured by the Stroop Test with congruent and incongruent conditions, wherein the conditions were presented by way of mixed design. **Results** The main findings indicated that although there was no significant difference regarding reaction times among the three groups, irrespectively, regarding the Stroop congruent and incongruent conditions, the serial skill-related exercise group showed significantly better accuracy in the incongruent mode, compared with the continuous skill-related exercise group and the control group. **Discussion** This finding suggests that participating in exercise involves complex skills, which may benefit cognitive functions, particularly the executive function aspect of cognitive processing. STATE OF THE ART REVIEW: BENEFICIAL INFLUENCE OF AEROBIC EXERCISE ON THE BRAIN

Félez Nóbrega, M., Puig Ribera, A., Hillman, C.H.

Universitat de Vic

Introduction The aim of this study is to provide a review of cross sectional (CS) and exercise intervention studies examining the relationship between regular aerobic exercise (AEX) and brain structure and function in adult populations. We target this age group because synaptic plasticity appears to peak in young adulthood (Oberman et al., 2013). **Methods** The literature review was performed using ISI Web of Science, PubMed, Google Scholar, and references of retrieved articles between the years 2000-2014. The main search terms were: "aerobic exercise", "physical activity", "aerobic training", "exercise", "cognitive function", "memory", "executive function" and/or "adults". The applied inclusion criteria were: (1) human studies; (2) adults between 18-47 years old; (3) without any known medical condition; (4) CS studies and one or more than 1 week AEX interventions. A total of 21 studies were included in the review. **Results** There are 7 interventional studies with young-adults (4 examining memory processes, 2 focused on executive functions and 1 assessing brain structure changes). 14 studies were CS (1 focused on memory processes, 11 on executive functions, 1 on global intelligence measures and 1 assessing brain structure changes). Interventional studies generally revealed positive effects of AEX on memory, executive functions and neuroprotective effects. CS studies also suggested that AEX has beneficial effects on memory, is positively associated with global intelligence measures and changes in brain structure. Inconclusive results appear for the association between AEX and improvements in executive function; nevertheless, several neuroimaging studies have shown evidence for increased efficiency on brain function with no differences in cognition. **Discussion** The findings suggest that regular physical activity engendered via AEX can have beneficial effects in healthy adult populations. Although, the nature of CS analysis, the very few interventional studies and the small samples used in the majority of the studies limits the strength of the findings. Thus, there is a need for more research to clarify and confirm improvements in cognitive function in this age group as well as identify additional moderator variables (Hopkins et al., 2012; Strooth et al., 2010). **References** Oberman, L., Pascual-Leone, A (2013). *Prog Brain Res* 207:91-120. DIFFERENCES IN SENSORIMOTOR MU RHYTHM BETWEEN EXPERTS AND BEGINNERS IN SUCCESSFUL GOLF PUTTING PERFORMANCE

Wang, K.P.1, Cheng, M.Y.1, Shen, C.1, Huang, C.J.2, Hung, T.M.1

1: NTNU (Taipei, Taiwan), 2: uTAIPEI (Taipei, Taiwan)

Introduction The profile of peak performance is related to flow, a state that of being in complete control and focused attention in performers (Mihaly, 1990). The role of the mu rhythm over the sensorimotor region has been associated with movement coordination (Csibra, 2008). Past studies have shown that mu rhythm affects attention during motor execution (Pineda, 2005). However, previous studies have mainly investigated the mu rhythm in simple motor skills. How Variation in mu rhythms when experts perform complex motor skills is less understood. Therefore, this study aims to investigate sensorimotor mu rhythm variation between experts and beginners during successful golf putting. **Method** Ten expert golfers and nine beginner golfers were recruited. All participants were right handed and requested to perform 40 putts at an artificial golf green. Pre-putt sensorimotor mu rhythm in successful golf putting was compared between the two groups by a 2 (level: expert, beginner) x 3 (epoch: -1.5s~-1s, -1s~-0.5s, -0.5s~0s) x 3 (electrode: C3, CZ, C4) ANOVA. **Result** ANOVA analysis revealed a significant interaction effect between level and electrode. Post hoc analysis indicated that the power of mu rhythm at C3 and C4 were smaller than Cz in experts. However, such differences were not found in beginners. **Discussion** The main finding of this study showed that mu rhythm power over the sensorimotor area (C3,C4) was smaller than the supplementary motor area (Cz) in experts prior to successful golf putting execution. We infer that the two hand sensorimotor area of experts may have better motor control. The no significant effect observed in beginners suggests that beginners are unable to exactly control motor activity in putting. Thus, we can conclude that experts have greater motor modulation than beginners in successful putting performance. **Reference** Csibra, G. (2008). EFFECTS OF ACUTE EXERCISE IN INHIBITION PROCESS IN CHILDREN WITH ADHD: AN EVENT-RELATED POTENTIAL STUDY

Llin, C., Chuang, L., Tsai, Y., Hung, T., Huang, C.

National Taiwan Normal University

Introduction Previous studies have evidenced that exercise can promote cognitive function. However, the Attention-Deficit/Hyperactivity Disorder (ADHD) population has been sparsely discussed. Therefore, the main purpose of this study was to explore the influences of acute exercise on sustained attention and response inhibition in children with ADHD, and understand the underlying neural mechanisms by way of event-related potential (ERP) which is characterized by high temporal resolution. **Methods** Twenty-one children with ADHD (aged between 8 and 12 years old) were recruited. This study was conducted with within-subject design, and therefore, all participants received both thirty minutes intervention of running exercise and video watching on different days. All participants also performed a Go/Nogo task after exercise/video watching and EEG was recorded as the participants executed the task. The behavioral data (reaction time/error rate) was assessed using paired t-test and the ERP data was subjected to condition (exercise/video watching) x stimulus type (Go/Nogo) x electrode (Fz/FCz/Cz/CPz/Pz) repeated-measures ANOVAs. **Results** There was no significant interaction or main effect on behavioral data. As for ERP data, condition x stimulus interaction, $F(1, 20)=5.616, p=.028$, partial $\eta^2=.219$, revealed that P3 latency was shorter for Nogo than Go after video watching. In the Go condition, P3 latency was shorter after exercise than video watching. **Discussion** Shorter P3 latency represents less time needed for recruiting attention resources, and acute exercise leads to shorter P3 latency. However, similar behavioral performance between conditions may result from insufficient exercise. **References** KEITA KAMIJO, MATTHEW B. PONTIFEX, NAIMAN A. HIGHER SENSORY MOTOR RHYTHM ASSOCIATED WITH BETTER PERFORMANCE IN SKILLED AIR PISTOL SHOOTERS

TU, Y., Cheng, M., Huang, C., Hung, T.

National Taiwan Normal University

Introduction EEG signatures such as temporal, central, and occipital alpha, frontal midline theta, and intra- and inter-hemispheric coherence have been related to superior motor performance in recent years. The sensorimotor rhythm (SMR) is a special frequency band of 12-15 frequency in the sensorimotor area. The power of SMR is inversely related to the activation of this area. Research has shown that SMR is related to the automaticity of motor process. Therefore, this study intended to explore the relationship between SMR and shooting performance in skilled air pistol shooters. **Method** Twenty-four skilled shooters (aged 18 ± 2.5 yr) with 3.7 ± 2.6 years of shooting experience were recruited to shoot for 40 shots while EEG was collected. **Results** SMR for the 10 best shots (9.77 ± 0.22) was contrasted with the 10 worst shots (7.61 ± 0.61). The 2 x 3 (performance x epoch: -3000 to -2000, -2000 to -1000, -1000 to 0) ANOVA showed significant a interaction effect and epoch main effect. Simple main effect analysis revealed that the SMR of the third epoch for good performance was significantly higher than that of the poor. **Discussion** The results suggest that when the skilled shooters reduced the sensory motor activity during the aiming period, they performed better. This finding may shed light on the understanding of fine mental regulation during the short period of aiming processes. **Reference** Babiloni, C., Del Percio, C., Iacoboni, M., Infarinato, F., Lizio, R., Marzano, N. et al. THE EFFECTS OF DIFFERENT EXERCISE TYPES ON INHIBITORY ABILITY IN THE ELDERLY- AN ERP STUDY

Hung, T., Yu, J., Chung, J.

National Taiwan Normal University

Introduction Previous studies have shown the positive effects of exercise on cognition in the elderly. However, moderators such as type of exercise haven't yet been determined. The purpose of this study was to investigate the effects of different exercise types on inhibition related executive function in the elderly using behavior and neuroelectric measures. **Methods** Twenty-one previously sedentary elderly persons were randomly assigned to a table tennis, jogging/ walking, or non-exercise group. All participants were administered a Stroop task while event-related potential (ERP) was recorded before and after four months of exercise intervention. The intensity of exercise was set at 50% maximum heart rate and the duration 40 minutes. **Results** Although no significant differences were found among the three groups in the behavioral measures, N1 latency of the posttest was shorter than the pretest for table tennis and walking groups and control group in parietal and occipital areas, respectively. The walking group showed shorter N1 latency in the posttest than other groups. **Discussion** The N1 component has been hypothesized to reflect the visual discrimination process and attention (Vogel & Luck, 2000). The finding of shorter N1 latency in the posttest across the three groups may suggest a learning effect. Significantly the finding of a shorter N1 latency in walking group after a four month intervention is interesting. To date, no studies have examined the N1 component in the relationship between exercise type and cognition in the elderly, however, studies have demonstrated longer N1 latency for older adults when compared to their younger counterparts (Curran et al., 2001). Our findings suggest that four months of aerobic exercise can facilitate the speed of early visual discrimination processing and engagement of attention in the elderly. This beneficial effect will not be observed from behavioral measurement, but in the ERP data. **References** Curran, Tim, Hills, Alex, Patterson, Marian B, & Strauss, Milton E. (2001). THE EFFECTS OF THREE COGNITIVELY DEMANDING TASKS ON PSYCHOLOGICAL AND PERFORMANCE INDICATORS OF COGNITIVE FATIGUE.

Smith, M.1,2, Fransen, J.2, Coutts, A.1

1:UTS (Australia), 2: UGent (Belgium)

Introduction Recent research reveals impairments to exercise performance following cognitively demanding computer tasks (Marcora et al., 2009; Brownsberger et al., 2013). However, at present, there is poor understanding of appropriate methods for inducing cognitive fatigue in experimental conditions. Indeed, the recovery pattern of cognitive fatigue following cognitive tasks is not well understood, nor is the most appropriate method for assessing cognitive fatigue. Therefore, the purpose of the present study was to i) determine appropriate computer tasks for inducing cognitive fatigue ii) examine the recovery of fatigue following these tasks; and iii) determine the efficacy of tools for detecting cognitive fatigue. **Methods** Seventeen participants completed three 45-min cognitively demanding computer tasks and watched a 45-min documentary (control condition) in a randomised order on separate days. The three computer tasks included the Psychomotor Vigilance Task (PVT), AX-Continuous Performance Test (AX-CPT) and Stroop task. Subjective fatigue was assessed before, and at 10-min intervals following each task (up to 60-min) using a visual analogue scale (VAS). Cognitive performance (3-min PVT) was assessed before, as well as 0, 30 and 60 min post task. **Results** Subjective fatigue significantly increased after all computer tasks ($P < 0.05$) but not following the documentary. Repeated-measures MANOVA revealed a significant increase in 3-min PVT reaction time ($P < 0.05$); however follow up analysis revealed no significant pairwise differences. No significant differences in false starts or missed cues existed between time or condition for 3-min PVT. Post-task subjective fatigue remained higher than pre-task measures for 20, 50 and 60 min following the PVT, Stroop and AX-CPT respectively. **Discussion** Similar to previous investigations using 90-min tasks (Marcora et al., 2009; Brownsberger et al., 2013), all three current tasks induced subjective fatigue, suggesting that tasks of just 45 min are sufficient for this purpose. Interestingly, 3-min PVT performance did not significantly increase following any tasks. Therefore 3-min PVT performance may be a less sensitive measure of cognitive fatigue than VAS. This may however be a result of the longer inter-stimulus intervals (2-10 s) used in the current study compared to previous research (1-4 s; Basner et al., 2011). Subjective fatigue remained significantly increased for longer in the AX-CPT and Stroop than in the PVT. Therefore tasks requiring response inhibition should be used for future research as they appear to induce fatigue for longer periods than those solely demanding attention (Pageaux et al., 2014). **References** Basner M, Mollicone D, Dinges D. SPORTS PRACTICE IN THE ADOLESCENCE: FIT AND VIGILANT

Ballester, R., Huertas, F.1, Yuste, F.1, Llorens, F.1, Navarro, C.1, Sanabria, D.2

1: Universidad Católica de Valencia "San Vicente Mártir". UCV (Valencia, España) 2: Mind, Brain, and Behavior Research Center, Universidad de Granada. UGR (Granada, España)

Introduction: The interest on the relationship between sport practice, cardiovascular fitness, and cognitive processing is increasing in recent years(1). Here, we focus on sports practice as a key factor involved in fitness level, speed processing and vigilance (i.e., the ability to maintain focused attention) in male and female adolescents. **Method:** Two groups of participants (n=75) were selected on the basis of their sports training habits and experience. Participants were evaluated in two separate occasions. In one session participants completed the Psychomotor Vigilance Task(2). In the other session participants performed the Leger Multi-stage fitness test(3). In addition, a brief anthropometric assessment was conducted to obtain their body mass index. **Results:** Physical fitness: The analysis on the Time-to-exhaustion (TTE) data revealed a main effect of sports practice, $F(1,73)=144$, $p < .001$, and a main effect of Sex, $F(1,71)=27.65$, $p < .001$, with larger $\dot{V}O_2\max$ values for the trained than for the non-athletes group and for males than for females participants. Cognitive processing: The analysis of the mean reaction time (RT) data showed a main effect of sports practice, $F(1,73)=17.27$, $p < .001$, with athletes responding faster than non-athletes, and a main effect of Time on task, $F(2,146)=5.84$, $p < .01$, with athletes responding slower as the time on task increased. The analysis on the number of lapses ($RT > 500\text{ms}$) revealed a main effect of Time on task, $F(2,146)=7.41$, $p < .001$, with the number of lapses increasing as time on task went by, a significant main effect of sports practice, $F(1,73)=15.08$, $p < .001$, with athletes committing fewer lapses than their untrained counterparts and a significant interaction between Time on task and sports practice, $F(2,146)=3.20$, $p = .04$, with the vigilance decrement being more pronounced in athletes than in non-athletes. **Discussion:** The results confirmed our predictions, with athletes showing better cardiovascular fitness than untrained participants. Sports practice also resulted in improved

performance in the PVT. Athletes responded faster, committed fewer lapses and seemed to be less prone to vigilance decrement over time than controls. The present study revealed the impact of sports practice on cardiovascular fitness and vigilance performance. In line with previous studies, we suggest that cardiorespiratory fitness(4) and sports practice itself(5) may be important factors to explain the differences in cognitive performance. References: 1. Rehabilitation

APPLICATION OF INTERVAL TRAINING AND AEROBIC RESISTANCE IN PATIENTS WITH STABLE COPD ASSESSED 6 MINUTES WALKING DISTANCE TEST <6MWD>.

Herrera Pacheco, M., Montiel Navas, C.

Universidad Complutense Madrid

INTRODUCTION: The exercises are beneficial for metabolism and muscle recruitment demand and are required to improve cardiovascular and muscular endurance in patients with COPD. Aerobic training plus resistance training are more effective in improving strength and functional capacity than single aerobic workout. (1) There is a correlation between the results of 6MWD and quality of life (2). **METHODS AND PATIENTS:** 18 outpatients with moderate to severe COPD, clinically stable, were included; they were evaluated before and after the 6MWD constant measure clinics and walked distance. Interval aerobic and resistance training was applied for 6 weeks, three times a week. Improvement is defined as an increase of 54 meters in the rear 6MWD (3). **RESULTS:** The results obtained were as follows: the mean age of patients was 66.5 years; the male occupied 88%, an increase of 12.2% of the total distance walked in 6MWD was observed later, also a decrease in TAS and TAD of 9 mmHg and 2 mmHg respectively. The data were averaged and compared with ease using the median and media statistic function. **CONCLUSION:** With this analysis we can see that the application interval training aerobic and resistance in patients with stable COPD, increases the distance in meters, which has a positive impact on the quality of life of these patients, and may also be reflected in the carrying out of activities of daily living. The 6MWD has an easy application in sports medicine and also has advantages over other test, as it was better tolerated, making it an instrument of low-cost, a rapid test, has an affordable and fast access to health workers in the Sports scope. **REFERENCES:** Abramson M, Brown MJ, Crockett A (et al). THE EFFECTIVENESS OF ROBOT-ASSISTED TREADMILL TRAINING IN MS PATIENTS CONCERNING THE OUTCOMES GAIT VELOCITY, DISTANCE AND ACTIVITY OF DAILY LIFE VERSUS OVER-GROUND WALKING TRAINING: A SYSTEMATIC REVIEW

Knocke, K.

Friedrich-Alexander-University Erlangen-Nürnberg

Background: Gait abnormalities are common disorders in multiple sclerosis (MS) that often limit participation in social life. Different therapy approaches such as treadmill or robot-assisted gait training have been used to reduce these disabilities. **Objective:** To estimate the effectiveness of robot-assisted gait training in MS patients compared to over-ground walking training. **Outcome measures** were gait velocity, gait distance and activity of daily life. **Data sources:** A systematic review of four randomized controlled trials (RCT) using PubMed and Scopus as Databases. **Search terms** being used were robot, robot-assisted, gait, therapy and multiple sclerosis. **Study selection:** Randomized controlled studies in English or German that fulfilled at least one gait parameter outcome or an activity of daily life outcome were included. Furthermore, only patients with MS were involved. **Intervention** had to be robot-assisted gait training compared to over-ground gait training. **Extraction:** Independent extraction of articles by one author. **Results:** Four RCT's were taken in the comparison. Overall there were 152 patients in all studies that were randomly sorted into robot-assisted gait training (RAGT) or conventional treatment (CT) involving over-ground gait training. Patients were treated in nine to fifteen sessions during three to six weeks. Therefore patients received treatment two to five times per week. Each therapy lasted at least 30 minutes. **Assessments** were taken at baseline, post intervention, three and six months post intervention. **Data** showed a positive effect in walking distance in RAGT compared to CT. Velocity and activity of daily life improved as much as in CT group. **Effects** lasted up to three months. All results vanished after six months follow up. **Conclusion:** Robot-assisted gait training seems to be an effective alternative to over-ground gait training. However, more homogenous studies with a larger number of participants are needed.

EFFECTS OF RESISTANCE EXERCISE WITH BLOOD FLOW RESTRICTION ON VASCULAR FUNCTION

OKITA, K., TAKADA, S., KADOGUCHI, T., HORIUCHI, M., KINUGAWA, S., TSUTSUI, H.

Hokusho University

Introduction Resistance exercise with blood flow restriction (BFR) is a new training method providing significant training effects despite the use of low-intensity loads (1-4). It is stated that it would be clinically useful in frail subjects or females for whom high-load exercise is not indicated. Unexpectedly, a couple of recent studies (4-7) reported that standard resistance exercise could have adverse effect on aortic stiffness. However, there is insufficient evidence regarding the impact of resistance exercise with BFR on vascular function. The aim of this study is to clarify the effect of low-intensity resistance exercise with BFR on vascular function as well as muscle mass and strength. **Methods** Fourteen young males participated in this study. For training, right calf plantar flexion exercise at 20% of 1-RM with BFR and a pressure of 1.3 times systolic blood pressure (SBP) was used. Training was conducted 3 days/wk for 4 wk. **Muscle cross sectional area (MCA)**, 1-RM, blood pressures (bilateral brachial and ankle), and systemic vascular function assessed by cardio ankle vascular index (CAVI) were measured pre and post training. **Results and Discussion** MCA and 1-RM increased significantly (5.0% and 13.7% vs pre training, $p < 0.05$). Blood pressure decreased significantly only in the right ankle (trained limb, 134 vs 126 mmHg, $p < 0.05$), while CAVI remained unaltered.

Decreased blood pressure might be due to reduced vascular tone and improved stiffness. Systemic parameter of CAVI could not reflect the functional change in local artery. Recent meta-analysis (8) showed that resistance training might provide favorable effect on blood pressures, while its adverse effects could not be ignored. Resistance exercise with BFR is a valuable method that can significantly increases muscle mass and strength, and might have favorable effect on vascular function. References 1. Okita K. (2010). *Adv. THE EFFECT OF 12 WEEKS OF ACCELERATED REHABILITATION EXERCISE ON ISOKINETIC MUSCLE FUNCTION OF PATIENTS WITH ACL RECONSTRUCTION OF THE KNEE JOINT

Gi Duck, P., Seong Duek, Y., Jung Chul, L.

Kyungpook National University

Introduction To examine changes in the knee joint's isokinetic muscle functions following systematic and gradual rehabilitation exercises lasting for 12 weeks for male and female patients who underwent anterior cruciate ligament (ACL) reconstruction. Differences in muscle functions between the uninvolved side (US) and the involved side (IS) before surgery, differences in muscle functions between US and IS after rehabilitation exercises lasting for 12 weeks, and changes in muscle functions on US and IS between before and after surgery were analyzed to examine the effects of accelerated rehabilitation exercises after ACL reconstruction. **Methods** To examine changes in the knee joint's isokinetic muscle functions following systematic and gradual rehabilitation exercises lasting for 12 weeks for male and female patients who underwent anterior cruciate ligament (ACL) reconstruction. Differences in muscle functions between the uninvolved side (US) and the involved side (IS) before surgery, differences in muscle functions between US and IS after rehabilitation exercises lasting for 12 weeks, and changes in muscle functions on US and IS between before and after surgery were analyzed to examine the effects of accelerated rehabilitation exercises after ACL reconstruction. As a measuring tool, a Biodex Multi-joint system 3pro (U.S.A.), which is an isokinetic measuring device, was used to examine the flexion and extension forces of the knee joint. **Results** At 60°/s, the isokinetic muscle functions of the females did not show any significant change between before and after surgery in any of the variables on both US and IS. At 60°/s, the isokinetic muscle functions of the males did not show any significant change between before and after surgery in the peak torque, average power, and entire work done on US. In extension, peak torque on IS did not show any significant change. **Discussion** Studies related to the evaluation of ACL reconstruction patients' muscle strength report that an analysis of the deficit ratio of IS to US is more valuable than the evaluation of individual muscle strengths 1), 2). Therefore, we consider 12-week duration rehabilitation exercises are incapable of improving knee joint extension muscle functions in females, but are capable of partially recovering extensor muscle functions on IS in males.

PHYSICAL ACTIVITY IN EPILEPSY: RELATIONS BETWEEN QUALITY OF LIFE AND DEPRESSIVE SYMPTOMS

Kishimoto, S., Yoshida, H., Analha, G., Fernandes, P.

State University of Campinas

Introduction Epilepsy is considered a chronic neurological condition characterized by recurrent and spontaneous seizures. Considered one of the most stigmatizing diseases, due to unforeseen crises and dramatic nature, patients with epilepsy are often overlooked and neglected, leaving the physical activity and be exposing in different ways: social relationships, emotional aspects, higher levels of depressive symptoms, and lower scores of the quality of life. **Methods** We interviewed 80 patients at the Outpatient Clinic of Neurology of Clinical Hospital at UNICAMP, with mean age of 42 years old (range from 18 to 60 years, SD=10), 49 women and 31 men. To the screening for physical activity, it was applied the International Physical Activity Questionnaire (IPAQ). So, the subjects were divided into two groups: Active and Not Active Group. We have applied the QOLIE-31 to assess the quality of life in people with epilepsy and the Beck Depression Inventory (BDI), to measure the depressive symptoms. **Results** Referring to quality of life, the results showed that the active group (61 patients, 59% female) had better quality of life indices (mean score 66.71) compared to non-active group (19 patients, 68,4% female) (mean score= 49.98) ($p<0.001$). In relation to depressive symptoms, the active group had lower rates of depressive symptoms (average score=6.31) compared with the non-active group (average score= 16.21) ($p=0.001$). **Discussion** The low participation of people with epilepsy in physical activity may increase the risk of diseases and thus provide worse quality of life (Baker et al, 2005). Through this study, we found that the best scores of quality of life and lower levels of depressive symptoms are related to the physical active patients. During physical activity, the nervous system secret β -endorphins which acts as an anticonvulsant that inhibits the epileptic activity, and provide a feeling of well being, improved mood, stress reduction, anxiety and depression, directly influencing the patient's quality of life (Sahoo, 2004). Thus, we can say that physical activity can be used as an important therapeutic method in the prevention and improvement of quality of life and depressive symptoms in patients with epilepsy. **References** Baker GA, Jacoby A, Buck D, Stalgis C, Monnet D. EFFECTS OF LONG-TERM LOW INTENSITY EXERCISE ON AGE-RELATED ATROPHIED MUSCLE IN A RAT MODEL

Sakamoto, M., Isobe, M., Nakamura, A., Shimose, R., Yona, M., Muro, M., Tadano, C.

School of Allied Health Sciences, Kitasato University

Introduction Ageing leads to changes in skeletal muscle quantity and quality, especially in fast type muscle fibers. Several studies have shown that exercise improves age-related muscle atrophy. Conversely, it has been reported that muscle damage and dysfunction occur after exercise. Therefore, determining what is a safe and effective exercise intensity is important for the elderly. This study examined the effects of long-term low intensity exercise on muscle morphology. **Methods** Eight-week-old male Fischer 344 rats were used in this study. These rats were divided into non-exercise group (Control; N=5), flat loading group (0 degree; FL, N=2) and downhill loading group (-16 degree; DH, N=2) and reared from 8 weeks old until 112 weeks old. The FL and DH performed treadmill exercise (10 m/min, 15 min, 2 times/week) during the rearing period. One week after the last gait exercise, gastrocnemius and soleus muscles were excised and made into frozen serial sections. Serial sections were stained with ATPase, succinate dehydrogenase, hematoxylin and eosin. All fibers were classified as type I, IIa, IIb and IIc. The cross-sectional area of muscles was measured. **Results** were analyzed using Wilcoxon's signed

rank test. Results Regarding the histological features of skeletal muscles, small angular fibers and expansion of muscle interstitium were observed in both the control and exercise groups (FL and DL). However, age-related changes were mild in both FL and DL. In relation to the fiber cross-sectional area (CSA) of the medial gastrocnemius (GM) muscle, in the superficial region of GM the CSA of type IIA and IIB in FL was significantly larger than in the control. In the deep region of GM, the CSA of type I in FL and DH was significantly larger compared with the control. Also, the CSA of IIA and IIB fibers in DH were significantly larger than in the control. The CSA in both superficial and deep regions of the lateral gastrocnemius (GL) muscle was not significantly different between each of the exercise groups. In the soleus muscle, the CSA of type I was significantly larger in both the FL and DH groups compared with the control. Regarding fiber type distribution, in the deep region of the GL muscle, the distribution of type I fiber showed a significant increase in the DH group. Discussion In this study, the effects of FL and DH treadmill exercise differed in relation to each muscle, region and fiber type, perhaps because the contribution of synergists and recruitment pattern of motor units depend on exercise type. These results suggest that long-term low intensity exercise was effective against age-related muscle atrophy, and improved fatigue tolerance, without muscle damage.

EFFECTS OF RESISTANCE TRAINING WITH BLOOD FLOW RESTRICTION ON STRENGTH, FUNCTIONALITY, PAIN, AND QUALITY OF LIFE IN WOMEN WITH KNEE OSTEOARTHRITIS

Roschel, H., Ferraz, R., Sá-Pinto, A.L., Lima, F.R., Kurimori, C.O., Fuller, R., Gualano, B.

University of Sao Paulo

Introduction: Strengthening exercises are widely recommended for improving muscle functionality, pain, and quality of life in patients with osteoarthritis (OA). It has been consistently shown that high-intensity resistance training (i.e.; 70-85% of the maximum dynamic strength – 1RM) is effective for both muscle mass and strength gains. However, patients with OA are often unable to exercise at such high-intensities. Alternatively, low-intensity resistance training (e.g. 20-30% 1RM) combined with partial blood flow restriction (LIO) has been alleged to induce similar gains in muscle function which could be beneficial for OA, as lower loads represents less stress to the affected joints. Therefore, the aim of this study was to evaluate the effects of a LIO training program on clinical outcomes in patients with knee OA. **Methods:** Twenty-eight women diagnosed with knee OA grades II and III (age: 60.5 ± 3.0 years, height: 1.58 ± 0.06 m, weight: 74.2 ± 12.6 kg, BMI: 29.4 ± 3.8 m/kg²) were randomly allocated into one of the three groups: low-intensity training (30% 1RM) associated (LIO) or not (LI) with partial blood flow restriction, and high-intensity training (HI: 80% 1RM). All patients underwent a 12-week, twice a week supervised training program and were assessed for lower-limb 1RM (leg-press and knee extension), functionality (timed-stands test - TST and timed-up-and-go test - TUG), and disease-specific inventory (Western Ontario and McMaster Universities Osteoarthritis Index - WOMAC) at baseline (PRE) and after the protocol (POST). Between-group differences in absolute change in scores were assessed by ANOVA. **Results:** LIO and HI resulted in similar increases in both leg-press (LIO: 34.5%; HI: 28.6%, $p=0.1761$) and knee extension 1RM (LIO: 22.7%, HI: 23.1%; $p=0.6504$), and those changes were significantly greater ($p<0.05$) than those of the LI group (leg press: 11.8%; knee extension: 5.9%). LIO and HI showed comparable improvements in both the TST (LIO: 9.0%; HI: 14%) and TUG tests (LIO: -6.5%; HI: -3.3%) and those were greater than the LI group scores (6 and 0%, respectively). Change in WOMAC scores were comparable ($p>0.05$) across groups for the pain (LIO: -40.0%; HI: -31.7%; LI: -42.0%), stiffness (LIO: -41.2%; HI: -41.9%; LI: -32.0%), and functionality (LIO: -47.7%; HI: -41.5%; LI: -43.0%) domains. The change in the global score for the WOMAC was also comparable ($p>0.05$) between groups (LIO: -45.3%; HI: -37.7%; LI: -42.0%). **Discussion:** LIO training was demonstrated to be as effective as conventional high-intensity resistance training in improving lower-body strength and functionality in OA patients. However, LIO training may be more advantageous than conventional resistance training as lower training loads may be both safer and more enjoyable to these patients while maintaining training effectiveness. We conclude that LIO training constitute a promising strategy for OA management and a possible alternative to higher-intensity conventional resistance training programs.

OVERWEIGHT ADOLESCENTS AND β 2-ADRENERGIC RECEPTOR GENE POLYMORPHISMS: METABOLIC RESPONSE AFTER 12-WEEKS AEROBIC TRAINING

Leite, N.1, Milano-Gai, G.E.1, Lazarotto, L.1, Milano, G.E.1,3, Radominski, R.B.2, Andrade, F.1,3, Furtado-Alle, L.3

Federal University of Paraná

Federal University of Paraná (UFPR, Curitiba, Brazil), 1: Department of Physical Education; 2: Department of Endocrinology; 3: Department of Genetics **Introduction** The β 2-adrenergic receptor gene (ADRB2) polymorphism has been associated with obesity in adolescents (1). This study investigated the responses on metabolic, cardiorespiratory and anthropometric variables after 12-weeks of aerobic training (AT) in overweight adolescents and ADRB2 polymorphisms. **Methods** Eighty three overweight adolescents were evaluated for Arg16Gly and Gln27Glu polymorphisms of ADRB2 gene, height, weight BMI Z-score, waist circumference (WC), blood pressure (BP), total cholesterol (TC), insulin, high density lipoprotein (HDL-C), low density lipoprotein (LDL-C), triglyceride (TG), blood glucose and maximal oxygen uptake (VO₂max), Homeostasis Metabolic Assessment (HOMA2-IR) and Quantitative Insulin Sensitivity Check Index (QUICKI). Exercise bout session consisted of 45-minute indoor cycling and 45-minute walking during the 4 first weeks with 35-55% of VO₂max intensity, and progressive increasing up to 55-75%, 3 times a week, totaling 36 sessions. **Results** Were observed 11 subjects (18.6%) with the genotype Arg16Arg, 24 Arg16Gly (40.7%) and 24 Gly16Gly (40.7%) for the Arg16Gly polymorphism. For Gln27Glu polymorphism, 19 subjects (52.7%) had the genotype Gln27Gln, 8 Gln27Glu (22.2%) and 9 Glu27Glu (25.1%). In the initial phase, the values of BP and TG were higher in carriers of the Glu27 allele than usual ($p<0.05$). After 12-weeks of AT, both groups with the mutated allele (Gln27Glu+Glu27Glu and Arg16Gly+Gly16Gly) showed weight, BMI Z-score, WC, BP, TG, HOMA2-IR reduction and increased HDL, QUICKI and VO₂max ($p<0.05$), except the VO₂max in the Glu27 group. The results of mutant alleles ADRB2 were not different in relation to the usual groups. **Discussion** This study worked with genetic interaction and early obesity. The results suggest that AT can be used as strategy in reducing weight and improving health in carriers of the mutant alleles and usual individuals. The highest initial values of BP and TG in carriers of the Glu27 allele were also observed in other studies (2, 3). After 12-weeks of AT, the results in carriers of the mutant alleles ADRB2 were similar to adolescents with usual allele. In summary, all groups showed improvement in metabolic and anthropometric variables. **References** 1. Chou, Y.; Tsai, C.; Lee, Y.; Pei, J. (2012). *Pediatrics International*, 54, 111-116. 2. DEVELOPMENT AND APPROBATION OF MANAGEMENT AND ANALYSIS SYSTEM FOR SCIENTIFIC AND PROJECT ACTIVITIES

Kuleva, M., Mihailov, D., Chalukov, M., Djobova, S.

National Sports Academy

Introduction National Sports Academy "Vasil Levski" (NSA) is the only specialized higher education institution in Bulgaria which educate specialist in the field of coaching, physical education, kinesitherapy and other sports related specializations. With the development of the new trends in European higher educational zone, are creating conditions where the universities are facing new challenges. With the opening of the doors of educational institutions to third countries (Erasmus +) impose rapid change in existing processes in universities to meet challenges of the highly competitive market. Currently, in the NSA - Sofia, we developed a modern system (web-based platform) that can quickly and easily generate references to published scientific articles, published books, participation in research projects and leading/tutoring of PhD students. Our aim was to build and approbation such a system, in which the professors and lecturers from NSA, easily by them self, to be able to enter the needed information of various activities in the web-based platform, which we believe will facilitate the process of collecting and summarizing information. Such information is necessary for the administration of scientific evaluation processes in the NSA and periodic reporting of the development of sport science at the NSA. The aim of study is to analyze the development and trends of the sport science in the NSA during the years, through the created web-based platform. **Methods** 1. An interview with the academic staff (350 people) for their satisfaction of working with the system, and the difficulties encountered. 2. Content and factor analysis of the most frequently used keywords in the scientific work of the teaching staff. **Results** At this interim level of development, we have the following result from the interviews with the lecturers: 77% of respondents expressed satisfaction with the work of the established system and found it efficient. 15% found it insufficiently developed, and 8% had a neutral opinion. From the data and keywords entered into the system by the teachers themselves, for the period from 2010 to 2013, we have determined the following results: the most common theme in scientific research is coaching methodology and talents identification. **Discussion** At the environment of high competitiveness among higher educational institutions and the necessity of quick access to information it was necessary to conduct a research for the development of the sports science, trends and the general situation, publications and participation in conferences of teachers of NSA. The initial data gathered will give us opportunity to conduct national project for defining the trends in the national sports science.

THE CASE OF BRAZIL'S ADVENTURE SPORTS COMISSION: AN ABANDONED POLICY AGENDA

Bandeira, M.M., Silva, D.S., Amaral, S.C.

Campinas State University

Introduction This article, part of doctoral research supported by FAPESP, investigated why the demand for the regulation of adventure sports in Brazil ceased to be an issue after the creation of a governmental body to attend to it. **Methods** Document analysis of different official publications by the Brazilian government was conducted based on the documental criticism method (Cellard, 2008). **Results** Due to a disagreement with tourism bodies over the regulation of the practice of adventure sports, the Sports Ministry created, in 2006, the Adventure Sports Comission (CEA) at the request of representatives of sports associations. The CEA has as its objective the elaboration of a national policy for alternative and outdoor sports, and the standardization of the concepts and techniques used by confederations, federations, and associations already existing in Brazil. Therefore, two concepts were developed: one for adventure sports and another for radical sports, officially defined in a 2007 publication. The intention was to disseminate these concepts at events that sought the standardization of safety norms. However, these efforts never were carried out. The commission was never convened again and its plans ceased to move forward. **Discussion** The state of adventure sports is part of a larger picture. Brazilian sports legislation, since its creation in 1988, is conceptually incongruent and privileges high-revenue sports, especially male professional football (Castellani, 2008). The Lula administration, in 2003, opened up the possibility of changing this with the National Sports Conference, a biennial space where the public gives input into the creation of policies for the sector. The decisions taken at the 2004 and 2006 reinforced the focus on leisure sports, but nothing was implemented. After the 2008 conference failed to be convened, the government's priority in 2010 came to be the hosting of sporting mega-events such as the FIFA World Cup in 2014 and the Olympic Games in 2016, and the inclusion of Brazil in the top 10 ranking at the Olympics (Mascarenhas, 2012). In 2012, the Conference also didn't happen, and the Sports Ministry neglected other discussions, such as adventure sports regulation. **References** Castellani, L. COMMUNITY CAPACITY BUILDING EVALUATION OF THE ORGANISATION OF A WALKING SCHOOL BUS PROGRAM IN TWO SOCIOECONOMICALLY CONTRASTED SETTINGS - PRELIMINARY RESULTS

Lapointe, L., Laberge, S.

Université de Montréal

Introduction: The proportion of students who walk to school in Canada has decreased significantly over the past ten years. Based on its expertise in community engagement and partnerships, the Canadian Cancer Society created Trotibus, a volunteer-driven Walking School Bus (WSB) program, to address this problem. It is known that, over time, the declining in the volume of volunteers, and the burden placed on those who continue to participate, seems to be problematic in WSB programs (Buliung et al., 2011). The development of community capacity building (CCB) as a health promotion strategy seems to be a promising approach to sustain such programs (Labonte et al., 2002). This study aims to understand the processes involved in the organisation of a WSB program and to explore the facilitators and barriers to the development of CCB in two different settings that are socioeconomically contrasted. **Methodology:** We conducted semi-structured interviews with stakeholders from two implementation sites in Montreal. The two communities were selected for their socioeconomic contrast because this variable is one of the most influent social determinants in health inequalities (Marmot, 2005). We investigated respondents' perspectives on the factors contributing to the organisation of a WSB in their community. **Results:** Our preliminary findings suggest that CCB processes involved in the organisation of a WSB program differ in each sites of this study. In the socioeconomically

privileged community, the leadership and the involvement of a few volunteer citizens in partnership with the school principal and other community organizations seems to be the key elements of the WSB organisation. In the socioeconomically underserved community, it appears to be more difficult to recruit participants to organize and take in charge broader responsibilities. The main barriers to their involvement include working part-time with unstable schedules, having other priorities to deal with and not being able to communicate in the local language. Having an external community organisation leading the project seems favourable to the WSB program on a short-term in such a setting, but limits the development of CCB. Further analysis is required to better understand the CCB dimensions involved in the organisation of a WSB program in different settings. Buliung, R. et al. THE POWER OF THE BIAS ATTITUDE IN THE FITNESS CLUB.

Jeong Min, K., So Ra, K., Jung Rae, L.

Kyungpook National University

Introduction Almost people are interested in the healthy life. Therefore, participants of fitness club are increased for a variety of reasons. The purpose of this study is to analyze about obese participants who felt the bias attitude from other people in the fitness club. **Methods** Participants of this study were 10 people who are obese. Data were collected by using in-depth interview, related data and text analysis. **Results** The results were as follows: First, obese participants had negative attention from other people. And the bias attitude could make uncomfortable to obese participants. Second, bias attitude of other people influenced obese participants, it made uncomfortable to obese participants, so they take exercise another place where there were not many people. Third, the influence of people bias attitude, in severe cases participants not only stress but also avoid workout. **References** 1) Nam, Sang-woo: The power of the Public in sporting Events: Articulation of crowd Riots, Synopticon and Customerism. 2009. 2) Kim, in-sook, Kim, min-ju: Reproduction of Obesity Stigma in Korean TV Diet Survival Programs : Focused on 'BIGsTORY' and 'Diet War'. 2012. 3) Jang, seung-hyun: Fitness Club Space's Sociologic Implication and Reproduction. 2013.

UNDERSTANDING FEMALE BODYBUILDER'S EMOTIONAL ACCEPTANCE ACCORDING TO REACTION FROM AN AUDIENCE IN THE BODY-BUILDER COMPETITION.

Jung Rea, L., Jeong Min, K., Sora, K.

Kyungpook National University

Introduce. Body-builder competition is held as male or female. In case of female's competition, it consists of body-builder and fitness. Competition which is female body-builder was developed as traditional type and recently competition which is female fitness was added as new contest. Since female's competition was divided into body-builder and fitness, the reaction of audience who enjoyed female body-builder is changed. This study is to find out how female body-builder accept judgment from audience's reaction in the contest of body-builder. **Methods** In this study, 9 female participants who are body-builder were selected. Data were collected by using in-depth interview and related data that researcher observed them and then wrote record. **Result** The results were as follows: First, female body-builders were aware of difference which is audience's reaction between body-builder and fitness. Second, because of differentiated reaction from audience, female body-builders got relative distinctions. Also, they confused about their identity as athlete. Third, for the reason which is differentiated reaction about fitness from audience, female body-builder are considering to change to be a female fitness.

THE PRETEST OF SCUBA DIVING AS OTHER LEARNING EXPERIENCE IN STUDY THE CHANGE OF GENERIC SKILLS AND PHYSICAL ACTIVITY PATTERNS OF SECONDARY STUDENTS IN HONG KONG

Cheng, Y.C., Yeung, Y.W., Chan, C.C.

The Chinese University of Hong Kong

Introduction Scuba Diving is one of the adventure sports featuring physical exertion and highly specific equipment. It is not included as teaching sports in the Hong Kong secondary physical education curriculum. As scuba diving requires certain kind of physical fitness and relies on buddy system, learning this sport is a new other learning experience for the secondary students. The students may be inspired their motivation on physical activity and their mutual generic skills after learning scuba diving. According to the physical activity pyramid (ACSM, 2013) suggested that enjoy leisure activity two to three times per week can enhance physical fitness. Besides, students can communicate with hand signals underwater, they might develop certain extent of generic skills during taking the course. **Method** 12 students among two classes (60 students) from the Hong Kong Aberdeen Baptist Lui Ming Choi College were invited to participate in this study. A Chinese version of questionnaire on physical activity participation (Hui et al., 2013) was used to assess leisure time physical activity patterns and generic skills of the students. The scuba diving course includes theory lessons, confined water and open water training. They will have open water certification after fulfill all the requirements. The questionnaire and group interviews will be conducted to study their changes of physical activity pattern and generic skills after learning the scuba diving course. **Results** Results of the pretest findings: 1. There was 17 students (28%) reported they have one or two times twenty minutes light intensity exercise weekly. 2. There was only 11 students (18%) reported that they have regular exercises on daily leisure time besides taking physical education lessons. 3. There were 36 students (60%) reported that they would share their experiences on participation of physical activities with other persons. 4. There were 24 students (40%) reported that they have tried to create new dancing posture, gymnastic exercise and skills on participation of physical activities. **Discussion/Conclusion** The findings showed that not many students like physical activities and would often engage in regular physical activities. The different kind of sports that they learned on the physical education lessons may not have strong inspiration on their daily leisure time physical activities. More than sixty percent of the students would share their experiences on participation of physical activities with other persons. Some of the students may not be very creative in thinking on physical activity as shown from the results. This study will investigate the change of generic skills and physical activity patterns of the students after learning adventure sports like scuba diving course. **References** ACSM. (2013). Sport Management

SELECTED VARIABLES THAT AFFECT BASKETBALL FANS' DECISIONS OF PARTICIPATION IN THE BASKETBALL MATCHES

Yildiz, A., Kocak, M.S., Altunsoz, I.H., Devrilmez, E.

Middle East Technical University

Introduction Watching sports events became a long tradition, which began in the first Olympics in 776 BC, and today sport spectating is one of the most important forms of leisure behavior in contemporary society (Trail & James, 2001). Understanding the motives of spectators to participate in a basketball match is important for increasing the number of spectators. Main purpose of this study was to analyze the selected variables that affects on fans' participation in basketball matches. Methods Supporters of two Turkish professional basketball teams formed the sample of the study (n = 259). Data were collected in the sports hall before these teams' matches. Participants were sampled by convenience method. Fans' Participation Decision Scale (Gençer & Aycan, 2008) was used to assess the factors that make participants decide to attend a match. Those factors are such as physical environment, rival team, favorite team, convenience of the organization, attraction of the match, and socialization opportunity. Results Descriptive and MANOVA analyses were used in data analysis process and the analyses were conducted by IBM SPSS 22 package program. Number of male (75.68 %) participants in this study was dominantly more than female (24.32 %) participants. Mainly; participants declared that they participate matches with their friend(s) (63.71 %) and they follow matches once in a week (33.98 %). MANOVA results showed that there is a significant difference between attending type and factors ($F(1, 212) = 2.83, p < .05$), and 2 main effects were found between attending type variable and socialization opportunity ($F(2, 215) = 7.19, p < .008$). Discussion Similar with the previous studies (Gençer & Aycan, 2008; Kahle, Duncan, Dalakas, & Aiken, 2001); quantity of female fans is less than male fans. This shows us that basketball teams need to take attentions of female participants in their marketing activities. According to another finding; most of the participants attend matches with their friends. Creating an appropriate environment for families may increase number of fans. Socialization opportunity scores of the participants who attend matches alone are significantly higher than the ones who attend with family and friends. Hence, it might be concluded that people who attend alone consider the match venues as places to socialize. References Gençer, R. T., & Aycan, A. (2008). CUSTOMER PRODUCTIVITY IN TECHNOLOGY-BASED SELF-SERVICE OF SCREEN GOLF

Son, J.I, Lee, H.2, Kim, T.I, Chang, K.I

1:Sungkyunkwan University, 2:Sangmyung University

Introduction Technological innovation has influenced business practices for several decades, and many service firms including sports service firms are also recently utilizing technology extensively in order to reduce the use of labor. As more and more service firms adopt technologies in order to encourage customers to perform services on their own, the growth of technology-based self-service (TBSS) has been remarkable. To have customers perform certain tasks, normally undertaken by employees, is an important means to improving productivity. This study investigates how the user's perception of technology-based self service affects customer productivity, and how the customer productivity evaluated by TBSS influences the customer's intentions to reuse. Methods We have selected screen golf (i.e. virtual golf simulator), which is a widely successful serious game in Korea. The participants in the study were drawn from 15 screen golf centers in Seoul, Korea. The questionnaire, which contained the measures of TBSS perceptions, customer productivity, and intention to reuse were distributed. To test the hypotheses, structural equation modeling was performed using LISREL. Results The results revealed that customers' perceptions of TBSS (i.e. ease of use, performance, fun, and a sense of presence) have all contributed positively to customer productivity. It was also found that the customer productivity gained in screen golf TBSS positively influences the customer's intentions to reuse. Discussion This research has important implications for the enhancement of the TBSS in sports marketing literature. Although previous TBSS research in sports has been limited, this exploratory research provides some important issue such as how customers are affected by TBSS; and ways to influence customers' patronage intentions by using TBSS. Contact skkusport@gmail.com

THE USE OF SPORTS COMPETITIONS TO ENRICH STUDENTS' VOCABULARY IN FRENCH AS A FOREIGN LANGUAGE

Hamdy, A.A., Hassan, M.R.

Damietta University, Egypt; Montreal University, Canada

Introduction Researchers have suggested that sports and physical activities can support intellectual development and improve academic performance of students. According to Joe (1998), to acquire a word, we must first detect its meaning, then we must understand its meaning in another context, and finally we must use it. Sports have an important place in the lives of students. Competitions can motivate them to excel even more in their studies and this would produce very successful students. A number of studies showed that the students of French as a foreign language in Egypt are not able to communicate verbally through language. They can't do that because of their lack of vocabulary. In addition, the vocabulary is not the subject of a systematic learning in the classroom. The teachers considered it as a supplement in learning and give little or no consideration to the acquisition of vocabulary. It therefore seems noteworthy to undertake further studies to enrich the vocabulary of the students in French through sports competitions. Methods The study was limited to four sports: basketball, volleyball, football and tennis of table. These four competitions focus on learning vocabulary. The vocabulary knowledge was measured by a test administered to 60 students at the beginning and at the end of the four week of study. The lexical items on the test were selected from terms that are used widely across the four games. The students were divided randomly and evenly into two groups: control group and experimental group. Results A comparison of the two group's results suggests a trend toward the effectiveness of sports competitions as a method that helps acquire foreign language vocabulary. The sports competitions approved a positive and profound effect in vocabulary enrichment. The authors suggest that incorporating sports activities into student learning can improve student vocabulary learning by increasing word acquisition at students. Discussion This finding reaches similar conclusions reached by Newton (2013) and Joe (1998), that gives too much weight to related vocabulary learning in classroom communication tasks. The teachers must give consideration to the effects of vocabulary in foreign language acquisition and to the role of group activities to facilitate understanding, learning definitions of words and lexical memory of students. References Joe, A. (1998). What effect do text-based tasks promoting generation have on incidental vocabulary learning. *Applied Linguistics*, 19, 357-377. Newton, J. (2013). Incidental

vocabulary learning in classroom communication tasks. *Language Teaching Research*, 17(2), 164–187. Contact: aladdin@du.edu.eg, rania.mohamed.hassan@umontreal.ca

SUPPORTING THE STUDENT ATHLETES' EDUCATIONAL DEVELOPMENT AND SPORTING PERFORMANCE IN THE UK

Lee, P., Jiang, R., Huang, H.

National Taichung University of Education; National Taiwan University of Physical Education and Sport; National Cheng Kung University

Introduction It is increasingly recognized that helping talented student-athletes to cope with their academic studies and sport is one of the most commonly encountered issues in different countries. In the UK, the partnership of providing student-athlete support between organizations such as Universities, English Institute of Sport (EIS), NGBs and so on, has been seen as an example of contributing to student-athletes' training and competing support, to develop and reach their maximum potential, whilst at the same time continuing their academic studies. **Objectives** This discussion is about elite, or high performance, sport and primarily about how the British universities and other actors provide lifestyle support for the talented student-athletes. **Materials & Methods** The researchers employed a range of qualitative research methods to conduct the study by drawing on empirical materials from interviews with actor representatives, together with analysis of British sport official reports, academic articles, and media commentaries etc. In total, 8 interviews were conducted in the UK between 1st to 9th November in 2013. In addition, 33 references were reviewed and 18 commentaries were identified to conduct this research. **Results & Discussion** In the UK, the Sports Development Center (SDC) in universities works with EIS and with NGBs to assist student-athletes to maintain a balance between sports' and education and other life pressures. Services provided by such a collaboration between the SDC and other organizations include sports science, medical support, lifestyle support/mentoring, and education/career support. The SDC provides student-athletes with support, such as a specific performance sport induction, a leadership skills program, a mental service, and an anti-doping educational program etc. Working with academic departments, under university policies, is one of the SDC's main tasks, by offering stretching degrees and exam flexibility for student-athletes. **Conclusions** In short, the major contribution of delivering services, related to performance lifestyle for student-athletes by the SDC in British universities, is career development. To some extent, it has met those 'needs' of the educational institutes, EIS, NGBs, and student-athletes in some elements. This implies that such a partnership is able to assist student-athletes by enhancing them aside from their academic career and their main sporting core career. In other words, to get the best out of student-athletes' sporting side as well as developing them for a future career.

ESTABLISHMENT THE TAIWAN DOMESTIC BIDDING FRAMEWORK FOR THE REPRESENTATIVE CITY OF HOST AN INTERNATIONAL MEGA SPORT EVENT

Huang, H.

National Cheng Kung University

Introduction Hosting international mega sport events has been listing as an important context of sport policy in Taiwan. After successful hosting 2009 World Games in Kaohsiung, as well as Deaflympics in Taipei, the overwhelming atmosphere gave the Taiwan society realized the positive impact of the international sport event. More local city governments expressed their interests to bid for more mega sport events. However, many local governments or politicians who only thinking about the positive influence of increasing tourists, expansions, employment rate, reputation but ignoring many practical preparing works need to be done before starting a bid. Therefore, the study tried to establish a domestic bidding procedure and evaluation framework for selecting the best candidate city in Taiwan. **Materials & Methods** The researchers employed a range of qualitative research methods to conduct the study by drawing on empirical materials. First, the study tried to identify the sport event legacy items which could be suitable for establishing in Taiwan's society. Then, the study selected four sport event and analysis the cost into three categories, as fix-cost, variable-cost and value adding-cost. Final, the study organized four interviews and two focus group discussions with actor representatives. The main topics covered areas from confirm sport event legacy to positive impact and sport event cost structure of international multi-sport event, and the bidding guideline. **Discuss & Conclusions** After analyzing data from meetings as well as interviews, it proposed several important findings. First, the legacy evaluation framework for international multi-sport events is created. This framework consisted of seven themes, including economic, politic, city infrastructure, tourism, social-cultural and sport legacy. Several dimensions were grouped under each legacy based upon its homogeneous. Second, evaluation item and weighting in the financial plan were clearly stated. Evaluation items included local sport achievement (10%), legacy aspect (20%), financial aspect (30%), facility aspect (10%), public support aspect (10%), and others (10%). Ratio of reimbursement and reimbursed item would be based upon its event category. Three, financial scheme reviewing operation procedure would be divided into bidding and organizing period. In the bidding period, five steps started from the announcement of event hosting policy and event candidature proposal, open period of event bidding and financial reimbursement proposal, screen of event bidding proposals, organization of reviewing meeting, reimbursement for a bidding task. The local organizing committee would be required to send its event preparation scheme for further screening after its successful bidding.

Sport Statistics and Analyses

THE DEVELOPMENT OF A PERFORMANCE ANALYSIS SYSTEM FOR FREESTYLE SWIMMING START PERFORMANCES IN ADOLESCENT MALE SWIMMERS

Dormehl, S.

Manchester Metropolitan University

This study aimed to develop a notational analysis system to identify key performance indicators in freestyle starts using adolescent males in competition. Ultimately 19 performance indicators, split into five phases, were described and refined following discussion with expert coaches. Overall Cohen's Kappa values for reliability were acceptable (0.66 - 0.72) according to published sport-determined thresholds, despite definition interpretation discrepancies and difficulties in observing post-event video footage, reducing intra-operator reliability in some performance indicators. Operator experience improved inter-operator reliability. Six performance indicators appeared to contribute most to faster 15 m start times, although it was also apparent that the inclusion of the underwater phase would be relevant to any future studies when providing feedback to coaches.

DIFFERENCES IN SITUATIONAL INDICATORS AT K-1 GP FINAL 1993-2010

Kapo, S., Čutuk, H., Hasanović, E., Kapo, A., Čutuk, M., Merdzanic, S.

Faculty of Sports and Physical Education, University of Sara

Introduction Various observations and analysis, live fights, match recording details by various profiles of experts led us to the expansion and consolidation of knowledge on different possibilities of action and to concretizing of components that are important for success in K-1 sport (Kapo 2006). This article focuses to identify the parameters of K-1 fighters situational efficiency based on the registration of events during the competition with the support of a set of technical and tactical elements that are performed during the Final of K-1 Grand Prix tournaments in 1993 and 2010. **Methods** The sample consisted of sixteen top K-1 heavyweight crown competitors who are specialists in certain martial arts (Box, Kick box, Karate, Muay Thai, etc.) competing by the rules of K-1. Total number of variables for this study was 38, in order to produce a detailed record on the condition of represented technical and tactical elements. Analysis of the K-1 tournament was based on data collected from video records of fourteen fights. Collected data were processed by descriptive statistics. **Results and discussion** Basic descriptive parameters of the technical and tactical elements indicate that the overall frequency of hand kicks is 1796, of which in K-1 WGP 1993 Final was 512, or 28.5%, and in K-1 WGP 2010 Final, frequency of hand kicks was 1284 or 71.5%. Total use of leg kicks was 1011, of which at K-1 WGP 2010 Final frequency was 699 or 69%, and in K-1 WGP 1993 Final frequency was 312 or 31%. The higher frequency of leg kicks application is remarkable in the K-1 WGP Final 2010 at low circular kick – lowkick 43%, while the fighters in 1993 tournament were more efficient in advanced techniques highkick 5%. Application of defense during competition had a higher frequency with K-1 fighters in WGP 2010 Final and it was 1,646, of which 1,327 or 81% and fighters in K-1 WGP 1993 Final had a defense application frequency of 319 or 19%. The manner in which they achieved win, points out the greater efficiency of fighters from the tournament in 1993 and they have ended the fight before the regular expiration of the match so they had a frequency of five wins by knockout or 36%, while fighters in 2010 tournament had more frequent wins by decision of the judge, 4 or 29%. **Conclusion** The obtained statistical indicators show us that success in K-1 sport is determined by level and structure of a large number of skills, knowledge and qualities that can be measured and analyzed and then by appropriate means and methods can be improved during sports career of K-1 fighters and on that way give contribution to the efficient dealing with the toughest martial arts nowadays. **References** 1.Kapo, S. (2006). Structural Analysis and Model of K-1 Top Level Fighters. Dissertation (In Bosnian). Faculty of Sports and Physical Education, University of Sarajevo. BiH. 2.Cikatić B., (2012). EXPERT ANALYSIS 1993 K-1 GP FINAL JAPAN, Master's Paper, Faculty of Sports and Physical Education, University of Sarajevo, BiH

PERFORMANCE ANALYSIS IN SOCCER: FACTS AND FALLACIES

Broich, H., Seifriz, F., Yue, Z., Wigger, U., Mester, J.

Bayer04 Leverkusen, German Sport University Cologne

Introduction Compared to the popularity of soccer game all over the world, the performance analysis for soccer games is still very limited because of the complexity of the games. The motions of players are not deterministic, but always with some random factors. This causes the difficulty of performance analysis. Although a huge amount of data of soccer games is now available, it is still challenging how to extract useful information from the data in order to hopefully reveal some insights into the game which would be more or less helpful to the coaches. Following our former researches in this area (Yue, Broich, Seifriz, Mester, 2008a,b; 2011, 2014), the present analysis will focus on one point: the statistical influence of the running distance to the result of the game. **Methods** The present statistical analysis is based on the 17 "playing days" ("Spieltag" in German, which actually includes three days and 9 matches) of the current Soccer Season of Bundesliga (Aug. 10, 2013 – Jan. 29, 2014). Although the Soccer Season is still going on, 17 "playing days" (9×17=153 matches) are just enough for each of the 18 teams in Bundesliga to compete against each of other 17 teams. The correlation analysis among various team parameters are carried out. The purpose is to find how various parameters are statistically related to the result of a game. One naive idea could be that a stronger team should be more active in the game and therefore would run a longer distance back and forth during the 90 minutes of the game. But our statistical analysis shows that this is not the case. **Results** The correlation between the total distance and the total points is insignificant. The correlation between the total distance and the total goals is also insignificant. All running parameters such as sprints, running etc. do not correlate with performance. **Discussion/Conclusion** The "point" a team obtained from a match is defined by 3, 1 and 0 for winning, drawing and losing respectively. Thus, the ranks of all the 18 teams after the 17th "playing day", are completely determined by the total "points" obtained by each team during the 17 matches it has participated in. In all cases, the running parameters do not all contribute to variance of performance. We can also see that different teams have different performing styles. Among the strong teams, the teams with the ranks 1 (FC Bayern München), 2 (Bayer 04 Leverkusen), 5 (VfL Wolfsburg) and 7 (FC Schalke 04) run shorter distances than the teams with the ranks 3 (Borussia Mönchengladbach), 4 (Borussia Dortmund) and 6 (Hertha BSC). **References** Yue Z., Broich H, Seifriz F, Mester J. BMI, BODY MASS AND HEIGHT, AND THE LEVEL OF SPORTS COMPETENCE IN THE PARTICIPANTS OF THE WINTER OLYMPIC GAMES IN 2010

Szmatlan Gabryś, U.1, Stanula, A.2, Ozimek, M.U.1

University School of Physical Education, (Cracow, Poland)1, The Jerzy Kukuczka Academy of Physical Education, (Katowice, Poland)2.

Introduction Somatic parameters such as body height, body weight or body mass index (BMI) have a bearing on training strategy, as they can affect the technique and tactics of competition and athlete's specialization within a given discipline (Wilmore, 1983). The aim of this study was establish the body height, body mass, and BMI values characterizing the athletes that participated in the Winter Olympic Games in 2010 in Vancouver, and to assess whether these are associated with the metabolic requirements of their respective sports. **Methods** The sample consisted of athletes in the top 20 places of each of 14 sports disciplines played at the WOG in 2010 (1460 cases). The sampled athletes were grouped according to the predominant type of energy metabolism during competition using criteria such as duration and intensity of effort (Åstrand et al., 2003). A cluster analysis was then applied to aggregate the particular disciplines and events of the Winter Olympic Games into groups based on anthropometric characteristics. **Results** The groups of winter sports derived from a cluster analysis based on the somatic parameters and those produced based on the predominant type of energy metabolism were dissimilar. This implies that in particular disciplines of most winter sports (excluding luge, bobsleigh and alpine skiing) the athletes have different body build, so a single profile of the athlete cannot be established. **Discussion** The contemporary winter athlete has well-

trained strength and anaerobic endurance. These characteristics are related to larger body mass and higher BMI values. Strength and speed endurance training is becoming increasingly important for athletes' performance. The results seem to indicate that the somatic parameters of the athletes in winter sports disciplines such as cross country, biathlon, and speed skating reflect a shift in the direction of athletic training (Stanula et al., 2013). THE ROLE OF COMMUNITY DENSITY IN THE DEVELOPMENT OF ELITE HANDBALL AND FOOTBALL PLAYERS IN DENMARK

Rossing, N.I, Nielsen, A.I, Elbe, A.2, Karbing, D.S.I

Aalborg University

Introduction Birthplace studies (Macdonald et al., 2009; Côté et al., 2006) highlight the critical role that an individual's early environment plays in facilitating athletic development and participation in sport. These studies have shown across various sports and nations that elite athletes tend to come from communities with 100.000-500.000 inhabitants (Côté et al. 2006). Bruner et al. (2011) suggested that the proportional number of youth players could explain the effect, which later studies have supported. The purpose of this study was to investigate which communities, Danish elite football and handball players primarily have lived during their development years and which communities have the highest proportions of youth players. **Method** The sample included 366 male handball and football players from the best Danish leagues in the season 2011-2012 and a comparison sample of 147,221 football and 26,290 handball male youth players under the age of 12 from 2003 corresponding to the youth development years of the elite players. Communities were divided into six subdivisions by population density. Population density was used as a proxy since this should reflect the built and the psychosocial environment. Odds ratios (OR) were calculated for community sub-divisions by comparison with census statistics. Results were considered significant if 95% confidence intervals (CI) for OR did not include 1. Results Communities with the highest density (≥ 1000 pop./square km) produced a disproportionately high number of elite football players (OR [CI]) (2.08 [1.55-2.81]). Contrary to football, communities with a medium population density (100 to < 250 pop./km²) produced a higher number of elite handball players (1.79 [1.27-2.53]). However, there were few youth players in both sports in communities with high density (≥ 1000 pop./square km) (football: 0.70 [0.69-0.71]), handball: 0.48 [0.46-0.50]), and an overrepresentation in rural communities (< 50 pop./km²) (football: 1.42 [1.40-1.44]), handball: 1.81 [1.81-1.81]). **Discussion** The study indicates that communities with different population densities affect the talent development process, and that it is sports dependent. This may be due to built and psychosocial environment, such as sport facilities, sports culture etc. Youth and elite players were overrepresented in different density sub-divisions indicating that the birthplace effect is not only related to the number of registered youth players in Danish football or handball. MORTALITY IN ACTIVE PROFESSIONAL ATHLETES

Lemez, S., Wattie, N., Baker, J.

York University

Introduction Public perceptions of the long-term value of being a professional athlete may be somewhat distorted by social media. For instance, deaths of widely known active athletes are known to the public, which may lead to public perceptions of early death in professional sport despite evidence suggesting otherwise. Teramoto and Bungum's (2010) literature review suggested athletes exposed to more aerobic actions had greater lifespan longevity gains than the general population. Further, athletes are not homogeneous; the relationship between mortality and professional sport is likely more nuanced than previously considered. The purpose of this study was to analyse mortality causes and trends among professional athletes who died during their playing careers. **Methods** Participants included 212 deceased professional athletes from the four major sports in North America: the National Basketball Association (NBA), National Football League (NFL), National Hockey League (NHL), and Major League Baseball (MLB). All players had to have played at least one game in one of the four aforementioned sports and been part of an active roster on a professional team when they died. Descriptive and odds ratio (OR) analyses were performed using the Statistical Packages for the Social Sciences Version 21 (IBM Corp., 2012). Data were collected through a variety of verified sources (e.g., official team press releases, encyclopedias, almanacs). **Results** Descriptively, the mean (M) death age was lower for NFL (25.8 years) and NBA (26.7 years) players than for the MLB and NHL players (28.5 years). Overall, the leading causes of death were from car accidents (n = 53; 25%), homicides (including casualties of war; n = 20; 9.4%), plane crashes (n = 19; 9%), cardiac diseases (n = 15; 7.1%) and suicides (n = 14; 6.6%). NFL and NBA players had a higher likelihood of dying in a car accident (OR = 1.87; CI (95% confidence interval) = 0.99-3.51), although the relationship just missed significance. Mortality rates were higher from 1960 to present (n = 147; 69.3%) when compared to the earlier decades (<1960). **Discussion** In this sample, the youngest age at death was 18 years and the oldest was 44 years (M = 27.5). Given the variability of age at death (standard deviation = 4.45), career length did not appear to influence mortality trends in active professional athletes. Further, some similarities existed in the leading causes of death compared to the North American general population. In a broad sense, a global understanding of the implications of involvement in professional sport is necessary for the formation of evidence-based models of athlete development and care. CHANGES OF PLASMA ANGIOGENIC FACTORS DURING CHRONIC RESISTANCE EXERCISE IN TYPE I DIABETIC RATS

Shekarchizadeh, P., Karimian, J., Sheikholeslami, S.

university

Objective: Exercise has several beneficial effects on cardiovascular system. However, the exact mechanism is unclear. The purpose of this study was to evaluate the effects of chronic resistance exercise on some plasma angiogenic factors in type 1 diabetic rats. **Methodology:** Thirty male Wistar rats were divided into three groups of control, diabetic and diabetic trained (n = 10 each). Diabetes was induced

by a single intraperitoneal injection of streptozotocin (55 mg/kg). The rats in the trained group undertook one training session per day, 3 days/week, for 4 weeks. Blood samples were taken and the concentrations of plasma glucose, lipid profile, nitric oxide (NO), vascular endothelial growth factor (VEGF) and soluble form of VEGF receptor-1 (sFlt-1) were determined. Results: We found a significant reduction in plasma NO concentrations in diabetic rats compared to the controls ($p < 0.05$). After four weeks of resistance training, plasma NO concentrations increased ($p < 0.05$). Plasma VEGF concentrations were not significantly different between diabetic and control groups ($p < 0.05$). However, plasma sFlt-1 concentrations in diabetic rats were significantly higher than the controls ($p > 0.05$). There were no significant differences in plasma VEGF and sFlt-1 concentrations between diabetic sedentary and trained groups ($p > 0.05$). Moreover, VEGF/sFlt-1 ratios in diabetic animals were lower than the control group and resistance exercise could not increase this ratio in diabetic animals ($p > 0.05$). Conclusion: Resistance exercise could not change plasma VEGF, sFlt-1 and VEGF/sFlt-1 ratio. However, it increased plasma NO concentrations in diabetic animals. More studies are needed to determine the effects of this type of exercise on the angiogenesis process.

EFFECT OF RESISTANCE TRAINING ON PLASMA NITRIC OXIDE AND ASYMMETRIC DIMETHYLARGININE CONCENTRATIONS IN TYPE I DIABETIC RATS

Karimian, J., Shekarchizadeh, P.

university

Background: Asymmetric dimethylarginine (ADMA) has a predominant role in progression of some cardiovascular diseases, including diabetes. It interferes with L-arginine in production of nitric oxide (NO) by inhibition of NO synthase. The purpose of this study was to evaluate the effect of resistance training on plasma NO and ADMA concentrations in type 1 diabetic male rats. **Methods:** Thirty-six male wistar rats were randomly divided into four groups: (1) control; (2) diabetic; (3) diabetic trained, and (4) control trained ($n=9$ each). In the trained groups, the animals undertook one training session per day, 3 days/week, for 4 weeks. At the end of experiment, blood samples were taken and the concentrations of plasma glucose, insulin, lipid profile, NO and ADMA concentrations were determined. **Results:** plasma ADMA concentration showed a significant increase in diabetic rats compared to control group (0.73 ± 0.07 vs. 0.62 ± 0.04 $\mu\text{mol/l}$; $P < 0.05$). The plasma ADMA level in the trained diabetic and control were lower than the sedentary groups, although it was not statistically significant. Plasma NO concentration in diabetic group was lower than control ($P < 0.05$). Resistance training significantly increased plasma NO concentration in diabetic animals ($P < 0.05$). **Conclusion:** Elevated ADMA level in diabetic animals can normalize during resistance exercise. Reduced ADMA level and increased NO level following resistance training might improve cardiovascular risk in diabetic subjects.

THE EFFECTS OF ACUTE EXERCISE ON SERUM LEVELS OF GROWTH FACTORS IN HUMAN

Kim, H.

Kyungnam University

Studies have shown that, depending on intensity, endurance exercise increases neurotrophins and thereby induces neuroplasticity. Previous studies have demonstrated that acute and chronic exercise leads to increases in growth factors in various brain regions. In order to discover how brain cell generative factor changes during exercise, and if the effect continues even after the termination of exercise, and the relation between energy consumption, changes in exercise intensity and change of brain cell generative factor during exercise, we had hourly analysis on BDNF, IGF-1, NGF, energy consumption, and intensity of exercise according to the implementation of integrated functional Taekwondo program for generating brain cells. As a result, there was no change made in the level of BDNF for control group in comparing all the phases. However, BDNF in exercise group had no significant increases until 30 minutes past from exercise, then it showed considerable increase constantly from 60 minutes to 90 minutes, which was close to the termination of exercise. As terminating exercise and having a rest, it started to go down, and reached to the stage of before exercise in 30 minutes. The changes of BDNF, IGF-1, and NGF in control group indicated no significant correlation with total energy consumption and average intensity of exercise. By contrast, in the exercise group showed the following correlations that they have a significant positive correlation between NGF and average exercise intensity in the section from the beginning of exercise to 30 minutes, have a significant positive correlation between BDNF of during and after the exercise and total energy consumption during 90 minutes of exercise, have a significant negative correlation between NGF and total energy consumption, and have a significant positive correlation between IGF-1 during and after 120 minutes including 90 minutes of exercise and 30 minutes of rest and total energy consumption. Through this study results, we can find out an acute bout of integrated functional Taekwondo program has an effect on the increasing of BDNF and also find out that the changes of total energy consumption and exercise intensity have a relation with the changes of BDNF, IGF-1, and NGF.

CLINICAL EFFECTS OF FOOD AND PHYSICAL EXERCISE ON ANAPHYLAXIS

Kwak, Y.

DONG-EUI UNIV

Food-dependent exercise-induced anaphylaxis (FDEIA) is a distinct form of food allergy which is induced by different types and various intensities of physical activity. It has been shown that allergen food consumption followed by exercise causes symptoms which vary depending on exercise duration and/or intensity. Allergen food or medications intake before exercise is a major predisposing factor. Urticaria and severe allergic reactions are general symptoms of FDEIA. Skin tests and serum food-specific IgE assays are the typical prescreening methods, and have been used during several decades. However, those screening tests are not sensitive enough to detect the FDEIA. Physical exercise may stimulate the release of a sufficient amount of mediators from IgE dependent mast cells and when exceeding a certain threshold can result in FDEIA. Degradation of mast cells might be the major factor but it has not been well elucidated yet. A number of food triggers have been suggested to be involved in FDEIA. The most commonly reported foods are wheat, eggs, chicken, shrimp, shellfish, nuts, fruits, vegetables, and some drugs. It is known that aspirin enhances the induction of type I allergy symptoms when combined with specific foods. Moreover, high intensity and frequency of physical exercise are more likely to provoke an attack than low ones. In this paper, we present the current views of the pathophysiological mechanisms that induce FDEIA and to consider these mechanisms within the wide context of exercise immunology to further enrich our understanding. We also present the details of FDEIA's definition, etiologic factors, and medical treatment for cholinergic urticaria and exercise-induced anaphylaxis.

THE USE OF COGNITIVE BEHAVIORAL THERAPY WITH CHIROPRACTIC TREATMENT AFTER SURGERY FOR ATHLETES ATTENDING THE SPORT MEDICINE FEDERATION OF IRAN

Same Siahkalroodi, L.

Sport Medicine Federation of Iran

Introduction The main objective of the present study was to investigate the effectiveness of cognitive behavior therapy along with chiropractic treatment of musculo-skeletal pain in athletes who have undergone surgery due to sports injuries. **Methods** To assess the initial state variables and collect data at baseline (phase A) and experimental phase (Phase B) of the following tools were used. 20 subjects according to diagnosis and referral to physician of chiropractor and psychologist using the results of the medical examination, clinical interview based on DSM-IV-TR, MMPI (Short form, 72 Question) and SCL-90-R tests before intervention have been selected and divided into 2 groups; 10 athletes in cognitive - behavioral therapy combined with chiropractic treatment group (combination therapy) and 10 athletes in cognitive - behavioral therapy group (individual therapy). All questionnaires (MMPI and SCL-90-R) and research tools (interview-based diagnostic criteria for DSM-IV-TR, using X-ray imaging and somatosensory potential test) for all subjects individually and run explained. **Results** The present findings indicate that interventions based on cognitive - behavioral techniques combined with chiropractic care effective in improving musculo-skeletal pain such as back and neck pain. Results also showed that cognitive - behavioral therapy alone is very effective role in improving musculo-skeletal pain. **Discussion** The results were indicated the high efficiency of both combination therapy and individual therapy. Comparative psychological profiles of subjects in both groups before and after intervention effectiveness is indicated. So that after the intervention, not only in the marital dissatisfaction indicators of somatization and physical condition has been significantly reduced, but also the subjects' scores on measures of depression, anxiety, obsession and suspicion toward others has dropped to normal levels. **References** Palmieri, H., & Smoyak, T. UNEXPECTED GENETIC MUTATIONS IN HIGHLY TRAINED ATHLETES WITH ELECTROCARDIOGRAPHIC PATTERNS EFFORT RELATED

Stoian, I.M., Antonescu, S., Stoian, I.

Prof. CC.Iliescu Emergency Cardiovascular Diseases Institute, Bucharest; **Romanian Academy, Medical Centre, Prevention, Diagnosis, Bucharest; *National Institute of Sports Medicine, Bucharest*

Introduction Electrocardiograms (ECG) in elite endurance athletes show sometime bizarre patterns suggestive of inherited channelopathies (Brugada syndrome, long QT syndromes) responsible for unexpected sudden cardiac death (SCD). Apparently effort related, these abnormalities could be true manifestations of electrical heart disease. The athletes, most of them without symptoms, have normal physical exams and no history of dramatic cardiac events. Other diagnostic tests are required, including specific genetic analysis. **Method** Preparticipation screening. Endurance sports (canoeing, rowing)-347 athletes (190 Seniors-101 M, 89 F; 157 Juniors -111M, 46F mean age 20y.o). Group (control)-505 normal aged-matched sedentary subjects (280M, 225F, mean age 21y.o). Standard ECG with high right precordial leads (V1-V3). ECG patterns in highly trained endurance athletes were classified. (1,2). **Echocardiography:** Two-dimensional, Doppler/TDI. **Genetic:** 227 athletes (114 Seniors, 113 Juniors), 35 normals selected. The ECG inclusion criteria for genetic study: Distinctly abnormal (inverted Twaves>2mm). Bifid T waves with distinct peaks and prolonged QTc. Brugada type 2/borderline Brugada. Long QT. Genomic DNA(200µl blood). SCN5A, KCN mutations studies (MLPA, MRC Holland). SALSA P108 for SCN5A; SALSA P114 for KCNQ1, KCNH2, KCNE1, KCNE2. **Results** Seniors: RSR'(V1-V3) in 45(23.68%), 5 of them with Brugada type 2. V1-V3 ST convexity and negative T wave, 34 (17.89%). Brugada type 1, 1(0.52%) with no SCN5A abnormalities. Epsilon waves 3(1.57%) and no gene mutations in specific tests. Juniors: Precordial V1-V3 with ST elevation 39(24.84%), 9(5.73%) of which with borderline Brugada sign; gene duplications: KCN (n=1), SCN5A (n=1). Bifid T wave, 39(24.84%), 5 of which with QTc(0.48'-0.56') and KCN gene mutations so, 7 athletes with gene abnormalities. **Discussion** Asymptomatic endurance athletes have sometime uncommon and training-unrelated ECG patterns, suggestive for electrical heart diseases responsible of SCD. The confirmation of these diseases, through specific tests including the genetic analysis is mandatory. In this study, the majority of athletes have ECG abnormalities confirmed to be training related. In few athletes the ECG abnormalities were associated with gene mutations. The preparticipation screening and follow-up are mandatory for the identification of athletes with SCD risk diseases. **References** 1.D.Corrado et al Recommendations for interpretation of 12-lead electrocardiogram in the athlete Eur Heart Journ (2010)31,243-259. 2.J.A.Drezner et al Abnormal electrocardiographic findings in athletes: recognizing changes suggestive of cardiomyopathy. INVESTIGATION OF THE SPORT INJURIES IN ELITE KAYAK ATHLETES: PREVALENCE AND CAUSES

Sohrabian Moghadam, A., Habibinava, R., Hassanloei, H.

Islamic Azad University, Boomhen

Investigation of the sport injuries in elite kayak athletes: prevalence and causes **Introduction:** Recent advances in sport medicine to improve the effectiveness of sport injury prevention notwithstanding, sport injury has increased in the past 15–20 years, and still remains a major reason for early retirement in elite athletes (Knowles et al., 2006). **Aim:** the aim of the this study was to investigate the prevalence and causes of sport injuries in elite male and female kayakers **Method:** 80 professional kayakers (68 male and 12 female) have been investigated in the current study. A questioner has been used to collect the information regarding the causes, types and the onset time of the injuries from athletes. **Result:** The results showed that the most injuries were common on upper limbs including palm and wrist. **Discussion:** Our results indicated injuries are common in palm and wrist, therefore great care should be taken during training and exercise in order to prevent early retirement in elite athletes. Injuries, kayak, elite

THE EFFECTS OF ACUPUNCTURE ON THE MUSCLE REACTION TIME OF THE TRUNK IN SUBJECTS WITH LOW BACK PAIN DURING UPPER LIMB MOVEMENT.

Kondo, H., Masunari, A., Kunugi, S., Yoshida, N., Izumi, S., Miyamoto, T., Miyakawa, S.

National University Corporation of Tsukuba University of Technology

Introduction Acupuncture has been reported to have immediate as well as sustained effects for relieving pain and recovering functional impairments. This study aimed to examine the effects of acupuncture stimulation on the abdominal and lumbar erector spinae muscle EMG activity during upper limb movement. **Methods** 6 subjects with lower back pain (mean age: 19.8 ± 1.1 years). Assessment items were muscle reaction time of Trunk muscles EMG activity during upper limb movement. The electrode was placed at internal oblique muscle, multifidus muscle and deltoid muscle. Acupuncture was performed as an intervention for the left-right lumbar erector spinae muscles (L4 and L5) with an electrical stimulus of 1 Hz for 10 min. We were compared before and after intervention the difference between the muscle reaction time of the trunk muscles and the deltoid muscle. **Results** After acupuncture stimulation, the mean muscle reaction time of the multifidus was 11.6ms extension. The mean muscle reaction time of the internal oblique muscle was 1.5ms reduction. However, There was no significant difference in the before and after acupuncture stimulation. **Discussion** In previous studies, as moving the upper limb, to muscle activity on the abdominal and lumbar erector spinae muscle prior to the deltoid muscle has been reported. The results obtained showed the same tendency as the previous studies. Immediately after the acupuncture stimulation, there is a muscular strength decreases transiently. However, this study suggested that it does not affect muscle reaction time of trunk muscles by acupuncture. **References** Hodges PW, Richardson CA. (1996). *Spine*, 21, 2640-50. REPEATED BOUTS OF FAST BUT NOT SLOW VELOCITY ECCENTRIC CONTRACTIONS INDUCE ATROPHY OF GASTROCNEMIUS MUSCLE

Ochi, E.1,2, Nosaka, K.3, Nakazato, K.4

1: Meiji Gakuin University (Yokohama, Japan), 2: Okayama University (Okayama, Japan), 3: Edith Cowan University (Joondalup, Australia), 4: Nippon Sport Science University (Tokyo, Japan)

Introduction One bout of exercise consisting of fast velocity eccentric contractions of triceps surae muscles increased muscle protein degradation in rats (Ochi et al., 2010), but repeated bouts of slow velocity eccentric contractions performed every 2 days for 10 times increased medial gastrocnemius muscle mass (Ochi et al., 2011). However, changes in muscles after repeated bouts of fast velocity eccentric contractions have not been investigated. The present study tested the hypothesis that repeating four bouts of fast velocity eccentric contractions would activate molecules associated with atrophy and induce muscle atrophy, but repeating slow velocity eccentric contractions would not. **Methods** Male Wistar rats were randomly placed into 3 groups; fast velocity (180°/s) eccentric exercise group (180EC, n=7), slow velocity (30°/s) eccentric exercise group (30EC, n=7), and sham-treatment group (control, n=7). All rats received 4 sessions of either eccentric exercise consisting of 4 sets of 5 maximal eccentric contractions of triceps surae muscles or sham treatment every 2 days. All rats were sacrificed at 24 hours after the fourth exercise session, and target muscles were removed for the measurements of wet mass, cross sectional area (CSA), and western blot analyses for molecules associated with atrophy and hypertrophy. **Results** Medial and lateral gastrocnemius wet mass were 4-6% smaller, medial gastrocnemius CSA was 6-7% smaller, and isometric tetanic torque of triceps surae muscles was 36% smaller ($p < 0.05$) for 180EC than control after the fourth session, but no such differences were evident between 30EC and control. The expressions of atrophy-related molecules such as FoxO1, FoxO3 and myostatin were up-regulated (78-229%) only for 180EC, but an increase in phosphorylated p70s6k (227%) was found only for 30EC after the fourth session ($p < 0.05$). The level of Bax, a pro-apoptotic protein, was greater ($p < 0.05$) for 180EC than control. No apparent damaged muscle fibers infiltrated by inflammatory cells were found in any of the groups. **Discussion** These results support the hypothesis that muscles are degraded and atrophied by repeated bouts of fast but not slow velocity eccentric contractions. It is interesting that the atrophy was not associated with muscle fiber damage. It appears that fast velocity eccentric contractions increase protein breakdown by inducing FoxOs proteins and myostatin, but the underpinning mechanisms how this occurs are currently unknown. **References** Ochi et al. COMPARISON OF BODY COMPOSITION BETWEEN ELEMENTARY SCHOOL AND JUNIOR HIGH SCHOOL BASEBALL PITCHERS

Tsai, Y.S., Chang, C.K., Chen, E.Y., Wu, C.H., Juang, L.G.

University of Taipei

Introduction Growing may change body figure and body composition in teenagers. The main purpose of the study was to compare the differences in body composition between elementary school and junior high school baseball pitchers and to investigate their relationships with ball throwing velocity. **Methods** Twenty four elementary school pitchers (EP) (age: 11.7 ± 0.8 years, body height (BH): 155.5 ± 11.3 cm, body mass (BM): 49.4 ± 14.2 kg, BMI: 20.0 ± 3.6 , ball velocity (BV): 24.5 ± 2.0 m/s, experience: 1-2 years) and 28 junior high school pitchers (JP) (age: 14.6 ± 0.7 years, BH: 168.8 ± 7.4 cm, BW: 65.8 ± 12.7 kg, BMI: 23.0 ± 3.8 , BV: 30.4 ± 2.2 m/s experience: 2-4 years) who had experience of playing organized baseball games were invited to participate in this study. Ball velocity was measured with a sports radar gun in a human performance laboratory with a custom-made pitcher's mound and standard throwing distance for each age level. BH and BM were measured by the same standard scales for each player. Body composition was measured by a dual-energy X-ray absorptiometry (DXA). Independent t-tests were used to compare all variables between the two groups of players. Pearson correlation coefficients were used to investigate the relationships between each body factor and BV within each group of players. **Results** The JP group had greater amounts of net bone mineral and lean muscle mass and bone mineral density (BMD) than the EP group in both upper and lower extremities (UE and LE) and trunk. No significant differences in the amount of net fat mass were observed between the two groups. BH ($r = 0.691$), BM ($r = 0.494$), and the amounts of net bone mineral ($r = 0.564$ - 0.633) and lean muscle mass ($r = 0.600$ - 0.665) of each body part had low to moderate relationship with BV in the EP. In the JP group, BH ($r = 0.385$) and the amounts of net bone mineral ($r = 0.422$ - 0.650) and lean muscle mass ($r = 0.476$ - 0.625) of each body part had low to moderate relationship with BV, but no relationship between BM and BV was observed. The relationships between BMD of each body part and BV were only found in the EP group ($r = 0.426$ - 0.571). No relationships between the percentages of bone mineral, lean muscle, and fat mass in each body part and BV were observed in both groups. BMI was also not correlated with BV in both groups. **Discussion** Owing to growing taller and stronger, youth baseball pitchers may increase net bone mineral and lean muscle mass and BMD during the early growing stage of teenage period. However, only

amounts of net bone mineral and lean muscle mass may contribute to BV. Changes in the percentage of body composition may not be correlated with BV. While planning physical training and nutrition supplement for these players, the results of this study may be taken into consideration. Contact yungshentsai@gmail.com

THE EFFECT OF MILD HYPERBARIC OXYGEN ON OXIDATIVE STRESS REGULATION SYSTEM AFTER TREADMILL RUNNING

Kudo, H.

Mejiro University

Introduction It is known that oxidative stress occurred by exercise and the oxidative stress causes many exercise-induced disorder. In recent years, Hyperbaric oxygen (HBO) is under study to promote the healing process with sports injuries, and a care program after training or sports games for athletes (Ishii Y. et al., 1995, 1997) (Imada T. et al., 2006, Yanagishita K. et al., 2006). The purpose of this study was to evaluate the quantitative effect of HBO using Reactive Oxygen Metabolites (d-ROMs) and Biological Anti-oxidant Potential (BAP) after treadmill running. **Methods** This study comprised twelve healthy male volunteers. All volunteers performed treadmill running for 30min with 10min/hour speed, and two mode of recovery (mHBO and control). The condition of inhaling air in the mHBO capsule was set at an atomic pressure of 1.3ATA of 30% O₂. The value of d-ROMs and BAP were determined at time of pre-running, immediately after running, and after recovery in mHBO capsule. The quantitative analysis of the oxidative stress regulation system was calculated as potential anti-oxidative stress ability (BR-ratio=(BAP/d-ROMs)/7.541). **Results** The potential anti-oxidative stress ability of mHBO and control had mean BR-ratio of 0.91+/-0.08 and 0.91+/-0.12 respectively, before running. The BR-ratio (immediately after running & after recovery) of mHBO and control changed by 0.85+/-0.14, 0.92+/-0.12, and 0.86+/-0.05, 0.86+/-0.08 respectively. Although there were not significant difference between mHBO and control, the potential anti-oxidative stress ability showed much recovery in mHBO. **Discussion** This result suggests that mHBO might have been able to recover the oxidative stress induced by exercise. Although more studies will be needed for the mechanism of mHBO effects, the mHBO can be a promising method in the care for athletes and the sports medicine field. **References** Ishii Y, Miyanaga Y, Shimojo H, Asano K. *Jpn. IS THE CARDIOPULMONARY TEST A USEFUL TOOL IN EVALUATING PATIENTS WITH NON-COMPLICATED HYPERTENSION?

Palazzolo, G., Olla, S., Sanna, I., Mulliri, G., Milia, R., Roberto, S., Concu, A., Crisafulli, A.

University of Cagliari

Introduction. The slope of pulmonary ventilation/carbon dioxide production ratio (Ve/VCO₂) during exercise is a useful parameter for the clinical and prognostic evaluation of cardiovascular as well as of pulmonary diseases. The Ve/VCO₂ slope is normally increased in several pathologies such as heart failure and COPD. The aim of the present investigation was to evaluate whether this parameter was increased in hypertensive patients. **Methods** 14 hypertensive subjects (5 females and 9 males, HTS) under therapy with a single drug and without any other clinical complication were recruited in this study. Their mean age was 52.4 ± 10.6 years. They underwent an incremental exercise test on cycle ergometer until exhaustion with gas exchange assessment (CPX test) by means of a gas analyser (Ultima CPX, Med Graphics, USA). Oxygen uptake (VO₂), VCO₂, Ve, and Ve/VCO₂ slope were assessed throughout test and values were compared with those of a population of healthy subjects (CTL). **Results** VO₂, VCO₂, and Ve at maximum workload were not different between HTS and CTL (23.8±9.5 ml•Kg⁻¹•min⁻¹ vs 34.4±6.2; 2228.1±1054.7 ml•min⁻¹ vs 3245.6±956; 61.9±25.3 l•min⁻¹ vs 69.8±18.5 respectively). Moreover, Ve/VCO₂ slope was 23.5±5.1 and 25.6±0.5 for the HTS and the CTL group respectively. Statistics did not find out any difference between values. **Discussion** Data of the present investigation provide evidence that the CPX test can not differentiate between HTS and CTL subjects. Actually, none of the studied variables exhibited any difference between groups. It should be pointed out that patients were under therapy, which probably improved their cardiovascular status. Moreover, they did not have any clinical complication due to hypertension, such as myocardial ischemia and heart failure. It is then possible to hypothesized that late hypertension complications would result in different outcomes. Further study is needed to better clarify this point. **References** Cardiovascular and ventilatory control during exercise in chronic heart failure: role of muscle reflexes. THE RELATION OF NITRO-OXIDATIVE STRESS WITH CARDIOVASCULAR RISK IN ELITE ATHLETES AND NON-ATHLETES

Zembron Lacny, A.1, Orysiak, J.2, Kalina, K.1, Morawin, B.3, Turowski, D.2, Pokrywka, A.2

1: UZ (Zielona Gora, Poland), 2: IS (Warsaw, Poland), 3: USPE (Poznan, Poland), Poland

Introduction It is well recognised that physical activity reduces vascular nitro-oxidative stress, increases nitric oxide (NO) production via eNOS reaction, modifies the lipid profile (Banfi et al. 2006, Bjork et al. 2012, Durstine et al. 2001, Ribeiro et al. 2010), and also inhibits the production of pro-inflammatory and pro-apoptotic cytokine TNFα (Petersen and Pedersen 2005). However, observations were performed on healthy non-active subjects, patients with coronary artery disease or older adults. It has not known how the long-term physical activity effects on nitro-oxidative markers and cardiovascular risk (CVD). Also, no studies have examined whether the effects of training on nitro-oxidative stress level are related to changes in nitric oxide bioavailability, indexed as the blood level of nitrotyrosine (Nitro). We designed our study to demonstrate the effects of sport training on nitro-oxidative stress and its interaction with CVD risk markers in elite athletes in comparison to non-athletes. **Methods** Blood samples were collected from twenty four athletes at 18-27y old (national team: kayakers and Greco-Roman wrestlers) during preparatory period for the new season (pre-season, January) as well as from non-athletes (n=12). Body mass (BM) and body composition (fat-free mass FFM and fat mass FM) were estimated using a bioelectrical impedance (BIA). **Results** Serum NO concentration did not differ between groups while Nitro was significantly higher in athletes than non-athletes. Similarly, TNFα, oxLDL and hsCRP levels were elevated in athletes compared to non-athletes. Wrestlers showed the highest levels of Nitro, TNFα, hsCRP, total cholesterol, LDL lipoproteins and atherogenic index. Nitro concentration correlated with hsCRP (r=0.609, P<0.001), TNFα (r=0.822, P<0.001), and atherogenic index (r=0.456, P<0.01). Fat mass index negatively correlated with TNFα concentration. **Discussion/Conclusion** The findings show that sport training is associated with lower level of NO bioavailability, and that nitro-oxidative stress markers are relat-

ed to levels of other conventional CVD risk factors. References Banfi G, Malavazos A, Iorio E, Dolci A, Doneda L, Verna R, Corsi MM. (2006). *Eur J Appl Physiol*, 96, 483-486. PGC-1 α GENE EXPRESSION INDUCED BY MODERATE INTENSITY INTERMITTENT EXERCISE

Aoyagi, R., Shiose, K., Ueno, S., Higaki, Y., Kiyonaga, A., Tanaka, H.

Fukuoka university

Introduction Peroxisome proliferator-activated receptor gamma co-activator-1 alpha (PGC-1 α) plays a key role as an activator of mitochondrial biogenesis. Our previous study demonstrated that PGC-1 α mRNA was increased by continuous exercise at intensity above the Lactate Threshold (Tobina et al., 2011). Recently, there is an increasing evidence to suggest that intermittent exercise (IE) at high intensity induces PGC-1 α mRNA expression. However little is known about the effect of IE at moderate intensity on PGC-1 α mRNA expression. Since moderate intensity IE is safe, practical and well tolerated by untrained individuals, it is important to determine whether moderate intensity IE induces PGC-1 α gene expression. Therefore, the purpose of this study is to examine whether moderate intensity IE induces PGC-1 α gene expression. **Method** Nine subjects performed three different IE in random order at least 6 days apart. They repeated 20 exercise-rest cycles (5 min per cycle). Exercise intensity corresponded to Ventilatory Threshold (Low), intermediate intensity between VT and maximal oxygen uptake (VO₂max) (Medium), and VO₂max (High). In the High condition, one cycle composed of 1 min exercise followed by 4 min rest. Exercise duration was adjusted in the Low and Medium conditions so that total amount of exercise was the same. Muscle biopsy was taken from the vastus lateralis muscle before, immediately after, and 3 hours after exercise. Blood lactate was measured before and after exercise. RPE was recorded every 5 cycles were completed. **Result** PGC-1 α mRNA was unchanged immediately after exercise relative to rest. However, PGC-1 α mRNA was increased 3 hours after exercise at all three intensities (Low: 2.8 ± 1.3 - fold, Medium: 2.5 ± 1.3 - fold, High: 6.3 ± 2.3 - fold, $p < 0.05$, respectively). Blood lactate was higher after exercise in the High condition than in the Low and Medium conditions (Low: 1.2 ± 0.3 to 1.0 ± 0.2 , Medium: 1.2 ± 0.2 to 1.9 ± 0.5 , High: 1.3 ± 0.3 to 4.4 ± 1.6). RPE was not different among different exercise intensities. These results indicate that PGC-1 α mRNA expression was induced by moderate intensity IE without elevation of blood lactate. However the degree of expression was not as high as high intensity IE. **Conclusions** Moderate intensity IE can induce PGC-1 α mRNA expression. **References:** Tobina T, Yoshioka K, Hirata A, Mori S, Kiyonaga A, Tanaka H. THE EFFECTS OF PILATES EXERCISE TRAINING ON PHYSICAL FITNESS AND MENTAL HEALTH IN ELDERLY: A SYSTEMATIC REVIEW FOR UPCOMING EXERCISE PRESCRIPTION.

Gobbo, S., Bullo, V., Bergamin, M., Zaccaria, M., Ermolao, A.

University of Padova

Introduction: Reducing the risk of falls and associated medical costs are a major global health concern in elderly populations. The aim of this systematic review is to summarize and analyze the effects of Pilates exercise training (PET) in elderly populations on fall prevention and the effects on physical fitness, mental health, quality of life and functional autonomy. **Methods:** Keyword "Pilates" associated with "elderly", "aging" and "old subjects" were identified as terms for the literature research in Medline bibliographic online database, PubMed and Scopus. Only studies published in indexed and peer reviewed journals, written in the English language, were considered. The studies had to provide a PET- intervention and age of participants had to be higher than 59 years. **Results:** 10 studies were identified, consisting of 6 RCTs, and 4 uncontrolled trials. Participants were mostly female, averaging 5 weeks to 12 months. Overall, PET training showed 80.2% reduction in numbers of falls, improving in static and dynamic balance, strength, walking performance, depression level, quality of life, functional autonomy and elderly population. **Discussion:** PET training should be considered as a way to improve quality of life of elderly, thanks to the imparted benefits of fall prevention, physical fitness, and mental health. Physicians should recommend this type of training for elderly patients since evidence has shown positive effects in several outcomes including static and dynamic balance, strength, walking performance, depression level, quality of life, functional autonomy and numbers of falls.

MUSCLE ACTIVITY IN THE ANTERIOR CRUCIATE LIGAMENT DURING A DROP-LANDING MANEUVER OF SUBJECTS WHO HAD UNDERGONE RECONSTRUCTIVE SURGERY

Hoshiba, T., Fukubayashi, T.

Waseda University

Introduction Reinjury to the anterior cruciate ligament (ACL) after a reconstructive surgery commonly occurs within the first postoperative year, especially among people who engage in sports that involve a jump-landing maneuver. Although previous studies have reported that muscle strength and/or lower limb activity after a reconstructive surgery is a key preventive factor for ACL reinjury, the manner in which a reconstructive surgery affects muscle activity remains unknown. This study aimed to observe the effect of reconstructive surgery on muscle activity during a landing maneuver a year after the surgery. **Methods** Seven subjects (5 men and 2 women; mean \pm SD age, 20.6 ± 1.3 years; height, 165.4 ± 7.6 cm; and body weight, 65.6 ± 7.9 kg) who underwent double-bundle ACL reconstructive surgery with a semitendinosus graft were instructed to perform a double-leg drop jump. An eight-camera motion analysis system and electromyographic (EMG) system were used to record the landing mechanics and EMG activity during the drop-landing task. Thirty-five reflective markers were attached to the body, and 6 EMG electrodes were placed on the rectus femoris (RF), biceps femoris (BF), and semitendinosus (ST) muscles. The following variables were extracted from the time-series data before and after landing: hip extension/flexion angle, knee extension/flexion angle, ankle dorsi/plantar flexion angle, BF/RF activity ratios, and ST/RF activity ratios. Each parameter was compared between the reconstructed and contralateral limbs by using a paired t test, with statistical significance set at $p < 0.05$. **Results** No significant difference in lower limb kinematics during the drop-landing task was observed between the reconstructed and contralateral limbs. In the EMG analysis, the BF/RF activity ratio after landing was significantly greater in the reconstructed limbs than in the contralateral limbs ($p < 0.05$), whereas no significant difference in ST/RF activity ratio before or after landing was observed between the reconstructed and contralateral limbs. **Discussion** As for kinematics, the reconstructed and contralateral limbs demonstrated the same landing mechanics, implying that no compensatory movements occurred in the sagittal plane. However, the BF/RF activity ratio in the reconstructed limb increased after landing. All the subjects in this study underwent reconstructive surgery with a semitendinosus graft;

therefore, the maturation level of the semitendinosus after reconstructive surgery might affect the activities of the other hamstring muscles. Reference Salmon L. (2005). Arthroscopy, 21, 948-957. Shelbourne KD. (2009). Am J Sports Med, 37, 246-251.

THE MOTION CHARACTERISTICS OF MEDIAL TIBIAL STRESS SYNDROME BASED ON THE 3-DIMENSIONAL ANALYSIS DURING BAREFOOT AND SHOD RUNNING IN FOOTBALL PLAYERS

Byungjoo, N., Masunari, A., Mori, T., Miyakawa, S.

University of Tsukuba

Introduction Medial Tibial Stress Syndrome (MTSS) is one of the most common causes of exercise-induced lower leg pain during running (Clanton & Solcher, 1994). But the literature regarding MTSS which was analyzed dynamically is not seen. Therefore, the aim of this study was to determine as well as the kinematics of lower extremity during running with and without shoes for medial tibial stress syndrome. **Methods** Sixteen collegiate football players participated in this study. We divided 16 volunteers into two groups (8 MTSS and 8 non-injured). Three-dimensional marker positions were recorded with a twelve-camera motion capture system (Vicon) operating at 250 Hz while the subjects ran along a 20 m runway at a speed of 3.3 m/s. And the ground reaction forces (GRF) were collected with a force platform (Kistler) at 1000 Hz. Each subject completed three trials of running with and without shoes for which a single trial was collected for analysis. Three-dimensional kinematics were computed. **Results** Results shown that the angular change of knee joint during shod running was significantly larger than barefoot running in MTSS group ($p < 0.05$). The ankle joint was significantly dorsi flexed during shod running than barefoot running in MTSS group ($p < 0.05$). However, there was no interaction effect between two groups and shoes. There were no significant differences in knee and ankle joint angles during running with and without shoes between two groups ($p > 0.05$). **Discussion** Hubbard et al. (2009) reported that increased ankle joint plantar flexion was found to be risk factor for MTSS. However, in this study, we cannot find significant differences about angular change of ankle joint between two groups. In the previous study, it is measured range of motion of ankle joint statically. However, it is possible that such differences do not appear in actual running. Thus, it is necessary to further examination. **References** Clanton TO. and Solcher BW. (1994). MUSCLE STRENGTH IN PATIENTS WITH PRE-DIALYTIC CHRONIC KIDNEY DISEASE.

Rezende, R., Mansur, H.N., Ribeiro, M., Tinucci, T.

University of São Paulo

Muscle strength in patients with pre-dialytic chronic kidney disease. **Introduction** Chronic kidney disease (CKD) reduces physical fitness, decreasing strength, which compromises the ability to perform daily tasks. The time course of strength impairment throughout the disease process has been little studied. This is an important knowledge to establish at which stage of the disease strategies to reduce strength should be employed. In particular, it is not known whether strength impairment is already present in pre-dialytic patients. Thus, the aim of this study was to evaluate muscle strength in pre-dialytic CKD patients. **Methods** Nine patients with CKD (stage 3 - 50 ± 13.13 yrs) and 9 healthy subjects (46 ± 9.45 yrs) were studied. All subjects were sedentary. Strength was assessed by strength-time curve. Both groups performed five maximal voluntary contractions (MVC) to exhaustion of the exercise with the dominant arm. Data was analyzed in MatLab by a specific algorithm that evaluated maximal strength (Force100%) and the lap time for reducing strength from 100 to 90% (Time 100/90), from 90 to 80% (Time 90/80) and from 80 to 70% (Time 80/70). Data between groups was compared by a paired t-Test with $P < 0.05$. **Results** Force 100 was similar in CKD and Controls (22.80 ± 7.58 vs. 24.90 ± 9.33 Kg, respectively, $P > 0.05$). Time 100/90, 90/80 and 80/70 also did not differ between CKD and Controls (4.51 ± 1.98 vs. 3.81 ± 2.34 ; 6.06 ± 2.54 vs. 5.92 ± 2.88 ; and 9.68 ± 4.38 vs. 7.85 ± 3.08 s, respectively, $P > 0.05$). **Discussion and Conclusion** The present study showed that pre-dialytic CKD patients do not have strength impairment in comparison to healthy subjects. These findings are agreement with other studies that report that pre-dialytic patients do not have muscle cachexia (Foley et al, 2007), which is usually entailed by uremic myopathy commonly developed at the end stages of CKD (Campistol, 2002). However, initial signs of myopathy may appear in stage 3 of CKD (Foley et al, 2007; Johansen et al, 2005). Thus, even without presenting a significant decrease in strength at this disease stage, strategies to avoid strength loss may be initiated in pre-dialytic patients. **References** 1 - Foley RN, Wang C, Ishani A, Collins A, Murray AM. HOW DOES A 4-MONTH RESISTANCE TRAINING INFLUENCE SARCOPENIC MUSCLE CELLS? - AN IN VITRO CELL CULTURE MODEL

Heber, A.1, De La Haye, H.1, Pyka, A.1, Stöver, K.2, Brinkmann, C.1, Bloch, W.1, Eichberg, S.2, Brixius, K.1

1: *Institute of Cardiology & Sports Medicine, German Sport University Cologne, Germany*, 2: *Institute of Movement & Sport Gerontology, German Sport University Cologne, Germany*

Introduction Due to demographic changes sarcopenia is a phenomenon in elderly as an acute geriatric syndrome. Research on muscle tissue by means of biopsy is often a painful intervention especially for elderly. The aim was to prove to what extent C2C12 cells could be used as in vitro model in geriatric research to show effects of resistance training on fusion and accumulation of myonuclei and myotubes in sarcopenic muscle cells incubating human serum. **Method** 10 sarcopenic, obese, non-active men (age: 72 ± 3 years, BMI: 35 ± 2 kg/m²) worked out twice a week with 80-85% of 1RM regarding the main muscle groups, 3 sets, 8-12 repetitions over 4 month. The cohort was selected due to the cut-off points of EWGSOP (Cruz-Jentoft, et al., 2010; Janssen et al., 2002) for muscle mass (skeletal muscle mass index) (bioelectrical impedance analysis), muscle strength (kg) (leg press, hand dynamometer), 4m-gait-speed (m/s) and fitness level (watt) (spiroergometry). To determine metabolic changes in the muscle cells, C2C12 cells were incubated with men's blood serum before and after training comparing the Fusion Index (FI) (%) (myonuclei in myotubes/total amount of myonuclei). **Results** The mean Fusion Index increased significantly after the intervention as well as leg strength and 4m-gait speed. No significant differences were measured in the mean handgrip strength, BMI, muscle mass and fitness level comparing data before and after the intervention. **Discussion** An in vitro model incubating human serum on C2C12 cells could be a suitable model to study muscle alterations measuring accumulation and fusion of myonuclei/myotubes. The results provide convincing evidence that hyperplasia and recovery are stimulated through a 4-month resistance training although the stimulus does not seem to affect the total amount of muscle mass significantly. To support these findings

further studies with bigger cohorts are indicated. ASSOCIATION BETWEEN SENSORY FUNCTION AND MEDIO-LATERAL KNEE POSITION DURING DYNAMIC TASKS IN PATIENTS WITH ANTERIOR CRUCIATE LIGAMENT INJURY

Cronström, A., Ageberg, E.

Department of health science

Background Patients with anterior cruciate ligament (ACL) injury often exhibit worse movement quality during dynamic tasks, observed as the appearance of the knee with a medial position relative to the foot. This movement pattern is suggested to be more common in women than in men. Possible contributing sensorimotor factors for this altered knee position are poorly studied in these patients. **Objective** To elucidate the influence of sensory function on the medio-lateral knee position during dynamic tasks in men and women with ACL injury. We hypothesized that worse sensory function would be related to a knee medial to foot position during dynamic tasks and that this relation would be more evident in women than in men. **Methods** Fifty-one patients (23 women), range 18–40 years, with ACL injury were included in this cross-sectional study. Measures of sensory function were assessed by the threshold to detection of passive motion (TDPM) for knee kinesthesia and by the vibration perception threshold (VPT) at the metatarsophalangeal joint 1 (MTP1), the medial malleolus (MM) and the medial femoral condyle (MF) for vibration sense. Movement quality was assessed by visual observation of the position of the knee in relation to the foot during four functional tasks; single-limb mini squat, stair descending, forward lunge and drop-jump. The mid-point of patella in line with the talocrural joint indicates good movement quality and was scored as “0”. The mid-point of patella medial to the talocrural joint indicates poor movement quality and was given the score “1” (fair) or “2” (poor). Spearman’s rank correlation coefficient was used to determine the relationship between the sensory measures and the knee score during the functional tasks. **Results** No difference was observed in the sensory measures or in knee position score between men and women for any of the functional tasks ($p > 0.101$). In women, worse TDPM was associated with a knee medial to foot position during drop jump ($r_s = 0.469$, $P = 0.106$) and worse vibration sense was associated with a knee medial to foot position during stair descending and forward lunge ($r_s = 0.453 - 0.626$, $p < 0.025$). In men, worse TDPM was associated with a knee medial to foot position during drop jump ($r_s = 0.423$, $p = 0.044$). No relation was found between vibration sense and medio-lateral knee position in men ($r_s < 0.330$, $p > 0.079$). **Conclusion** These results indicate that men and women with ACL injury that have worse kinesthetic acuity also exhibit worse movement quality during drop jump, a test resembling sport activity. Women with worse vibration sense at the foot exhibit worse movement quality during functional tasks resembling activity of daily living, whereas this was not observed in men.

AVOIDANCE OF POST-PRANDIAL HYPERGLYCAEMIA AND ASSOCIATED RISES IN INFLAMMATORY MARKERS WITH A LOW GI POST-EXERCISE MEAL IN T1DM

West, D.J.1, Walker, M.2, Stevenson, E.J.1, Cassidy, S.2, Gonzalez, J.T.1, Turner, D.3, Bracken, R.M.3, Shaw, J.A.2, Campbell, M.D.1

1Northumbria University, 2Newcastle University, 3Swansea University

INTRODUCTION Type 1 diabetes patients (T1DM) reduce the insulin-to-carbohydrate ratio with meals consumed before and after exercise to combat exercise-induced changes in insulin sensitivity and prevent hypoglycaemia (Campbell, Walker et al. 2013), but consequently inducing post-prandial hyperglycaemia. Potentially, this may be offset by manipulating the glycaemic index (GI) of the meal (Parillo, Annuzzi et al. 2011). However, few dietary guidelines exist regarding post-exercise food choices for patients, and the subsequent metabolic and inflammatory implications occurring are largely unknown. As such, the aim of this study was to investigate the influence of the GI of foodstuffs consumed following exercise on glycaemia, metabolic and inflammatory parameters in T1DM. **METHODS** Ten male patients with T1DM (mean \pm SEM) age 27 ± 1 years, HbA1c $6.7 \pm 0.2\%$ attended the laboratory on two evenings (~17:00 PM). On both occasions, patients consumed a standardised pre-exercise carbohydrate bolus with a concomitant rapid-acting insulin dose, reduced by 75%, before the performance of 45-min of intensive treadmill running. Following 60-min of rest, patients consumed one of two meals (1.0g carbohydrate.kg⁻¹BM) matched for macronutrient content but differing in GI (HIGH=92; LOW=37) with a 50% dose of rapid-acting insulin. Blood glucose, serum β -hydroxybutyrate, and plasma IL-6 and TNF- α were measured for 180-min. **RESULTS** All patients were protected from hypoglycaemia during the entire time under both conditions. However, HIGH induced hyperglycaemia (13.5 ± 1.2 mmol.L⁻¹) and caused marked increases in TNF- α ($38.1 \pm 8.7\%$) and IL-6 ($62.0 \pm 15.4\%$) in all patients ($p < 0.05$). Conversely, patients under LOW maintained relative euglycaemia (7.7 ± 0.8 mmol.L⁻¹, $p < 0.001$) and avoided inflammatory cytokine elevation ($p > 0.05$). Neither condition affected the appearance of β -hydroxybutyrate remaining similar to rest throughout the study ($p > 0.05$). **DISCUSSION** We show that GI has significant implications for post-prandial glycaemia, metabolism and circulating inflammatory markers following exercise in T1DM under conditions of a reduced insulin-to-carbohydrate ratio. Specifically, inflammatory cytokine elevation can be avoided by substituting a high GI meal for an otherwise similar meal but of low GI, whilst reducing hyperglycaemia without risk of hypoglycaemia. In addition, this strategy has no bearing on ketonaemia. These findings are of importance as offsetting hyperglycaemia and preventing ketogenic or inflammatory disturbances are important for preventing diabetes complications in regularly exercising patients (Rosa, Oliver et al. 2011).

THE PHYSIOLOGICAL RESPONSES TO T30 FRONT-CRAWL TRIAL

Farag, A., Heshmat, H.

Faculty of P.E, Port Said University

Introduction The physiological responses to T30 front crawl trial were assessed on 10 swimmers (age 14.75 ± 0.71 years, weight 56.63 ± 0.74 kg, height 159.75 ± 2.31 cm, HR_{Rest} 63.5 ± 1.69 BPM, and BMI 22.2 ± 0.57) in a swimming pool. Growth hormone, lactate concentration, glucose level, urinary albumin, serum triglycerides and catecholamine together with heart rate were performed before and after the trial. Average trail length was 1787.5 ± 83.45 m., and time record was 30.20 ± 0.1 min. **Methods** 10 swimmers chosen from Ismailiy sports club exposed to T30 front crawl swim. Laboratory blood tests were carried out to determine serum triglycerides and catecholamine. Also, urinary albumin. But the lactate concentration detected by Accu sport. **Results** Results indicated that growth hormone together with catecholamine increased significantly, also triglycerides increased significantly, as for urinary albumin and lactate concentration they did not change and glucose level, heart rate increased significantly. **Conclusion** It may be concluded that prolonged exercises may be accompanied by decreases in skeletal muscle and liver glycogen stores, resulting in hypoglycemia, the increase in triglycerides concentrations

in the blood is accompanied by increased growth hormone and catecholamine for gluconeogenesis. The increased in heart rate after trial may indicated the swimming pace and velocity was increased toward the end of the trial, suggesting that swimmers adopted a positive pacing toward the end of the trial. The unchanged albumin and lactate concentration suggest that the overall effort did not alter renal function or lactate balance. Key words: Front crawl, hormonal and biochemical parameters, heart rate, and time record.

PHYSICAL FITNESS, MOTOR PERFORMANCE, AND HEART RATE VARIABILITY IN CHILDREN WITH AND WITHOUT ADHD

Lin, W.S., Su, C.T., Tseng, Y.H., Lee, H.F., Yang, A.L.

University of Taipei

Introduction Attention deficit hyperactivity disorder (ADHD) is one of the most prevalent pediatric disorders, characterized by hyperactivity, impulsivity, and/or inattention. Recently, the concerns of problems on physical performance and autonomic nervous function in children with ADHD have been rising. Although children with ADHD have been found difficulties in movement, studies that explored their physical performance and autonomic nervous function remain insufficient. Thus, the purposes of this study were to compare physical fitness, motor performance, and heart rate variability (HRV) between children with ADHD and typically developing children. **Methods** We recruited 26 children, including 14 children with ADHD and 12 matched typically developing children (control group), to participate in this study. Physical fitness, motor performance, and HRV of each participant were assessed. Physical fitness tests included the measurement of height, weight, body mass index, body fat, sit and reach test (flexibility), sit-up test for 1 minute (muscle endurance), standing long jump (instantaneous power), and 3-min step test (cardiorespiratory endurance). Motor performance was assessed by Movement Assessment Battery for Children-Second Edition (MABC-2). HRV was measured by Polar heart rate monitor and accompanying software. **Results** Our results indicated that the overall performance of MABC-2 in the ADHD group were significantly poorer than the control group, especially the balance and aiming & catching subtests. However, no significant group difference was found in the physical fitness assessment. Moreover, the measurement of HRV revealed significantly poorer level of autonomic nervous function in the ADHD group. **Discussion** This study indicated the problems of motor performance and heart rate variability for children with ADHD. Also, the inconsistent findings between MABC-2 and physical fitness tests suggest that a more holistic assessment should be conducted for a better understanding of physical performance in children with ADHD. Our results encouraged further research to explore the possible influence of exercise intervention on the motor performance and heart rate variability in children with ADHD. **References** Harvey, WilliamJ, Reid, Greg, Grizenko, Natalie, Mbekou, Valentin, Ter-Stepanian, Marina, & Joobar, Ridha. EFFECTS OF 8-WEEKS TREADMILL TRAINING ON BLOOD PRESSURE, INSULIN-INDUCED VASORELAXATION, AND ANTIOXIDANT ACTIVITY IN POSTMENOPAUSE WITH HYPERTENSION

Su, Y.F.1, Yang, A.L.1, Su, C.T.2, Tseng, Y.H.3

1: University of Taipei; 2: Fu Jen Catholic University

Introduction It has been known that exercise training has positive effects on cardiovascular disease, such as hypertension and menopause-related cardiovascular dysfunction. Menopause-related cardiovascular dysfunction could be aggravated by the presence of hypertension. However, whether exercise training influences blood pressure, vascular function, and antioxidant activity in postmenopause with hypertension remains unclear. Therefore, the purpose of this study was to investigate the effects of 8-weeks treadmill training on blood pressure, vascular function, and antioxidant activity in postmenopause with hypertension. **Methods** Four-month-old female spontaneously hypertensive rats (SHR) were used as the animal model. They were divided into three groups: the sham control (SHR-sham), the ovariectomy without training (SHR-O), and the ovariectomy with training (SHR-OT) groups. The Wistar-Kyoto (WKY) rat was used as the normotensive control group. The training program was conducted by the treadmill at moderate intensity for 1 hr/day, 5 days/week for 8 weeks in the SHR-OT group. After treadmill training, the blood pressure and serum levels of antioxidant and oxidant activities, including superoxide dismutase (SOD), catalase, and thiobarbituric acid reactive substance (TBARS), were measured. Also, rat aortas were isolated for the measurement of the insulin-induced (endothelium-dependent) vasorelaxation by the organ bath system. **Results** Compared with the SHR-sham and SHR-O groups, the 8-weeks treadmill training significantly ($p < 0.05$) decreased systolic blood pressure, but not diastolic blood pressure, in the SHR-OT group. Also, it significantly ($p < 0.05$) improved the insulin-induced (endothelium-dependent) vasorelaxation in the SHR-OT group, to a nearly normal level. The serum levels of SOD and catalase activities ($p < 0.05$), but not TBARS level ($p > 0.05$), were significantly increased in the SHR-OT group after treadmill training. **Discussion** This study indicated that 8-weeks treadmill training could partly improve blood pressure, vascular function, and antioxidant activity in postmenopause with hypertension. It implicated that chronic exercise intervention would ameliorate the cardiovascular function in the population of postmenopause with hypertension. **References** Barton M, Meyer MR. COMBINED EFFECTS OF SELF-MASSAGE AND EXERCISE INTERVENTION ON MENTAL HEALTH AND HEALTH RELATED QUALITY OF LIFE IN MIDDLE-AGED JAPANESE MEN

Terada, K.I, Nakatani, T.I

1: Tenri University

Introduction A substantial body of evidence supports the value of exercise or massage therapy program in the treatment of people with mental illness and the improvement of health related quality of life (HRQOL). The purpose of this study was to investigate the interactive influence on mental health and HRQOL of self-massage intervention and exercise programs in middle-aged and elderly persons via a randomized controlled trial. **Methods** The study was approved by the research ethics committee of the Faculty of Health, Budo and Sports Studies, Tenri University. Twenty-two healthy male adults aged between 40 and 69 years were randomly and equally assigned to two groups: the exercise and self-massage intervention group (massage group, $n = 11$, 51+9 yrs), exercise training intervention group (exercise group, $n = 11$, 49+6 yrs). Members of the massage group underwent a structured manual self-massage, and their exercise regimen consisted of group-based and home-based training, which included resistance training of upper and lower limbs and abdominal muscles, endurance training, plyometrics, and alertness training for 12 weeks. Exercise group members underwent the same exercise program as the massage group members for 12 weeks. The outcome measures were the 30-Item Japanese version of General Health Questionnaire (GHQ-30), the Medical Outcomes Study (MOS) 36-Item Short-Form Health Survey (SF-36), the evaluation by visual analogue

scale (VAS) of the severity of subjective symptom and the Japanese version of Roland-Morris Disability Questionnaire (RDQ). The data obtained were statistically analyzed using two-way analysis of variance (ANOVA) test. Results At baseline, two groups were well matched in physical characteristics and age. After 12 weeks of intervention, two-way ANOVA showed significantly greater improvements (-69.5% , $p < 0.05$) in measures of total score and the factor I (depression) of GHQ-30 in the S group, however, no significant changes were observed in any of the measurements in the E group. Conclusion These results suggest that the effect of exercise regimen consisted of group-based and home-based to alleviate depression is enhanced by concurrent self-massage intervention. EFFICACY AND SAFETY OF A DIETARY SUPPLEMENT CONTAINING MUCOPOLYSACCHARIDES, COLLAGEN TYPE I AND VITAMIN C FOR MANAGEMENT OF TENDINOPATHIES AND PLANTAR FASCIITIS

Bui, B.H., Nguyen, L.N.T., Nguyen, H.M., Tran, H.M.T., Nguyen, N.V., Ramirez, P., Martinez Puig, D.

Bach mai Hospital, Hanói, Vietnam

Introduction and Objectives Overuse tendon injury (tendinopathy) occurs in loaded tendons of the upper and lower limb and results in pain, decreased exercise tolerance of the tendon and a reduction in function. Characteristic changes occur in tendon structure, resulting in a tendon that is less capable of sustaining repeated tensile load. The aim of this study was to evaluate the efficacy and safety of a food supplement containing mucopolysaccharides, collagen type I and vitamin C on the clinical symptoms, pain and tendon structure of patients with tendinopathy of Achilles, supraspinatus, lateral epicondyle or plantar fasciitis. **Material and methods** Patients with clinically and sonographically diagnosed tendinopathy were randomized to receive two capsules per day of Tendoactive® (TA) (435mg of mucopolysaccharides, 75mg of collagen type I and 60mg of vitamin C) or two identical capsules of placebo (PBO) during 90 days. An oral NSAID (Mobic® 7.5 mg/day) was allowed in both groups as rescue medication for a maximum of 30 days. Patients were monitored monthly during the study period. Clinical assessments included presence/absence of clinical symptoms (swelling, burn and redness) and pain intensity using a visual analog scale (VAS). Tendon structure was characterized sonographically and presence/absence of tendinopathy was reported. **Results** A total of 60 patients were included, 30 assigned to each treatment group. Average age was 41.4 ± 1.50 years in TA group and 40.2 ± 0.26 years in PBO group. They were mostly women in both groups (83.3% and 86% in TA and PBO groups respectively). The percentage of patients presenting each clinical symptom was progressively reduced in both groups, reaching lower values in the TA group at each time point. Pain level assessed by VAS was comparable between groups at baseline (5.82 ± 0.21 vs 5.71 ± 0.23 in TA and PBO groups respectively). It was significantly reduced in both groups during the study period, but patients supplemented with TA had significantly lower pain value at 90 days (2.5 ± 0.22 vs 3.20 ± 0.20 in TA and PBO groups respectively; $P < 0.05$). At the end of study, no patient in the TA group was diagnosed for tendinopathy according to ultrasounds assessment. **Conclusions** The overall results of this randomized, placebo-controlled study show that Tendoactive® supplementation is a safe and effective therapeutic option to improve both clinical symptoms and structural evolution of injured tendons as demonstrated in Achilles, supraspinatus, lateral elbow epicondyle and plantar fasciitis.

EFFECT OF BEETROOT JUICE SUPPLEMENTATION ON SWIMMING PERFORMANCE

Roberto, S.1, Pinna, M.1, Milia, R.1, Marongiu, E.1, Olla, S.1, Loi, A.2, Migliaccio, G.M.2, Tocco, F.1, Concu, A.1, Crisafulli, A.1

1-Sports Physiology Lab., University of Cagliari (Italy); 2-Regional School of Sport of Sardinia, Italian Olympic Committee, (Italy);

Introduction: Recent evidence suggests that beetroot juice supplementation (BJS) may improve the physiological responses to exercise (Bailey et al. 2009). The beneficial effects of BJS have been tested during cycling, walking, and running. However, to the best of our knowledge none has investigated on its effect during swimming, probably because the measurement of certain physiological parameters such as oxygen uptake (VO₂) and anaerobic threshold (AT) during swimming suffers from technical limitations. The aim of the present study was to discover whether BJS could improve performance in swimmers. **Methods** Fourteen moderately trained male master swimmers were recruited and underwent two incremental swimming test in a pool: a control swimming test (CSW), and the other was a swimming test after six days of dietary supplementation with NO₃- rich beetroot juice (0.5l/day organic beetroot juice containing about 5.5 mmol of NO₃-). During each test workload, oxygen uptake (VO₂), carbon dioxide production (VCO₂), pulmonary ventilation (VE), and aerobic energy cost (AEC) of swimming were measured by means of a portable gas analyser (VO2000, MedicGraphics, USA) through telemetric transmission. This system has been shown previously used during swimming (Pinna et al. 2013). **Results** Results show that workload at anaerobic threshold was significantly increased by BJS as compared to the CSW test (6.3 ± 1 and 6.7 ± 1.1 kg during the CSW and the BJS test respectively). Moreover, BJS reduced aerobic energy cost of swimming at submaximal workload, as shown by the significantly reduced of AEC at anaerobic threshold during the BJS test (1.9 ± 0.5 during the SW test vs. 1.7 ± 0.3 kcal•kg⁻¹•h⁻¹ during the BJS test). This finding is in agreement with previous research showing that dietary NO₃- supplementation by beetroot juice can reduce aerobic cost of submaximal strain in various kinds of exercise (Bailey et al. 2009). None of the other variables were affected by BJS. **Discussion** The present investigation provides evidence that BJS can positively affect performance of swimmers as it reduces the AEC and increases the workload at anaerobic threshold. Further research is needed to clarify whether beetroot juice supplementation may be beneficial also for highly trained swimmers. **References** Bailey SJ et al.(2009). *J Appl Physiol* 107:1144-1155. CARDIOPULMONARY TEST PARAMETERS IN MULTIPLE SCLEROSIS

Magnani, S., Marongiu, E., Olla, S., Tocco, F., Marcelli, M., Loi, A., Corona, F., Crisafulli, A.

University of Cagliari

Introduction. Multiple sclerosis (MS) is characterized by episodes of focal inflammation in the central nervous system which lead to progressive disability and impairment in exercise capacity. An established tool to evaluate patients' physical capacity is cardiopulmonary testing (CPET). However, there are few studies comparing CPET response of MS patients with those from healthy subjects. The aim of the present investigation was to compare CPET parameters of MS individuals to those from a normal control population to find out which among them show the more striking differences from the normal condition. **Methods.** A group of 44 MS patients (20 females and 24 males) along with a control group (CTL) of healthy persons (10 females and 10 males) were enrolled and underwent CPET on a electro-magnetically braked cycle-ergometer (protocol 10watt/min up to exhaustion). Heart rate (HR) was assessed by electrocardiographic

monitoring. Oxygen uptake (VO_2), carbon dioxide output (VCO_2), and pulmonary ventilation (V_e) were measured throughout this test by means of a metabolic measurement cart (MedGraphics Ultima CPX, St. Paul, USA). Data derived from these variables were oxygen pulse (OP, defined as VO_2/HR) and ventilator-carbon dioxide linear regression slope (V_e/VCO_2 slope). Results. SM group reached a significantly lower values of VO_2 max (1359.95 ± 551.16 vs 2014.36 ± 678.03 $\text{ml} \cdot \text{min}^{-1}$), VCO_2 max (1661.43 ± 675.28 vs 2459.16 ± 929.16 $\text{ml} \cdot \text{min}^{-1}$), V_e max (48.83 ± 21.87 vs 71.09 ± 26.84 $\text{L} \cdot \text{min}^{-1}$), workload max (99.09 ± 42.19 vs 174.5 ± 64.84 Watt), HR max (140.95 ± 20.88 vs 165.15 ± 17.49 bpm) and OP (9.57 ± 3.33 vs 12.12 ± 3.77 $\text{ml} \cdot \text{bpm}^{-1}$). No statistical difference was found in V_e/VCO_2 slope between groups. Conclusions. These results show that VO_2 max, workload max, and OP variables show lower values in the MS as compared to the CTL group. Thus, these parameters may be preferentially used as prognostic and clinical indicators of exercise intolerance in MS disease rather than rely on subjective symptoms. References. Jaussaud et al. INFLUENCE OF CONTINUOUS AND DISCONTINUOUS PROTOCOLS WITH DIFFERENT INITIAL SPEEDS ON THE VPEAK DETERMINATION

Mezzaroba, P.V., Alves, J.C.C., Peserico, C.S., da Silva, D.F., Kravchychyn, A.C., Machado, F.A.

State University of Maringá (Maringá, Brazil)

Introduction The maximum speed obtained in an incremental test called peak speed (V_{peak}) present high correlations with endurance performances, and can be used as a good parameter for training prescription and monitoring. However the design protocol may influence the determination of this variable. Therefore, the aim of this study was to investigate the influence of continuous and discontinuous protocols with different initial speeds on the V_{peak} determination and correlate V_{peak} values with a 10-km running performance. **Methods** Seventeen healthy male runners performed four maximal incremental running tests using a treadmill preceded by a three minutes warming at $6 \text{ km} \cdot \text{h}^{-1}$; it was tested the beginning of the protocol at $8 \text{ km} \cdot \text{h}^{-1}$ (Cont8) and $10 \text{ km} \cdot \text{h}^{-1}$ (Cont10) with increments of $1 \text{ km} \cdot \text{h}^{-1}$ every three minutes. The discontinuous protocol was similar to the continuous except for additional 15 s pauses between each stage for blood sampling of the earlobe, and thereafter the determination of blood lactate concentration, characterized as a discontinuous protocol (Descont8 and Descont10). Participants also performed two 10-km running performances in a running track field it was considered for the analysis the best mean speed (V_{mean}) of the performance. It was adopted a significance level of $P < 0.05$. **Results** The V_{peak} values were not influenced by incremental protocol with different initial speeds (Cont8= $15.4 \pm 1.5 \text{ km} \cdot \text{h}^{-1}$; Cont10= $15.2 \pm 1.6 \text{ km} \cdot \text{h}^{-1}$) but for different protocol types (Descont8= $13.1 \pm 1.1 \text{ km} \cdot \text{h}^{-1}$; Descont10= $13.8 \pm 1.1 \text{ km} \cdot \text{h}^{-1}$). The V_{peak} determination by the protocol Cont8 presented the highest values of correlation with the 10-km running performance ($r = 0.92$). **Discussion** Some studies verified that the incremental test design influenced the V_{peak} determination (Machado et al., 2013; Kuipers et al., 2003), and the relationship between V_{peak} and endurance running performance (Machado et al., 2013). Our study verified the influence of pauses between each stage, and similar to Midgley et al. (2007) we found that the V_{peak} values were influenced by the protocol types (continuous vs discontinuous). However, V_{peak} values were not influenced by different initial speeds. Furthermore, as verified in other studies (Machado et al., 2013; Noakes et al., 1990), the V_{peak} values were highly correlated with 10-km running performance. **References** Kuipers H, Rietjens G, Verstappen F, Schoenmakers H, Hofman G. RAPID WEIGHT LOSS AFFECT RESPIRATORY CONDITION IN JUDOISTS

Imai, T., Watanabe, K.

University of Tsukuba

Introduction Judo competitions are divided into body weight classes. In most cases, athletes reduce body weight in a short period before competitions. However several investigations have reported that athletes undergoing RWL presented decreased short-term memory, vigor, concentration and self-esteem as well as increased confusion, rage, fatigue, depression and isolation. On the other hand, there is only limited data about respiratory condition on rapid weight loss among judoists. Judoists who reduced quickly body weight dehydrate extremely because they restrict intake of water and food. Dehydration may cause reduction of the mucus secretion in upper respiratory mucous membrane. And drying of upper airway may evoke airway inflammation. **Purpose** The purpose of this study is to examine that rapid weight loss affect a respiratory condition in judoists. **Methods** 13 collegiate judoists participated in this study. And 8 judoists reduced their body weight about 10 days(RWL). 5 judoists kept their body weight (NWL). We investigated their history of respiratory symptoms, inflammation, resistance and function. The respiratory resistance at 5-Hz (R_5) and frequency of resonance (F_{res}) were measured by using forced oscillation technique. The pulmonary functions including forced expiratory volume in 1 second as percent of FVC ($\text{FEV}_{1.0}(\%)$) were measured by spirometer. And fraction of exhaled nitric oxide (FeNO) was measured by a portable NIOX MINO. Judoists measured FeNO and body weight three times before competition. **Result** Age of judoists was 20.3 ± 0.9 yr. Average height was 170.2 ± 6.7 cm, and body weight were 76.3 ± 14.1 kg. There weren't difference of physical characteristics, respiratory resistance and function in RWL and NWL. RWL reduced their body weight from 74.0 ± 12.5 kg to 71.1 ± 12.8 kg. Four RWL increased FeNO after more than 4% body weight loss. FeNO didn't alter in NWL. **Discussion** The 5% reduction in body mass affected metabolism and muscle contraction pattern, thereby increasing exposure to injury. 4 judoists who reduced more than 4% body weight, increased in their FeNO . Therefore, rapid body loss may affect respiratory condition. However, when they reduced less than 4% body weight, FeNO didn't alter in RWL, except one judoist. Respiratory conditions may get worse by more than 4% reduction in body weight. **Conclusion:** Respiratory conditions of judoists were worsened by more than 4% reduction **References** Artioli GG, Iglesias RT, Franchini E, Gualano B, Kashiwagura DB, Solis MY, Benatti FB, Fuchs M, Lancha Junior AH (2010). *J Sports Sci*, 28(1):21-32. GENDER DIFFERENCES IN POTENTIAL CONTRIBUTORS OF DYNAMIC KNEE VALGUS DURING SINGLE-LEG SQUATTING AND LANDING IN BASKETBALL PLAYERS

Kagaya, Y., Kiba, K., Fujii, Y., Nishizono, H.

Showa University

Introduction Dynamic knee valgus is considered a risk factor of non-contact anterior cruciate ligament (ACL) injury. To identify athletes at a higher risk, we developed a two-dimensional (2D) video-based screening test to determine hip abductor function as well as dynamic rearfoot and knee valgus (Kagaya et al., 2009). However, gender differences in hip or rearfoot motion as a contributor to dynamic knee

valgus remains unclear. The purpose of this study was to determine gender differences in the contribution of hip or reafot motions as well as hip flexibility to dynamic knee valgus. **Methods** One hundred fourteen basketball players (59 females and 55 males) agreed to participate in this study. Their mean age was 18.3 ± 2.2 years, height and weight were 168.7 ± 8.3 cm and 62.5 ± 8.8 kg, respectively. Subjects performed single-leg squatting and drop landing from a 30-cm box which provided a knee-in distance (KID) and a hip-out distance (HOD). This procedure was recorded simultaneously using a 2D video camera in the front and the back on the subject. KID was measured as the distance from hallux to the point where the line connecting the center of the patella and the anterior superior iliac spine (ASIS) intersects the floor. HOD measured as the distance from hallux to the projection of ASIS on the floor. Hip abductor function and rearfoot dynamic alignment was evaluated by a dynamic Trendelenburg test (DTT) and a dynamic heel-floor test (HFT), respectively, during squatting and landing. Additionally, we measured the general joint laxity and the range of motion in hip internal and external rotation, ankle dorsi-flexion. **Results** Females demonstrated greater KID and HOD during squatting and landing than males, while occurrence rates of DTT- and HFT-positives in females and males were not statistically different. The range of motion in females was significantly greater than in males in hip internal rotation ($p < 0.001$), whereas smaller in hip external rotation ($p < 0.001$). Scores of general joint laxity in females were significantly greater than in males ($p < 0.05$). **Discussion** Many researchers reported that female athletes were greater dynamic knee valgus than males (Pappas et al., 2007, Zeller et al., 2003). It is concluded that the females demonstrates greater dynamic knee valgus in this study. Contributions of hip and reafot action may not be different between the genders. Greater hip internal rotation and limited hip external rotation in females may be a contributor of the increased dynamic knee valgus. **References** Kagaya Y, Nishizono H, Fujii Y. (2009). *Jpn J Phys Fitness Med*, 58, 55-62 (In Japanese). Pappas E. et al. (2007). *Clin. J Sports Med*, 17, 263-268. Zeller BL. et al. (2003). *Am J Sports Med*, 31, 449-456. RESISTANCE EXERCISE TRAINING IN ELDERLY: METABOLIC AND PHYSIOLOGICAL ADAPTATION

Frank, P., Andersson, E., Pontén, M., Sahlin, K.

The Swedish School of Sport and Health Science

Introduction Resistance exercise is an effective countermeasure for age related muscle atrophy and loss of muscular function. The aim of this study is to investigate the effect of short term resistance exercise training on insulin sensitivity, muscle strength, VO₂ max, fiber type and fat metabolism. **Methods** Elderly (age 71.7 ± 0.9 , BMI 23.8 ± 0.7) women and men were randomized into a resistance training (RT, n=12) or control (CON, n=9) group. The intervention consisted of 8 weeks training at 80 % of 1 RM, 3 sessions per week. Muscle biopsies, oral glucose tolerance test and physiological tests were performed before and after. **Results** Bodyweight and fat free mass were not changed. Glucose tolerance was improved in RT (reduced plasma glucose at 120 min post glucose intake and a trend ($p=0.07$) towards reduced area under the curve for glucose). VO₂ max increased by 9.3 % in RT and there was a trend ($p=0.08$) towards increased fat oxidation during submaximal aerobic exercise. Knee extensor strength improved in RT during isometric (10.4 %), concentric (9.5 %), and eccentric (7.8 %) maximal voluntary contractions. Preliminary data from histochemical analyses (6 RT subjects) shows an increased proportion of type IIA fibers (51 %), a trend ($p=0.07$) towards a reduced proportion of Type IIX fibers (39 %) and unchanged levels of intramyocellular lipids. The above outcomes remained unchanged in CON. **Discussion** Short term resistance training in elderly can improve not only muscle strength, but also aerobic capacity, glucose tolerance and fat metabolism. EFFECTS OF RAPID WEIGHT LOSS ON BODY FLUIDS AND AEROBIC PERFORMANCE AMONG COMBAT ATHLETES.

Feist, J.1, Reljic, D.1,2, Jost, J.2, Kieser, M.3, Friedmann Bette, B.1

1:Medical Clinic 2:Olympic Training Centre 3:Institute of Biomedical Biometry, University Heidelberg (Germany)

Purpose It was recently shown that rapid weight loss (RWL), which is practiced by many combat athletes before competition, is nearly exclusively achieved by a loss of body water resulting in hypohydration (Reljic et al., 2013). The purpose of this study was to test the hypothesis that the hypohydration impairs aerobic performance. **Methods** During a normal training period (t-1), ~1-2 days before competition (t-2) and 1 week after competition (t-3), data was collected from 14 athletes (weight loss group, WL; 22.6 ± 4.0 y; 176 ± 8 cm; 77.0 ± 12.9 kg) who reduced their body weight (BW) before competition within a few days by individual methods and from 14 subjects who did not reduce BW (control group, CG; 23.8 ± 4.8 y; 178 ± 8 cm; 78.3 ± 11.6 kg). Total body water (TBW), intra- (ICW) and extracellular water (ECW) were estimated by bioelectrical impedance analysis and urine specific gravity (USG) was determined. Thereafter, a step-wise graded treadmill-test was performed to determine performance at 4-mmol- (4LT) and individual (ILT, basic lactate +1.5 mmol) lactate thresholds as well as peak-performance and VO₂peak. **Results** In WL, a BW reduction by $5.5 \pm 0.9\%$ led to significant losses in TBW ($6.5 \pm 2.9\%$, $p < 0.001$), ECW ($4.8 \pm 2.3\%$, $p < 0.001$) and ICW ($4.8 \pm 2.3\%$, $p < 0.001$). At t-3, body fluids had returned to baseline levels. USG had increased from 1020 ± 8 (t-1) to 1026 ± 7 (t-2) and had decreased again to 1021 ± 7 at t-3. In CG, no significant changes occurred. In WL, peak performance (15.9 ± 1.5 km/h) and VO₂peak (4.2 ± 0.7 l) had decreased at t-2, but were not statistically different compared to t-1 (16.2 ± 1.3 km/h, 4.4 ± 0.6 l) and t-3 (16.2 ± 1.6 km/h, 4.3 ± 0.7 l). Relative VO₂peak did not change significantly. Peak lactate values ($p < 0.01$) and respiratory exchange ratios (RER) ($p < 0.001$) decreased significantly from t-1 to t-2 (10.9 ± 2.2 to 9.3 ± 2.2 mmol/L; 1.16 ± 0.08 to 1.07 ± 0.07) and almost returned to baseline values at t-3. 4LT-running speed at t-2 (3.81 ± 0.35 m/s) was higher compared to t-1 (3.65 ± 0.34 m/s, $p < 0.01$). Speed at ILT did not change significantly. In CG, no significant changes occurred in VO₂peak, peak-, 4LT- or ILT-performance. **Conclusion:** The ~6% hypohydration after RWL did not significantly affect peak performance and speed at the ILT. However, the significant decrease in peak lactate and peak RER as well as the increased speed at 4LT suggest glycogen depletion. **References** Reljic D, Hässler E, Jost J & Friedmann-Bette B. FAILURE OF A PHARMACOLOGICAL INTERVENTION TO IMPROVE ENDURANCE EXERCISE PERFORMANCE IN SIMULATED HIGH-ALTITUDE

Paris, H.L.R., Beals, J.W., Giordano, G.R., Sevits, K.J., Biela, L.M., Scalzo, R.L., Bell, C.

Colorado State University

Introduction During brief sojourns to high altitude, endurance exercise performance is diminished; pharmacological approaches have been proposed as potential strategies to reverse this performance decrement. In this regard, the anti-sickle cell agent, 5-hydroxymethyl-2-furfural (5HMF), may have benefit. The purpose of this study was to investigate the hypothesis that acute administration of 5HMF would promote endurance exercise performance in simulated high-altitude. **Methods** 11 young, healthy, recreationally active men (age: 27 ± 2 years; body mass index: 24.3 ± 0.5 kg/m²; maximal oxygen uptake: 52.9 ± 2.6 ml/kg/min; mean \pm SE) completed four trials, in a ran-

dom order, on four separate days. Each trial began with oral administration of either placebo, or 1g or 3g of 5HMF. Research participants rested in a seated position in normoxia ($\text{FIO}_2 = 0.21$) before transferring to an environmental chamber, adjusted to either normoxia or hypoxia ($\text{FIO}_2 = 0.14$). Within the chamber, research participants completed a standardized exercise bout (30-minutes of stationary cycling at 100W) and a 7.75-mile (12.5 km) time-trial. Results Compared with placebo, neither dose of 5HMF influenced resting heart rate, blood pressure or oxy-hemoglobin saturation in normoxia (all $P > 0.05$). During standardized exercise, hypoxia increased heart rate, although this increase did not attain statistical significance ($P = 0.08$). Oxy-hemoglobin saturation was lower in hypoxia at all time points compared with normoxia ($P < 0.001$); neither dose of 5HMF affected oxy-hemoglobin saturation in hypoxia ($P > 0.70$). Neither hypoxia nor 5HMF influenced blood pressure ($P > 0.76$) or ratings of perceived exertion ($P > 0.17$). Consistent with the response to standardized exercise, during the time-trial hypoxia lowered oxy-hemoglobin saturation ($P < 0.001$); 5HMF did not influence this response ($P > 0.70$). Neither hypoxia nor either dose of 5HMF affected heart rate, blood pressure or rating of perceived exertion (all $P > 0.49$). Compared with normoxia, the time taken to cycle 7.75 miles (22.4 ± 0.7 min) was slower in hypoxia after consumption of placebo (24.5 ± 0.5 min), 1 g (24.0 ± 0.7 min), and 3 g (24.6 ± 0.6 min) of 5HMF (all comparisons $P < 0.001$). There were no differences in hypoxic time-trial performance between placebo and 5HMF doses (all $P > 0.26$). Summary These data suggest that 5HMF does not attenuate hypoxia-mediated decrements in endurance exercise performance in young adult males. Contact christopher.bell@colostate.edu

CARDIOVASCULAR SCREENING IN MIDDLE-AGED INDIVIDUALS ENGAGED IN HIGH INTENSITY SPORTS ACTIVITIES: IMPLICATIONS, YIELD AND COST-ANALYSIS

Siragusa, P.1, Di Valentino, M.2, Foglia, P.2, Porretta, A.2, Romano, G.A.1, Pezzoli, R.1, Maggi, M.1, Moschovitis, G.3, Gallino, A.2, Menafoglio, A.2

1 Ospedale la Carità Locarno (Switzerland); 2 Ospedale San Giovanni Bellinzona; 3 Ospedale Civico Lugano (Switzerland)

Purpose: the European Association of Cardiovascular Prevention and Rehabilitation (EACPR) has recently edited recommendations for cardiovascular screening in middle-aged individuals engaged in sports activities. However, there are very few data on the impact of such position stand. The aim of this study was to assess implications, yield and costs of this preventive evaluation. Methods: prospective observational multicenter study including individuals from 35 to 65 years engaged in high intensity sports activities > 2 hours per week and free from cardiac diseases. Athletes were examined following the EACPR protocol: history, physical examination, 12-lead resting electrocardiogram (ECG) and risk stratification according to the Systematic Coronary Risk Evaluation (SCORE). Athletes with abnormalities at screening or at high risk underwent additional examinations. The costs of the overall screening program until diagnosis were calculated according to Swiss medical rates. Results: from January to December 2013, 761 athletes were examined (73% males, 46.8 ± 7.3 years). Running (33%) and cycling (23%) were the sports most frequently represented. Athletes trained 5.7 ± 4.1 hours/week during the last year. A total of 110 athletes (14.4%) required additional examinations: 13 (1.7%) due to history, 34 (4.5%) due to physical examination, 40 (5.3%) because of abnormal ECG and 32 (4.2%) considered at high risk (SCORE system). A previously unknown cardiovascular abnormality was established in 20 (2.6%) athletes, a severe hypercholesterolemia (> 8 mmol/l) was discovered in 8 (1.0%) athletes and diabetes mellitus type 2 in 1 (0.1%) athlete. Three (0.4%) athletes were considered not eligible for high intensity physical exercise (hypertrophic cardiomyopathy, old myocardial infarction with ventricular arrhythmia and aneurysm of ascending aorta of 50 mm). The cost was 111775 Euros () for the overall program, 147 per athlete and 3'854 per finding. Conclusions: cardiovascular screening in middle-aged athletes allows to discover a significant number of new cardiovascular abnormalities and major cardiovascular risk factors that in selected cases preclude high intensity physical exercise. The cost of the overall screening program appears reasonable. Contact: patrick.siragusa@eoc.ch; andrea.menafoglio@eoc.ch

PHYSICAL ACTIVITY IN SOLID ORGAN TRANSPLANT RECIPIENTS: PRELIMINARY RESULTS OF THE ITALIAN PROJECT

Capone, S., Peruzzo, M., Carraro, N., Roi, G.S., Totti, V., Nanni Costa, A., Ermolao, A.

ospedale di padova

Organ transplantation has become the most frequent choice for most patients suffering of renal failure, end stage liver disease or heart failure. Owing to the increasing number of transplantation and recipients' survival, a greater incidence of cardiovascular and metabolic complications can be observed. Further, kidney, liver and heart transplants present a general reduction of functional capacity. Exercise prescription can be an efficient method to improve cardiovascular state, functional capacity and quality of life of these patients. Aim: To assess the effect of supervised protocol of endurance and resistance training on quality of life and physical fitness in a sample of liver, kidney and heart transplant. Methods: Up to now 111 subjects between the age of 20 and 70 (47.8 ± 10.9) were evaluated. These subjects were evaluated at the Transplant Centre and they were assigned through a non-randomized method to 2 cohorts: Exercise Cohort (EF) and Control Cohort (CT). Then, each participant was evaluated at the Sport Medicine Centre, where they underwent test of physical strength, body composition, and aerobic capacity. Afterward, EF Transplant ($n=72$) received a tailored exercise prescription lasting 12 months, while no intervention was proposed to CT. Checkups and related test were performed after 6 and 12 months. Results: Up to now, 50 patients completed the 12-month evaluation. At baseline, the two groups (EF and CT) showed similar anthropometric characteristics. After 12 months, EF presented a significant improvement of strength parameters, maximal power and aerobic capacity ($p < 0.05$). After the Mixed Procedure analysis for repetitive data applied to both groups, Groups Effect was statistically significant only for strength value of right and left quadriceps ($p=0.0047$ and $p=0.033$, respectively). Group x Time interaction between the two cohorts was significant for all muscular groups and for VO_2max and maximal workload during incremental test ($p < 0.05$). Conclusions: Our study was aimed not only to investigate the effect of physical activity on transplant patients, but it also wants to develop the practice of exercise prescription within the standard approach for patient's management. The results show that a tailored exercise program, including both resistance and endurance training, can contribute to improve physical fitness and health-related quality of life in these subjects.

TRUNCAL ANESTHESIA AND US-GUIDED INFILTRATION FOR PLANTAR FASCIITIS TREATMENT

Del Castillo González, F.1, Rodríguez Fabián, G.1, Ramos Alvarez, J.J.2, Del Castillo Díez, F.1, González Pérez, J.1, Jiménez Herranz, E.3

Complutense University2. Deyre Clinic1. Camilo José de Cella University3

TRUNCAL ANESTHESIA AND US-GUIDED INFILTRATION FOR PLANTAR FASCIITIS TREATMENT INTRODUCTION The plantar fascia is a fibrous layer that provides strength and flex to the plantar arch. Normal ultrasound appearance is similar to a tendon and its normal thickness less than 3 mm (1). In plantar fasciitis, a collagenous-fiber degeneration occurs and manifest as heel pain, especially in runners (2).

Classic treatment consist in orthosis correction, stretching exercises and physiotherapy. Corticoids infiltration has been considered as an alternative to resistant cases (3). **MATERIAL AND METHODS** The population studied was made up of 50 patients, 30 men and 20 women who were amateur runners with clinical diagnosis of plantar fasciitis and confirmed by ultrasound with hypoechogenic appearance and more than 4 mm thickness. All patients were treated with conservative methods one month at least with no response. Under mepivacaine anesthesia of tibial posterior nerve in medial retromaleolar recess, US-guided plantar infiltration was performed. Clinical and imaging controls were performed along 3 months for evaluation of pain, size and thickness of the fascia. An analogic visual scale (AVS) was used for pain measures. **RESULTS** Before treatment an 8, 5 in AVS was obtained (range 7-10). After 15 days treatment an 3, 75 in AVS was obtained (range 1-5) and a mean 2, 5 (range 1-4) in 1 month after treatment. At 15 days were incorporated into the regular sports practice. Two patients had a recurrence after treatment and were properly treated with physiotherapy. Before treatment an 4,75 mm. plantar fascia thickness (range 3,9 -7,1) measurements was obtained. After 1-month period from injection a 4,1 mm mean size (range 3, 9-6, 9) was obtained. Three months post treatment mean size was 4 mm. and none exhibit hypoechogenic appearance. He had obtained a significant decrease in pain remaining constant thickness fascia. **CONCLUSIONS** US-guided plantar infiltration with troncular anesthesia is an excellent option for plantar fasciitis treatment. Truncal anesthesia decreases pain and discomfort from the plantar injection. US is a proper technique for diagnosis and evolution surveillance of plantar fasciitis. **BIBLIOGRAFIA:** 1- Naredo E, Bijlsma J. ACTIVE PLAY IN CHILDREN WITH ASTHMA; A PILOT INTERVENTION STUDY

Nilsen, T., Westergren, T., Fegran, L., Haraldstad, K., Kittang, O.B., Berntsen, S.

University of Agder

Introduction: A physically active lifestyle is important in children with asthma. Still there is limited information on how the physical exercise interventions should be designed for this group of children. The aim of the present pilot study was to determine the feasibility of a group-based exercise program focusing on active play in children with asthma. **Methods:** 6 children (4 boys and 2 girls) with asthma, aged 10-12 years took part in a 6 weeks exercise intervention, two times a week for one hour, respectively. The location was an indoor gym, and the exercises were designed as different games, like relays, tags etc. The children wore a heart-rate monitor for recordings of exercise intensity. Before and after the intervention, the children wore a physical activity monitor to record moderate- to vigorous intensity physical activity level (MVPA) for four consecutive days, performed a VO₂ max test on a treadmill, and completed questionnaires on health- related quality of life (Pediatric Quality of Life Questionnaire) and asthma control (Asthma Control Questionnaire). The children took part in three focus-group interviews and field observations were conducted during the VO₂ max tests and 5 exercise sessions. **Results:** All 6 children were physically active doing sports and other leisure activities. 4 children had MVPA level above the recommended 60 minutes/day. Median (interquartile range) pre- and post scores for VO₂ max were 48.7 (10.9) and 49.7 (8.8) ml/kg/min, respectively. Total scores on quality of life were 6.3 on the pre-test and 6.6 on the post-test, while total scores on asthma control were 0.7 on the pre-test and 0.6 on the post-test. No exacerbations were observed during the sessions. The attendance rate was 90% (one child was included in the study after the forth exercise session). The children had an average intensity level $\geq 80\%$ of their maximal heart -rate for 22 minutes per session. From the focus group interviews children reported that they liked the exercises, especially the competitive games and relays. Being social in the training situation, familiarity with activities, and encouragement by instructors were reported as motivational factors. **Discussion:** This physical exercise program focusing on active play was feasible in the way that the children enjoyed taking part and liked the exercises, resulting in relatively high exercise intensity with no children experiencing exacerbations. Future exercise interventions for children with asthma should include enjoyable activities that could be of high intensity.

SLEEPING PATTERNS OF AFRICAN ELITE SOCCER PLAYERS DURING PRESEASON TRAINING CAMP

Brito, P.1, Casanova, F.1, Fonseca, M.2, Brito, J.3

1: FADEUP (Porto, Portugal) 2: CRD Libolo (Libolo, Angola) 3: National Sports Medicine Programme, Excellence in Football Project, Aspetar – Qatar Orthopaedic and Sports Medicine Hospital (Doha, Qatar)

Introduction During a preseason training camp, players are subject to very demanding loads for several days, with little time for recovery. Sleep is known to be an important component of recovery of training due to its physiological and psychological restorative effects (Leeder et al, 2012). Despite the importance of sleep in recovery, studies on the sleep-wake behaviour of elite athletes are rare. The present study aimed to describe the subjective quality of sleep (i.e. tiredness at bedtime, tiredness at waking-up, and the number of waking-up times) of African elite soccer players over 9 days of a preseason training camp. **Methods** Twenty-six elite male soccer players (aged 27 \pm 4 years) from a team competing in CAF Champions League answered a daily questionnaire regarding sleep quality (Batista & Nunes, 2006). The questionnaires were obtained during breakfast. During the 9 days of training camp, 248 questionnaires were obtained and considered for the analysis. Descriptive statistics were mean and standards deviation for quantitative data and absolute (counts) and relative values (percentages) for qualitative/categorical data. Chi-square and regression models were employed to test associations. **Results** During the training camp, the average time to lie down in bed was 23:22 (\pm 58 min). The players reported to take about 18 \pm 33 min to feel asleep. The average time to wake up was 7:51 a.m. (\pm 39 min). This accounted for an average of 8h17 min (\pm 1h48) of sleep time during the training camp. In 52% of the individual questionnaires, the players reported to wake up at least once during the overnight sleep. When we compared tiredness at bedtime and waking-up time, an agreement of 61% was detected ($\chi^2=126.984$; $p<0.001$). There was also an association between sleep time and the state of tiredness of the players. Athletes who spent less time of sleep were more tiredness at waking-up. ($t=-2.789$; $p=0.006$). **Discussion** During the training camp, the players might have not had enough time to recover from the training demands. The overnight sleeping time appeared not to be sufficient for complete recovery; the players reported that it was frequent to wake up at least once during the night, and this has been associated with waking up tired. However, it seems that sleep time is an important variable to predict tiredness on waking, due to the association observed between duration of sleep and tiredness on waking-up. **References** Batista B, Nunes M (2006). SERUM IMMUNOGLOBULINS AND WHITE BLOOD CELLS IN POLISH ATHLETES FROM DIFFERENT SPORT DISCIPLINES

Witek, K.1, Orysiak, J.1, Sitkowski, D.1, Lerczak, K.1, Malczewska Lenczowska, J.1, Grochowska, J.1, Pintera, M.1, Hubner Wozniak, E.2, Pokrywka, A.1

1. Institute of Sport; 2. Jozef Pilsudski University of Physical Education in Warsaw

Introduction Immunoglobulins (Ig) and white blood cells (WBC) are very important elements in the immune system, playing a role in defense against disease agents. Regular physical exercise influences the number of immune markers. However, these changes depend on the type of physical exercise (Saygin et al. 2006, Orysiak et al. 2012). The aim of this study was to compare the levels of serum immunoglobulins (IgA, IgM, IgG), white blood cell counts and their subsets (neutrophils, lymphocytes and monocytes) in ice hockey players, volleyball players and rowers. **Methods** The samples were collected from 125 male Polish athletes (aged 18.2±3.1 years) that were representing three different sport disciplines: ice hockey, rowing and volleyball. Blood samples were taken after night fasting from healthy, medically examined athletes. The haematology parameters were measured using haematology analyzer ADVIA 120 (Siemens, Germany). Immunoglobulin concentrations were measured using turbidimetric methods by means of biochemical analyzer PENTRA 400 (Horiba, France). **Results** The lowest concentrations of IgA, IgG and IgM were found in ice hockey players (1.42 ± 0.59 g/l, 8.85 ± 2.06 g/l, 0.81±0.29 g/l, respectively). The lowest WBC, neutrophil and lymphocyte counts were noted in rowers (5,83±1.50 x103/ul, 3,02±1.41 x103/ul, 1,97±0.46 x103/ul, respectively). In this study, only IgG concentration was significantly different among sport disciplines. Significant changes in IgG concentration occurred in ice hockey players compared with rowers and volleyball players (8.85±2.06 x103/ul, 10.87±2.65 x103/ul, 13.60±2.32 x103/ul, respectively; p<0.05) and in rowers compared with volleyball players (p<0.05). **Conclusion** The observed differences in IgG levels depend on the sport disciplines and could be related to the adaptive response to the physical exercise. The study was financially supported by Ministry of Sport and Tourism - Fund for Development of Physical Culture (agreement numbers: 2013/0209/0223/SubB/DSW/DK/JD) **References** Orysiak J, Witek K, Zmijewski P, Gajewski J. A NOVEL APPROACH TO PREVENT MUSCLE CRAMPS IN ATHLETES?

Behringer, M., Moser, M., McCourt, M., Montag, J., Mester, J.

German Sport University Cologne

INTRODUCTION: Athletes are sometimes forced to stop training or even competition due to sudden involuntary and painful contractions of the musculature, known as skeletal muscle cramps (SMCs). In sports, muscle fatigue – especially in combination with low temperature – seems to be the most common trigger of SMCs. Interestingly, it could be shown that the individual cramp susceptibility is correlated with the threshold frequency (CTF) of electrical muscle stimulation (Miller et al., 2009). By chance we found a training method that substantially increases the CTF. **METHOD:** Calf muscles of one leg in 10 healthy male subjects (25.2 ± 3.1 years) were electrically stimulated twice a week in a shortened muscle position (CT), over a period of six weeks (Impulse width: 150ms, 30Hz above the individual CTF, and at 85% of the maximal tolerated stimulation energy). The calf muscles of the opposite leg were stimulated with the same stimulation settings, but were hindered from cramping by fixating the ankle in a neutral position (NCT). Lower legs of 5 healthy male subjects served as control (CG). **RESULTS:** The CTF was significantly increased in the calf muscles that were stimulated in a shortened position from 23.3 ± 5.7 to 35.3 ± 6.0. By contrast the CTF remained unchanged in the opposite leg (pre: 23.6 ± 5.7, post: 22.5 ± 2.1) and in both legs of the control group (pre: 21.8 ± 3.2, post: 21.4 ± 2.3). **DISCUSSION:** To date there is an overwhelming lack of evidence for non-drug therapies for lower limb muscle cramps (Blyton et al. 2012). The present findings are the first of its kind. However, the underlying mechanisms remain unclear. We hypothesize that the applied training induced a set-point change for Golgi-tendon organ (GTO) or muscle spindle activity in contractions at short muscle lengths. **CONCLUSION:** The huge increase in CTF following the applied training protocol may help to prevent SMCs in athletes during training and competition. Further studies are needed to test, if the same effects can be elicited in subjects with increased cramp susceptibility and how long the achieved effect will last. **REFERENCES** Miller KC, Knight KL. Electrical stimulation cramp threshold frequency correlates well with the occurrence of skeletal muscle cramps. *Muscle Nerve* 2009 Mar;39(3):364-8. Blyton F, Chuter V, Walter KE, Burns J. IMPAIRMENT OF DYNAMIC VISUAL PERFORMANCE AT ALTITUDE

Krusche, T., Limmer, M., Jendrusch, G., Platen, P.

Ruhr-Universität Bochum

Department of Sports Medicine and Sports Nutrition, Faculty of Sports Science, Ruhr-Universität Bochum, Germany **Introduction** Dynamic vision and motion perception are important factors for safety and performance in sports (Jendrusch et al., 2010). Movement control and balance regulation require visual information. In the context of modern mountaineering these skills are essential. Reduced visual performance has been demonstrated during hypoxic conditions (Basnyat et al., 2004). Dynamic and static visual abilities are independent from each other. It is unclear so far in which way hypoxic exposure has an effect on dynamic visual performance (DVP). The purpose of the study was to investigate DVP during hypobaric hypoxic conditions in healthy young hikers. **Methods** 11 hikers (male: n = 9, female: n = 2; 24.0 ± 2.5 years; refraction error ≤ 2.5 dpt) were investigated before (d0: 154 m) and during a 6-day high-alpine hike (sleeping level: 3029 - 3647 m). DVP was analyzed in four different sectors of the foveal/parafoveal visual field (left, right, top, bottom) at day 5 (d5: 3647 m) and day 6 (d6: 4454 m). DVP was assessed by a form-from-motion test analogue to the Landolt test as developed by Wist et al. (1998) on a calibrated high definition notebook in a light-impermeable tent. In addition, oxygen saturation (SaO2) and Lake Louise score (LLS) were determined. **Results** DVP was decreased significantly in the bottom parafoveal sector (median (M); d0: M = 80 %, P25 = 30 %, P75 = 100 %; d5: M = 60 %, P25 = 20 %, P75 = 90 %; d6: M = 30 %, P25 = 40 %, P75 = 70 %; p < 0.05). Summed DVP (over all sectors) remained constant during altitude on d5 and d6 compared to d0 (d0: M = 85 %; d5: M = 75 %; d6: M = 75 %; p > 0.05). No subject was diagnosed with acute mountain sickness (LLS ≤ 3), and all had SaO2 values > 80 % (range = 80 - 91 %). **Discussion** Our data suggest that hiking in hypobaric hypoxia results in lower DVP in healthy young people. This is in line with studies demonstrating the sensitivity of mainly central retinal cell clusters to hypoxic stimuli (Feigl et al., 2007), and an over-representation of hypoxic sensible cells in the superior retina (Curcio et al., 1990). Whether this hypoxia-induced impairment in DVP affects the quality of balance regulation has to be analyzed in future studies. It can be assumed that reduction of visual perception performance at high altitude adversely affect motor performance and coordination and increases the risk of accidents (e.g. falls). **References** Basnyat B, Wu T, Gertsch JH. THE EFFECT OF BODY ARMOUR, EXERCISE AND DISTRACTION ON LANDING FORCES

Dempsey, P.C., Handcock, P.J., Rehrer, N.J.

University of Otago, New Zealand

Introduction Since 2007, New Zealand frontline police officers have been required to wear stab-resistant body armour (SRBA) vests. The vests are similar to those used by many other international law enforcement agencies, including Europe and the USA. Such added load may impair police physical performance (e.g. Dempsey et al., 2013), which can sometimes involve physically demanding situations and decision-making under duress. As part of our larger study, we investigated the impact of added load and intense exercise on jump and landing performance and vertical ground reaction force (VGRF) during landings where attentional demand was varied. **Methods** Fifty-two males (37 ± 9.2 years, 180.7 ± 6.1 cm, 90.2 ± 11.6 kg, $VO_{2max} 50 \pm 8.5$ ml/kg/min, $BMI 27.6 \pm 3.1$, mean \pm SD) completed the study. A randomised cross-over design was used where two experimental conditions were completed (≥ 4 days in-between) in a counterbalanced order, one while wearing body armour and appointments (LOADED; fitted SRBA vest plus weight representative of a standard police duty belt and accessories, $7.65 \text{ kg} \pm 0.73$, mean \pm SD) and one without additional load (UNLOADED). A countermovement vertical jump, a drop landing concentrating on safe touchdown, a drop jump, and a drop landing with an attentional distraction were performed. These tasks were then repeated after an intense 5-min treadmill run at a speed of 13 km/hr. **Results** Mean jump height decreased by 12% ($P < 0.001$) with loading and by a further 6% following the running task. Peak VGRFs were increased by 13–19% with loading ($P < 0.001$) depending on the landing task demands and by a further 4–9% following intense exercise. The distracted drop landing had significantly higher vertical VGRFs (12–36%) compared with all other landings while participants were loaded ($P < 0.001$). **Discussion** This study indicates that carrying added load significantly decreases jump height and increases VGRF when landing. These loading effects are exacerbated when preceded by intense exercise and when individuals are unable to focus their full attention on their landings. While prior exercise does not appear to significantly affect the VGRF of unloaded individuals, peak VGRFs were significantly increased after a short bout of intense running when SRBA vest and accessories were worn. Such increases in VGRF apply to police officer performance in their duties and may increase the risk of injury. The addition of kinematic data, such as joint angles, peak torque and muscle activation, would provide useful information regarding jumping and landing mechanisms when loaded. **References** Dempsey P.C, Handcock P.J, Rehrer N.R. (2013). *Appl Ergon*. 44(6), 957-961. Contact Paddy.Dempsey@bakeridi.edu.au

Training and Testing

COMPARISON OF ENERGY EXPENDITURE IN CONTINUOUS EXERCISE AND INTERMITTENT EXERCISE BOUTS DURING EXERCISE AND RECOVERY

LEE, H.K.

SANGMYUNG UNIVERSITY

Introduction According to previous research, there was non-significant difference in estimated energy expenditure between the three 10min bouts of treadmill walking and running and a single 30min bout of exercises at the same intensity (Peterson, M. J., et al., 2004; Darling J. L., et al., 2005). But it didn't try on the bicycle ergometer exercise. The aim of this study was to estimate and compare energy expenditure in a 30min continuous bout of bicycle ergometer cycling at 80% of HRmax reserve with 45min of recovery and in 10min intermittent bouts of exercise with equally divided into three 15min periods of recovery. **Methods** Subjects were fourteen college-aged males (age: 22 ± 1.8 years, height: 173 ± 6.5 cm, weight: 70 ± 13.8 kg, %body fat: 19 ± 6.5 %) volunteered to participate. Energy expenditure was measured with the POLAR(S 800 CX and exercise record/analysis program) at warm up, exercise and during recovery. The 30 min continuous bouts of exercise included a 45 min recovery and each of the three 10 min bouts included 15 min of recovery. Workload was adjusted during exercise to maintain at 80% target HR. Setting of target HR was at 1/3 position of main exercise and maintaining to the end of the exercise. Differences in energy expenditure between continuous and intermittent exercise, recovery from exercise, as well as the combination of exercise and recovery were assessed with a paired t-test. Significance was set at $p < 0.05$. **Results** The energy expenditure for exercise only was no significantly greater (6.3 kcal) with continuous bout of exercise than intermittent bouts of exercise. On the other hand, during recovery from exercise, they expended more energy (22.7 kcal) following intermittent exercise than following continuous exercise. The total energy expenditure for the combination of exercise and recovery was no significantly greater (16.3 kcal) than intermittent bouts of exercise. **Discussion** According to the previous researchers, In exercise, energy expenditure for 30 min bout of walking or running to be higher than three 10 min bouts of walking or running. On the other hand, intermittent exercise has been shown to increase energy expenditure during recovery (Fulton et al, 2001; Darling J. L., 2005). Also, it is that energy expenditure for 30min of treadmill running was very similar between a continuous bout of exercise with recovery and accumulation of intermittent bouts of exercise with recovery (Darling J. L., 2005). In the present investigation, it showed similar results as a previous studies. **References** Peterson, M. J., D. R. Palmer, and L. L. Laubach. (2004). *J. Strength Cond. HOW SHOULD COMPETITIVE SWIMMERS PERFORM POWER SWIM-TRAINING?

Matsunami, M.1, Taba, S.2, Ichikawa, H.2, Taguchi, M.2, Taimura, A.3, Funai, Y.1

1:Nishi-Nippon Junior College (Fukuoka, Japan), 2:Fukuoka Univ. (Fukuoka, Japan), Nagasaki Univ. (Nagasaki, Japan)

Introduction Power training in the pool (power swim-training) that provides a specific overload has been carried out as underwater resistance training. When performing the power swim-training, swimmers are instructed to continuously maintain a high stroke rate. However, if the stroke technique degrades, the training is insufficient. The purpose of this study was to determine whether training performed in a high stroke rate is appropriate as power-swim training method. **Method** Nine experienced collegiate sprint swimmers (5 male, 4 female, age 20.8 ± 1.2 yrs.) were participated in this study. Each subject swam 25 m twice with maximum effort under three conditions: no load (SS), with load (PS), and with load and controlled stroke rate in SS (CPS), respectively. Power swimming with load was performed using the resistance tools (Swim Parachute, FINIS Inc., USA) that the swimmers use in their usual training. Moreover, the stroke rate was managed using a portable waterproofed metronome (Tempo Trainer, FINIS Inc., USA). The swimming time was measured in sections of 0 to 15 m, and 15 to 25 m, and the swimming velocity in each section was computed. The stroke rate was determined by measuring the duration of three strokes in the section of 15 to 25 m with a stopwatch. The stroke length was computed from the swim-

ming velocity and stroke rate in the section of 15 to 25 m. Results The stroke rate in PS (51.99 ± 1.39 stroke/min) decreased significantly as compared with SS (55.16 ± 1.07 stroke/min) ($P < 0.05$). Although the stroke rate increased in CPS (55.07 ± 1.07 stroke/min) significantly as compared with PS, there was no significant difference in swimming velocity between CPS (1.20 ± 0.04 m/s) and PS (1.18 ± 0.03 m/s) in the 15-25 m section. In the 15-25 m section, the stroke length in PS was significantly longer (1.37 ± 0.05 m/stroke) as compared with CPS (1.31 ± 0.05 m/stroke) ($P < 0.05$). Discussion The results of this study showed that, in power swim-training, the training method of continuing to maintain a high stroke rate reduce stroke length. Therefore, the quality of the stroke technique degrades and it is supposed that there may be no suitable load for the active skeletal muscles. In conclusion, it is suggested that power swim-training to be performed by the swimmer's own maximal effort is desirable method than controlled training to force a high stroke rate. AN EXPERIMENTAL RESEARCH FOR PUSH-UP TO DETERMINE EFFECTS OF TECHNICAL PERFORMANCE WITH PUSH-UP COUNTER

Eynur, B.R.1, Çetinkaya, E.2, Sorgunlu, H.2

DÜMLÜPINAR UNIVERSITY

Introduction In foundation of every sportive movement, there is a correlation of technics-performance. With correct teaching method educated technics are foundation of winner performance emerging. Therefore, push-up technics must be right learned, practised and analyzed by trainers. Therefore, this study examined this technics with push-up counter. Methods In this study, a tool that correct push-up maker, counter and when doing push-up tell us right or false was created. We call them push-up counter. Sampling was created by university student who never doing physical activities or sport. As not significantly different, Total 56 male university student divide in 2 groups. Experimental group was used push-up counter and the other group (control) trained by traditionally. In this study, last test with control group research design was selected research design. In this research design, randomly selected two groups are created. One of these is selected experimental, the others control group. To these groups, only last test is practised (KARASAR, 2005). The independent t-test was used for second measurements of experimental and control groups. Significant level was accepted as $p < 0.05$. Results In the first tests that measure push-up count in 2 minutes, there is no significant level between groups ($t_{0.05} = 0.126$; $p > 0.05$) but in second tests there is significant level between groups ($t_{0.05} = -10.081$; $p < 0.05$). Discussion In this study according to control groups students experimental group students' showing significant performance; can thought wants to be correct technics by machine. Nonetheless, examined in one study, 8 week different flat trainings was determined not show significantly performance between individuals (Chulvi-Medrano, Martínez-Ballester, & Masiá-Tortosa, 2012). This result supports our study. In push-up trainings, coaches can be wrong, but push-up counter wants correct performance by sensor. Because long trainings can be exhausting, coaches can wrong evaluation for technics and performance. Machine kill that conditions. THE DEVELOPMENT OF AN EVALUATION TO ASSESS PHYSICAL FITNESS OF KINESIOLOGY CANDIDATES

Reilly, E., Walker, A., Williford, H., Esco, M.

Auburn University at Montgomery

Introduction The National Association for Sport and Physical Education (NASPE) sets standards for Physical Education Teacher Education (PETE) in the United States. According to these standards, PETE candidates are expected to demonstrate health-enhancing levels of physical fitness. In order to meet the standard, universities should implement procedures to measure fitness levels of teacher candidates throughout their programs. Auburn University at Montgomery (AUM) met this need by modifying a national fitness test to administer to teacher candidates. Methods The elements of the AUM Health and Physical Fitness Test are the 20-Meter Shuttle Test, Push-ups, Sit-ups, and Sit-Reach. Candidates were required to take the test initially before admission into upper-level courses in their field (PETE, Sport Management, or Exercise Science). The final test was required to be taken and passed prior to being permitted to intern and graduate. Passing scores are based on meeting healthy standards for their age and gender. Results A total of 98 candidates completed the initial AUM Health and Physical Fitness Test. Seventy-two percent of the candidates met the acceptable standard by passing all of the test items. The following are the passing rates for each test item: 75% passing rate for the 20 meter shuttle test, 96% passing rate for the push-ups, 98% passing rate for the sit-ups, and 99% passing rate for the sit-reach. A total of 37 candidates completed the final AUM Health and Physical Fitness Test. Ninety-seven percent passed all elements of the test; one candidate did not pass the 20 meter shuttle test. Discussion Individuals who did not meet the designated standards were put on remediation programs in order to improve their fitness levels prior to internships and graduation. Results indicate that implementing a physical fitness requirement can effectively motivate candidates to increase physical fitness to healthy standards, thereby meeting national standards. EFFECT OF A 6-WEEK SPEED AND STRENGTH TRAINING ON THE FEMALE FENCERS DURING PREPARATORY PERIOD

Jastrzebski, Z.

Gdansk University of Physical Education and Sport

Introduction Fencing is a sport involving high-intensity performance and short recovery breaks (Tsolakis et al. 2006). Therefore, the assessment of explosive strength and running speed are crucial for the assessment of the effectiveness of applied training load. There are numbers of studies regarding the effectiveness of speed and strength training in different sports (Jastrzebski et al., 2014). Therefore the main aim of this work is to study the effectiveness of 6-week speed and strength training in elite female fencers during preparatory period. Methods Ten elite female fencers volunteered for the study (21 ± 2.79 yr, 64.73 ± 7.98 kg, 172.3 ± 5.6 cm). Explosive power was measured by tensometric mat (Smart Jump Mat 120 x 120 cm - Fusion Sport, Cooper Plains, Australia). The subjects performed a single vertical jump with arms swing (Hfmax) and a series of maximal vertical jumps with arms swing within 10s period (Hfmean). After 10 min of recovery, running speed of 5, 10m was measured by double photocells (Smart Speed, Fusion Sport, Cooper Plains, Australia). Total anaerobic work and peak power were measured by 30-s Wingate test on cycloergometer (Monark Ergonomic 894 E, Monark, Sweden). Statistical analyses were performed using STATISTICA (data analysis software system), version 10 software (StatSoft, Inc., 2013). Results Significant differences ($p < 0.05$) were revealed for maximal power (PRE, 8.76 ± 0.95 W/kg; POST, 9.25 ± 0.68 W/kg) and total work (PRE, 208.82 ± 18.76 J/kg; POST, 217.41 ± 18.92 J/kg) for the female fencers after the 6-week experiment. Moreover, a considerable ($p < 0.05$) improvement in running speed on the distance of 10m was observed (PRE, 2.08 ± 0.15 s; POST, 1.99 ± 0.15 s) though no relevant differences

occurred for 5m run (PRE, 1.18 ± 0.07 s; POST, 1.16 ± 0.06 s). No significant differences were stated for power tested during vertical jump (PRE, 32.76 ± 4.31 W/kg; POST, 32.65 ± 3.52 W/kg), nor for the mean values of 10s jumps (PRE, 30.74 ± 4.24 W/kg; POST, 30.11 ± 3.53 W/kg) measured for the subjects after the 6-week experiment. Discussion The results of the study regarding running speed and explosive strength proved effectiveness of the applied speed and strength training over a 6-week period. Similar results regarding this type of training program were revealed in the studies by Tsolakis et al., (2006) conducted on male fencers and by Jastrzebski et al., (2014) who tested football players during several-week training experiments including speed and explosive power drills. The literature available does not provide research data regarding the effectiveness of the speed and explosive strength training of elite female fencers. References Tsolakis CH. K., Bogdanis G. AEROBIC FITNESS IN MALE ELITE ATHLETES AGED 11-16 YEARS: THE INFLUENCE OF AGE, MATURATION PARAMETERS, AND BODY COMPOSITION

Noffz, J., Hacke, C., Weisser, B.

Christian-Albrechts-University Kiel

INTRODUCTION: The relationship between age and aerobic capacity has been reported in a number of studies. The aim of this study was to consider the relationships between chronological age (CA), maturation parameters, body composition, and aerobic fitness in young male elite athletes. **METHODS:** 127 male subjects aged 11–16 years were investigated. They were recruited during medical examinations for elite athletes or sent by their coaches from two local elite clubs (handball and soccer). Height and weight were measured with standard anthropometric methods. Body composition (muscle mass) was determined with eight-polar bioelectrical impedance analysis. During an incremental submaximal cycling exercise blood lactate concentration was measured and the performance at 4 mmol/l lactate was determined (OBLA). Maturity status was obtained by calculating the percentage of predicted adult height attained at the time of the study. In addition a prior validated questionnaire was used to determine the pubertal maturation (Pubertal Development Scale = PDS). Ethic approval was obtained from the Ethics in Human Research Committee of Kiel University/Medical Faculty. All athletes and their parents signed a consent form. **RESULTS:** 127 athletes were included, mean age 14.2 y, standard deviation; range (+/- 1.3; 11.0–15.9), mean height was 170.8 cm (+/- 13.0; 137.0–194.0), mean percentage of predicted adult height was 93.7 % (+/- 6.3; 79–106), mean score in PDS was 12 (+/- 3.7; 5–19), mean muscle mass was 30.2 kg (+/- 7.55; 17.5–47.2), mean performance at OBLA was 149 Watt (+/- 35.4; 99–223). For all subjects, a significant relationship existed between aerobic capacity (OBLA) and age, muscle mass, percentage of predicted adult stature and pubertal development ($p < 0.001$). Using multiple regression analysis the model explained 53 % of the variance in exercise performance. Muscle mass was the only significant predictor for aerobic capacity. **CONCLUSION:** In the present study muscle mass had the predominant influence in aerobic fitness. The results highlighted the importance of considering the varieties of pubertal maturation for the assessment of aerobic exercise performance in young athletes. The muscle mass is an easy to gain, non-invasive marker. This information has to be considered when lactate thresholds are used to determine aerobic performance of adolescents.

EFFECTS OF PARKOUR TRAINING ON AEROBIC FITNESS PARAMETERS IN ADOLESCENTS

Dvorak, M., Bunc, V.

Charles University in Prague

Introduction The aim of the study was to describe effects of parkour training on selected aerobic fitness parameters in adolescents. These parameters were chosen according to Léger (1996) - maximal aerobic power (VO₂ max), economy of movement (VO₂ at 10 km/h) and anaerobic threshold (AT) parameters (VO₂, HR, running velocity). **Materials and Methods** Ten participants (age = 16 ± 2 years) took part in a controlled indoor parkour intervention. They underwent ten weeks of training. Duration of each unit was one hour with the frequency two times a week. Training units were prepared in accordance with the Parkour Generations teaching materials (Parkour Generations, 2013). Training intensity was set at 85% of HR max. Treadmill running test with graded protocol and respiratory gas analyzer Cortex Metalyzer (Cortex, Germany) were used to quantify effect of parkour training. We measured before and after parkour intervention. We observed changes in VO₂ max and VO₂ at velocity 10 km/h. VO₂, heart rate and running velocity for level of anaerobic threshold were specified. Paired t-test ($p = 0.05$) and omega squared were calculated to assess the differences between pretest and posttest. **Results** We found a significant differences after parkour intervention in VO₂ max ($p = 0.001$, $\uparrow 2.5$ ml/min/kg, omega squared = 0.69); VO₂ at 10 km/h ($p = 0.002$, $\downarrow 1.0$ ml/min/kg, omega squared = 0.62); VO₂ at AT ($p = 0.001$, $\uparrow 2.1$ ml/min/kg, omega squared = 0.70); HR at AT ($p = 0.001$, $\downarrow 3$, omega squared = 0.82); running velocity at AT ($p = 0.011$, $\uparrow 0.2$ km/h, omega squared = 0.46). (Tab. 1) **Discussion** We stated VO₂ max 52.4 ± 4.3 ml/min/kg after parkour intervention. Leite et al. (2011) stated lower level of VO₂ max for parkour practitioners 44.2 ± 5.6 ml/min/kg. This difference is possible to interpret by higher level of VO₂ max for participants in the beginning of our intervention. Leite's results could be affected by using field testing method. We declare improvement in economy of movement which is expressed by decrease of VO₂ at the velocity 10 km/h. We have found a significant increase of VO₂ at AT, running velocity at AT and significant decrease of heart rate at AT. All these changes can indicate improvement in aerobic fitness of participants achieved by parkour training. The main limitation of the study is the small sample size and the absence of control group. **Conclusion** In conclusion, the parkour training increased maximal aerobic power, improved economy of movement and positively affected parameters on level of anaerobic threshold. CONTRIBUTION OF HAND AND LEG MOVEMENTS TO THE THROWING PERFORMANCE OF WATER POLO PLAYERS

Komori, Y., Kitada, K., Segwa, E., Shimura, Y., Kono, I.

Osaka International University

Introduction Throwing is one of the most important skills in water polo. However, the throwing movement in water differs from that on dry land since no ground support is available in the water. Throwing movements in the water require the use of highly complicated and very important underwater techniques, such as sculling (hand movements) and eggbeater kicking (lower leg movements). Therefore, the present study aimed to examine the contribution of the body parts to throwing performance, particularly the effect of hand movements and lower leg movements on throwing velocity in the water. **Methods** A total of 19 male high school water polo players participated in

this study. Each player threw the ball three times for each pattern using three different penalty throw patterns while shooting at the goal. The throwing patterns were as follows: normal; one arm immobilized (AI); and both lower legs immobilized (LI). The following indicators of throwing performance were used: initial throwing velocity detected using speed gun Doppler ultrasonography, and head height at the moment of ball release using a high-speed video camera. Results The mean initial throwing velocities of the normal, AI, and LI patterns were 60.0 ± 5.7 km/h, 56.6 ± 4.5 km/h, and 49.9 ± 4.6 km/h, respectively. AI and LI throwing velocities were lower than that of the normal pattern. The LI pattern showed a 16.8% depreciation compared with the normal pattern. Furthermore, head heights at ball release in the AI and LI patterns were lower than that in the normal pattern. Discussion On dry land, the throwing velocity of the LI pattern showed a depreciation of 16.0 % compared with that of the normal pattern (Toyoshima, 1973). The present study showed a similar rate of decrease in the LI pattern throwing velocity compared with the normal pattern throwing velocity, suggesting a similar contribution of the lower legs to throwing velocity in water compared to that on dry land. A correlation between throwing velocity and water jump height was noted in water polo players (Ross, 1999). The present study showed that the head height at ball release in the LI pattern was lower than that in the Normal throwing pattern. Therefore, the use of an underwater technique involving the legs that raises the body high above the surface of the water appears to be required to maintain throwing velocity. In conclusion, the results of this study suggest that lower leg movements are an important factor of throwing performance in the water. . References Toyoshima, S., et al. (1973). Biomechanics, 169-174. University Park Press, Baltimore. Ross H.S. (1999). J Appl Biomech, 15, 284-291. Contact komori@oiu.jp

A WEARABLE SENSOR SYSTEM FOR SPORTS AND FITNESS APPLICATIONS

Blank, P.1, Kugler, P.1, Schlarb, H.2, Eskofier, B.M.1

1: University Erlangen-Nuremberg; 2: adidas AG Herzogenaurach

Introduction Wearable sensors are an important tool in sports. They can provide individualised feedback during training sessions, give feedback to athletes, and improve their personal health status. Common to all applications is to measure physiological data or biomechanical motion data. Therefore, we present a wearable, small and lightweight low power sensor system that allows long-term monitoring of physical quantities while maintaining a high sampling rate. It can be integrated into clothing or sports equipment without affecting the athlete's performance and behaviour. Methods We designed a new sensor system based on available low power components. It contains an inertial measurement unit (IMU) including a 3-dimensional accelerometer, gyroscope and magnetometer. Furthermore, temperature and barometric sensing were added. The core is a powerful ARM Cortex-M3 microcontroller with on-node processing capabilities. Sensor data is stored using a NAND flash memory, while an EEPROM stores permanent configurations. The system is powered by a small lithium-polymer battery which provides long runtime and is monitored by a special fuel gauge. A high precision real time clock enables a constant sampling rate and synchronises multiple sensors by supplying an exact global time. These are important features to allow sophisticated signal processing algorithms to be used on highly dynamic sports motions. All parts are mechanically combined in a plastic enclosure, which has similar dimensions of present wearable monitoring systems. This enables fast and easy sensor integration into clothing and sports equipment. Results The system was able to successfully record all nine IMU axes plus barometric data at 1 kHz for up to 20 h. Additionally, a maximum sampling rate of up to 8 kHz has been tested. Accelerometer and gyroscope range was adjustable from ± 2 g to ± 16 g and from ± 250 deg/s to ± 2000 deg/s respectively. Data transmission was realised by USB. Synchronisation of multiple sensors could be achieved with a maximum clock deviation of 8 ms over 1 h. The dimensions are about $40 \times 30 \times 8$ mm. Discussion Sampling rate and storage capacity should be sufficient for most applications in sports or fitness. It is possible to record data over a long period of time or to measure at higher sampling rates for a shorter time period. The USB connection is more suitable than wireless data transmission regarding energy consumption and the high data volumes caused by long-term measurements. This sensor system allows an easy way to instrument clothes or sports equipment. In the future it will be applied in biomechanical studies and enable a precise analysis of highly dynamic sports movements indoors and outdoors. Contact {peter.blank@cs.fau.de}

THE METABOLIC RESPONSE TO THE SPECIFIC EFFORT CORRELATED WITH THE EFFORT ZONES IN WATER POLO PLAYERS – JUNIORS 14 TO 15 YEARS OLD

Marinescu, Gh., Tocitu, D., Ticală, I.D., Moscaliuc, C., Zamfir, V.M., Jari, S., Oussama, R., Petre, A.T.

National University of Physical Education and Sport

Introduction Our study aims to examine the metabolic response to the effort of the water polo players, in correlation with the effort zones and the training intensity, by measuring the blood lactic acid. The specialty literature is poor in data about the metabolic cost of the effort in children and juniors – water polo, as compared to seniors. Methods We used 3 swimming drills specific to the following effort zones: Anaerobic threshold (20 x 50 m Freestyle / start at every 50 sec.), VO2 max (3 x (4 x 100 m Freestyle) / a 10 sec. break between repetitions and a 5 min. break between series) and Tolerance to lactate (6 x 200 m Freestyle / start at every 7 min.), as well as 2 drills specific to the game phases: the former is addressed to the anaerobic threshold effort zone (20 x 25 m ball carrying / a 10 sec. break), while the latter simulates a game action: attack 10 m Freestyle – fallback 10 m Backstroke – counter-attack 10 m Freestyle – shot on goal preceded by two feints. The results of the collected blood tests were analyzed and interpreted at the Biochemistry Lab within the INCS - Bucharest, by means of the ABL 835 Analyzer and of the SPOTCHEM EZ Dry Chemistry Analyzer, Model: SP – 4430 – Arkray. Results The values of the blood lactic acid concentration during the 3 swimming drills were: Anaerobic threshold – basal mean 2.27 mmol / after the effort 8.68 mmol, VO2 max – basal mean 0.92 mmol / after the effort 10.86 mmol, Tolerance to lactate – basal mean 1.61 mmol / after the effort 12.50 mmol. Game-specific drill 1 – anaerobic threshold – basal mean 0.6 mmol / after the effort 9.76 mmol; game-specific drill 2 – basal mean 2.7 mmol / after the effort 9.07 mmol. Discussions By analyzing the obtained results, we can assert that the junior water polo players are not ready to swim with specific tempo and rhythm means, that is why they don't keep to the intensities imposed by the effort zones and their metabolic cost is higher than the effort requirements. The effort at the anaerobic threshold intensity has a lactic acid accumulation in the blood of 8.68 mmol, on an average, for the swimming drills, and of 9.76 mmol, for the polo game-specific drill 1, which corresponds to the VO2 max zone. CORRELATION BETWEEN THE NONVERBAL COMMUNICATION AND THE ATTENTION MOBILITY IN RENDERING EFFICIENT THE PERFORMANCES OF THE ROMANIA BASKETBALL REPRESENTATIVE TEAM – JUNIORS U16

Zamfir, V.M., Marinescu, G.H., Pelin, F., Ticală, L.D., Mujea, A.M., Pană, G., Dulceață, V., Toader, Ș.

National University of Physical Education and Sport

Introduction This research aims at optimizing the performance capacity in the basketball game training and competition, by establishing some relationships between the nonverbal communication and the distributed attention capacity of mobility. The game speed increase generates the achievement of many simultaneous activities in the game tactics implementation. Throughout the years, different throwing, passing and dribbling techniques have been developed, but also techniques related to the players' positioning in the offensive and defensive structures, as well as different communication / interrelation forms ; Predescu, T., Ghițescu, G., (2001). **Methods** The research sample is represented by 20 athletes, components of the Romania basketball team U16 (juniors). They were administered the PONS (Profile Of Nonverbal Sensitivity) test and the PRAGA test (for the distributed attention). **Results** The scores expressed through points at the PONS test are significant: the arithmetical mean 29.4 represents a high level of the nonverbal competence; the standard deviation ± 2.436 and the coefficient of variability 8.26% show us a high homogeneity and a small dispersion of the scores. The scores expressed through points at the PRAGA test are significant: the arithmetical mean 36.55 indicates that attention has a good capacity of mobility; the standard deviation ± 9.654 and the coefficient of variability 26.4% show us a low homogeneity and high dispersion of the scores. The value of Pearson's coefficient of correlation between the two tests $r = 0.634$ reveals a substantial association degree (Davis, apud Kotlik and Williams, 2003). **Discussions** Mastering and knowing the communication process in the basketball game progress is an essential element in managing the team, the interrelations within the group of players or between players and coaches, in order to construct an efficient game tactics. By analyzing the distribution of scenes based on nonverbal responses expressed through body gestures or mimics, correlated with a higher capacity to mobilize the attention, we can assert that the performances in both training and competition have increased. **References** Kotlik, J.W., Williams, H.A., (2003), The incorporation of effect size in information technology, learning, and performance research, Ed. Information technology, learning and performance Journal, 21 (1); Predescu, T., Ghițescu, G., (2001), Baschet. Pregătirea echipelor de performanță, Ed. SEMNE, București.

LEFT ATRIAL DIMENSIONS IN SOCCER PLAYERS

Olm, T., Baskin, K., Herde, K.

Tallinn University

Introduction In the last decade, the left atrial (LA) size has been shown to be a significant predictor of cardiovascular outcomes. The aim of this study is to assess the echocardiographic characteristics of soccer players in order to elucidate determinants for cardiac adaptations. **Methods** The subjects were 209 soccer players of the best clubs of Estonia. In the first group (n=127) average age was 19.2 ± 1.2 and in the second group (n=82) 24.6 ± 2.9 years. The test battery included ECG, treadmill test; BLa, VO2max and the anaerobic threshold were recorded. The echocardiography was performed using GE Vivid E/9. The t-test and Pearson product moment correlation coefficients were calculated. **Results** Most indices of the older athletes were greater than in youngsters but the differences between the indices varied. The mean BSA of the older group was greater by just 1.1%. Regarding BSA, AO was greater by 1.5%, LVIDd by 2.6%, SV by 6.8% and LVM by 9.3%. The smallest difference (0.91%) occurred between the LA diameters of the two groups. The calculated correlation coefficients between the mean indices shows that the LA measures of the youngsters group have strong correlations between BSA, AO, and a moderate relationship with others echocardiographic characteristics. Age, training experience and indices characterizing aerobic and anaerobic working capacity were not found to be correlated with the LA diameters. In the older group all correlations were the same but weaker. **Discussion** Left atrial size, having reservoir, conduit and contraction functions, has been shown to strongly correlate with diastolic dysfunction and be a predictor of cardiac diseases as atrial fibrillation, flutter and stroke. Considerable LA enlargement (>4.5 cm) was rare ($<2\%$) in athletes (1). Our players' largest LA size was 3.8 cm. Hoogsteen et al (2) compared atrial dimensions in young cyclists (17 ± 0.2 years) and in older cyclists (29 ± 2.6 years) and found significantly larger LA dimensions in the older athletes. In our research the means of the LA of the two age groups didn't differ significantly. The reasons for the somewhat unlike data might be: a. A structural cardiac alteration is more common in endurance athletes than in intermittent activity athletes. b. Enlarged LA is more common in older athletes. Our mean age in the older group was just 24.6 ± 2.9 years. **Conclusion** We can conclude that soccer's sport-specific influence is not determinant to the enlargement of left atrial size. **References** 1. MODERATE INTENSITY EXERCISE PROGRAM ON HEALTH PARAMETERS ON PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Ferreira, M.G.A.M., Zaia, J.E., Tonello, M.G.M., Neiva, C.M.

Universidade de Franca

Introduction: Reduced exercise tolerance is a common feature in patients with Chronic Obstructive Pulmonary Disease (COPD), being complex and multifaceted. The identification of factors limiting exercise in these patients contributes significantly in the choice of therapy to be adopted. The literature presents several causes for the decrease in exercise tolerance in COPD patients, involving pulmonary and extrapulmonary factors. Pulmonary Rehabilitation is a program of care for patients with chronic respiratory diseases, individually designed to optimize physical performance and autonomy of these patients. **Objetive:** The objective of this study was to identify the action of exercise on health parameters and quality of life of patients with COPD. **Methods:** We evaluated 20 patients with chronic obstructive pulmonary disease, clinically stable, ex-smokers who were admitted to the pulmonary rehabilitation program from Public Health System (PSF), Paracatu - Brazil. All patients were evaluated before and after exercise program to rehabilitation (PR), composed of cardiorespiratory continuous exercise in Monark cycle- ergometer and resistance training with weights, both on the moderate intensity. With regard to spirometric and blood gasometric variables, before and after the PR program, there were statistically significant only in PaO2. **Results:** It was also observed, statistical difference ($p < 0.05$) in the pre and post PR program in relation to the values of the Saint George's questionnaire, in respiratory disease scores for activity, impact and total, increase significant change in distance test of six-minute walk test and the maximum load for the upper limbs. **Discussion:** For this study we conclude that the PR program proposed has significantly contributed in increasing physical functional capacity of the patient. It is still possible to conclude that the mixed protocol consisting of

load resistance exercises for upper and intense aerobic exercise, proposed to PR program in this study produced beneficial effects on health status and quality of life of patients with COPD, breaking the vicious cycle of disease should be considered effective as a treatment. INFLUENCE OF REACTION TIME IN TABLE TENNIS PLAYERS

Rossi, A., Romano, V., Boccolini, G., Alberti, G.

Università degli studi di Milano

Introduction Successful performance in table tennis depend upon the skill to react to an external stimuli. The reaction time (RT) is the time spent from the moment the subject perceives the stimulus to the moment it begin the response. In table tennis players (TTP) the velocity to response to a visual stimulus (VS) is very important (Bootsma et al., 1990). The aim of this study was to compare the RT after a VS between the athletes that was positioned lowers (L500) and uppers (U500) 500 Italian rank position. **Methods** Twenty male subjects (22.5 ± 4.09) with at least three years of experience were selected. Before the tests the athletes performed a standardized warm up. The TTP performed five test: squat jump (SJ), countermovement jump (CMJ), reactivity in lower limbs (RLL), reactivity in upper limbs (RUL) and reactivity in fingers (RF). The RLL, RUL and RF after VS was performed for dominant and non-dominant limb. The vertical jump capacity and the RT were recorded using OptoJump Next system (Microgate, Bolzano). To compare the data, the athletes were divided in two groups in according to the Italian ranking (lowers and uppers the 500 rank position, 8 and 12 respectively). The statistical analysis were performed using Prism (GraphPad Software, San Diego). **Results** It was found that in the SJ test the subjects L500 performed a high jump vs the U500 (39.82 ± 6.01 cm and 34.63 ± 5.29 cm respectively; $p=0.02$; $ES=0.92$). We have also found that the TTP had a lower RT in dominant lower limb between L500 and U500 (0.63 ± 0.02 s, 0.66 ± 0.03 s respectively; $p=0.04$; $ES=1.2$), but we have found an opposite trend in dominant upper limb between L500 and U500 (0.42 ± 0.02 s, 0.40 ± 0.03 s respectively; $p=0.04$; $ES=1$). However, we have not found a significant statistical difference in CMJ ($p=0.10$), in dominant RLL ($p=0.56$), in non-dominant RUL ($p=0.52$), in dominant RF ($p=0.86$), and in non-dominant RF ($p=0.26$) between L500 and U500. **Discussion** The strength (vertical jump capacity) and the reactivity (particularly in non-dominant limb) in lower limbs could influence the ability of TTP. Disagreeing with what we expected, the TTP L500 had an upper RT in dominant upper limb. The RT in upper limbs is not critical because in Donovan et al. study (2006) found that the difference between trained and non-trained athletes was the hit velocity and not the RT. The well trained subjects performed lower RT (Welford, 1988). Based on these finding, it is important to train the TTP on lower limb RT after a VS. If the athletes is fast moving with lower limbs, they will prepare before to perform the hit. In this way the TTP could perform a good hit because they have more time to prepare it. **Reference** Bootsma RJ et al., 1990. *J Exp Psychol Hum Percept Perform*. 16, 21–29. THE CONSISTENCY OF PHYSIOLOGICAL AND METABOLIC RESPONSES DURING A LABORATORY BASED, SIMULATED FOOTBALL GAME

Peters, G.S., Henderson, K., Stone, M.R.

Bucks New University

Introduction Invasive field games, such as soccer, are characterized by intermittent activity profiles. This separates soccer from sports that exhibit a more continuous exercise profile (e.g. running), which results in the physiological demands being more complex. The study aimed to test the reliability of an intermittent football specific treadmill protocol on recreationally active male participants. **Methods** Participants ($n = 5$) visited the laboratory on four separate occasions. The first visit entailed the assessment of the individuals maximal oxygen consumption (VO_{2max}) using a graded exercise test to volitional exhaustion as per Lansley (2011). The criteria of the British Association of Sport and Exercise Sciences (BASES) were used to ensure that VO_{2max} had been reached (Bird and Davidson, 1997). The following three visits followed the modified Drust Intermittent treadmill protocol (MDIT), consisting of two 45 min bouts of intermittent exercise with a 15 min rest period in between (Drust et al 2000). All visits will be at the same time of day (± 2 h) to minimise the effects of circadian changes (Atkinson et al 1996), at least seven days apart. Heart rate was recorded at various time points, and pulmonary gas exchange and ventilation were continuously measured on a breath by breath basis via a Medgraphics Ultima metabolic cart (Medgraphics, St. Pauls, USA). **Results** Mean responses during the three trials was 137 bpm ($\pm SD$ 24), and 31.1 ± 3.4 ml/kg/min for heart rate and oxygen uptake respectively. Typical error between trials for heart rate was 0.45 (CV% 4.2), and $V \dot{O}_2$ typical error was 0.45 (CV% 5.9). **Discussion** Typical error indicates that the Drust intermittent treadmill protocol is a reliable protocol for repeated testing of recreationally active males. **References** Atkinson G, and Reilly T. TESTING OF SOCCER TECHNICAL SKILLS UNDER PHYSICAL LOAD BY MEANS OF TWO DFB-TESTS

Portela, J., Hartmann, U.

University Leipzig - Faculty of Sport Science

Introduction Technical components are performed in soccer under high physiological loads. The ability to perform them with high accuracy and efficiency until the end of the game is decisive (Rampinini et al., 2009). Lyons et al. (2006) notice a research deficit in this area in sport-specific studies. Hence, the aims of this study were to evaluate two soccer technical tests as research tools to identify how physical strain influence technical skills in soccer. **Methods** Eight male youth elite soccer players (15.60 ± 0.4 y, 63.8 ± 6.9 kg, 175 ± 7 cm) performed the ball control and shooting tests of the German Football Association-test battery (DFB-1b) three times in the following order: at rest, after an

intensive 5 min-shuttle run of 20 m at 11.9 km/h using a acoustic pulse tone, and after a shuttle run at 14.5 km/h until subjective exhaustion (average duration 2:04 min). Heart rate (HR) and blood lactate [LA] were measured. Dependent variables were time to complete the control ball test; and the accuracy for the shooting test. Previously, physical performance tests were executed: countermovement jump with arm swing (ACMJ), 20 m sprint, agility test from DFB-tb and incremental running test (RT) starting with 10 km/h by 2 km/h increase every 5 min until exhaustion. Results Baseline ACMJ, sprint, agility and RT were completed with 40.9 ± 4.1 cm, 3.21 ± 0.08 s, 7.89 ± 0.14 s and 1207 ± 122 s, respectively. Physiological results of the RT were: HRpeak 190 ± 9 b/min, relative oxygen uptakepeak 59.1 ± 3.0 mL/kg/min and [LA]peak 7.3 ± 3.1 mmol/L. The subjects performed the ball control test with 8.02 ± 0.74 s at rest, 9.75 ± 2.77 s after first running load ([LA] 3.4 ± 1.8 mmol/L, HR 187 ± 8 b/min) and 9.18 ± 2.1 s after exhaustion ([LA] 7.6 ± 1.5 mmol/L, HR 191 ± 9 b/min). The shooting test was performed with 11.0 ± 4.2 , 11.5 ± 4.2 and 11.6 ± 5.0 points, respectively. Discussion On the basis of these results it was not possible to determine in spite of apparent increasing physiologic load whether technical decrease occurs, probably because of the insufficient sensitivity of the two technical tests. Based on Impellizzeri et al. (2008), in this explorative study a 5 min-interval for loading was chosen. It would be required to prove it by a longer loading phase, because the game demands could cause others more complex fatigue mechanisms (Mohr et al., 2005). Further investigations are necessary. THE EFFECT OF VVO2MAX PROTOCOL ON PREDICTING 3000M RUNNING PERFORMANCE

Baker, J.I, Rathbone, A.I, Johnstone, J.I, Barnes, R.2, Scruton, A.I, Gordon, D.I

Anglia Ruskin University

Introduction Velocity at VO2max (vVO2max) describes individual differences in aerobic performance which VO2max and running economy alone do not. To date, only a single study has compared the methods of vVO2max determination concluding each generate different physiological outcomes (Hill et al., 1996). However, limitations exist in this study, detracting from the conclusions. Hence the purpose of this study was to compare the validity of vVO2max protocols and to ascertain which method most accurately predicts middle distance running performance. Method Following University institutional ethical approval, 8 male middle distance runners (age; 31 ± 5 yrs, height; 178.8 ± 3.3 cm, mass 69.9 ± 4.7 kg, 3km run time 588.93 ± 39.35 s, VO2max; 67 ± 4.8 mL·kg⁻¹·min⁻¹), completed four maximal trials, (3 on a motorised treadmill and one field based trial) with an additional method (Lacour et al., 1990) consisting of intermittent running on a treadmill. Prior to laboratory testing participants completed a 3km time trial to ascertain individual middle distance performance. Method (M) 1; Billat et al., (1994), M2; Lacour et al., (1990), M3; Daniels et al., (1985), M4; Noakes (1988) and M5; Cooper (1968). Data was analysed using Limits of agreement (LOA) and an ANOVA to compare differences in running velocity at VO2max. Results Predicted 3000m performance was significantly affected by vVO2max protocol ($p < 0.01$). All methods described significantly different speeds to 3000m performance ($p < 0.05$), apart from method 2 ($p > 0.05$). M1 ($r = 0.96$), 4 ($r = 0.92$), 5 ($r = 0.94$) correlated with 3000m performance. Method comparison showed agreement with 3km run speed however, all predictions for 3km velocity showed a positive bias. Discussion All methods tended to overestimate 3km running velocity however, M5 may be preferable due to its lower bias (0.36 km·hr⁻¹) and narrower confidence limits. Furthermore, M5 is a non-invasive and cost effective protocol to monitor running performance. References Billat V, Pinoteau J, Petit B, et al. (1994). ANTHROPOMETRIC AND PHYSICAL PERFORMANCE CHARACTERISTICS OF COLOMBIAN ELITE MALE WRESTLERS

Ramírez Vélez, R., Argothy, R., Meneses Echavez, J., Sánchez Puccini, M.B., Lopez Alban, C.A., Cohen, D.D.

Universidad Manuela Beltrán, Universidad Santo Tomás, Universidad de Santander

Aim: The objective of the present study was to evaluate anthropometric and physical performance characteristics of elite male wrestlers. Methods: The Colombian Wrestling Team was evaluated while in preparation for the Olympic Games ($n = 21$, age 27.9 ± 6.7 years). Athletes were tested on anthropometric and fitness parameters: body composition, somatotype distribution according to Heath-Carter, aerobic capacity, vertical jump, and anaerobic power. Results: The results in mean \pm SD and (95%CI) showed a percentage of body fat 13.6 ± 3.0 (95%CI 12.2 to 15.0); muscle mass 46.4 ± 2.2 ; (95%CI 45.4 to 47.4); ponderal index 41.0 ± 1.8 (95%CI 40.2 to 41.8); body adiposity index (BAI) 25.1 ± 3.6 (95%CI 23.5 to 26.8) and somatotype distribution mesomorphic-ectomorph (5.3-1.6-3.8). Mean aerobic capacity was 45.9 ± 6.6 (95%CI 42.8 to 48.9 mL·kg⁻¹·min⁻¹), vertical jump was 36.4 ± 6.6 (95%CI 11.8 to 16.6 cm) and anaerobic power was 92.6 ± 19.5 (95%CI 83.7 to 101.5 kg·s⁻¹). Conclusion: These results may provide a profile of elite wrestlers that can be used as training targets for developing athletes. The results may also provide information for training and tactical emphases.

INTERNAL TRAINING LOAD OF RHYTHMIC GYMNASTICS ATHLETES.

Antualpa, K.I, Schiavon, L.2, Arruda, A.I, Fernandes, S.I, Moreira, A.I

1:USP - São Paulo's University (São Paulo, Brasil), 2:UNESP Rio Claro (Rio Claro, Brasil)

Introduction The ability for coaches to monitor training load is essential to optimize the process of training. Internal training load (ITL) has been suggested to be an efficacious method for monitoring athlete's response to a training dose (Impellizzeri et al., 2004). Indeed, session rating of perceived exertion (sRPE) was proposed as a useful, noninvasive, and valid method for monitoring ITL (Wallace et al., 2009). However, there have been few data about the ITL periodization in rhythmic gymnastics athletes. The aim of this study was to describe the ITL of gymnastics rhythmic athletes via sRPE during an 8-week training period. Methods Twenty-seven female rhythmic gymnastics athletes subdivided in two groups (G1: $n = 18$, 10.7 ± 1.0 yrs; G2: $n = 9$, 14.1 ± 2.2 yrs) participated. Athletes completed 4 (G1) or 5 (G2) training sessions per week (~14 and 18 training h/week, respectively). The ITL for each session was calculated using the sRPE (CR-10 scale) which was collected 30 min after each training or competitive session. To determine the ITL, the product of session duration (min) and sRPE score rated by the athletes was used. Data are reported as means \pm SD. The assumptions of normality and homoscedasticity were verified. A Mixed Model for repeated measurement was applied. The level of significance was set at 5% ($p < 0.05$). Results Higher mean ITL values were verified for G2 compared to G1 (4460 ± 812 AU vs. 2248 ± 682 AU). There was an interaction effect (Week*Group), and

higher values were observed for weeks with competitions (weeks 3, 7 and 8 for G2, and 3 and 8 for G1) compared to weeks without competitions. Discussion The present results suggest that the ITL assessed by means of sRPE method is a useful and sensitivity tool for monitoring training of gymnastics rhythmic athletes. The higher training volume performed by G2 compared to G1 seems to have a key role in elevating the ITL. Indeed, higher ITL values could be expected during weeks with official competitions. These results could be taken into account by coaches when planning and monitoring training. References Coutts AJ, Rampinini E, Marcora S, Castagna C, Impellizzeri F. ACUTE EFFECTS OF A VIBRATION EXPOSURE WITH AND WITHOUT LOADING ON JUMPING PERFORMANCE

Smirniotou, A., Douskas, T., Tsolakis, C., Paradisis, G., Zaharogiannis, E., Maridaki, M.

Kapodistrian University of Athens

Introduction This study aimed to examine the effect of (eight) different vibration conditions-with and without extra loading added- on muscle power output, measured by Counter Movement Jump (CMJ). **Methods** 16 male collegiate P.E. students participated in a randomized cross over study. 30 sec of dynamic squats (90° knee flexion) with tempo 2/2 (2 sec concentric / 2 sec eccentric phase), with subjects loaded with 20%, 40% and 60% of Body Mass (BM) or unloaded (0% of BM), were performed on a vibration platform (30Hz, 2-4 mm). CMJ was measured before, immediately after and 4', 8', 12', 16', 20' and 24' minutes after each vibration condition (Vib 0%: vibration + BM, Vib 20%: vibration + BM + 20% of BM, Vib 40%: vibration + BM + 40% and Vib 60%: vibration + BM + 60%). 48-72 hours rest was set between conditions. Results The Vib 0% condition had no effect on CMJ. In the Vib 20% condition CMJ was statistically decreased immediately after and remained lower than the baseline levels at 12, 20 and 24 min after. Similarly, CMJ in the Vib 40% was significantly decreased immediately after and remained lower in comparison to the baseline levels at 20 and 24 min after while in the Vib 60% condition CMJ was significantly lower immediately after and remained lower 24' after the vibration exposure. **Discussion** Previous research indicated that performance after a heavy-loaded exercise is determined by the interrelationship between fatigue and PAP and that this interrelationship is also been influenced by the recovery time differences (Zong - Rong Chen et al., 2013, Naclerio et al., 2014). In this study the results revealed that load intensity is a crucial factor for leg muscle power production and it is obvious that neuromuscular fatigue surpassed the PAP effect resulting in decreased subsequent performance. THE EFFECT OF 8 WEEKS STRENGTH TRAINING PROGRAM ON NAVY CADETS PHYSICAL CONDITIONING PARAMETERS

Chatzinikolaou, A.1, Vantarakis, A.1,2, Vezos, N.2, Avloniti, A.1, Tsakonitis, C.H.1, Draganidis, D.1, Stampoulis, T.H.1, Leon-tsini, A.1, Kampas, A.D.1, Jamurtas, A.Z.3, Fatouros, I.1

1:Democritus University of Thrace2: HNA (Piraeus, Greece), 3: UTH- DPES (Trikala, Greece)

Introduction During military service, changes in diet and physical conditioning training may affect performance and body composition of soldiers and military officers. The aim of the present investigation was to determine the effects of an 8-week periodized strength training protocol to specific and general conditioning parameters of navy cadets. **Methods** Thirty-one navy cadets participated in the study and were randomly divided in an experimental (E, n=16) and a control group (C, N=15). All participants were engaged in a standard navy academy fitness program but those in E additionally performed a strength training program for 8 weeks according to a linear periodization protocol (8 exercises, intensity 67-90% 1RM; volume 3-4 sets and 3-15 repetitions per muscle group; rest periods between sets ranged from 1-3 min, acute program variables changed every 2-3 weeks). At baseline and at the end of the training period, participants had their anthropometric measurement profile (body weight and body composition), VO2max (Grade Exercise Test to exhaustion on a treadmill), maximal strength (one Repetition Maximum, 1RM in chest press and squat exercises) and specific navy trial performance assessment (time to complete a navy-specific endurance test). Data were analyzed with 2-way ANOVA repeated measure (post-hoc????). **Results** In general conditioning, the two groups demonstrate the comparable improvements in VO2max (8-12%, p<0.05). However, participants in E group showed greater improvements in maximal strength performance (16-20% and 18-22%, respectively; p<0.05) and navy-specific testing (by 10-12%, p<0.05). **Discussion** Results of the present study indicate that a navy-specific fitness program may improve general physical conditioning but not the navy-specific one. Previous literature suggests that military training and living may actually increase body weight and fat and reduce the physical performance (Santtila et al. 2006, Sharp et al. 2002). In accordance with existing knowledge for general public and athletes (Kraemer et al. 2004), the addition of a periodized strength training protocol to a standard navy fitness program, seems to induce positive alterations both in general and specific physical conditioning. Considering that the physical requirement during service on a war ship requires balance and strength of upper and lower body, the addition of a structured strength training program to standard navy fitness procedures may be required. MAXIMAL HEART RATE IN SOCCER PLAYERS: MEASURED VS. AGE-PREDICTED

Kostoulas, I.1, Tasiopoulos, G.I.2, Nikolaidis, P.T.1

1 Hellenic Army Academy, 2 University of Peloponnese

Introduction A daily concern of coaches and fitness trainers is whether their exercise program has adequate intensity in order to stimulate the targeted physiological adaptations. On the other hand, the exercise intensity should not exceed a threshold, over which the risk of overtraining is increased. Although maximal heart rate (HRmax) is used widely to assess exercise intensity in sport training, and particularly in soccer, there are limited data with regards to the use of age-based prediction equations of HRmax in soccer players. The aim of this study was to compare the measured-HRmax with two widely used prediction equations (Fox-HRmax=220-age and Tanaka-HRmax=208-0.7×age, suggested by Fox, Naughton and Haskell (1971) and Tanaka, Monahan and Seals (2001), respectively) in soccer players. **Methods** Adolescent (n=162, 15.8±1.5 yr) and adult players (n=158, 23.4±4.6 yr), all members of competitive clubs, voluntarily performed a graded exercise field test (Conconi protocol) to assess HRmax. **Results** The measured-HRmax (197.6±9.4 bpm in total,

200.2±7.9 bpm in adolescent and 195.0±10.0 in adult players) was explained by the formula $HR_{max}=212.3-0.75 \times age$ ($r=-0.41$, $p<0.001$, $SEE=8.6$) in the total sample, $HR_{max}=223-1.44 \times age$ ($r=-0.27$, $p<0.001$, $SEE=7.6$) in the adolescent group and $HR_{max}=213.2-0.78 \times age$ ($r=-0.36$, $p<0.001$, $SEE=9.4$). In the total sample, the Fox-HRmax overestimated measured-HRmax (2.8 bpm (1.6;3.9)), whereas Tanaka-HRmax underestimated HRmax (-3.3 bpm (-4.5;-2.2)). In adolescents, Fox-HRmax overestimated measured-HRmax (4.0 bpm (2.5;5.5)) and Tanaka-HRmax underestimated HRmax (-3.2 bpm (-4.7;-1.8)). In adults, Tanaka-HRmax underestimated HRmax (-5.0 bpm (-5.3;-4.7)), whereas there was not any difference between Fox-HRmax and measured-HRmax (1.6 bpm (-3.4;0.2)). Conclusions The results of this study failed to validate two widely used prediction equations in a large sample of soccer players indicating the need for a sport-specific equation. Thus, coaches and fitness trainers should be aware that using Tanaka-HRmax might lead to prescribe inadequate exercise intensity, whereas using Fox-HRmax might lead to prescribe higher exercise intensity than the desired increasing the risk of overtraining. On the other hand, the new equations that we presented should be investigated further by future studies before being adopted by coaches and fitness trainers. SEX DIFFERENCES IN PHYSICAL AND ANTHROPOMETRIC CHARACTERISTICS IN CHILDHOOD

Maridaki, M., Tampaki, M., Karanastasis, G., Philippou, A.

University of Athens

Introduction Volleyball is a sport that requires, among others, to jump high and to shifts suddenly and quickly. The height of various types of vertical jumps could serve for the assessment of muscular strength and power. Prepubertal period is the most sensitive time for the maximal influence of high-impact exercises because simple jumps can produce ground reaction forces of 3.5–5.0 times body weight and force rates of around 500 times of body weight in prepubertal children. The purpose of the present study was to investigate differences in physiological characteristics of pre-pubescent boys and girls. **Methods** One hundred and ninety children involved in volleyball training for 2 years, 2h/week, derived in two groups according to their sex (boys age 11-12 yrs and girls 10-11yrs) (Blimkie, 1992). Stage Tanner was evaluated by a physician and was at II-III stage. Body mass, body height, the thicknesses of skinfolds at the biceps, triceps, subscapular and suprailiac sites were measured. Vertical jump and 20m speed test were counted by Tandem Sport Vertical Challenger Jump Tester and Sprint Timing System respectively. Peak (PPO) and mean power (MPO) were calculated, according to formula of Harman. Results are presented as mean ± SE. Results Mean body mass and body height differed significantly between boys and girls (38.6 ± 0.6 vs. 40.5 ± 0.6 kg, $p<0.05$, and 146.8 ± 0.6 vs. 150.7 ± 0.6 cm, $p<0.001$, respectively). Also the sum of thicknesses of four skinfolds differed significantly where boys had 27.6 ± 1.3 mm and girls had 33.9 ± 1.23 mm ($p<0.001$). Vertical jump was differed significantly between groups where boys jumped 28.7 ± 0.7 cm and girls 25.9 ± 0.7 cm ($p<0.01$). Performance in 20m speed test was significant different (3.8 ± 0.07 vs. 3.9 ± 0.03 sec, $p=0.2$). There was significant difference in vertical jump where boys jumped 28.7 ± 0.7 cm and girls 25.9 ± 0.7 cm ($p<0.01$). There were no significant differences in PPO and MPO (3171.2 ± 43.2 vs. 3069.08 ± 50.41 watt, 1496.7 ± 17.44 watt vs. 1481.47 ± 20.69 watt, respectively). **Discussion** A key factor in athletic performance is speed (Markovic et al., 2004) and strength of lower limbs (Bosco et al., 1983). In the present study it was observed that girls although one year younger receiving the same training load and possessing similar Tanner stage (II-III) to boys, are heavier and taller compared to their counterparts. However girls performed power as indicated by vertical jump. The differences are not significant when the performance and jumping expressed as PPO and MPO (due to use of body mass). THE DEVELOPMENT OF SWIMMING POWER

Leban, B.1,4, Gatta, G.2, Paderi, M.1,4, Migliaccio, G.M.3, Pau, M.1,4

1: *University of Cagliari (Cagliari, Italy)*, 2: *University of Bologna (Bologna, Italy)*, 3: *CONI – Italian Olympic Committee (Sardinia, Italy)*, 4: *TecnologicaMente S.r.l.(Italy)*.

Introduction The aim of this study was to investigate the transfer of strength training on swimming power according to the method proposed by Cometti (1990), previously tested in soccer, volleyball and basketball but never on swimmers. The principle of this approach is to stimulate the muscle fibers using a weight of about 80% of a maximum repetition immediately followed by the execution of technical movements specific of each discipline. The goal would be to stimulate the muscle fiber with an overload that is impossible to reproduce in water because of the lack of stable points of resistance. The quantitative evaluation of the effectiveness of the Cometti method was performed by measuring the swimmer's power using a semi-tethered swimming test. **Methods** Twenty male swimmers "master" were randomly allocated to strength (n= 10, ST) and swimming training (n=10, SW) groups. Both groups performed six-weeks training based on swimming training only (SW) and strength training which consisted in a weight training session immediately followed by maximal swimming velocity. The performance was assessed by calculating the Maximal-Mechanical-External-Power (MMEP) before and after the six-weeks period using a custom ergometer designed and built by Tecnologicamente S.r.l. (Italy). MMEP test consisted in 15 m all-out front-crawl swims across the pool while pulling increasing loads according to the procedure described by Dominguez-Castells et al. (2013). After a standardized 800m warm-up, the test started with a load of 45 N, which was subsequently increased of 25 N for each trial. The trial was considered concluded when the swimmer was not able to advance. Results A significant increase of MMEP in ST group (5.73% with $P<0.05$) was obtained, as results of increased strength (11.70% with $P<0.05$) and decreased velocity (4.99% with $P>0.05$). Conversely, in SW group we detected a decrease in MMEP, force and velocity (7.31%, 4.16%, and 4.45%) although not significant. **Discussion** This study showed that the transfer training method, based on combination of weight training (in dry condition) immediately followed by fast swim significantly improves swimming-power in master athletes. Thus, it looks like even in the case of water sports, mixed training (land and water) is suitable to develop muscle strength. The 6 weeks explosive-type strength training resulted in considerable improvements in selected neuromuscular characteristics, although a large volume of endurance training was performed at the same time. However it is not clear whether the increases in MMEP and strength in the ST group can be considered sufficient or not to satisfy the needs of training. The results of our experiments also confirm that is quite difficult to develop strength in the swimming, as previously observed by other authors. References Cometti G. ACUTE EFFECTS OF INTERMITTENT AND CONTINUOUS STRETCHING ON VERTICAL JUMPING ABILITY IN ELITE ATHLETES

Donti, O., Bogdanis, G.C., Tsolakis, C.

ATHENS KAPODISTRIAN UNIVERSITY

Introduction Previous studies suggested that the total stretch time in a day is more important than single stretch duration for flexibility enhancement (Cipriani et al., 2003). However, little evidence exists on the acute effect of different stretch durations on the ability of the stretched muscles to generate power output. The aim of this study was to examine changes in leg muscle power after two static stretching protocols with the same total stretch time, but different duration of single stretches. **Methods** Nine elite male gymnasts members of the Greek national team (age: 21 ± 2 y, training experience: 15.8 ± 2 y, height: 168 ± 5 cm, body mass: 66.3 ± 4.1 kg) participated in this study. A repeated measures, within subject randomized design was used to compare the effects of the two different stretching protocols on single-leg counter-movement jump (CMJ) height and power. The stretching movement of the modified Thomas test with force applied by an investigator, was used to stretch the quadriceps muscle of one leg. On one occasion, the static stretching protocol included 3 stretches of 30 sec (intermittent or INT protocol) with a 30 s rest interval in between. On the other occasion one stretch of 90 s (continuous or CON protocol) was applied on the other leg. One leg CMJ was measured after warm-up, immediately (15 s) after stretching and at 1, 2, 3, 4, 6, 8 and 10 min after stretching. Data were analyzed using a 2-way repeated measures ANOVA (protocol x time) and Tukey's post-hoc test ($p < 0.05$). **Results** The two stretching protocols had different effects on CMJ and leg power (main effect "protocol", $p = 0.045$, and "protocol x time" interaction, $p = 0.01$). The INT protocol resulted in an increase in CMJ that peaked on the 4th min after stretching (from 18.6 ± 1.9 to 23.5 ± 2.7 cm, $p < 0.001$). In contrast, the CON protocol resulted in a decrease in CMJ performance that peaked 1 min after stretching (from 19.5 ± 1.5 to 15.9 ± 1.2 cm, $p < 0.001$). CMJ performance returned to baseline levels after the 6th and 2nd min after stretching in the INT and CON conditions, respectively. **Discussion** The results of this study showed that INT and CON stretching protocols have opposite effects on CMJ performance in elite athletes. The decrease of CMJ performance after the CON protocol may be due to impaired muscle activation due to the prolonged stretch (Behm et al., 2001), while the increase of CMJ performance after INT may be due to the force applied on the stretched quadriceps muscle during the stretching movements in an intermittent, short-term manner that prevented muscle inactivation. **References** Behm DG, Button DC, Butt JC (2001). *Can J Appl Physiol*, 26(3):261-72. WEIGHT STATUS AND PHYSICAL FITNESS IN FEMALE SOCCER PLAYERS – IS THERE AN OPTIMAL BMI?

Nikolaidis, P.1, Tasiopoulos, G.1,2, Kostoulas, I.1

1Hellenic Army Academy, Vari, Greece; 2University of Peloponnese, Sparta, Greece

Introduction The aim of this study was to examine the relationship between weight status and physical fitness in female soccer players. Particularly, we examined (a) whether a higher BMI is related to lower physical fitness, and (b) whether a group with BMI ~ 22 kg.m⁻², which corresponds to values of elite players, differs from groups with higher or lower BMI with regards to physical fitness, anthropometric characteristics, body composition and somatotype. **Methods** For this purpose, 54 soccer players (21.7 (4.0) yr, 60.5 (7.0) kg, 164.3 (4.7) cm, mean (standard deviation)) underwent a physical fitness battery. To study this relationship we used a correlation analysis and we compared three groups differing in BMI: group A (BMI < 21 kg.m⁻²), B ($21 \leq \text{BMI} < 22$ kg.m⁻²), C (BMI ≥ 22 kg.m⁻²). **Results** We found very large correlations between BMI and the components of somatotype ($0.70 \leq |r| \leq 0.92$, $p < 0.001$). BMI was also correlated with isometric muscle strength and leg muscle power (W) assessed by the Wingate anaerobic test (WAnT) and force-velocity test. In contrast, when muscle power was expressed as W.kg⁻¹, the correlation was negative. We also found an inverse relationship between BMI and fatigue index of WAnT ($r = -0.36$, $p < 0.05$), the higher the BMI, the higher the decrease of performance during this 30 s all-out test. The comparison between A, B and C groups revealed differences in the same direction as the correlation analysis did. **Conclusions** We concluded that weight status is closely related with body composition, somatotype and leg muscle power. Therefore, achieving an optimal BMI might result in improvements with regards to physique and anaerobic power, and consequently in performance enhancement. Based on the findings of this study and of the existing literature (Nikolaidis, 2014; Nikolaidis, 2010), we recommend a BMI of 22 kg.m⁻² as the target for female soccer players. **References** Nikolaidis, PT. EFFECTS OF A SIMULATED TAEKWONDO MATCH ON STRENGTH, POWER AND KICKING PERFORMANCE

Tasiopoulos, I.G.1, Kostoulas, I.2, Nikolaidis, P.T.

University of Peloponnese

Introduction Although upper and lower limbs muscle strength is important for performance in martial arts, there are limited available data concerning the acute response of muscle strength to an official or a simulated match (e.g. Chiodo and colleagues, 2012, in taekwondo; Tasiopoulos and Nikolaidis, 2013, in kickboxing). Therefore, the aim of this study was to examine the effect of a simulated taekwondo match on performance indices. **Methods** Twelve young taekwondo athletes (3 female, age 15.5 ± 2.7 yr, mean \pm standard deviation, stature 169.6 ± 10.4 cm, body mass 55.2 ± 11.9 kg, experience 10.3 ± 3.9 yr, weekly training units 3.7 ± 1.1 , unit duration 92.5 ± 8.7 min and completed games 44.5 ± 36.6) participated in this study. They performed a simulated taekwondo match (3 rounds \times 90 s with 60 s break) using the official World Taekwondo Federation equipment, and were examined for handgrip strength, countermovement jump and kicking against the Daedo trunk protector in four occasions: pre-match (T1), first break (T2), second break (T3) and post-match (T4). **Results** Countermovement jump was 36.5 ± 2.3 , 37.1 ± 2.0 , 37.5 ± 2.2 and 38.3 ± 2.3 cm ($p = 0.071$), dominant handgrip strength was 394 ± 150 , 402 ± 146 , 386 ± 155 and 398 ± 144 N ($p = 0.308$), and non-dominant handgrip strength was 376 ± 143 , 363 ± 130 , 367 ± 128 and 363 ± 139 N ($p = 0.296$) in T1, T2, T3 and T4, respectively. The kicking performance of dominant lower limb was 40.6 ± 14.9 and 38.5 ± 14.5 ($p = 0.333$), and that of non-dominant lower limb 40.5 ± 13.9 and 42.7 ± 14.5 ($p = 0.188$) in T1 and T4, respectively. The change in dominant handgrip strength between T1 and T4 did not correlated with respective changes in non-dominant handgrip strength ($r = 0.20$, $p = 0.553$). On the contrary, the change in kicking performance of dominant lower limb was correlated with the respective change of non-dominant lower limb ($r = 0.77$, $p = 0.006$). **Conclusions** In summary, no change was observed in the indices of performance under examination. We did not confirm the findings of Chiodo and colleagues (2012), who revealed decrease of handgrip strength during match, which should be due to the older age of the present sample. However, what is novel is that we observed different patterns in upper and lower limbs with regards to correlation between dominant and non-dominant limb's strength changes.

DIFFERENCES IN ANTHROPOMETRIC AND PHYSICAL CHARACTERISTICS OF PREPUBESCENT FEMALE ATHLETES PARTICIPATING IN DIFFERENT SPORTS.

Theos, A., Moustogiannis, A., Argeitaki, P.

University of Athens

Introduction Sport performance is influenced by physical strength, body weight and body height (Latt et al., 2009). Furthermore different sports seem to promote different adaptations regarding the morphological and physiological characteristics (Novak et al., 2013). The purpose of the present study was to investigate differences in anthropometric and physical characteristics of prepubescent female athletes participating in different sports. **Methods** Thirty prepubescent female athletes participated in this study (age: 10.0 ± 0.9 yrs, maturity status: $P=2.0 \pm 0.1$ according to Tanner's stage for pubic hair) and were allocated in two groups according to the sport they were practicing. Group G (N=15) consisted of gymnasts and group T.F. (N=15) consisted of track and field athletes. All subjects had a training experience of at least 2 years and participated regularly (3-4 days/week) in sport specific one hour training sessions. Anthropometric characteristics as well as flexibility (sit and reach test), lower limbs strength (squat jump), arm strength (handgrip) for both arms and agility (agility T-Test) were measured. Differences between groups were analyzed using student's t-test. Results are presented as mean \pm SD. Results Body height (G= 131.7 ± 8.0 vs. T.F= 140.2 ± 4.0 cm, $p<0.01$), body weight (G= 30.9 ± 6.2 vs. T.F= 37.0 ± 3.8 kg, $p<0.01$), BMI (G= 17.5 ± 2.0 vs. T.F= 18.9 ± 1.3 kg/m², $p<0.05$) and flexibility (G= 27.3 ± 2.9 vs. T.F= 23.7 ± 4.8 cm, $p<0.05$) differed significantly between groups. No statistically significant differences between groups were observed in squat jump (G= 29.9 ± 6.4 vs. T.F= 31.0 ± 3.4 cm, $p=0.56$) arm strength for right (G= 9.0 ± 2.5 vs. T.F= 10.0 ± 1.3 kg, $p=0.19$) and left (G= 7.5 ± 2.5 vs. T.F= 8.8 ± 1.6 kg, $p=0.11$) arms or agility (G= 15.3 ± 1.4 vs. T.F= 15.0 ± 0.7 sec, $p=0.21$). **Discussion** The results of the present study indicate that sport specific training in prepubescent female athletes doesn't seem to affect strength or agility performance. The differences observed in anthropometric characteristics like body height, body weight and BMI highlight their importance in sport's selection. **References** Lätt et al., (2009). *Coll Antropol.*, 33(1): 117-122. Novak et al., (2013). *Coll. Antropol.*, 37(S2): 107-112.

RELATIONSHIP BETWEEN SPRINTING, JUMPING ABILITY AND AEROBIC FITNESS IN PUBERTAL BOYS

Veligekas, P., Bogdanis, G.C.

University of Athens, GREECE

Introduction Sprinting ability and leg muscle power are important determinants of performance in power sports. Although there is information regarding the changes in these parameters during growth (Papaiakovou et al., 2009), there is limited data on the relationships between speed, muscle power and aerobic fitness in children (Mendez-Villanueva et al., 2010). The purpose of the present study was to examine sprint ability, muscle power and aerobic fitness in pubertal boys. **Methods** Twenty-two pubertal boys (age: 14.2 ± 0.7 y, height: 166 ± 9 cm, body mass: 58.1 ± 9.2 kg, body mass index: 21.1 ± 3.0 kg/m²) with training history of 6.1 ± 1.8 y) took part in the study. Sprint ability was assessed by a 30 m sprint using photocells to measure 10 m and 30 m time, vertical jump ability (no arm swing) and muscle power were measured using a countermovement jump (CMJ) on a contact mat, while aerobic fitness was estimated using the intermittent recovery 1 (IR1) yoyo test. Relationships between variables were examined using the Pearson's product-moment correlation coefficient. Results 10 m and 30 m sprint times were 1.82 ± 0.10 s and 4.60 ± 0.31 s (average speed: 6.55 ± 0.44 m/s), respectively. CMJ was 30.1 ± 6.4 cm and relative leg peak power was 40.4 ± 5.2 W/kg. The distance covered during the IR1-yoyo test was 1062 ± 394 m and the maximal running speed reached during this test was 15.45 ± 0.63 km/h (average speed: 4.39 ± 0.18 m/s). Chronological age was positively correlated with average speed during 30m ($r=0.82$, $p<0.01$), CMJ performance ($r=0.76$, $p<0.01$), leg peak power ($r=0.84$, $p<0.01$) and peak yoyo test speed ($r=0.63$, $p<0.01$). A high correlation ($r=0.81$, $p<0.01$) was also found between average sprint speed and leg peak power ($r=0.83$, $p<0.01$). Finally, average sprint speed was correlated with maximal aerobic (yoyo test) speed ($r=0.54$, $p<0.01$). **Discussion** The results of the present study confirm previous studies showing that speed and explosive leg performance depend on age during puberty and that they are interrelated. Also, the relationship between sprinting and peak aerobic speeds show that fast athletes also perform better in aerobic field tests that are based on increasing running speed and leg power. **References** Mendez-Villanueva A, Buchheit M, Kuitunen S, Poon TK, Simpson B, Peltola E. ANTHROPOMETRIC CHANGES IN ELITE ROWERS

Mladen, M.

Faculty of Kinesiology

Introduction Variations in body size due to environmental influences are much larger than those resulting from genetic differences (Johnston, 1995). Changing the status of morphological characteristics, in relation to the movement of change of motor skills in sport has always had an interest in tracking parameters in elite sport. Also interesting were the changes in the morphological status of the sport maturing rowers. Knowledge in this area should provide guidance in the treatment of rowers in their development. The aim of this study was to determine the size and direction of changes in anthropometric characteristics of elite rowers over 7-year time span. **Methods** In a sample of 11 top rower and Olympic medal winner at the World Championships was applied ex post facto study with the aim of monitoring changes in the morphological characteristics. The same surveyor has made measuring 21 morphological variables in both measurements. Data at initial measurements were taken in the last year of junior or first year of senior age. At that time, none of the rowers had recorded excellent results at the international rowing scene. Final measurements were taken after seven years, when all observed rowers have won a medal at the Olympics or World Championships. Of course, some of the observed rowers had medals from both competitions. In the observed sample variables was applied unilateral variance analysis using the statistical package version 11 STATISTICS. Results In addition to age, which is expected statistically significant difference, statistically significant differences were obtained for seven parameters. A significant increase (by F values) was achieved in biacristal breadth, biepycondilar femur, forearm girth, upper arm girth flexed and chest girth. At the same time, significant decrease of triceps skinfold, while the other two skin folds numerically lower but not statistically significant. **Discussion** The obtained data indicate a statistically significant increase in soft tissue that connects the upper body and lower body extremities, as well as the associated skeletal system that merges the underlying musculature. The same is consistent with the results obtained by transversal research of rowers in relation to the age group (Marinovic, 1996), as well as motor skills accountable for better results in the execution of the rowing ergometer (Marinovic, 1999). **References** Johnston FE. (1995). London: Castlemead Publications; p. 402-13. Marinovic, M., Kosinac, Z. (1996). *HSmv*, 11, 2-3, 1996. Marinovic M.(1999). *Sport Kinetics '99*. Contacts mladen.marinovic@st.t-com.hr

LONGITUDINAL GROWTH AND DEVELOPMENT OF BODY HEIGHT AND LOWER LIMB MUSCLE THICKNESS IN JAPANESE JUNIOR SPEED SKATERS

Kumagawa, D., Tsunoda, N.2

Japan Institute of Sports Sciences 1, Kokushikan University

Introduction It is well known that the force and power generation capacities of the lower limb muscles are improved by speed skating training in young speed skaters (Nemoto et al. 1990, de Koning et al. 1991). In addition, senior speed skaters have a relatively high muscle mass in the lower limbs, which is closely related to short-distance skating performance. However, the growth trends in lower limb muscle mass in young speed skaters are not known. Therefore, this study investigated the longitudinal growth and development of body height and lower limb muscle thickness in junior speed skaters. **Methods** Eight male Japanese speed skaters were followed from the age of 11-12 years (first year) to 17-18 years (final year). All subjects were members of the same speed skating club and underwent speed skating training throughout the year. Body height, thigh girth (at 50% of thigh length), and lower leg girth (at 30% of lower leg length) were measured in both legs. The muscle thickness of the anterior thigh (MTTa), lateral thigh (MTTl), posterior thigh (MTTp), anterior lower leg (MTLa), and posterior lower leg (MTLp) was measured on B-mode ultrasonic imaging. These measurements were performed once a year for 6 consecutive years and changes in the parameters were calculated. **Results** The skaters had almost achieved full height by year 4 (age 15-16 years). The girth and muscle thickness of the thigh and lower leg both increased gradually with age. However, the girth of the thigh was remarkably increased compared with that of the lower leg at the age of 17-18 years. Strong correlations were observed between change in body height and lower leg girth (right leg: $r=0.803$; left leg: $r=0.758$) compared with thigh girth. With regard to muscle thickness, MTTl and MTTa in the left leg showed a high rate of change compared with lower leg muscle thickness between the first and final year. Strong correlations were also observed between change in body height and MTLp (right leg: $r=0.774$; left leg: $r=0.770$). However, the correlation of body height with MTTa, MTTl, and MTTp ($r=0.518-0.659$) in both legs was lower than that with MTLp. **Discussion** The growth trends in the development of muscle thickness in the lower limbs in young speed skaters may differ between particular muscle sites. In particular, muscle thicknesses of the thigh increased remarkably more than that of the lower leg during adolescence, and the change in lower leg muscle thickness correlated with the change in body height. Based on these results, the development of muscle thickness correlates strongly with changes in body height. **References** de Koning J J, Bakker F C, de Groot G, van Ingen Schenau G J, (1994), *J Appl Physiol*, 77, 2311-2317. PHYSIOLOGICAL, BIOMECHANICAL AND ENERGETIC PARAMETERS CHANGES DURING DESCENDING FRONT CRAWL SWIMMING IN YOUNG ATHLETES

Ozimek, M., Kucia Czyszczorń, K., Szmalan Gabryś, U., Gabryś, T., Stanula, A., Nowakowska, M.

University School of Physical Education in Cracow

Introduction The recording of pulmonary VO_2 (pVO_2) in the initial exercise phase, provides important information on the growth dynamics of muscle VO_2 (mVO_2). With the onset of physical exercise metabolite concentration starts to change, activating mitochondrial oxidative phosphorylation and causing mVO_2 to increase. This research was to determine the relationships in relevant biomechanical, energetic and physiological parameters between 200m front crawl incremental swimming performance in male and female adolescent swimmers. **Methods** The study involved 6 girls (aged 14.5 ± 0.54 years, height 169.00 ± 4.14 cm, body mass 57.83 ± 5.77 kg) and 7 boys (aged 14.7 ± 0.42 years, height 174.71 ± 3.81 cm, body mass 59.71 ± 8.86 kg). Measurements enabling the biomechanical assessment of swimming velocity (V), stroke rate (SR) and stroke length (SL) were performed. Blood lactate concentrations were established with the enzymatic-ampereometric method. Swimming economy was assessed as described in Capelli et al., 1995 and was expressed as a ratio between end-exercise VO_2 at 80% volume total (VT) and velocity. Values of minute ventilation (VE), end-tidal partial pressure of oxygen, end-tidal partial pressure of carbon dioxide, carbon dioxide output (VCO_2), respiratory-exchange ratio (RER), and oxygen uptake (VO_2) were continuously measured by a breath-by-breath gas-exchange using the measurement system Cosmed K4b2 Aquatrainer. **Results** The levels in both genders of swimming velocity was determined by the energetic parameter – stroke index SI. The performance of 15 years old boys and girls in 200 m front crawl at intensities ranging from 60 to 100% VO_2max , depends on the interaction of biomechanical (SL, SR), energetic (SI) and relative carbon dioxide output parameters, and relative oxygen uptake and respiratory exchange ratio. **Discussion** There was no significant correlation in swimmers based on gender in biomechanical and energetic and physiological parameters, same as in the findings of authors Barbosa and Costa (2010), in which both genders have androgynous body build at this age. Increased swimming velocity is achieved by increasing stroke length (SL) (Barbosa and Costa, 2010) and that the higher swimming performance, the higher SI (Jesus et al., 2010). From the biomechanical perspective, swimming velocity (V) can be expected to rise when the stroke rate (SR) increases and the stroke length (SL) is consistently high. Our comprehensive investigations on swimmers have greater potential for forecasting their future achievements and for explaining why particular swimmers differ in swimming performance than studies targeted at particular parameters (Dekerle et al. 2005). **References** Barbosa T.M., Costa M. THE RELATIONSHIP BETWEEN FITNESS PARAMETERS AND SUCCESS IN THE PROGRESSIVE THROW DISCIPLINE IN BOCCIE

Sentija, D., Ritosa, G.

Faculty of Kinesiology, University of Zagreb

Introduction There are no literature data on the fitness profile of elite bocce players. Because of high pace and comparatively high physical demands of the progressive throw discipline, we presumed a positive relationship between the fitness level of players and success in this discipline. Therefore, the aim of this study was to define fitness characteristics of bocce players and their relationship with success in the progressive throw discipline. **Methods** Eight elite bocce players (age = 22.9 ± 4.7 years, body weight = 74.3 ± 5.9 kg, height = 179.8 ± 4.6 cm and % body fat = $12.5 \pm 3.9\%$) at the end of the regular competitive season underwent measurements in order to determine parameters defining body morphology, speed, strength, power and agility, while an all-out graded exercise test was performed on the treadmill (1.5% inclination, speed increase by 1 km/h every minute) for determination of aerobic capacity measures. **Results** For bocce players of international rank, strong relationships between several fitness parameters and success in the progressive throw discipline were found. Within the battery of applied fitness tests, the relative repetitive strength of lower extremities ($\text{RS}=53.9 \pm 5.6$ rep, measured as the number of deep squats in 60 s) was statistically significantly correlated with success of bocce players in the progressive throw disci-

pline ($R=0.68$ for number of throws, and $R=0.81$ for number of hits; $p<.05$). The maximal oxygen uptake ($VO_{2max}/kg=55.1 \pm 3.5$ ml/kg/min) was also highly and significantly correlated with the number of throws in the progressive throw discipline ($R=0.87$, $p<.05$), while for the relationship between VO_{2max}/kg and the number of hits there was a visible positive trend, although not reaching statistical significance ($R=0.61$, $p=.08$). Conclusion For success in the game of bocce, specifically in the progressive throw discipline, a high level of repetitive strength as well as a high level of aerobic endurance are required. STUDIES ON PHYSICAL FITNESS OF SPEED AND AGILITY IN UNIVERSITY ELITE TENNIS PLAYERS

Umebayashi, K., Suzuki, N., Imanishi, T.

Osaka University of Health and Sport Sciences, Rikkyo University

It is reported that high speed and agility are necessary as physical fitness factors in the manifestation of performance in tennis. Until now, 5-directional running has been used as an item to evaluate agility, but because this measurement takes 10 seconds or more, it would seem to not fit with the characteristics of the game of tennis, in which 1 PLAY is reported to take 10 seconds or less. Therefore, I thought that utilizing a direction-changing run which includes quick turn actions and ends in a shorter amount of time would be appropriate. The purpose of this research is to compare the 5-direction run and other direction-changing runs (forwards-backwards run, T-test) in university elite tennis players, and verify the relationship between said direction-changing runs and items of measurement which evaluate speed (shuffle run, 10m run, 20m run) and lower-limb strength (standing long jump). With 17 male and 10 female tennis players of the skill level of having appeared in the All-Japan student tennis championship series as the subjects, and using a tennis court (hard), I had the subjects perform the 5-direction run, forwards-backwards run, shuffle run, 10m run, 20m run, and standing long jump, and I conducted a correlation analysis between the respective physical fitness items of these. As a result, a significant correlation was seen in both the males and females between the 5-direction run and the forwards-backwards run as well as the T-test. Furthermore, compared to the other direction-changing runs, a significant correlation was seen in the forwards-backwards run between many of the speed and lower-limb strength items of measurement. Based upon these facts, it would seem that the forwards-backwards run is more capable of evaluating agility, and that it is a more fitting item of measurement for tennis.

ANALYSIS OF INTENSITY OF EXERCISE LOAD OF JUNIOR ICE HOCKEY PLAYERS DURING A CHAMPIONSHIP MATCH – CASE STUDY

Vala, R.1, Valová, M.1, Cipryan, L.1, Petr, J.2

University of Ostrava

1; University of Ostrava, Ostrava, DCHM, Czech Republic 2; HC Vítkovice Steel, Ostrava, Czech Republic Introduction The relation between the physical load during the match and physical load during the training belongs to the most important problems of ice hockey training. Monitoring the heart rate (further referred to as HR) enables us to record and collect data on the exercise load of individual players during the match. The subsequent analysis is very important for the creation of the training schedule and control and management of the training (Vala and Lišchmannová, 2012). The main goal of this paper, which has the character of a case study, was to analyze the intensity of exercise load of Extra-league ice hockey players during a match of the junior top event, depending on the player's position. Methods The heart rate of players during the match was monitored using the Polar Team2 system. The calculations of average HR only used the sections of the match where the players were actively involved in the game and the game clock was running, i.e. the so-called "live time" (Abdelkrim et al., 2007). Results The study results indicate statistically significant differences in the intensity of exercise load of players according to players' positions (i.e. between the load of attack and defense players) in all parts of the game ($p = \text{value} < 10^{-3}$), where the highest values were obtained for attack players during the second period ($95.0 \pm 5.8\%$ of HR_{max}). The average calculated HR value for the most active attack players in the game was $94.4 \pm 6.1\%$ of HR_{max} , while the average value for defense players was $93.5 \pm 6.1\%$ of HR_{max} . Discussion In addition to the players' positions, the intensity of exercise load could also have been affected by the actual outcome of the game, strategies chosen by coaches and of course, playing while using four complete formations (i.e. the number of players in the game). Monitoring the intensity of exercise load in sports games with interval load is problematic. However, unlike specific indicators as oxygen consumption (VO_2), monitoring of HR is a practical and widely applicable, and at the same time reliable method for assessing the intensity of exercise load (Benson and Connolly, 2011). INVESTIGATION OF HEART RATE RESPONSES DURING THE KORFBALL GAME TO DETERMINE EXERCISE INTENSITY IN SEDENTARY

Yildirim, A.1, Ertas Dolek, B.2, Gurses, V.2, Oskouei, M.M.2

(1) Middle East Technical University. (2) Ankara Üniversitesi

Introduction: For the last few decades, physical activity has become important in terms of preventing diseases because it reduces the health risks. Korfbal which is an enjoyable sport played by women and men has less physical action than the other team sports. So korfbal is considered as an effective sport to be used for increasing physical activity level. The aim of this study is to determine the intensity of exercise during the game. 6 women and 8 men in total 14 university sedentary students who play korfbal have participated in the experiment. Methods: The measurement has been made during the game twice in 60 minutes. The heart rate (HR) of students during the game has been calculated by Polar Team2. The average and the standard deviation of collected data have been categorized individually. Results: According to the results, average play duration of men was 30.77 ± 10.10 minutes, minimum HR was 127.50 ± 15.25 , average HR was 162.12 ± 15.54 , maximum HR was 187.37 ± 12.70 and average play duration of women was 23.79 ± 11.80 , minimum HR was 132.66 ± 18.48 , average HR was 164.83 ± 15.05 , maximum HR was 188.33 ± 6.40 . Discussion: It is recommended that health related aerobic exercise can be effective when moderate to vigorous intensity (20- "60 min.day-1; totally 75 min.week-1) per season for healthy sedentary (Garber et al, 2011). Additionally it has been reported that interval training is more enjoyable exercise than continuous exercise (Bartlett et al, 2011). Our result showed that the average intensity was 65-75% of HR max during the game. As a result, korfbal is an enjoyable game and it is efficient way to improve the physical activity level.

AN INVESTIGATION OF MOTORIC CHARACTERISTICS OF A TURKISH 2ND DIVISION WOMEN BASKETBALL TEAM PLAYERS IN ÇANAKKALE, TURKEY

Özgider, C.1, Yurdakul, H.Ö.2, Beyan, Ö.2

1: METU, (Ankara, Turkey), 2: ÇOMÜ, (Çanakkale, Turkey)

Introduction Motoric characteristics are one of the most important factors for efficiency in basketball. There are common motoric characteristics such as; jumps, sprints, and sudden movement changes for all playing positions (Sevim, Y., 2006). Therefore, this study mainly aimed to investigate and analyse the motoric characteristics of a Turkish 2nd division women basketball team players in Çanakkale, Turkey. **Methods** This study was conducted by descriptive research method. Motoric characteristics of the basketball players were measured by using following tests; 30 meter sprint test, push-up test, sit-up test, vertical jump test, standing long jump test, 3-5-10 step jump test, flamingo balance test. Their height and total body weight were also measured and the BMI were calculated. The subjects of this investigation composed of 13 women basketball players (aged 18-25) who were playing in 2nd Division of Turkish Women Basketball League. **Results** Motoric measurements' means scores are as following; 30-meter sprint test; $5,51 \pm 0,52$ second, 1-min push-up test; $28,00 \pm 6,65$, 1-min sit-up test; $35,30 \pm 10,48$ vertical jump; $37,94 \pm 6,92$ cm, standing long jump test; $1,72 \pm 0,12$ m, 3-5-10 step jump tests; $5,46 \pm 0,34$ m, $9,14 \pm 0,55$ m, $18,32 \pm 1,17$ m. respectively, flamingo balance test; $3,84 \pm 1,40$, and the mean BMI score was $21,68 \pm 1,77$ kg/ m². **Discussion** Our findings on 30-meter sprint test coincide with the studies in the literature in which the results for 30-meter sprint test score as $5,15 \pm 0,13$ and $4,9 \pm 0,22$ respectively (İmamoğlu et al., 2004; Erden et al., 2005). In terms push-up test scores; in another study (Arabacı R., 2003) wrestlers were measured and their 30 seconds push-up test score was $49,4 \pm 7,7$ which is higher than the present study's results. I might be caused that their subjects were wrestlers and they had a training regimen mainly focused on lower extremities. With regards to vertical long jump scores, our research is in contradistinction with the other studies in the literature (Gökdemir et al., 2009; Besler et al., 2010; Yüksek et al., 2004). These differences might be results of the using different participant groups; In other words, different sports has different training regimen and this affects some of the motoric characteristics. **References** Bompá, T. EFFECTS OF DRY-LAND TRAINING IN FEMALE SWIMMERS

Leko, G., Siljeg, K.

Faculty of Kinesiology

Introduction According to the development plan of the Croatian Swimming Association, female swimmers aged 12 to 13 fall into the cadet or pre-junior category whose task is to train for competitions. The above implies inclusion dry-land training with the aim to improve strength, endurance and flexibility (Guy, 2000). The aim of the paper is to determine whether the six month dry-land training in swimming brings about positive results in female swimmers' basic motoric ability in the age group 12-13. **Methods** The sample of subjects consisted of 29 female swimmers aged 12-13. All participants were in good health, and they had been involved in swimming training process for the last 6 years. They train six times per week in water and three times per week they were conducting dry-land training. A variable sample includes 13 tests for the assessment of basic motor skills that measured: explosive power (4 tests), muscular strength endurance (4 tests) and flexibility (5 tests). **Results** Statistic for Windows version 10.0 was used for the statistical analysis of specific motor skills. The following was computed: basic statistical parameters. The data was analyzed using MANOVA and ANOVA for repeated measurements to determine differences between measurements. Statistical significance was set at $p < 0.05$. Multivariate variant analysis showed a statistically significant improvement in the observed group of tests that define basic motoric abilities of female swimmers. A series of univariate analyses showed that only test for the assessment legs explosive power and endurance have a statistically significant improvement. **Discussion** Results indicate insufficient dry-land training for trunk stability and upper body. Some authors (Šimek et al, 2002) in their paper indicates that arms and shoulders in women are the weakest link if viewed from the point of view of strength. In swimming, upper limbs make the biggest propulsion, and therefore it is necessary to increase their strength, endurance and flexibility. Flexibility can maintain or increase joint range of motions, allowing for longer and more efficient strokes (Salo, 2008). **References** Erladson M.C. Sherar L.B., Milwald R.L. (2008). Med. Sci. MALE 400 M HURDLES: RUNNING DYNAMICS

Babic, V., Borcic, L., Katovic, D.

University of Zagreb

Introduction The 400 m hurdle is a very complex track and field event. Since the velocity curve of different runners' quality is well known for some other sprint events at the additional knowledge about velocity curve of 400 m hurdles elite runners is a prerequisite for improvement of training methods related to the quality and development of 400 m hurdles running/events. The aim of this study was to determine the 400m hurdles running dynamics of male athletes as well as to determine relations of all the segments of competition activity in 400 m hurdles with the (achieved) respective competition results. **Methods** The study was conducted on a sample of 156 elite hurdle runners who participated in the World Championship and the Olympic Games from 1968 to 2009. All data were taken from the publically announced official data and were given to the athletes, coaches and media. Dynamics of sprinting over 400m hurdles have been observed across ten segments (achieved time at each hurdle). Descriptive statistics were calculated on the 10 segments of running dynamics and on achieved final results. Multiple regression analysis was used to determine relations between all the segments of competition activity in 400m hurdles (independent variables) with the achieved competition results (dependent variable). **Results** The results showed that the analysed time parameters of rhythm/dynamics run can explain 97% of the total variance in running the 400 m hurdles. The following variables had the dominant influence on the overall achieved competition results: achieved time at the 1st ($p=0.02$), the 3rd ($p=0.05$), the 8th ($p=0.06$), the 9th and the 10th hurdle ($p=0.00$). **Discussion** Since we used data from the high ranked competitions, according to the IAAF rules, the sample used for the purpose of this study can be treated as highly valid. It seems quite logical that times achieved at the last three hurdles in the race have statistically significant influence on competition result. Statistically significant relations

obtained at the 1st and the 3rd hurdle points to the importance of sustainability of running rhythm from the beginning of the race onwards. It is possible to speculate that athletes who are able to maintain good rhythm during the race with as little oscillations as possible will have smaller number of strides between the hurdles as well as better performance time at each hurdle/segment. FMS AND INJURY IN GAELIC GAMES AND RUGBY

Lyons, M., Dunleavy, S., Dunphy, A., Cronin, G., McLoughlin, D.

University of Limerick

Sports scientists, strength and conditioning coaches and therapists alike are now focusing more attention on improving movement patterns. Linked to this, compensatory fundamental movement patterns have been shown to increase the risk of injury. These risks can be identified using a functional movement tool (Chorba et al, 2010). The Functional Movement Screen (FMS™) was devised by Cook (2001) as a means of categorising such functional movement patterns. In Rugby, the incidence of injuries has been reported to be very high at elite and sub-elite levels. Murphy et al (2012) also found that injury incidence in Gaelic Games is high in comparison to other sports. The aims of this study were (1) to explore FMS scores among Rugby and Gaelic Games players and (2) to examine whether there are differences in FMS scores in players with no previous injuries compared to those players with previous acute or chronic injuries. 45 Rugby and 121 Gaelic Games players each completed seven FMS tests whilst being video recorded in both the sagittal and frontal plane. Each player also completed a questionnaire related to their injury history. FMS tests were conducted during the competitive season whilst players were training and competing regularly. All players were free of musculoskeletal injury at the time of testing. The results revealed that Rugby players on average, scored higher than Gaelic Games players on five of the seven FMS tests. The mean composite FMS scores were lower in the Gaelic Games players compared to the Rugby players (14.87 ± 2.49 and 15.58 ± 7.57 respectively) although an independent t-test revealed that this difference was not statistically significant ($p > 0.05$). One-way ANOVA found no significant difference ($p > 0.05$) in composite FMS scores in players with no previous injuries, players with previous acute injuries or players with previous chronic injuries. Future research is warranted to specifically identify those factors that contribute most to injury risk in Rugby and Gaelic Games players. Injury prevention efforts should then focus on those modifiable factors which may include dysfunctional movement or asymmetries. Chorba et al. REPEATED SHORT STATIC STRETCH INCREASED RANGE OF MOTION WITHOUT ISOMETRIC AND ECCENTRIC ISOKINETIC TORQUE VARIATION

Leon Prados, J.A., Weissland, T., Leprêtre, J.M.

Pablo de Olavide University, Seville, Spain; Université de Picardie Jules Verne, Amiens, France

Introduction A dose-response effect was described between the duration of passive static stretching (SS) and the change in performance. Detrimental effect was reported for longer stretch period than 60s while no significant incidence on performance and muscle response was found after shorter SS (≤ 30 s; Behm and Chaouachi. 2011). To limit the loss of maximal muscle strength after stretching, some authors recommended short SS duration (Siatras et al. 2008; Costa et al. 2013). Hence, the aim of this study was to investigate the effect of repeated bouts of short SS on ROM and muscle force production. **Methods** 25 students in sport sciences (20.8 ± 1.4 y, 1.75 ± 0.04 m, 69.3 ± 10.8 kg) performed two bouts of 1) a maximal passive hip flexion and 2) a maximal voluntary isometric (ISO), concentric (CON) and eccentric (ECC) hamstring (H) and quadriceps (Q) exertions intercepted by 4×15 s/30s rest intermittent assisted SS or passive recovery. Assisted hip flexion with straight knee ROM was measured before (Pre-S), immediately (Post-I) and 10-min after (Post-10) each recovery modality (Plurimeter-V, Dr Rippstein, Switzerland). ISO, CON and ECC isokinetic peak torques (PT) of the H, Q and a conventional H/Q ratio were measured before SS and 5min-after recovery on a isokinetic dynamometer (CybexNorm, Lumex, Ronkonkoma). **Results** Repeated ANOVA test revealed significant ROM increases between Pre-S - Post-I (10.8%, $p=0.03$) and Pre-S - Post-10 (13.8%, $p=0.004$) but not between Post-I - Post-10 (3.3%, $p=0.3$). H-CON PT (-3.7%; $p=0.02$) and H:Q ratio (-4.2%; $p=0.01$) were lower after SS compared to baseline values. No significant difference was found in ISO and ECC peak values. **Discussion** Our results showed the increase in ROM at least 10min after the repeated SS without significant reduction of isometric and eccentric isokinetic PT. Siatras et al. (2008) observed a loss of isometric and isokinetic quadriceps PT after 30s quadriceps SS. Recently, Costa et al. (2013) reported after flexors stretching an acute reduction on hamstring CON (-9%) and H:Q ratio (-7%) for the same time. We also observed a lesser variation to the reduction in H-CON PT and thus H:Q ratio ($p<0.05$). Four repeated bouts of 15s interrupted by 30s at rest could limit SS incidence on concentric strength deficit. For practical applications, repeated shorter static stretch will be recommended prior physical activities inducing isometric or eccentric muscle contraction. **References** Costa PB, Ryan ED, Herda TJ, et al. DETERMINATION OF THE TRAINING INTENSITY ZONES USING BREATH - BY - BREATH PARAMETERS AND ESTIMATED PERCENTAGES OF HRMAX

Vucetic, V., Reinholz, K.

Faculty of Kinesiology

INTRODUCTION: The way of determining the training intensity zones in a particular sport is often a source of problems in sports coaching. Since intensity zones form the basis of optimal programming training, they definitely need to take a higher dose of attention. For that reason, the goal of the research was to examine the differences in training intensity zones established experimentally and theoretically. **METHODS:** The sample consisted of 21 Croatian elite soccer players (Age = 18.9 ± 1.4 y; H = 181.4 ± 7.06 cm; W = 74.6 ± 8.14 kg). All subjects performed an incremental treadmill test (1 km/h per minute, 1.5% grade). Upper limits of training intensity zones were determined by V - slope method which have been attributed to the corresponding heart rate (HR_{exp}) and then, compared to the zones determined by algorithms of the percentage of the maximum heart rate (%HR_{max}). The model that was used consisted of the four training intensity

zones: recovery zone (RZ), the zone of extensive aerobic training (AEZ), the zone of intensive aerobic training (AIZ) and the zone of anaerobic threshold (ANZ). The ANOVA and the Bonferroni were used to determine differences in observed variables. RESULTS: By analyzing the data we obtained statistically significant differences ($p > 0.05$) in RZ (HR_{exp} = 127.19 ± 11.6 bpm; %HR_{max} = 114.66 ± 5.3) and in AEZ (HR_{exp} = 152.67 ± 10.3 bpm and %HR_{max} = 142.75 ± 5.1 bpm). In AIZ (HR_{exp} = 164.85 ± 8.4 bpm; %HR_{max} = 161.73 ± 5.8 bpm) and in ANZ (HR_{exp} = 172.46 ± 7.7 bpm; %HR_{max} = 171.3 ± 6.1 bpm) were no statistically significant differences. DISCUSSION: In comparison with experimentally determined zones, proposed algorithms of percentages of HR_{max} in the first two zones are too low. It can be attributed to the lack of attention giving zones with a light load, although they may be substantial in a variety of training programs. Furthermore, assessment of HR_{max} can be unreliable due to various intrinsic and extrinsic factors if it is not measured with appropriate test. In the last two zones is not necessary doing significant changes in determining the percentage of HR_{max}. CONCLUSION: Analysis has shown that the proposed percentages are miscalculated. Therefore the authors recommend raising the values, concretely, in the RZ for 5 % (from 60 % to 65 % HR_{max}) and in the AEZ for 5 % likewise (from 60 - 75 % to 65 - 80 % HR_{max}). In AIZ the range is 65 - 80 % HR_{max} and in the ANZ is 65 - 80 % HR_{max}. REFERENCES 1. Beaver WL, Wasserman K, Whipp BJ. ANTHROPOMETRY AND PHYSICAL PERFORMANCE OF ESTONIAN TOP-LEVEL FEMALE VOLLEYBALL PLAYERS

Stamm, M.1, Stamm, R.1, Aasorg, M.1, João, P.V.2

(1) Tallinn University, Estonia, (2) CIDESD-UTAD (Research Center for Sports Sciences, Health and Human Development, University of Trás-os-Montes and Alto Douro, Vila Real, Portugal)

Introduction Morphological characteristics are considered essential to achieve top-level performance in volleyball (Malousaris et al., 2008). The objective of this study was to examine the physical and anthropometric characteristics of Estonian top-level female volleyball players and to find if there is a relationship between physical fitness tests and competition results. **Methods** For this purpose, we studied 52 female volleyball players who belonged to the six best teams of Estonia; their age was 20.8 ± 4.2 years. The physical fitness tests included two jump tests, an endurance test, a speed test and a medicine ball throwing test. The anthropometric examination included 10 measurements: height, weight, lower chest circumference, waist circumference, hip circumference, upper and lower leg circumference, arm circumference, flexed and tensed arm circumference, wrist circumference. **Results** The endurance test correlated statistically significantly and negatively with body measurements – smaller players had greater endurance. For purposes of analysis, volleyball players' somatotype was established by physical anthropometry. It was possible to distinguish between players in different positions by their somatotypes in a 5 SD height-weight classification. Tempo players belonged to the big or the leptomorphous class, libero players belonged to the small or the pycnomorphous class, and setters were more often leptomorphous or small. Opposite players and outside attackers varied greatly and had different somatotypes. **Discussion** The physical fitness test results were also placed in the 5SD classification of weight and height. The classification showed that jumping ability and speed test results improved gradually from the small to the medium to the big class: leptomorphous players could jump higher than pycnomorphous ones. These results can suggest some indicators for selection volleyball players for different positions. We also verified that teams who had better results in physical fitness tests also got better places in Estonian championships. **References** Malousaris, G.G., Bergeles, N.K., Barzouka, K.G., Bayios, I. A., Nassis, G. P., Koskolou, M. D. (2008). Somatotype, size and body composition of competitive female volleyball players. *Journal of Science and Medicine in Sport*, 11(3), 337-344.

METABOLIC OPTIMIZATION OF THE BASKETBALL FREE THROW

Vando, S.1, Padulo, J.2, Migliaccio, G.M.3, Attene, G.3, Masala, D.4, Falese, L.4, Ardigò, L.P.5

1: University of Tor Vergata (Italy), 2: CNMSS (Tunis), 3: CONI (Italy), 4: University of Cassino (Italy), 5: University of Verona (Italy)

Introduction Due to its mixed physical-technical-tactical nature, basketball like other team sports needs attention on likely relationships between all its facets, e.g., metabolic power and technical skill. A common fundamental is the free throw (FT), which can be shot both when just come off the bench and when fatigued by previous actions. Our aim was to study the effect of different metabolic power values on successful FT percentage (FT%). **Methods** 28 male (Under 17) basketball players (age 16.0 ± 0.8 y, height 171 ± 10 cm, mass: 60.5 ± 9.2 kg, sport experience 7.9 ± 1.0 yrs). The participants shot FT under three randomized testing sessions one week later than a Yo-Yo Intermittent Recovery test level 1 (Yo-Yo IR1) (Castagna et al., 2008) administered to measure HR_{MAX} as a proxy of maximal metabolic power. All sessions consisted in 10 FT with 5-sec rest between subsequent FT, at different heart rates (HR): rest (0HR), after warm-up (HR at 50%HR_{MAX} [50HR], 80%HR_{MAX} [80HR]). The same procedure was repeated one week later to evaluate measures reliability. After 15' standard warm-up running each participants was administered 10 FT (with 5-sec rest intervals between subsequent FT) sessions at different intensities (0HR - 50HR - 80HR). Each intensity (HR monitored) was achieved by shuttle running (15+15 m). Reliability (Weir, 2005) of 0HR, 50HR and 80HR results was assessed by Intra-class Correlations Coefficient (ICC). A one-way within subjects ANOVA was performed to check for the differences between the three sessions with post-hoc Bonferroni test. The level of statistical significance was set at a $p < 0.05$. **Results** ICC showed a good reliability of 0HR (0.86), 50HR (0.88) and 80HR (0.95). Yo-Yo IR1 HR_{MAX} was 198.0 ± 6.9 bpm. ANOVA showed difference in FT% over sessions ($F(1.26) = 20.571$ and $p < 0.0001$) with 720 FT ($r = -0.529$ and $p < 0.0001$). Bonferroni test did not show any significant 0HR-50HR FT% difference (-2% and $p > 0.05$), while 80HR elicited significantly lower values with respect to both 0HR and 50HR (-23 and -22% and $p < 0.0001$, respectively). **Discussion** Our study provided two practical indications to keep high FT%: 1) no preliminary warm-up is needed, because the 0HR-50HR difference was not significant; and 2) 80HR decreases FT% significantly, providing therefore scientific support to the usual behavior by fouled players, who make use of all the allowed 30" to shoot each their FT. **References** Castagna C, Impellizzeri FM, Rampinini E, D'Ottavio S, Manzi V. FEMORAL ARTERY CROSS-SECTIONAL AREA IS MINIMALLY AFFECTED WITH DIFFERENT RESTRICTIVE PRESSURE LEVELS

Laurentino, G.1, Leão, A.R.2, Barroso, R.3, Tricoli, V.1

1: USP (Brazil), 2: DASA (Brazil), 3: UNICAMP (Brazil).

Do not insert authors here **Introduction** Partial vascular occlusion associated to strength training has been shown to elicit significant strength gains and muscle hypertrophy. It seems that the use of high restrictive pressure levels (>200 mmHg) causes only a small change in artery's caliber maintaining arterial blood inflow while occluding venous outflow distal to the occlusion site. However, there is no con-

sensus about the effect of different levels of restrictive pressure on the reduction of femoral artery cross sectional area (FACSA). Restrictive pressures varying from 100 to 300 mmHg have been used. Therefore, the aim of this study was to determine the effect of different restrictive pressure levels on FACSA. Methods Thirteen physically active males (age 28.5 ± 8.8 years, height 178 ± 0.6 cm, body mass 77.5 ± 5.5 kg) volunteered for the study. They wore a pressure cuff (17.5 cm wide) on the most proximal portion of the thigh. Subjects underwent six different randomly assigned conditions: resting (R, zero mmHg), 40, 80, 100, and 130% of leg's systolic blood pressure (~ 160 mmHg) and a 200 mmHg condition. The cuff was inflated and the restrictive pressure was maintained for five minutes. A 3-minute interval with free blood flow was allowed between conditions. FACSA was measured by resonance magnetic image. Comparisons between conditions were made using an one-way ANOVA with repeated measures. Results There was no significant change in FACSA at 40% (0.442 ± 0.069 vs 0.418 ± 0.117 cm², $p=0.264$) and 80% (0.442 ± 0.069 vs 0.420 ± 0.054 cm², $p=0.1823$). Resting FACSA decreased significantly by 15.9% at 100% leg's systolic pressure (0.442 ± 0.072 vs 0.380 ± 0.117 cm², $p=0.002$). The reduction of FACSA at 100% was significantly higher than 40% (3.6%, $p=0.013$) and 80% (4.3%, $p=0.008$) leg's systolic pressure. In addition, the femoral artery was completely occluded when 130% leg's systolic pressure and 200 mmHg were applied. Discussion We observed that FACSA was slightly reduced until 100% of subjects' leg systolic blood pressure (~ 130.9 mmHg) but it was totally occluded when a 30% over this pressure was used. Some studies have shown positive effects of partial vascular occlusion (~ 80 -100% systolic pressure) on strength and hypertrophy gains (Takarada et al. 2000; Laurentino et al. 2012). Thus, it appears that these responses may be due to venous pooling without severe arterial flow occlusion. References Laurentino, G. C. et al. *Med. Sci. THE EFFECT OF DYNAMIC GUN-EX ROPE TRAINING ON UPPER BODY STRENGTH

Strejcova, B., Mosna, P., Dvorak, M.

Faculty of Physical Education and Sport

Introduction Strength training of upper body limbs and shoulders is an integral part of rehabilitation after different kind of disorders or it could be used in athletic conditioning programs (Akuthota & Nadler, 2004; Holmberg, Lindinger, Stoggl, Eitzlmaier, & Muller, 2005). The first aim of this study was to assess the effect of dynamic Gun-ex rope training on isokinetic shoulder strength during flexion and extension. Secondly, we focused on the trunk isometric strength. Methods Sixteen participants were divided into two groups, the experimental group (6 men and 2 women, in the age 25 ± 2 years) and control group (6 men and 2 women, in the age 28 ± 7 years). Both groups were composed of active athletes. The experimental group consisted of 8 athletes who participated in the six weeks training program with the dynamic Gun-ex rope. The isokinetic strength on isokinetic dynamometer Cybex Humac Norm in three angular velocities (90, 180, 240°/s) was evaluated. For the trunk strength assessment the isometric dynamometer (Takei, Japan) was used. The Pre-test and post-test interval was six weeks in both groups. The results were evaluated by ANOVA with repeated measures (2x2). Results The isokinetic shoulder strength significantly increased after six weeks training program, exactly the peak torque (60°/s) of right shoulder strength in experimental group (from 93.5 ± 33.3 Nm to 99.8 ± 36.6 Nm) in comparison with control group (from 94.4 ± 24.1 Nm to 90.1 ± 25.3 Nm) ($p<0.05$, $\eta^2=0.26$). We reported significant changes in isometric trunk strength after six weeks training program in the experimental group (116.4 ± 44.2 kg vs. 129.8 ± 46.9 kg. $p<0.02$, $\eta^2=0.33$). There were no changes in the other isokinetic parameters of shoulder strength in angular velocities 180, 240°/s. Conclusion Our results showed that there was the effect of dynamic GUN-eX rope training only on the isokinetic strength of right shoulder extensors for 60°/s. There were no other significant changes for the other isokinetic shoulder strength parameters. There was also statistically significant increase of the isometric trunk strength after six weeks strength training. The study was supported by SVV 2014-267603 and GAČR P407/12/0166. PRELIMINARY EFFICACY OF 16-WEEK HIGH INTENSITY INTERVAL TRAINING AMONG HEALTHY MEN

Azuma, K.1, Osawa, Y.2, Nagano, M.1, Tabata, S.1, Horisawa, S.1, Katsukawa, F.2, Ishida, H.2, Oguma, Y.2, Matsumoto, H.1

Keio University (Tokyo & Kanagawa, Japan)

Introduction High intensity-interval training (HIIT) has been recognized as a useful option to improve aerobic fitness among sedentary people, due to time-constraint (Gibala et al., 2012). However, it would require higher level of motivation and can induce feeling of severe fatigue and therefore, it might be impractical to encourage untrained individuals to perform HIIT for long-term. In the current study we would examine the feasibility and preliminary efficacy of long-term interval training among healthy men. Methods Seven healthy male volunteers, aged 28-41 years, completed 24-week HIIT using leg-cycling (LC). Training program consisted of $>90\%$ VO₂ peak for 60 sec separated by 60 sec active rest period for 8-12 sets twice weekly for 16-week, followed by 8-week maintenance training once a week. Maximal exercise tolerance tests were performed before (0-week), 4-week, 16-week, and 24-week after intervention- maintenance program. Physical activity measurement other than HIIT, as well as body composition analyses was also performed. For the comparison, 9 other male volunteers completed either relatively long continuous moderate-intensity (70%VO₂ peak) training (CMT, n=4) with greater exercise volume or HIIT with same volume but half dose with arm-cranking (LC-AC, n=5), instead of LC only. Results VO₂ peak as well as peak watt was linearly increased after 4-week and 16-week LC-HIIT (41 ± 7 to 45 ± 5 , and 48 ± 5 ml/min.kg for VO₂ peak, 217 ± 30 to 237 ± 22 , and 267 ± 20 W for peak watt, both $p<0.05$), however, after once weekly maintenance period, this was not maintained ($p<0.05$). The improvement in aerobic fitness was about a half magnitude in LC-AC HIIT vs. LC-HIIT, and it was not significant in CMT group, though there was a significant increase in cross-sectional area of quadriceps femoris muscles among all the three groups ($p<0.05$). There was no decrease in physical activity other than LC-HIIT, despite of severe fatigue after the training. Discussion We have found that twice a week, 16-week, 8-12 sets of 1 min HIIT could induce $\sim 20\%$ increase in VO₂ peak and $\sim 25\%$ increase in peak watt, while more frequent and less long-term HIIT programs have showed similar improvements (Kessler et al., 2012). Considering the lower improvement in LC-AC group, and the decline during once a week maintenance period, the current LC-HIIT program may be near minimum amount in terms of the dose and the frequency of HIIT, and be feasible for long-term without decrease in daily physical activity. EFFECTS OF RESPIRATORY MUSCLE TRAINING ON EXERCISE PERFORMANCE FOR TENNIS PLAYERS : A PILOT STUDY

Wu, C.Y.1, Yang, C.H.2, Guo, L.Y.1

1: Kaohsiung Medical University, Kaohsiung, Taiwan; 2: Tzu-chi University, Hualien, Taiwan

Introduction There is considerable evidence that respiratory muscle training improves pulmonary function, quality of life, and exercise performance in healthy athletic populations. However the benefits for tennis players are not well understood. The purpose of this study was to investigate the differences between respiratory muscle training (RMT) and placebo training on exercise performance in tennis players. **Methods** Ten healthy tennis players (21.7 ± 1.9 yr old) were recruited and randomly assigned to a training or placebo group. The subjects trained their respiratory muscles for 6 weeks by using the POWER breathe® — Sport Performance Classic (IMT Technologies Ltd, UK). The training group underwent 30 trials of spontaneous breathing twice per day for 5 days per week. The placebo group performed the same training exercise without respiratory resistance. Balance tests (stork stand test), agility tests (star shuttle run test, shuttle run test), diaphragm thickness (Tdi), lung function, maximum inspiratory, and expiratory pressure (P_{lmax} and P_{Emax}) were used to evaluate the effect of training. **Results** Within the training group, there were clear increases in balance test (change percentage: 63.8% for right side; 68.7% for left side), Tdi (change percentage: 23.8%), P_{lmax} (change percentage: 42.0%), and P_{Emax} (change percentage: 22.5%) after training, whereas no changes occurred within the placebo group. In addition, there were no differences in agility test and lung function between the training and placebo groups. **Discussion** Previous studies used core muscle training to improve balance ability, however we used the RMT. Although these training methods are different, the results are similar (Chang et al., 2008). A potential increase in diaphragmic strength also causes an increase in intra-abdominal pressure to improve balance ability (Hodges et al., 2000). RMT can induce myofiber hypertrophy, causing increase in diaphragm thickness (DePalo et al., 2004). The results showed that P_{lmax} and P_{Emax} were also elevated after RMT, which demonstrated that RMT can improve respiratory muscle strength. **Conclusion** Six weeks of respiratory muscle training in tennis players was able to improve exercise performance, including balance, Tdi, P_{lmax} and P_{Emax}. **References** Chang HY. HEART RATE AND BLOOD LACTATE DURING FUTSAL MATCH: COMPARISON BETWEEN FIRST AND SECOND PERIOD IN BRAZILIAN PROFESSIONAL FUTSAL PLAYERS

Santos, J.

UNESP, São Paulo State University

Introduction Futsal is an adaptation of soccer for practice in gymnasium. Despite of its popularity in many countries of world, it has been little studied scientifically. Heart rate (HR) and blood lactate (BL) are frequently used as indicators of physiology demand in sports. Therefore, the aim of this study was verify the physiology responses in a futsal match, considering the differences between first (1T) and second (2T) period of match. **Methods** Seven professional futsal players, 24.0 ± 2.8 years, 73.9 ± 6.6 Kg, 171.6 ± 3.7 cm, 11.0 ± 4.0 % of fat from the one team of Futsal São Paulo League, Brazil, were evaluated during a friendly match, considering official rules, at pre-season (two weeks of training). HR was recorded by Polar Team System-2 every second, considering only the time with ball in the game (excluding time with clock stopped). HR maximum (HR_{max}) was considered as 220-age. Sample of blood (25 uL) was collected to analyze of BL by YSL 2300 lactate analyzer taken after each change of player and at end of 1T and 2T. Statistical analyze was performed by paired test-t, considering the mean of participation in first vs second periods of match ($P < 0.05$). **Results** HR and BL not presented significant difference between 1T and 2T. HR, 180 ± 6 vs 178 ± 11 bpm, (91 ± 2 vs 90 ± 5 % of HR_{max}), BL, 8.5 ± 3.0 vs 8.3 ± 2.4 mmol/L. Considering the match total, HR = 179 ± 8 bpm (91 ± 3 % of HR_{max}) and BL = 8.3 ± 2.9 mmol/L. **Discussion** The players maintained the same intensity during 1T and 2T. Possibly, the change of players during the match must have occasioned the maintaining of the intensity. In a simulated game (4 x 10 min) Castagna et al. (2009) not verified differences among the four periods. However, our results presented differences in comparing to the study of Barbero-Alvarez et al. (2008), which verified reduction of HR in second time (176 vs 172 bpm / 91 vs 88% of HR_{max}). BL was higher that reported in simulated game (4 x 10 min), which presented 5.3 mmol/L (Castagna et al., 2009). The differences in characteristics technical-tactic involving the populations of the present study (Brazil) and those others two studies cited (Spanish) and the difference between friendly and official match are factors that may also influence the results and need be more studied. **References** Barbero-alvarez, JC; Soto, VM.; Barbero-Alvarez, V.; Granda-Vera, J. COMPARISON OF A 6-WEEK FUNCTIONAL CORE TRAINING AND TRADITIONAL RESISTANCE TRAINING ON DYNAMIC BALANCE IN TENNIS PLAYERS.

Ng, S.K.1, Tsang, F.L.2

1 The Chinese University of Hong Kong 2 Middlesex University (UK)

Introduction Good core stabilization and dynamic balance is a vital component for tennis player to maximize performance and minimize the risk of injury (Leetun, 2004). There is a lack of studies in the literature comparing the effectiveness of different training protocols on dynamic balance of tennis players. Therefore, the aim of this study was to compare the effects of a 6-week functional core training (FCT) and traditional resistance training (TRT) on dynamic balance in tennis players. **Methods** The design of this study was a 2 (time: pre-test and post-test) X 3 (groups: FCT, TRT and control) factorial design. Thirty right-handed male tennis players (age= 27.4 ± 3.6 yr, tennis sport experience = 7.2 ± 1.8 yr, height= 170.2 ± 5.9 cm, weight= 72.1 ± 6.3 kg) were randomly divided into two experimental groups and one control group (n=10 in each group). All participants completed a pre- and post-test measurement of their dynamic balance using Y-balance test (Anterior, Posteromedial and Posterolateral) with their dominant extremity. Reach distances were normalized to limb length. The participants in the two experimental groups performed 12 sessions of a training protocol twice per week. FCT group performed 13 core exercises using Total Body Resistance Exercise (TRX) tool while TRT group conducted a similar programme using their body weight. Each exercise performed 15 repetitions. **Results** No significant difference was found for pre-test results for all excursions. Results of two way repeated measures ANOVA showed significant main effect for pre-test and post-test within participants in both FCT and TRT groups for all reach directions (anterior: $P < 0.001$, posteromedial: $P < 0.001$ and posterolateral: $P < 0.001$) but not in control group (anterior: $P = 0.328$, posteromedial: $P = 0.486$ and posterolateral: $P = 0.142$). There was no significant interaction between Time and Group ($P = 0.148$). Among the three groups, participants in FCT group improved greater anterior ($P < 0.001$), posteromedial ($P < 0.001$) and posterolateral ($P < 0.001$) reach difference. **Discussion** In the present study, the participants in the FCT training protocol exhibited greater functional capacity as measured by Y-balance test. This was in line with the finding of Aibele and Behm (2009) that the dynamic balance was improved with a 7-week

instability resistance training. However, it is difficult to unify the exercise intensity for both FCT and TRT groups in the present study, although they all involved the use of their own body weight and the same repetitions. The implementation of FCT for core stabilization-training is an effective way to enhance dynamic balance in tennis players. References Leetun DT (2004). DIFFERENCES IN HEART RATE AT FIRST AND SECOND LACTATE TURN POINT IN TREADMILL RUNNING AND ERGOMETER CYCLING IN WOMEN

Wallner, D., Buchegger, M.I., Simi, H., Tschakert, G., Hofmann, P.

*FH JOANNEUM; ** University of Graz

Introduction Based on the three-phase model, heart rate (HR) at the first (LTP1) and second lactate turn point (LTP2) represent reference points to set training intensities for continuous (Hofmann & Tschakert 2011) and intermittent (Tschakert & Hofmann 2013) exercises. Once determined, it is often attempted to apply HR recommendations from one type of ergometry to different kinds of exercises (Röcker et al., 2003). The aim of this study was to analyse the HR at LTP1 and LTP2 in treadmill running and ergometer cycling tests. **Method** 10 female student (22.1±2.2 years) performed two incremental tests within one week in randomized order. One test was performed as running test on the treadmill (RT) and the other as cycling test on cycle ergometer (CT). After 3 minutes warm up at 1.5 m/s at RT and 15 Watt at CT workloads were increased every minute by 0.2 m/s at RT and 15 Watt at CR, respectively to attain maximal power output within the same time frame. HR was measured continuously and blood lactate concentration (La) was measured at rest and after every load step. LTP1 and LTP2 were determined in both tests according to Hofmann & Tschakert (2011). **Results** Mean workloads at LTP1, LTP2 and at termination of the test (MAX) were 2.13±0.22 m/s (58.1±2.7% vMAX), 2.65±0.35 m/s (75.3±5.2% vMAX) and 3.52±0.30 m/s in RT and 75.2±14.7 W (39.9±6.0% PMAX), 127.6±13.5 W (68.1±2.3% PMAX) and 187.5±19.0 W in CT, respectively. La at LTP2 (3.41±0.63 mmol/l vs. 4.24±0.53 mmol/l) and MAX (8.96±2.26 mmol/l vs. 11.40±1.88 mmol/l) was significantly higher in CT (p<0.01), but not at LTP1 (1.83±0.37 mmol/l vs. 1.86±0.52 mmol/l). Heart rate in RT was significantly higher at LTP1, LTP2 and MAX (p<0.05) with a decreasing mean difference (166.3±8.7 min⁻¹ vs. 135.8±20.1 min⁻¹, 183.5±9.4 min⁻¹ vs. 167.7±8.5 min⁻¹ and 196.1±8.1 min⁻¹ vs. 190.5±10.9 min⁻¹). **Conclusion** A distinct difference and a highly individual variation in HR at the lower intensity range were found comparing running and cycling. Therefore sport specific tests are suggested to be essential for reliable heart rate based training recommendations. **References** Röcker et al. (2003) Heart-rate recommendations: transfer between running and cycling exercise? *Int J Sports Med* 24 (3), 173-178 Hofmann & Tschakert (2011) Special needs to prescribe exercise intensity for scientific studies. *Cardiology Research and Practice*. COMPARISON OF BIOELECTRICAL IMPEDANCE ANALYSIS AND SKINFOLDS TO DETERMINE BODY FAT IN RECREATIONAL ATHLETES.

Sanna, I., Ghiani, G., Palazzolo, G., Loi, A., Pinna, V., Olla, S., Marongiu, E., Angioni, G., Pusceddu, M., Concu, A., Tocco, F., Crisafulli, A.

University of Cagliari

Introduction. The body composition assessment and quantification of body fat are commonly used in many sport activities as they appear to be related to subjects' health status and athletic performance (Ostojic, 2006). Despite the increasing number of methods for assessing body composition, validation is still the most serious issue, and confusion exists on which method is the most accurate (Heymsfeld, 1989; Heyward, 1996). The purpose of this study was to compare two different methods for body fat estimation in recreational athletes: skinfolds (SKF) and Bioelectrical Impedance Analysis (BIA). **Methods.** Forty-seven athletes (19 females and 28 males, mean age 41 years) took part in the study. Skinfold thickness at 4-site were obtained using a Lange caliper, while body impedance was measured with a multiple-frequency impedance device (Handy 3000, Dietosystem, Italy). Statistical analysis was performed using Student's t-test and Bland and Altman statistics were carried out in order to evaluate the agreement between SKF and BIA. **Results.** Athletes showed a significant differences (P<0.05) between body fat estimated by SKF and BIA. The mean body fat estimated by the two methods was 20.4%. The differences between methods estimated by the Bland-Altman statistics were between (-9.68 and +5.64%), with a mean difference in the SKF-BIA of -2.02%. In term of percent difference between methods, limits were between -48 and +28%. **Conclusion.** The current study found that the estimation of body fat was quite different between SKF and BIA, as limits of agreement between methods were widespread. In fact, using SKF can introduce a difference between -48 and +28% with respect to BIA. Thus, these two methods can not be used interchangeably. It is mandatory that, when assessing body composition in athletes, methods employed are clearly specified. It should also be considered that neither SKF nor BIA are considered gold standard in assessing body composition. **References.** Ostojic S.M. (2006) *J Sports Med Phys Fitness*. RPE TO REGULATE EXERCISE INTENSITY AND PREDICT VO2PEAK IN HEART FAILURE PATIENTS

Morris, M., Lam, K.L., Wynn, G., Somauroo, J., Cotterrell, D., Buckley, J.P.

University of Chester

Introduction: The purpose of this study was to assess, for the first time, the validity and reliability of Borg's rating of perceived exertion (RPE) scale to regulate exercise intensity and predict peak oxygen uptake (VO2peak) in congestive heart failure (CHF) patients. **Methods:** Sixteen CHF patients on beta-blocker medication (70.4±7.0 y) completed one maximal GXT and two perceptually regulated exercise tests (PRET) on a cycle ergometer. Intensity was regulated to RPE levels 9, 11, 13 and 15 in a continuous, incremental (2 min) protocol. Cycle work-rate (Watts), heart rate and oxygen uptake (VO2) were recorded continuously. As most participants were unable to sustain exercise at RPE 15 (>75%VO2peak), data analysis was performed on the range RPE 9 to 13. Individual VO2 peak predictions were based on linear extrapolations from RPE 9 to both RPE 19 and 20. **Results:** Regulation of intensity at RPE levels 9, 11 and 13 produced intensities of 42.0±13.9, 52.5±14.6 and 64.1 ± 13.0 %VO2peak, respectively. RPE targets of 11 and 13 agreed (p< .05) with recommended European and US guideline intensities. Actual and predicted VO2 peak (16.5 ± 4.9 and 16.3 ± 5.1 ml/kg/min, respectively) showed a non-significant bias (p= .40) and favourable 95% limits of agreement (95%LoA); -0.6±5.3 ml/kg/min for the RPE 19 prediction model. Reliability statistics for the pre-

dicted VO₂ values were: 0.4±6.5 ml/kg/min (95%LoA) and 2.4 ml/kg/min (Typical Error). Conclusion: Regulating exercise intensity in CHF patients at RPE levels 11 and 13 elicited intensities commensurate with current recommendations. There was a favourable reliable and valid prediction of VO₂peak, but further evidence is required to qualify such predictions as being useful for accurately assessing improvements following a standard CHF rehabilitation programme.

PEAK HAND-GRIP FORCE PREDICTS COMPETITIVE PERFORMANCE IN ELITE FEMALE CROSS-COUNTRY SKIERS

Carlsson, M.1,2,3, Carlsson, T.1,2,3, Olsson, M.3, Brorsson, S.2,3, Malm, C.1, Tonkonogi, M.2

Medical science

1: Umeå University (Umeå, Sweden); 2: Dalarna University (Falun, Sweden); 3: Dala Sports Academy (Falun, Sweden) Introduction: The relationship between grip force and racing success has previously been evaluated for non-elite male skiers and no significant correlation was found (Niinimaa et al., 1978). However, no study has investigated if there is an association between grip force and competitive performance for elite female cross-country skiers. Therefore, the purposes of the study were: 1) to investigate the relationship between mean peak hand grip force (GF) and competitive performance for elite-standard female cross-country skiers and 2) to examine if GF is related to mean lean mass in the arms (LM). Methods: Fifteen elite female cross-country skiers (age: 22.7 ± 3.0 years (mean ± SD), body mass: 60.2 ± 5.4 kg, stature: 169.5 ± 6.3 cm) completed a grip force test (Grip-it, Brorsson Innovation AB, Falun, Sweden) to determine peak force for both hands and a dual-energy x-ray body composition test (GE Healthcare Lunar, Madison, USA) to determine LM. Performance data were collected from a sprint prologue race in classical technique (SPR) and a 10-km distance race in free-style technique (DR). Statistical analyses were processed using SPSS with all tests performed at an alpha of 0.05. Results: The test variables obtained were GF: 307.3 ± 53.0 N and LM: 2.5 ± 0.3 kg. Mean completion time for SPR and DR were 262.5 ± 12.3 s (n = 12) and 1828.7 ± 84.7 s (n = 10), respectively. The GF were correlated with SPR (r = -0.69, P = 0.012), DR (r = -0.73, P = 0.016), and LM (r = 0.78, P < 0.001). Discussion: A muscle's ability to produce maximal force has previously been correlated with the cross-sectional area of the muscle (Häkkinen et al., 1989), which supports the relationship between GF and LM. Grip force has been related to maximal force in bench press (Vaara et al. 2012). Moreover, correlations between bench press variables and maximal speeds (V_{max}) in different skiing techniques have been reported (Stöggl et al., 2011) and V_{max} was related to performance in elite male cross-country skiing (Sandbakk et al., 2011). This reasoning supports the results presented in the present study. In conclusion, GF appears to reflect an important physiological ability for success in elite female cross-country skiing independent of the race distance and skiing technique. ERGOGENIC CAPACITY OF MELATONIN DURING SLEEP AND WAKEFULNESS PERIOD IN SWIMMING RATS

Beck, W., Forte, L.D.M., Scariot, P.P.M., Dos Reis, I.G.M., Messias, L.H.D., Campesan, Y.S., Gobatto, C.A.

University of Campinas

Introduction Melatonin administration has been extensively investigated owing to its countless properties, some related to endogenous clock master control and other to metabolic and physiological influence during physical exercise. Thereat, its ergogenic effect has been hypothesized, but it was not tested at anaerobic threshold intensity (iAnT). So, we tested the ergogenic capacity of melatonin through an exercise until exhaustion at iAnT (TTE) during sleep and wakefulness period. Methods Forty Wistar male rats were maintained at 12/12h of light cycle (switched on at 06:00h) and were submitted to an incremental swimming exercise with an initial overload of 3% of body mass (%bm), increments of 0.5%bm each 5 minutes, performed until 6.5%bm or exhaustion. We determined iAnT when blood lactate concentration (BLC) increases disproportionately in relation to exercise intensity. Such procedure was conducted at 12:00h or 20:00h, characterized by sleep or wakefulness period, respectively. Respecting 48h interval, 10mg/kg of melatonin was administered for half animals at 12:00h or 20:00h (M12 and M20, respectively) while other animals received only saline (C12 and C20). Thirty minutes after the IP injection, all animals performed TTE at iAnT and group's time of day. Statistical significance was set at p<0.05. Results For C12, C20, M12 and M20, iAnT were correspondent to 4.8±0.6, 5.3±0.4, 4.7±0.35 and 5.1±0.3%bm, respectively, being only C20 higher than C12 (p=0.01). The BLC correspondents to such intensities were 3.7±1.2, 4.2±1.3, 3.0±0.9 and 4.0±0.9mM, respectively, showing no significant difference among groups (post hoc) and no two-way ANOVA effect. TTE was 43.5±21.7min for C12, 98.1±55.5min for C20, 105.32±88.1min for M12 and 188.8±121.1min for M20, being M20 higher than all groups (p<0.05). We found significant time of day effect for intensity and TTE (12:00h < 20:00h, p=0.01, for both). Melatonin does not affect iAnT determination (p=0.30), however, promotes higher TTE when compared to saline (p<0.01). Were not found interactions between tested effects for iAnT (p=0.52) and TTE (p=0.57). Discussion Melatonin has been associated to its anti-inflammatory and antioxidant features and to increase fatty acid availability during exercise. Despite not certain, such characteristics summed to exercise performed at wakefulness period could lead us to the found results, which showed that drug administration effect was amplified at night, when melatonin elicits its physiological peak. We conclude that melatonin possesses significant ergogenic effect for exercise at iAnT in swimming rats, which was potentiated at dark period. Supported by FAPESP-Proc. 2011/13226-1 and 2012/20501-1. DO CORE STABILIZATION EXERCISES ENHANCE CYCLING EFFICIENCY?

Weijmans, E.J.1, van Berkel, S.1

1: Isala (Zwolle, the Netherlands)

Introduction Core stabilization exercises have been advertised as potential enhancers of endurance and efficiency in cycling. A steady core is said to allow for proper body positioning, preventing unnecessary energy loss and will thus allow for maintaining speed and power for a longer time. Previous studies published on core stabilization training in other sports show mixed results. However, no studies addressing a potential effect on gross cycling efficiency (GE) have been published. The aim of this pilot study was to analyze the possible effect of an eight week core-stability training program on trunk balance and gross cycling efficiency. Methods 13 well-trained cyclists were included in an 8 week core-stability training program. The daily program consisted of both static and dynamic versions of the plank, side plank, bird-dog, superman, cycling crunch and pulse up exercises lasting an average of 10 minutes per session. Steady-state oxygen uptake and GE were determined as subjects approached RER 1.0 (de Koning et al., 2012). Grip-strength and the Y-balance test (Coughlan et al., 2012) were used to measure balance. Training compliance was monitored using an online log. GE and core-stability measurements were performed at baseline and after 8 weeks. Results Preliminary results show a trend (p=0.22) towards an improvement of gross cycling efficiency (average at baseline 22.0%; after training 22.5%). Compliance to the program was very good, with an

average of 84% (75 – 98%) sessions trained. All subjects demonstrated an improvement in postero-lateral reach. Three subjects reported an episode of lower back discomforts which they attributed to the superman exercise. Discussion Our preliminary results suggest that it might be possible to improve GE after an 8 week core-stability training program. However, current sample size is small and reported values are very close to the $\pm 2\%$ error margin of the spirometry hardware used. In 2 subjects, we were unable to accurately determine GE. According to our spirometry readings they were unable to attain a steady state in the second test. However, mentioned subjects reported a perceived rate of exertion that was lower than expected at RER 1.0. The reason for this discrepancy is unknown. A possible measurement error can be assessed by measuring blood lactate in future tests. As competitions can be won or lost in fractions of seconds, improving one's gross efficiency by means of core-stability training could be beneficial. The trend found in this pilot study is encouraging to continue the research in this area. References Coughlan GF, Fullam K, Delahunt E, Gissane C, Caulfield BM. 5 KM SELF PACED RUNNING IN THE HEAT IMPROVES VERTICAL JUMP PERFORMANCE

Coelho, L., FERREIRA-JUNIOR, J., MIRANDA, G., CAMPOS, B., OLIVEIRA, G., SILVA, C., DINIZ, M., CARMO, A., SANTOS, W., NUNES-LEITE, M., REIS, B., BORBA, D., VENEROSO, C., PRADO, L., SILAMI-GARCIA, E.

5 KM SELF PACED RUNNING IN THE HEAT IMPROVES VERTICAL JUMP PERFORMANCE 1:UFMG (Belo Horizonte, Brazil) 2:CEFET-MG (Belo Horizonte, Brazil) 3:UnB (Brasília, Brazil) 4:IFTM (Paracatu, Brazil) Introduction Warm-up has been recommended before exercise in order to improve muscle performance. A typical warm-up may consist of exercises, such as cycling, running, jumping, sprint and squats. Acute performance enhancement at explosive activities (e.g. jump) has been observed when preceded by resistance exercises. However, it is unknown if an endurance warm-up performed in a hot environment could improve muscle power performance. The aim of this study was evaluate the effects of 5 km self paced running in the heat on vertical jump performance. Methods Eleven men (24 ± 2 years, 174 ± 5 cm, 71 ± 4 kg, 42 ± 5 mL O₂/kg/min) were exposed to two randomized conditions (35° C and 50% RH) separated by 3 to 7 days apart: 1) control condition (CON) (30 min of resting) and 2) running condition (RUN) (5 km self paced running). In both conditions, subjects performed seven countermovement jump (CMJ) before (PRE) and immediately after (POS). The significance level was set at $p < 0.05$. Results Mean CMJ was higher in POS (38.0 ± 5 cm) than PRE (31.6 ± 4 cm) in RUN ($p < 0.001$) and was not different between PRE (31.8 ± 4 cm) and POS (31.9 ± 4 cm) in CON. Rectal temperature was lower in PRE ($37.06 \pm 0.32^\circ$ C) than POS ($39.04 \pm 0.6^\circ$ C) in RUN ($p < 0.01$) and did not differ between PRE ($37.23 \pm 0.29^\circ$ C) and POS ($37.22 \pm 0.31^\circ$ C) in CON. Discussion CMJ increased 18% after self paced running, despite the increase of rectal temperature. Our results did not support the hypothesis that increased core temperature impairs muscle power performance (Thomas et al., 2006). Nevertheless, our findings agree with Boulosa et al. (2011) who observed an increase in CMJ after maximum aerobic test. Ferreira-Junior et al. (2013) also suggested that high intensity warm-up may enhance muscle performance by postactivation potentiation (PAP). Thereby, considering that in self paced exercise the subject performs the running at maximal intensity, PAP may have occurred during RUN condition. Finally, our results indicate that 5 km maximal self paced running may improve CMJ performance. References Ferreira-Júnior JB, Bottaro M (2013). LACTATE THRESHOLD IN SQUAT EXERCISE WITH INCREMENTAL RESISTANCE

Haramura, M., Takai, Y., Yoshimoto, T., Funahashi, T., Fukunaga, Y., Yamamoto, M., Kanehisa, H.

National Institute of Fitness and Sports in Kanoya

Purpose: Resistance exercise can produce favorable adaptation in each of the muscular, cardiorespiratory and metabolic capacity. To determine the exercise intensity at which lactate starts to accumulate in the blood, i.e., lactate threshold (LT), is important to scheme resistance training program, because LT is a measure representing metabolic profile during the exercise adopted. However, there is little information on the LT during resistance exercise. Therefore, we aimed to clarify the LT in squat exercise with incremental resistance. Methods: Six young men (27.8 ± 6.2 years, 172.6 ± 3.9 cm, 68.5 ± 7.0 kg) performed an incremental resistance test (Sousa et al. 2011) consisting of squat exercise with external loads (0, 5, 10, 20, 25, 30, 40, 45, 50, and 60% of one repetition maximum; 1RM). At each load, the subjects performed the squat exercise ten times every 3 seconds with interval of 3 min between trials. During the exercise, blood lactate (fingertip), electromyograms (EMGs) from vastus lateralis (VL) and biceps femoris (BF) muscles, oxygen uptake (breath by breath), and heart rate (ECG) were measured. LT was calculated from the relationship between blood lactate concentration and external load (Orr et al. 1982). The EMG amplitudes of VL and BF during the squat exercise were normalized to those during maximal voluntary contraction, and expressed as % EMGmax. Results: Blood lactate ($y = 1.01x + 0.65$), % EMGmax of VL ($y = 40.90x + 0.29$) and BF ($y = 9.92x + 0.31$), oxygen uptake ($y = 0.54x + 0.23$), and heart rate ($y = 93.42x + 0.14$) were exponentially increased with increasing external load. The % 1RM at LT was $24.5 \pm 12.7\%$ 1RM (12.4 to 48.5% 1RM). Oxygen uptake and heart rate at LT were 0.7 ± 0.2 L/min and 106.7 ± 8.0 bpm, respectively. Blood lactate concentration was highly related to the % EMGmax values of both VL ($r = 0.84 - 0.97$, $P < 0.05$) and BF ($r = 0.82 - 0.97$, $P < 0.05$) across external load and subjects. Conclusion: In incremental resistance test with squat exercise, the exercise intensity corresponding to LT was about 25% 1RM. The current results may be useful to design resistance training program with squat exercise which can increase both aerobic and anaerobic capacity. ACUTE HAEMATOLOGICAL RESPONSES TO HIGH-INTENSITY EXERCISES: IMPACT OF DURATION AND MODE OF EXERCISE

Minuzzi, L., Carvalho, H.M., Rama, L., Teixeira, A.M.

University of Coimbra

Introduction The purpose this study was to investigate the patterns of acute haematological responses to maximal exercise and on the 24h post-exercise period in healthy adults. Methods Nine healthy voluntary participants performed two protocols of short-term high

intensity exercise in cycle-ergometer (30-s Wingate Anaerobic Test - WAnT, load set at 9% of individual body mass; Repeated-sprints Test - 10 repetitions of 10-s all-out effort with 30-s of passive recovery) and two protocols of long-term high-intensity exercise until exhaustion in cycle-ergometer (Continuous Incremental Test - 3-min stages starting at 75 W, with 25 W increases; Intermittent Incremental Test - 3-min stage starting at 75 W and increments of 25 W every 3-min period with 1-min of passive rest). The testing order was randomized with a period of 72 h between tests. Venous blood samples were collected at pre-exercise, immediately post-exercise, and 30-min, 1 h, 2 h, 12 h and 24 h post-exercise. Blood samples were analyzed for leucocytes, lymphocytes, granulocytes and monocytes cell counts and also for hemoglobin and hematocrit with a full cell count, using a blood analyzer (Beckman Coulter). Results The significant ($p<0.01$) increases in leukocytes and erythrocytes counts immediately post-exercise was observed in all exercise protocols, returning to pre-exercise values 30-min post-exercise. Increases between pre- and immediately post-exercise were significant for lymphocytes counts ($p<0.01$), but decreased below pre-exercise values until 2 h after exercise returning to pre-exercise values at a slower rate, between 12 to 24 h. Granulocytes decreased immediately post-exercise in all tests, except in the WAnT, and increased steadily until 2 h after exercise returning to baseline levels between 12 to 24 h post-exercise. No changes in the patterns of responses were apparent for monocytes. The haemoglobin responses for the short-duration tests and the long-duration intermittent test increased significantly ($p<0.01$) after exercise and return to pre-exercise values 30-min post-exercise in the WAnT, Repeated Sprints Test and long-duration intermittent test. No changes were apparent in the haemoglobin responses for the continuous long-duration test. Conclusions In summary, the acute changes in leukocyte subpopulations, hemoglobin and hematocrit to strenuous exercise varies slightly depending on the mode (intermittent vs continuous) and duration of the exercise. The manipulation of the exercises and consequent different metabolic demands seem to be important factors to take into account when looking at haematological changes. Contact lucielegm@gmail.com

THE INVESTIGATION OF THE IMPACT OF HAND PREFERENCE ON THE SERVICE, FOREHAND AND BACKHAND HITTING SPEED AND STRENGTH PARAMETERS AMONG STUDENTS TAKING TENNIS TRAINING AT UNIVERSITY

Erzeybek, M.S., Kaya, F., Eynur, R.B., Yıldız, S., Önen, M.E.

Dumlupınar University

INTRODUCTION AND OBJECTIVE: The objective of this study is to analyse the influence of university students' hand preferences upon the strength parameters (Leg and Shoulder) and specific tennis related qualities (forehand, backhand and service speed) during one academic term. **MATERIALS AND METHOD:** Participants were a total of 73 students (49 male ve 24 female) from various disciplines took 4 hour weekly tennis lessons consisting of 2 hours practical work. (average age 20.75 ± 1.21). During the course of 14 weeks (3.5 months) the training included basic and supportive hits and service skills focusing on the rapidity, strength and speed exercises. A total of 14 weeks and 28 practical lessons were applied. The pre and post test data were collected during the first and last weeks of the 2013-2014 academic year. The shoulder and leg strength levels were measured with Takkei shoulder dynamometer, speed measurements were done with pocketradar equipment. Hand preference was determined by the Edinburgh Oldfield questionnaire and the score was analysed in accordance with the Geschwind Score (GS). In order for the questionnaires to be completed correctly, necessary explanations were made about the importance of the survey. Points to be considered carefully were stated. **RESULTS:** Participants were totally free of any health problems. 76 percent were right-handed, and 24% were left-handed. It was observed that hand preference did not vary by gender ($\chi^2=0.99$, $p=0.319$). Among the right-handed females the comparative analysis between the pre and post test results in all parameters showed significant changes ($p<0.05$). Among the left-handed females with the exception of leg1 ($p>0.05$) all the parameters significantly changed between the pre and post test data ($p<0.05$). Among both left and right-handed males all parameters had significant differences between the pre and post test results ($p<0.05$). The left-handed females had significantly more improved results in their leg2 results than right-handed females ($p<0.05$). Other improvements had similar levels among both right and left-handed males and females ($p<0.05$). **CONCLUSION:** In conclusion the one term tennis program significantly contributed to the improvements in strength values together with forehand, backhand and service speed improvements both among left and right-handed male and female students. Hand preference and gender did not play a role in these improvements. **Key Words:** Tennis, Strength; Speed, Laterilisation, Forehand, Backhand **REFERENCES:** 1. Özer K. ISOMETRIC LEG PRESS TRAINING AT DIFFERENT KNEE ANGLES RESULTS IN A SHIFT OF THE FORCE-LENGTH RELATIONSHIP OF LEG EXTENSORS

Bogdanis, G., Selima, E., Methenitis, S., Veligeas, P., Tsoukos, A., Terzis, G.

University of Athens

Introduction Isometric strength training is a highly effective method to increase muscle strength, but its effect is highly length-specific, with large increases at the training joint angle and little transfer to other muscle lengths (Weir et al., 1995). The purpose of this study was to evaluate the effect of isometric leg press training at two different knee angles on muscle strength at a range of muscle lengths. **Methods** Fifteen male university students (age: 21.5 ± 2.0 yrs, height: 177 ± 5 cm, body mass: 78 ± 8 kg) were divided into two groups and trained three times per week for 6 weeks. One group ($n=8$) performed the isometric leg press exercise with knee angle set at 85° , while the other group ($n=7$) performed the isometric leg press with knee angle set at 145° (180° = full extension). Training involved 5-7 sets of maximal isometric leg press exercise with a 4 min rest between sets. Before and after training, isometric strength at 6 different knee angles and maximal half-squat strength were assessed using a force platform and free weights, respectively. Isometric force data were fitted with 3rd degree polynomials to obtain optimum angle for force generation and peak force ($r^2=0.937-0.991$). Data were analyzed using 2-way ANOVA with repeated measures and Tukey post-hoc test ($p<0.05$). **Results** Optimum angle for force generation and peak force were similar in the two groups before training (143 ± 3 vs. $144 \pm 2^\circ$ and 4004 ± 201 vs. 4013 ± 342 N, respectively). In the 85° training group, force was increased equally at all angles by an average of 12.3% (main effect pre vs. post training, $p=0.028$), but optimum angle remained unchanged (143 ± 3 vs. $148 \pm 4^\circ$). However, in the 145° group, peak force increased by 45.5% and optimum angle was shifted from 144 ± 2 to $158 \pm 5^\circ$, $p=0.001$). Maximal half-squat strength increased equally in both groups from 135 ± 5 to 149 ± 7 kg, $p=0.001$. **Discussion** The results of the present study show that training at a knee angle of 145° , results in a large and angle-specific increase in peak force, with a concomitant shift in the optimum angle for force generation. In contrast, training at a smaller knee angle, results in a much lower peak force increase with no changes in optimum knee angle. The lack of training angle specificity when training at small knee angles has been previously observed for knee extension (Kubo et al., 2006). However, the almost 4-fold lower strength gains may suggest that

training at larger knee angles may be preferable. References Kubo K, Ohgo K, Takeishi R, Yoshinaga K, Tsunoda N, Kanehisa H, Fukunaga T. (2006) *Scand J Med Sci Sports*, 16:159-67. INFLUENCE OF PRIMING EXERCISE ON LONG SPRINT RUNNING PERFORMANCE

Oliveira, M.F.M., Cruz, R.S.O., Junior, N.K., Caputo, F.

Santa Catarina State University

Introduction Warm-up is a well-accepted practice among athletes aiming performance improvements. It is generally accepted that prior exercise can enhance performance compared to situations in which no warm-up is performed. In this context, warm-up-related variables such as intensity, duration and recovery have been arranged to extract the best performance from the athlete. Therefore, this study investigated the effect of two warm-up protocols eliciting different pretest blood lactate concentrations (BLCPRE) on long sprint running performance and BLC response. **Methods** After a visit with the aim of familiarization with the 400-m performance test, eight active male subjects (22 ± 2 years, 75 ± 4 kg, 52 ± 3 mL·kg⁻¹·min⁻¹) were submitted to two different warm-up protocols on a treadmill, on different days. The easy protocol (WE) was performed at the velocity associated with the lactate threshold, resulting in BLCPRE indistinguishable from that of rest, while the hard protocol (WH) was conducted at the anaerobic threshold velocity and induced BLCPRE of approximately 4.6 mmol·L⁻¹. Both WE and WH exercise lasting for 15 min with a 5 min rest period followed by an all-out 400-m running performance in a synthetic track. **Results** There was a harmful effect of WH (67.01 ± 2.11 s) on 400-m performance when compared with WE (64.58 ± 1.56 s, $P=0.01$). Further 200-m split time analysis indicated an impaired second 200-m split about 4.4% after WH ($P=0.03$) compared to WE (WH: 37.14 ± 1.44 s; WE: 35.57 ± 1.21 s). The warm-up-induced effect on the first 200-m split time (WH: 29.87 ± 1.21 s; WE: 29.01 ± 0.89 s) presented a trend to be negative after WH (3%, $P = 0.08$). The amount of lactate accumulated with all-out 400-m performance was meaningfully decreased after WH (mean difference of 3 mmol·L⁻¹, $P=0.004$). **Conclusion** Our results showed that prior heavy-intensity exercise elevating pretest BLC above baseline levels result in a lower glycolytic contribution during the subsequent all-out performance than those performed without significant BLC accumulation. This impairment increased the time to complete the long sprint running, mainly during the latter half of the run, suggesting that subjects were getting increasingly slower throughout the race after the heavy protocol because of a limited anaerobic capacity. Whereas other modalities may be able to compensate this phenomenon by speeding VO₂ kinetics and increasing the aerobic contribution during exercise, long sprint running performed with an all-out strategy presents a very fast VO₂ kinetics, which proved unable to speed to a degree capable of overcoming the deleterious effect on anaerobic capacity. THE RELATIONSHIP BETWEEN PHYSICAL FITNESS PARAMETERS AND TECHNICAL EXECUTION IN YOUNG RHYTHMIC GYMNASTS

Kritikou, M., Donti, O., Bogdanis, G.C., Theodorakou, K.

National and Kapodistrian University of Athens

Introduction Faultless technical execution imposed on rhythmic gymnasts by the rules of the International Federation of Gymnastics (F.I.G) requires a high level of physical fitness parameters starting from a young age and continuing throughout a gymnast's career. The age between 9-12 years is considered as a critical period for future rhythmic gymnasts' evolution as physical fitness considerations optimize long-term training adaptations (Faigenbaum et al., 2009). Therefore, the aim of this study was to examine the effect of physical parameters on technical execution score in rhythmic gymnasts aged 9-12 years. **Methods** Nine rhythmic gymnasts (aged 9.0 ± 1.4 years, training experience 5 ± 1 years) all qualifiers of the all-around competition in the Greek national championship participated in this study. Technical execution was evaluated by two international judges according to the F.I.G Code of Points. The gymnasts underwent a series of physical fitness tests (body composition, active and passive flexibility, muscular power and endurance, agility and balance). Pearson's correlation coefficient (r) was used to detect linear associations among technical execution and physical fitness parameters. Univariate analysis of variance (ANOVA) examined the prediction power of several interactions of covariates on technical execution final score. **Results** There were significant correlations between the score of technical execution and balance, jump on the right leg and muscular endurance of the abdominals (0.737, 0.690 and 0.684 respectively, $p < 0.05$). Balance on the ball of the foot, single leg jumping ability and muscle endurance of the abdominals best predicted the final score of technical execution ($F=10.827$, $p=0.05$). ICC of the total score for the two judges was $r = 0.96$, $p < 0.01$. **Discussion** It is concluded that balance on the ball of the foot, jump ability on one leg and muscle endurance of the abdominals best predict technical execution in young rhythmic gymnasts. Rhythmic gymnasts are required to execute many different techniques of turns, jumps, leaps and balances structuring their future technical development. The results of this study provide information to coaches and specialists to understand the physical parameters that are related more with gymnasts' technical skill acquisition. **References** Faigenbaum AD, Kraemer WJ, Blimkie JR, Jeffreys I, Micheli LJ, Nitka M, Rowland TW. RESISTANCE TRAINING WITH SLOW MOVEMENT IN WING CHUN MARTIAL ARTISTS

Chirico, M., Rossi, A., Formenti, D., Alberti, G.

Università degli studi di Milano

Introduction The aim of this study was to evaluate the effect of a period with low intensity resistance training with slow movement until exhaustion (RTSM) in Wing Chun martial artists. It has been demonstrated that the ballistic training increases the movement velocity but decreases the force; in opposite the conventional resistance training increases the force but not the movement velocity (Olsen P.D., et al. 2003). Blood flow restriction resistance training with slow velocity of muscle action, without elastic cuff, performed with low load intensity, is considered an efficacy training method for improving muscular function (Alberti G., et al. 2013). Using resistance training in addition to standard ballistic training, may be a useful strategy for improving muscular function in martial artists. **Methods** 22 Wing Chun martial artists (31.82 ± 11.17 yrs; 23.64 ± 2.14 kg/m²) were randomly divided in 2 groups: experimental group (EG) performed 4 weeks, with 3 sessions per week, of RTSM (5s concentric and 5s eccentric) with 50% of 1RM in addition to the baseline training, whereas the control group (CG) continued their baseline training. Before and after the intervention, the subjects were tested on: 1 maximal repetition on bench press (1RM), peak power during bench press (PP) by using Kinovea (Balsalobre-Fernandez C., et al. 2014), and maximum punch repetition in 5s (MP5). To investigate within and between groups effect of the training intervention on these parameters, paired and unpaired t-test were performed. **Results** Significant difference was not found between the 2 groups before the training period. The EG improved PP ($p < 0.001$;

ES=0.63, moderate) and 1RM ($p<0.001$; ES=0.53, moderate), while the EG did not improve any parameters from pre to post training period. In the post test we found a significant difference between CG and EG only in 1RM ($p<0.05$; ES=1.11, very large). However the MP5 did not change from pre to post training in both groups. Discussion The higher values of EG in PP and 1RM in the post training showed that RTSM could be an efficient training method for improving general muscular function. Moreover, MP5 in EG did not decrease from pre to post training; this is probably due to the high specificity and the high neuromuscular demand of the punching technique (Vences Brito M., et al. 2011). These considerations demonstrate that such low intensity resistance method can be considered part of the routine training of Wing Chun martial artists. Reference Alberti G., et al. CALCULATING LACTATE ANAEROBIC THRESHOLDS IN DIFFERENT SPORTS

Gabryś, T.2, Szmatlan Gabryś, U.2, Stanula, A.1, Ozimek, M.1

University School of Physical Education, (Cracow, Poland)1, The Jerzy Kukuczka Academy of Physical Education, (Katowice, Poland)2.

Introduction Aerobic-anaerobic thresholds sought using methods that analyze changes in lactate concentration kinetics during incremental exercise are commonly used in athletic training as indicators of an athlete's endurance, preparedness, and training load parameters (Jacobs, 1985). The aim of this study was to establish the degree of similarity of exercise intensity values at the anaerobic threshold (AT) provided by five methods of lactate curve analysis, i.e., LT-AT, LT-loglog, 1 mmol AT, 4 mmol AT, and D-max. Methods All groups of athletes tested [Group 1: on-road cyclists ($n=19$) at international sporting level (participants of the Olympic Games and World Championships); Group 2: on-road cyclists ($n=20$) at national sporting level; Group 3: ice-hockey players ($n=24$) at international sporting level (Polish National Team); and Group 4: ice-hockey players ($n=22$) at international sporting level (Polish National Team U-20)] performed an incremental exercise. Results The greatest power values at the anaerobic threshold (PAT) were provided by the LT-AT (221.93 ± 34.5 W) and 4 mmol AT (226.38 ± 32.33 W) methods, whereas the lowest were provided by the LT-loglog (190.71 ± 25.92 W) method. The PAT produced by the LT-loglog method was statistically significantly lower ($p \leq 0.001$) than the values provided by LT-AT, 4 mmol AT, and Dmax. Discussion Analysis of PAT values in athletes representing disciplines involving different dominant types of energy metabolism (on-road cycling vs. ice-hockey) showed high repeatability of the parameter's values derived from different methods of lactate curve analysis (Stanula et al., 2012). Strong correlation between PAT was found in the international-level on-road cyclists, regardless of which method was used to find the LAT. References Jacobs I. (1986). Blood lactate. FOUR WEEKS OF CODS SPRINT TRAINING IMPROVE SPRINTING PERFORMANCE IN MALE ELITE JUNIOR SOCCER PLAYERS

Gundersen, H., Nilsen, A.K., Iversen, V., Myhre, Y., Kristoffersen, M.

Bergen University College

Background: Sprinting abilities are important in soccer, both linear speed and change of direction speed (CODS). The aim of this study was to investigate effects of two different training methods on linear sprint and CODS performance. Methods: 17 male junior elite soccer players (18 ± 1 years, 76 ± 4 kg) were divided into two groups and tested before and after a four week training intervention period. One group performed CODS training twice a week, whereas the second group performed repeated sprint (RS) training. 30m linear sprint and 30m soccer movement specific (SMS) sprint were tested. Times between 0–10m (T10), 10–20m (T10–20), 20–30m (T20–30) and 0–30m (T30) were recorded using Brower equipment. All tests were performed at an indoor area with synthetic grass, and same procedures were followed for all tests. Results: The results showed that CODS sprint training significantly improved performance on the 30m linear sprint test (T30: 4.20 vs. 4.16 sec, $p<0.046$, T10: 1.73 vs. 1.70 sec, $p<0.031$). They also improved the performance on the SMS sprint test (T30: 7.07 to 6.96 sec, $p<0.001$). There was no significant improvement on the 0-30m linear sprint test, or in the 0-30m SMS sprint test in the RS training group. Conclusion: CODS sprint training during 4 weeks is beneficial when acceleration improvement is important. Maximal speed is not influenced by CODS sprint training or by RS training.

SHUTTER GLASSES AS A TRAINING TOOL IN SPORTS VISION TRAINING – CHANGES IN VISUAL PERCEPTION ACCORDING TO FREQUENCY AND DUTY RATIO

Jendrusch, G.1, Platz, A.2, Sickenberger, W.2

1: Ruhr-Universität Bochum, Germany; 2: Ernst-Abbe-University of Applied Sciences Jena, Germany

Introduction Shutter glasses seem to be a tool for training visual functions in the context of sports vision training to increase movement coordination. Several studies discussed effects and non-effects of training with shutter glasses e.g. within coincidence anticipation (Smith & Mitroff, 2012; Reichow et al., 2010), motion cognition or short-time memory (Appelbaum et al., 2011 and 2012). No investigation justifies the training settings and strobe settings yet. Based on the necessity of an adequate load dosage to allow training effects, the present study intends to assess which strobe settings lead to a significant decrease of visual/perceptual performance. Methods 62 subjects (31m, 31f, median of age=25, median of visual acuity 1.6 (logMAR=-0.20)) took part in 13 test series to determine afferent motion perception (DTDS, Wist et al., 2000), reaction and anticipatory dynamic vision (Jendrusch & Ehrenstein, 2008), dynamic depth perception (three-rod-test according to Helmholtz) and peripheral awareness (Oculus Twinfield 2). The results with different randomized strobe rates (level 1-8) of shutter glasses (Nike Vapor Strobe) currently used in sports vision training have been compared. Results By increasing level (lower frequency and higher duty ratio) the afferent motion perception performance for stimulus motion duration of 280 and 420 ms decreases. Depth perception declines between level 2 and 8 respectively between level 5 and 8 according to the test velocity (7 vs. 2 mm/s). Maximum visual field decreases for blue stimuli between level 2 and 8 and for red stimuli between level 2 and 5. There is a larger decrease for red stimuli. These differences are statistically significant ($p \leq 0.05$). Reaction and anticipatory dynamic vision (timing) show no significant differences. Discussion For different visual performance skills lower frequency and higher duty ratio leads to increasing perceptual stress. No discrete levels for changes in performance were found. The combination of different requirements in sports needs an adjustment of training for each skill/sport-specific demand. However, generalized (nonspecific) training with the shutter glasses lacks effect-focused specificity. References Appelbaum LG, Schroeder JE, Cain MS, Mitroff SR. EFFECTS OF DIFFERENT EXERCISE PROGRAMS ON LACTATE RESPONSE

Onarici Gungor, E.1, Kurdak Sanli, S.2, Yilmaz, I., Ertan, H.1, Soyulu, R.3

1: AU (Eskisehir, Turkey), 2: CU(Adana, Turkey), 3 HU (Ankara, Turkey)

EFFECTS OF DIFFERENT EXERCISE PROGRAMS ON LACTATE RESPONSE Introduction An improvement in maximum oxygen uptake, exercise economy, lactate/ventilatory threshold parameters will result in an improvement of exercise performance (Jones and Carter., 2000). The effects of different exercise intensities on lactate responses and maximal oxygen consumption is not determined in inactive young males in previous studies. The goal of this study was to examine the changes of lactate responses and maximal oxygen consumption after sub-threshold and supra-threshold exercise program. Methods Twenty four (21 \pm 7 years) male volunteered participate in the study. All subjects were tested before and after exercise programs. Each subject underwent three exercise trials on a cycle ergometer. First, maximal progressive exercise test (pedaling rate=70 rpm; incremental work load 20 W.dk-1) was performed for to establish the individual VO₂max and ventilatory threshold (VT) and constant load cycle rides. After maximal test subjects performed sub threshold (%80 VT) and supra threshold (Δ 80%) constant load tests. Blood samples were taken every two minutes. Trainings were performed on a cycle ergometer four times per week for 30 min at sub-threshold (%80 VT) for 12 male and at supra-threshold (Δ 80%) for 12 other male. Results Lactate accumulation after the sub threshold and supra threshold exercise programs was statistically different ($P < 0.05$). The time to onset of blood lactate accumulation had increased after 6 weeks supra threshold exercise. Performance time was more after the two exercise programs ($P < 0.05$). But subjects attended supra threshold exercise terminated exercise 2 minute later. Sub threshold exercise elicited % 12,6 increase in maximum oxygen uptake ($P < 0.05$). Supra threshold exercise elicited % 16,2 increase in maximum oxygen uptake ($P < 0.05$). Discussion Performance time was more after two exercise program in this study. This result is supported with previous research (Esteve-Lanao et al., 2007). According to previous research the time to onset of blood lactate accumulation had increased after high intensity training. Although training loads were not the same their training load was also supra threshold (Jakeman et al., 2012). It can be said that supra threshold trainings more effective than sub threshold trainings for the onset of blood lactate accumulation. References Esteve-Lanao J, Carl F, Stephen S, Alejandro L. AEROBIC PARAMETERS AND MUSCLE STRENGTH: IS THERE A SINGLE MODE OF TRAINING ABLE TO IMPROVE BOTH CONCURRENTLY?

Caputo, F., Oliveira, M.F.M., Corvino, R.B., Denadai, B.S.

Santa Catarina State University

Introduction The use of multiple conditioning components to address both neuromuscular strength and aerobic fitness has become an important part of most recommended exercise regimens (ACSM, 2011). However, few studies have looked for training methods that can effectively and concurrently improve both cardiovascular and neuromuscular parameters using a single mode of training. Thus, the purpose of the present study was to verify the effects of low-intensity blood flow restricted interval training (BFR), high intensity interval training (HIT) and the combination of both (BFR+HIT) on aerobic indexes and muscle strength. Methods Thirty-three physically active male and female subjects were assigned to one of four groups: low-intensity interval training with (BFR, $n = 9$) or without (LOW, $n = 6$) blood flow restricted; HIT ($n = 9$) and BFR+HIT ($n = 9$). Before and after 4 weeks intervention period, all subjects performed the following tests on separated days: 1) incremental exercise to determine the maximal oxygen uptake (VO₂max) and maximal power output (PMAX); 2) maximal isometric knee extension torque (MVC). The interval training sessions consisted of 2 sets of 5-8 \times 2-min intervals with 1 min of rest, at 30%PMAX for LOW and BFR, at \sim 103%PMAX for HIT. BFR+HIT performing one set of each training mode (BFR and HIT) in the same training session. During BFR training mode a cuff was inflated (140-200mmHg) during the exercise bouts and deflated during rest intervals. Results The training-induced VO₂max and PMAX change scores percentages (median (25%-75%-percentiles) were similar among BFR [4.9(1.8/8.1); 11(7.8/15.2)], HIT [7.9(4.5/15.4); 15.0(9.3/18.5)] and BFR+HIT [6.9(4.9/8.0); 11.2(6.8/13.8)] respectively, but not for LOW [0.8(-2.4/2.1); 2.5(0.0/5.2)]. However, the training-induced MVC change score percentage was significantly higher in BFR [9.3(4.7/16.6)] compared to HIT [-2.9(-8.5/1.0)], BFR+HIT [-3.0(-8.2/1.7)] and LOW [-2.2(-7.4/3.0)]. Conclusion It can be concluded that BFR, HIT and BFR+HIT training modes are similarly effective in provoking the physiological adaptations, which acted collectively to improve the selected aerobic indexes (VO₂max and PMAX), in active subjects. However, significant changes on MVC were observed only for the group that performed two sets of BFR training mode. Therefore, the magnitude of increased metabolic and physiologic strains induced by blood flow restriction seem been responsible to trigger the adaptive responses linked to enhanced muscle strength. These findings support the feasibility of BFR training method for individuals who intend to maintain or increase both aerobic fitness and muscle strength levels, when high mechanical loads could be contraindicated. THE ROLE OF INSTABILITY WITH CORE STRENGTH TRAINING IN ADOLESCENTS

Granacher, U., Schellbach, J., Klein, K., Prieske, O., Baeyens, J.P., Muehlbauer, T.

University of Potsdam

Introduction It has been demonstrated that core strength training is an effective means to enhance trunk muscle strength (TMS) and mass as well as athletic performance in youth (Hoshikawa et al., 2013). Furthermore, the integration of unstable elements in strength training has been advocated to improve neuromuscular performance (Behm et al., 2010). However, the role of instability with core strength training is unresolved in youth. Therefore, this study investigated the effects of core stability (CST) vs. core instability strength training (CIST) in adolescents on measures of physical fitness (i.e., strength, speed, flexibility, coordination, balance). Methods Twenty-seven healthy adolescents (14 girls, 13 boys) participated in this study and were randomly assigned to a CST ($n=13$, age 13.7 ± 0.6 years) or a CIST group ($n=14$, age 13.8 ± 0.9 years). Both training programs lasted six weeks (2 sessions/week) and included the "big 3" core exercises (curl-up, side bridge, bird-dog). During CIST, these exercises were conducted on unstable surfaces (e.g., TOGU® DYNAIR CUSSIONS, TOGU® REDONDO BALLS, TOGU® SWISS BALLS). Pre and post measurements included the Bourban TMS test, the standing long jump test, the 20-m sprint test, the stand-and-reach test, the jumping sideways test, the Emery, and the Y balance test. Additionally, effect sizes (f) were calculated. Results Trends towards significance ($p < .10$) or significant ($p < .05$) main effects of time were observed for the Bourban TMS test, the standing long jump test, the stand-and-reach test, the jumping sideways test, and the Y balance test (0-22%, $f = 0.39-1.07$). We could not

detect any significant main effects of group. Significant Group x Time interactions were found only for the stand-and-reach test in favor of the CIST group (2%, $f = 0.54$). Discussion Core strength training resulted in significant increases in measures of physical fitness in adolescent boys and girls. However, CIST as compared to CST has only limited additional effects (i.e., stand-and-reach test) on physical fitness. Consequently, if the goal is to enhance physical fitness, CST appears to be a sufficient training stimulus. HYPERLACTEMIA INDUCTION MODES IN THE LACTATE MINIMUM TEST RESULTING IN DIFFERENT BLOOD PH AND BICARBONATE VALUES, BUT NOT AFFECTING THE LACTATE MINIMUM INTENSITY

Zagatto, A.1, Padulo, J.2, Müller, P.3, Miyagi, W.1, Malta, E.3, Papoti, M.4

1Sao Paulo State University (Brazil); 2Tunisian Research Laboratory

Introduction The lactate minimum test (LMT) is considered a valid procedure for estimating the maximal lactate steady state intensity (MLSS) in a single-session test (2), estimating the MLSS by using a direct physiological criterion to identify the maximal blood lactate production-removal equilibrium (1). Despite general acceptance of LMT, the effect of the hyperlactemia induction mode on lactate minimum intensity (LMI) determination is not well clarified and it could alter the LMI. The aim of this study was to verify the influence of hyperlactemia and blood acidosis induction on LMT. **Methods** Twelve males, who were recreationally trained and experienced in cycling (seven cyclists and five triathletes), participated in this study. The athletes underwent three lactate minimum tests (LMT) on an electromagnetic cycle ergometer. The hyperlactemia induction methods used were: graded exercise test (GXT), Wingate test (WAnT) and two consecutive Wingate tests (2xWAnTs). **Results** The venous pH after 2xWAnTs (7.11 ± 0.07) was lower ($P < 0.05$) than in the GXT (7.19 ± 0.05) and WAnT (7.20 ± 0.05) induction modes respectively. Similar findings were observed for bicarbonate concentration ($[HCO_3^-]$) (2xWAnTs lower than WAnT; 16.5 ± 2.5 mmol•L⁻¹ and 19.1 ± 2.2 mmol•L⁻¹ respectively ($P < 0.05$). In addition, the maximal aerobic power and total time measured during the incremental phase were higher in the LMT with WAnT (260.9 ± 11.4 W and 27.4 ± 2.6 min) than the other LMTs (248.4 ± 12.0 W and 25.1 ± 2.8 in GXT; 249.9 ± 10.4 W and 24.9 ± 2.3 min in 2xWAnTs). However, statistical differences in LMI values (187.6 ± 29.7 W in GXT, 194.4 ± 32.6 W in WAnT and 196.4 ± 27.7 W in 2xWAnTs) and respiratory parameters at LMI (35.6 ± 1.2 ml/kg/min in GXT, 38.0 ± 2.0 ml/kg/min in WAnT and 7.0 ± 1.5 ml/kg/min in 2xWAnTs) were not found. **Conclusion** Thus, we can conclude that despite the induction mode significantly affecting both pH and $[HCO_3^-]$, it did not alter the lactate minimum intensity and physiological parameters at LMI. Therefore, our findings conclude that the mode of hyperlactemia induction is not a parameter that affects LMI determination, but it can limit the maximal aerobic power and test duration. **References** 1. STATIC STRETCHING OF THE ANKLE DORSIFLEXORS IMPROVES VERTICAL JUMP PERFORMANCE IN YOUNG HEALTHY MEN.

Sempf, F.1, Brahms, C.M.2

1: Georg-August-University Göttingen, 2: University of Regina

Introduction Pre-exercise static stretching has been shown to negatively affect a muscle's force-generating potential (Rubini et al., 2007; Behm et al., 2007). Consequently, it has been suggested that this activity should be avoided prior to strength and power activities (Kokkonen et al., 1998). However, static stretching may also enhance force output of antagonist muscles and improve performance in antagonist-driven movements (Blazevich et al., 2011; Sandberg et al., 2012). The ankle plantarflexors contribute significantly to vertical jump performance (Luhtanen et al., 1978). Therefore, the purpose of this study was to examine if static stretching of the ankle dorsiflexors has a positive effect on vertical jump height. **Methods** 39 male subjects were randomly assigned to either a treatment (T) or a control group (C). Both groups performed a 5-minute warm-up on an elliptical trainer and were subsequently tested for their maximal CMJ height. Jump height was recorded using a GymAware Powertool that was connected via a waist belt to the participants. Retesting occurred after a 5-minute rest period, with the treatment group stretching the dorsiflexors for 45 seconds immediately before retesting. **Results** A significant main effect existed for test condition, while no main effect was found for groups. Vertical jump height of (T) was significantly higher after the stretching intervention, compared to baseline values ($+1.62$ cm; $p = .0008$). No significant changes were found between jumping trials in the control group ($+0.05$ cm, $p = .839$). **Discussion** The results show that individuals who stretched their dorsiflexors prior to a CMJ, significantly improved their vertical jump performance. Although the study did not investigate the possible causes of this effect, static stretching might inhibit the force output of the dorsiflexors, thus producing a greater plantarflexor moment at the ankle joint (Cramer et al., 2005). Mechanisms that have been proposed to cause a stretch-induced decline in muscle force are changes in the visco-elastic properties of skeletal muscle and altered neural drive (Behm et al., 2001; Kokkonen et al., 1998). **References** Behm D, Button D, Butt J (2001). *Can J Appl Physiol*, 26, 261-272. MUSCLE STRENGTHENING EFFECT OF URSOLIC ACID ON BODY BUILDERS

Seo, D.Y.1, Bang, H.S.2, Chung, Y.M.3, Oh, K.M.3, Kim, M.S.2, Kim, D.H.3, Lee, S.R.1, Kim, N.1, Rhee, B.D.1, Ko, K.S.1, Han, J.1

1Cardiovascular and Metabolic Disease Center, Inje Univ., 2Division of Humanities and Social Science, POSTECH, 3Department of Physical Education, Tong Myong Univ.

Ursolic acid (UA), a type of pentacyclic triterpenoid carboxylic acid purified from natural plants, may affect muscle mass and strength but its effectiveness in resistance-trained men is unknown. Here, we assessed whether UA has a beneficial effect on the adaptive response to prolonged resistance training (RT) in body builders. Sixteen male body builders (age, 29.37 ± 5.14 years; body mass index = 27.13 ± 2.16 kg/m²) were randomly assigned to RT (n = 7) or RT with UA (RT+UA, n = 9). Both groups completed 8 weeks of intervention consisting of 5 sets of 26 exercise, with 10-15 repetitions at 60-80% of one-repetition maximum intensity and a 60-90-s interval between sets, performed 6 times/week. UA or placebo was orally ingested as 1 capsule 3 times/day for 8 weeks. Although RT+UA supplementation

decreased body fat percentage, it did not change body weight, body mass index, lean body mass, or glucose and insulin levels. Levels of insulin-like growth factor-I, irisin, and maximal muscle strength significantly increased compared with baseline levels in the RT+UA group versus the RT group. Furthermore, RT with UA was able to reduce body fat and increase IGF-I, irisin, and muscle strength without increasing skeletal muscle mass.

"HEARING IMPAIRED" AND "NON-HEARING IMPAIRED" ATHLETES: WE CAN SPRINT TOGETHER!

Barmparigos, P., Argeitaki, P., Paradisis, G., Zaharogiannis, E., Theodorou, A., Tsiganos, G., Smirniotou, A.

National and Kapodistrian University of Athens

Introduction Hearing impaired (HI) and non-hearing impaired (NHI) track and field athletes do not participate in the same competitions. Auditory stimuli, tone and voice commands, used in the competitions for the NHI athletes, cannot be processed and controlled by HI athletes. What would happen if we used stimuli that produce the same level of comprehension in both categories of athletes? A pilot study was conducted aiming to examine if HI and NHI athletes can compete evenly in the same track event. **Methods** The possible changes in reaction time (RT) of HI and NHI athletes were evaluated during sprint start (SS), using 3 types of stimuli: auditory (AS), visual (VS) and audiovisual (AVS). Six HI athletes and 6 NHI athletes participated in the study. All followed the same familiarization and coaching procedures. Each subject performed 3 SS attempts to each stimuli, with a 4-minute interval in between. Each stimuli-testing procedure was executed on different days. RT to AS type of stimuli, evaluated by ReacTime Training System (RTTS), Lynx-USA. RT in the VS measured by a fixed self-constructed pattern which produced light and was synchronised with the RTTS, to ensure validity and reliability. The existence or absence of light was equivalent to voice commands and audible start up sounds of the RTTS. The same wiring was also used to evaluate RT with AVS. Means, standard deviation (\pm SD) and ANOVA was used to reveal the interactions of the variables. SPSS 20.0 was used for statistic analysis. **Results** The smallest RT value was achieved with the VS (110ms.). HI and NHI athletes demonstrated better RT with AS (382 \pm 234ms.) compared to VS (551 \pm 441ms.). The combined stimuli AVS was (662 \pm 521ms.). Men performed better RT (399ms.) compared to women RT (596ms.) (Shelton and Kumar, 2010). Additionally, RT (466ms.) of NHI athletes was better to that of the HI athletes (659ms.) to all stimuli. **Discussion** The smallest reaction time value was recorded using visual stimuli. Most athletes from both groups (hearing impaired and non-hearing impaired) demonstrated better reaction time with auditory stimuli (Pain and Hibbs, 2007) rather than with the audiovisual stimuli. Probably, this was due to the chronic familiarisation with auditorium stimuli, as opposed to the visual or audiovisual stimuli. Further research is needed to investigate if athletes can achieve better reaction times when they are familiarised to being trained under visual stimuli. In that case hearing impaired and non-hearing impaired athletes will be able to participate in the same events. **References** Shelton J., & Gideon Praveen Kumar G. P. (2010). *Neuro Science & Medicine*, 1, 30-32. Pain M. T., & Hibbs A. (2007). *Journal Sports Science*, 25 (1), 79-86. Contact prosportstrainer@yahoo.gr

RELATIONSHIP BETWEEN TRAINING LOAD AND DIFFERENT MONITORING MEASURES IN TEAM SPORTS

Everett, K.1, Janse de Jonge, X.1, de Jong, N.2, de Ruijter, C.J.2, Nosek, P.1, Hillebrandt, H.1, Clark, A.1

1 University of Newcastle Australia 2 Research Institute MOVE, VU University Amsterdam, the Netherlands

In order to achieve optimal performance it is essential to monitor an athlete's response to training load (TL). Especially in team sports it is important that monitoring methods are field based and quickly allow coaches to "red flag" players who may not be coping. Jump testing and wellness questionnaires are frequently used as monitoring tools in team sports. Furthermore TL based on Rating of Perceived Exertion (RPE) is easily collected and accumulated weekly TL is often used in periodisation planning. This study investigated the relationship between accumulated TL and both jump testing and a visual analogue scale (VAS) for fatigue as player monitoring tools. Twelve male professional soccer players (age 27 \pm 5 yrs, height 1.79 \pm 0.06 m, weight 78 \pm 7 kg) were monitored over eight weeks. During all training sessions (n=43) RPE was collected. Jump testing was performed two to three times per week (n=20) and consisted of 10 repeated stiffness jumps, 1 min rest, and 5 repeated counter movement jumps (CMJ). Flight and contact times were recorded (Optojump, Microgate, Italy) and used to calculate maximal power for stiffness jumps and maximal height for CMJ. At testing a VAS for fatigue was also completed. TL was estimated as session-RPE x duration. Daily TL was calculated and summated to create overall TL from 1 to 7 days leading up to jump testing. For each individual athlete correlations were calculated between TL and each of the monitoring measures (max power, max height, fatigue), as well as between jump measures and fatigue. The correlations between both jump performance measures and accumulated TL for one and two days prior to jumping were low. These correlations increased for TL over 3-7 days with a maximum correlation of -0.42 \pm 0.17 for stiffness jumps at 4 days and -0.37 \pm 0.17 for CMJ at 7 days. The fatigue VAS showed the highest correlation with accumulated TL over 2 days (0.56 \pm 0.23), then decreased to 0.37 \pm 0.27 over days 3-7. Correlation between fatigue and stiffness jumps was -0.29 \pm 0.22, and CMJ was -0.33 \pm 0.30. Large variation in all correlations was found between players, with 8 players in stiffness jumps and 5 players in CMJ recording correlations with TL stronger than -0.5. It appears that jump testing, in particular stiffness jumps, better reflects accumulated TL over 3-7 days, while fatigue VAS shows a more direct response to TL. The main limitation of this project, however, was that TL and testing days were set by coaching staff. Limited variation in accumulated TL may have contributed to weaker correlations. Overall, the combination of stiffness jump testing with fatigue VAS appears to provide a useful monitoring method to "red flag" team sport players.

SENSOR-BASED SIT-TO-STAND MEASURES ARE ASSOCIATED WITH FUNCTIONAL STATUS IN OLDER ADULTS

Regterschot, G.R.H.1, Zhang, W.2, Baldus, H.2, Stevens, M.1, Zijlstra, W.1,3

University of Groningen, University Medical Center Groningen

1: University of Groningen, University Medical Center Groningen, Center for Human Movement Sciences, Groningen, The Netherlands, 2: Philips Research, Eindhoven, The Netherlands, 3: Institute of Movement and Sport Gerontology, German Sport University Cologne, Cologne, Germany. **Introduction** Leg muscle power is associated with functional status in older people (Foldvari et al., 2000). The use of body-fixed motion sensors during sit-to-stand (STS) movements may provide clinicians with a practical method to estimate leg muscle power (Zijlstra et al., 2010). This study investigated whether sensor-based measures of STS performance (including STS peak power) are associated with functional status in older adults. This study also investigated the discriminative ability of sensor-based measurement of STS peak power for classification of higher and lower functioning older adults. **Methods** Participants (24 females, 12 males; age: 72-94 years) performed five normal STS movements while wearing a hybrid motion sensor on the hip and chest. Functional status was assessed using standard clinical measures (Timed Up and Go test, Five-Times-Sit-to-Stand test (FTSST), stair walk test, leg muscle strength, Groningen Frailty Indicator, Groningen Activity Restriction Scale). **Results** STS peak power and scaled peak power assessed at the chest

were significantly associated (r : 0.46-0.70; $p \leq 0.01$) with all measures of functional status. STS peak power and scaled peak power assessed at the hip showed significant associations (r : 0.34-0.51; $p < 0.05$) with all measures of functional status, except FTSST. Also STS maximal velocity and SD stabilisation phase measured at the chest were significantly associated (r : 0.43-0.76; $p < 0.05$) with all measures of functional status. STS peak power and scaled peak power assessed at the chest showed a moderate discriminative ability (area under the ROC curve: 0.75-0.90). Discussion This study shows that sensor-based STS measures are associated with functional status in older adults. Results indicated that STS measures assessed with a sensor at the chest are somewhat stronger associated with functional status than STS measures assessed with a sensor at the hip. Furthermore, this study shows that sensor-based measurement of STS peak power can be used to select higher and lower functioning older adults. The presented sensor-based method may be useful for the clinical evaluation of functional status in older people. ACCURACY AND RELIABILITY OF VXSPORT GLOBAL POSITIONING SYSTEM IN INTERMITTENT ACTIVITY

Malone, S.I, Collins, D.K.I, McRobert, A.P.2, Morton, J.2, Doran, D.A.2

1: ITTD (Dublin, Ireland), 2: LIMU (Liverpool, England),

Introduction The use of global positioning systems (GPS) technology for evaluation of match-play or preparatory practices is common place within team sports, however its use requires validation of distance traveled. The aim of the present study was to determine the accuracy and reliability of a 4Hz GPS device (VXsport, New Zealand). Methods Nine well-trained participants undertook the study. Five separate runs on a self-paced intermittent sport simulation (AFL) measured via trundle wheel (Hiscock et al., 2012) were completed. Each participant repeated the protocols at the same time of day no less than 7 days apart. Test-retest reliability for total distance (m), maximum speed (km.hr⁻¹) and average speed (km.hr⁻¹) were quantified. Data is communicated as mean \pm sd. To evaluate systematic differences, a paired t-test on the test-retest data was performed. Reliability was assessed using the typical error and the coefficient of variation (CV%), which were expressed with 95% confidence intervals (\pm 95% CI) (Hopkins, 2000). Results The test retest for total distance (300.5 \pm 3.3; 303.6 \pm 5.6 m), maximum speed (23.9 \pm 1.9; 24.1 \pm 1.3 km.hr⁻¹) and average speed (10.2 \pm 1; 10.2 \pm 0.9 km.hr⁻¹) showed no significant difference. The typical error (TE \pm 95% CI) was .84 \pm 0.3 for total distance, 0.75 \pm 0.26 for maximum speed and 0.55 \pm 0.19 for average speed respectively. All of the measured variables demonstrated a CV (CV% \pm 95% CI) of less than 5%, which was 1.0 \pm 0.4 for total distance, 4.2 \pm 1.5 for maximum speed and 4.4 \pm 1.5 for average speed respectively. Discussion These metrics are similar to that reported for other GPS devices. The data were found to be accurate and the devices are suitable for use in the measurement of intermittent physical activity during training practices and match play in games such as AFL, soccer, Gaelic football and other intermittent field sports. LONGITUDINAL CHANGES IN BODY COMPOSITION AND FITNESS PROFILES OF ELITE MALE JAPANESE WRESTLERS

Arakawa, H.

Japan Institute of Sports Sciences

Introduction Wrestling is a well-known combat sport that requires its practitioners to have enhanced physical fitness to attain competitive success. Examining how elite wrestlers develop their physical fitness over their careers would be beneficial to optimizing training programs and scouting new talent. However, no longitudinal study has followed up on the fitness profiles of successful wrestlers. The aim of this study was to investigate longitudinal changes in the fitness profiles of elite male Japanese wrestlers in their 20s, the period around which competitiveness reaches its peak. Methods We longitudinally analyzed a series of measurements of members of the Japanese national wrestling team. These measurements have been collected regularly for the past several years. Body composition, including percent body fat and lean body mass, was assessed by bioimpedance analysis. Anaerobic power and strength assessment included 3 \times 30 s sit-ups; 2 \times 6 m rope climbing; back strength; and 1-repetition maximum (1-RM) for bench press, high clean, and squat. Endurance assessment included 6 \times 300 m intermittent running (300 m IR), 1500 m running, and 12 min running. The data of each wrestler were assigned to 3 periods by age when the tests were conducted (20-22 y, 23-24 y, >25 y). Results Among the anaerobic power and strength measurements, number of sit-ups, back strength, and high clean 1-RM significantly improved by 19%, 7%, and 25%, respectively, over the observed period ($P < 0.05$). However, no significant improvements were detected in body composition. As for the endurance tests, although the total time for the 300 m IR test improved significantly over the observed period (5% decrease, $P < 0.05$), the results for the 1500 m and 12 min running tests did not. Discussion Results of the longitudinal analysis indicate that the elite male Japanese wrestlers had improved their performance in exercises related to anaerobic power and strength relative to when they were 20-22 years old. This finding suggests that wrestlers who will eventually become successful do not achieve their maximal anaerobic performances in their early 20s and instead have some trainability and further development potential. Furthermore, the results of the three endurance measures demonstrated that the wrestlers had improved their performance in only the 300 m IR test. This indicates that elite wrestlers specifically improve their endurance as it relates to high-intensity exercise. Such a specific development might be attributable to the specific characteristics of a wrestling match, such as its relatively short duration and high-intensity muscular output.

DIFFERENTIATED RATINGS OF PERCEIVED EXERTION: HOW DO PEOPLE PERCEIVE EXERTION DURING CYCLING AND HANDCYCLING?

Hettinga, F.J.I,2, Oldenburg, M.2

University of Essex

(1)University of Essex, School of Biological Sciences, Centre of Sport and Exercise Science, Colchester, United Kingdom; (2)Center for Human Movement Sciences, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands. ABSTRACT Introduction: Ratings of perceived exertion (RPE) provide a subjective estimation of exercise intensity, commonly used in lower body exercises such as cycling and running. However, the question as to whether these results can be applied in upper body exercise, as is relevant for wheelchair users or sports performance with a focus on upper body exercise, is debatable. Objective: The purpose of this study was to better understand (perception of) fatigue in upper body exercise. More specifically, the current study focused on whether differentiated RPE's (local, central and overall) were affected by exercise mode (upper versus lower body exercise) and by upper body training. Methods: Eight well trained male rowers (23.4 \pm 2.1yr; 87.9 \pm 9.2kg; 1.89 \pm 0.05m; 5.5 \pm 2.5h exercise per week) completed an incremental cycling

test (CY) and an incremental handcycling test before (HCpre) and after three weeks of handcycle training (HCpost). Non-Parametric Friedman tests were used to compare differences between CY/HCpost and HCpre/HCpost in central (RPE-C, reported on a 6-20 scale), local (RPE-L, reported on a 1-10 scale) and overall (RPE-O, reported on a 1-10 scale) perceived exertion ($P < 0.05$). Results: Participants reported higher peak RPE-C during CY compared to HCpost (resp. 17.4 ± 2.4 ; 15.9 ± 1.9). In contrast, higher values of peak RPE-O were reported during HCpost (CY: 8.3 ± 1.1 ; HCpost: 9.1 ± 0.6) ($P < 0.05$). After HC training, significant changes were noted in peak RPE-O (HCpre: 7.9 ± 0.9 ; HCpost: 9.1 ± 0.6) and peak RPE-C (resp. 14.6 ± 2.6 ; 15.9 ± 1.9). No differences were found for peak RPE-L between CY/HCpost and HCpre/HCpost. However, throughout the incremental HC tests, RPE-L was reported consistently higher in each sub/maximal stage than RPE-O at the same power output. Conclusion: At exhaustion, RPE-C seems to play a larger role in CY compared to HC. RPE-O on the other hand plays a larger role at exhaustion in HC. Furthermore, RPE-L is perceived higher than RPE-O during all sub-maximal stages of the incremental HCtest. Overall, these results suggest that exertion is perceived differently in upper body exercise compared to lower body exercise, with a somewhat larger peripherally oriented focus in handcycling compared to a more centrally oriented focus in cycling. The use of RPE-C as a measure of perceived exertion in upper body exercise, as is commonly obtained in lower body exercise, therefore needs to be interpreted with caution. The inclusion of an additional focus on local perceived exertion might be advisable when ratings of perceived exertion in upper body exercise are obtained in rehabilitation and/or sports settings.

COMPARISON BETWEEN VENTILATORY THRESHOLD AND HEART RATE VARIABILITY INDEXES IN NONATHLETES

Neumamm, L.B.A., Bartels, R., Leão Nunes, M.V., Jandre, F.C., Giannella Neto, A.

Federal University of Rio de Janeiro (UFRJ)

COMPARISON BETWEEN VENTILATORY THRESHOLD AND HEART RATE VARIABILITY INDEXES IN NONATHLETES Introduction Heart rate variability (HRV) is a non-invasive tool for cardiac autonomic modulation assessment. Classical HRV analyses are widely used at rest conditions. Alternative methods for assessing autonomic function in non-stationary periods, such as during exercise, allow the identification of the ventilatory threshold (VT) using HRV. However, few studies addressed this issue in untrained subjects. The aim of this study was to assess HRV methods for VT determination in nonathletes. Methods Fifteen healthy male, nonathletes subjects underwent a maximal progressive exercise on a cycle ergometer (CG-08, Inbrasport, Brazil). The protocol consisted in 3 min of rest followed by a 3 min warmup at 5 W. Then the work rate was increased by 25 W per minute, until volitional fatigue. Ventilatory variables (VO₂ and VCO₂) were obtained breath-by-breath using a gas analyzer (Innocor, Denmark). RR intervals were continuously recorded with an electrocardiograph (Ecafex, Brazil). The v-slope method (Beaver et al., 1986), was used as the gold standard method for VT detection and compared to three indexes derived from HRV analysis: visual stabilization of the RMSSD (HRVT1) (Karapetian et al., 2008); reduction of SD1 below 3 ms (HRVT2) (Lima and Kiss, 1999) and from frequency domain (HRVT3) (Cottin et al., 2004). Bland-Altman method and Wilcoxon test were employed to assess differences between VT, HRVT1, HRVT2 and HRVT3. Significance level was set at $p < 0.05$. Results No difference was found between VT (226.0 ± 60.5 (s); 81.6 ± 24.0 (W); 128.1 ± 22.0 (bpm)) and HRVT1 (174.8 ± 49.5 (s); 70.0 ± 35.6 (W); 108.8 ± 15.9 (bpm)) or HRVT2 (246.9 ± 141.2 (s); 98.3 ± 64.4 (W); 129.7 ± 18.5 (bpm)). However, significant difference was found between VT and HRVT3 (320.2 ± 123.6 (s); 116.6 ± 57.9 (W); 145.1 ± 17.6 (bpm)) ($p < 0.05$). HRVT1 tended to underestimate VT for higher VT values ($p < 0.05$). Discussion The bias found between VT and HRVT3 may be due to distinct physical training level of the participants in both studies, which indicates that this method can be accurate only for athletes. Besides no difference was found between HRVT1 and VT, it showed a trend to underestimate higher values of VT, suggesting that this method is acceptable for nonathletes, but may incorrectly detect VT in athletes. Therefore, due to the lack of difference from VT and trend of HRVT2, it seemed to be the best method to estimate VT for all training levels. THE INFLUENCE OF RESISTANCE TRAINING USING A LOAD OF 65% TO 85% MAXIMAL VOLUNTARY CONTRACTION WITH SHORTER INTERVAL ON THE INTRAMUSCULAR OXYGENATION IN BICEPS BRACHII AND TRICEPS BRACHII

Masahiro, G.1,2, Takafumi, H.1, Yuko, K.1, Tadashi, S.1, Toshiyuki, H.1, Shinsuke, N.1, Takeshi, S.1

Ritsumeikan University

Introduction Resistance training using a load of 65% to 85% maximal voluntary contraction with shorter interval is recommended for muscular hypertrophy. There is a greater increase in the area of fast twitch fibers compared to slow twitch fibers during several months after starting training (Tesch PA, 1988). On the other hand, there is also a report that the slow twitch fiber got hypertrophy on body builders (Kraemer WJ. et al., 1994). The aim of this study was to investigate the influence of long-term particular training on intramuscular oxygenation in biceps brachii and triceps brachii. Methods Twenty one male subjects were divided into three groups according to their training history, no-training history (group A), less than one year training history (group B), and over one year training history (group C). Isometric elbow joint flexion and extension exercise were performed for fifteen-second with thirty-second interval at intensities corresponding to 50%, 60% and 70% of maximal voluntary contraction (MVC). Oxygenated hemoglobin (O₂-Hb) and total hemoglobin (tHb) were measured with near-infrared spatial resolved spectroscopy from the biceps brachii and triceps brachii. Deoxygenation-rate during muscle contraction was calculated using Hamaoka's method (Hamaoka et al. 1998). Surface electromyographic (EMG) activities from the biceps brachii and triceps brachii were recorded. Root mean square (RMS) and mean power frequency (MPF) were calculated for each 1000 ms period. Results Deoxygenation-rate during isometric exercise of group C was the highest in both biceps brachii and triceps brachii. In all the loads, a significant difference was seen between group A and group C. MPF of biceps brachii at 70%MVC exercise were 46.5Hz on group A, 57.0 Hz on group B and 59.4Hz on group C. MPF of triceps brachii at 70%MVC exercise were 44.3Hz on group A, 58.5Hz on group B and 45.1Hz on group C. RMS on group B and C was higher than that of group A. Discussion The oxygen capability of group C was the highest, and it was suggested that the group C is producing ATP using more oxygen in all the exercise intensity. SUBJECTS VS INSTRUCTOR PERCEIVED TRAINING LOAD IN TRX FITNESS ACTIVITY

Giancotti, G.F.1, Foster, C.2, Alfaro Sanhueza, S.P.1, Capranica, L.3, Cortis, C.1

1 University of Cassino and Lazio Meridionale; 2 University of Wisconsin-La Crosse 3 University of Rome "Foro Italico"

Introduction The use of suspension straps (TRX) has recently become a popular form of exercise in fitness centers as a form of resistance training, designed to train stable body positions (McGill et al 2014). Rating of perceived exertion (RPE) and muscular pain (RMP) are widely used as estimate of exercise intensity and to quantify training load in sport activities. Few studies have investigated their applicability in fitness activities (Cortis et al 2013). Moreover, a lack of correspondence between the training load as designed by coaches and as executed by athletes has been demonstrated (Foster et al 2001), although comparable information has not been reported on fitness activities. Therefore, the aim of this study was to compare instructor's and subjects' perceptions of training load in TRX. **Methods** Following informed consent, 58 volunteers (M=21; F=37) regularly (3 weekly sessions) practicing TRX, participated in the study. RPE, upper (RMPU) and lower (RMPL) limb values were recorded for each subject (RPEs, RMPUs, RMPLs) 30-min following the exercise session (Foster et al 1995). Instructors filled in the rating of intended exertion (RPEi) and muscle pain (RMPUi, RMPLi) for each participant based on class observation. Differences ($p < 0.05$) between subjects' and instructor's values (RPEs vs RPEi; RMPUs vs RMPUi; RMPLs vs RMPLi) were tested by means of repeated measures and Pearson correlations. Results There were no differences between subjects' and instructor's values for RPE and RMPL, while RMPUi (6.2 ± 1.5) was higher ($p = 0.02$) than RMPUs (5.4 ± 2.3). Correlations were weak to moderate between subjects' and instructor's (RPE: $r = 0.5$, $R^2 = 0.3$, $p < 0.0001$; RMPU: $r = 0.6$, $R^2 = 0.3$, $p < 0.0001$; RMPL: $r = 0.4$, $R^2 = 0.1$, $p < 0.004$), with subjects (RPEs: 6.5 ± 1 ; RMPLs: 5.5 ± 1.8) perceiving training less intense than the instructors (RPEi: 6.8 ± 1.6 ; RMPLi: 6.2 ± 1.8). **Discussion** The present findings indicate reasonable correspondence between subjects' and instructor's RPE and RMPU, although weak correlation was found with respect to RMPL. RPEi and RMPUi could be a useful and practical method to monitor training load during TRX. RMPLi should be used cautiously, although it has to be considered that RMPU and RMPL strongly depend on the specific exercises and muscle involved during the session. **References** Cortis C et al (2013) Ital J Anat Embryol, 118: 64. EFFECTS OF SHORT-TERM TRAINING COMBINING STRENGTH AND BALANCE EXERCISES IN THE ELDERLY

Penzer, F., Duchateau, J., Baudry, S.

Université Libre de Bruxelles

Introduction Ageing is associated with reduced strength and impaired balance, both contributing to an increased risk of falling. If few studies have reported that training programmes combining balance and strength exercises improved postural control and muscle strength (Granacher et al. 2011), the optimal proportion of both types of exercises to improve the latter factors remains to be defined. The purpose of this study was to investigate in elderly adults the effects of two short-term training protocols differing in the respective proportions of strength and balance exercises. **Methods** Eighteen elderly adults (>65 yrs) completed a 6-week training programme (two sessions/week). Strength training (ST; 10 subjects) consisted of 75% and 25% of strength and balance exercises, respectively, whereas the proportion was reversed in the balance training (BT; 8 subjects). Before and after training, plantar flexors strength was assessed by maximal voluntary contraction (MVC). Superimposed train of three stimuli were used to determine the central activation ratio (CAR). In addition, torque steadiness was measured during submaximal isometric contractions at 10 and 20 % MVC torque. The centre of pressure (CoP) parameters and leg muscles activity (surface electromyography; EMG) were recorded during unperturbed upright standing on a force platform with eyes open or closed and when standing on foam mat. **Results** Both training programmes increased MVC torque (ST: +56.6%; BT +31.6%) and CAR (ST: +8.2%; BT +5.4%; $p < 0.001$) with a trend for a greater increase in MVC torque for ST ($p = 0.055$). The gains in maximal torque and CAR were positively correlated ($r = 0.87$; $p < 0.001$). Torque steadiness was also improved after training (10% MVC: $p = 0.02$; 20% MVC: $p = 0.016$). Regardless of the training group, CoP fluctuations in forward-backward direction were reduced ($p = 0.002$) when standing on foam, whereas plantar flexors EMG was reduced during upright standing in all balance conditions (p values < 0.05). **Discussion** Both training programmes increased muscle strength (Häkkinen et al. 2001) mainly through neural mechanisms. The increased postural stability and decreased leg muscles activity during upright standing, and the enhanced torque steadiness likely reflect an improvement in motor control after training. This study suggests that short-term training combining both strength and balance exercises increases muscle strength and postural stability, regardless of the proportion of both types of exercises. **References** Granacher U., Muehlbauer T., Zahner L., Gollhofer A., Kressig R.W. ASSESSMENT OF ANTHROPOMETRIC AND PHYSICAL PERFORMANCE CHARACTERISTICS BETWEEN PLAYING STANDARD AND POSITION IN YOUTH FEMALE TEAM HANDBALL PLAYERS

Moss, S.L., McWhannell, N., Michalsik, L.B., Twist, C.

University of Chester

Introduction This study examined the anthropometric and physical characteristics of female youth team handball players (16.07 ± 1.30 y) from Great Britain (non-elite; $n = 47$) in comparison to European sub-elite ($n = 37$), and elite players ($n = 29$). A secondary aim was to elucidate any positional differences between playing standard within these groups. **Methods** Anthropometric profiling included sum of eight skinfolds, body mass, stature, girths, breadths and somatotype. Performance tests included 20 m sprint, countermovement jump (CMJ), shooting velocity, a repeated shuttle sprint and jump ability test (RSSJA), and the Yo-Yo Intermittent Recovery Test Level 1 (Yo-Yo IR1). **Results** Elite players had greater body mass, lean mass, stature, limb girths and breadths than sub-elite and non-elite players ($P < 0.05$). Only stature and flexed arm were higher in sub-elite compared to non-elite players ($P < 0.05$). Sum of skinfolds and waist-to-hip ratio were similar between groups ($P > 0.05$). Elite players were better in all performance tests compared to both sub-elite and non-elite players ($P < 0.05$), while sub-elite outperformed non-elite players in shooting velocity only. Positional differences for anthropometric and performance variables were greatest within elite players, with less within-group variance for sub-elite and non-elite players. In elite players, goalkeepers differed most from back and wing players for body mass, humerus breadth, arm, waist and gluteal girths ($P < 0.05$), and from wings for shooting velocity, Yo-Yo IR1 and CMJ power ($P < 0.05$). In sub-elite, wings were most different to pivots for body mass and three skinfold sites ($P < 0.05$), and differed most to goalkeepers for shooting velocity and RSSJA time ($P < 0.05$). Non-elite wings were shorter than backs and had smaller subscapular skinfolds than pivots ($P < 0.05$). **Discussion** Our findings reveal that British (non-elite) handball players compare unfavourably to elite international European players in a variety of anthropometric and performance characteristics. Such differences are less obvious between sub-elite and non-elite handball players, with only shooting velocity distinguishing

between these groups. Positional differences are more obvious in U17-19 female international elite handball players compared to sub-elite and non-elite players of the same age, who show less variation between positions. These findings are useful for emerging team handball nations when designing appropriate training strategies and to improve talent identification processes. sam.moss@chester.ac.uk

METABOLIC POWER DURING CONSTANT AND SHUTTLE RUNNING IN AMATEUR SOCCER PLAYERS

Stevens, T.G.A.1, de Ruiter, C.J.1, van Maurik, D.1, van Lierop, C.J.W.1, Savelsbergh, G.J.P.1, Beek, P.J.1,2

1: Research Institute MOVE, Faculty of Human Movement Sciences, VU University (Amsterdam, The Netherlands), 2: School of Sport & Education, Brunel University (Uxbridge, Middlesex, UK)

Introduction Quantification of the soccer player's workload seems underestimated by traditional approaches, such as when running speed is used. An approach introduced by di Prampero et al. (1) allows an estimation of the instantaneous metabolic power of accelerated and decelerated running. The aim of this study was to evaluate the estimation of metabolic power by the di Prampero approach combined with Local Position Measurement (LPM) time-motion data for both constant and shuttle running. **Methods** Fourteen male amateur soccer players (23 ± 2 yrs; 183 ± 5 cm; 78 ± 8 kg) performed aerobic constant and 10m shuttle running tasks at 6 speeds (range 7.5-10 km/h) on artificial turf. A calibrated portable gas analyzer (Cosmed K4b2, Rome, Italy) measured oxygen consumption and metabolic power. This measured metabolic power was compared to estimated metabolic power calculated with the equation provided by di Prampero et al. (1) using speed and acceleration assessed by LPM (Inmotio Object Tracking BV, Amsterdam, The Netherlands; integrated Gaussian filter set at 100%) as input. The study was approved by the local ethics committee. **Results** For all runs except for some at the highest speed, RER was below 1.0. Measured metabolic power significantly ($P < 0.01$) increased with speed and was 21 to 29% higher ($P < 0.01$) for shuttle run (12.6 - 18.1 W/kg; range 7.5-10 km/h) compared to constant run (10.3 - 13.9 W/kg). The respective values for estimated metabolic power for constant (8.9 - 11.6 W/kg) and shuttle run (8.9 - 13.2 W/kg) were about 16 and 29% lower ($P < 0.01$) than measured metabolic power. Adding a terrain constant of 1.08 for artificial turf would decrease this underestimation of metabolic power to about 9 and 23%, respectively (2). **Discussion** Shuttle running raises the player's metabolic power compared to constant running at the same average speed. For both constant and shuttle running, average aerobic metabolic power is significantly underestimated when using the original di Prampero approach with LPM data as input, even when correcting for terrain. **References** 1. di Prampero PE, Fusi S, Sepulcri L, Morin JB, Belli A, Antonutto G. VARIATION IN RELATIVE WORKLOAD AND HEART RATE WITH SESSION-RPE HELD CONSTANT.

Evans, R., Lambert, M.

University of Cape Town

Introduction: Carl Foster adapted the Rating of Perceived Exertion (RPE) as a marker of the global intensity of a training session. This became known as the Session-RPE and is used to quantify internal training load (Foster et al., 1996). Since then this method has been used in a variety of sports. The measurement of Session-RPE is easy to implement, inexpensive and reasonably valid. However, as the measurement of Session-RPE is based on a subjective assessment, it remains to be seen how the measurement varies between subjects. This is an important question as training loads are often prescribed or assessed according to the Session-RPE. In a team setting variation between subjects must be accounted for or the interpretation of the measurement will be compromised. One approach to this question is to examine the variation in Session-RPE when the workload is held constant. However, difficulties arise in standardizing workload to ensure that the internal training load is constant (Mann et al, 2013). Another approach is to hold the Session-RPE constant and examine changes in workload. Therefore the aim of this study was to quantify the inter-subject variation in workload when the Session-RPE was kept constant. **Methods:** 37 moderately to highly active participants completed two experimental trials. During the first trial participants performed an incremental treadmill running test to determine peak treadmill running speed (PTRS) and VO_{2max} . After 48 - 96 hours, participants performed a 30 minute treadmill run where the pace was self-regulated to maintain a fixed Session-RPE of 7. **Results:** The descriptive characteristics of the participants were (mean \pm s); Age = 28 ± 7 years; Stature = 171.9 ± 10.1 cm; Body mass = 71.2 ± 10.1 kg; VO_{2peak} = 48.1 ± 9.3 ml.kg⁻¹.min⁻¹; PTRS = 15.8 ± 2.4 km.h⁻¹. Values obtained during the submaximal trial were: median (25th, 75th percentile); relative treadmill running speed 70% (65;73) of PTRS, heart rate 88% (83;93) of HR max and VO_2 73% (68;79) of VO_{2max} . The inter-subject variation during the submaximal trial was; relative treadmill running speed (CV = 9.8%), heart rate (CV = 6.3%) and VO_2 (CV = 11.7%) with a mean CV for all these variables of 9.0%. **Discussion:** The inter-subject coefficient of variation is representative of the biological variation between individuals. This variation in Session-RPE needs to be considered when designing studies and analyzing the measurement of internal training load. **References:** Foster, C., Daines, E., Hector, L., Snyder, A., & Welsh, R. Introduction Regular exercise training lowers indicators of cardiovascular diseases and diabetes risk including some inflammatory cytokines. However, there is limited research directly comparing different types of training. Thus, the purpose of this study was to compare the effects of nonlinear resistance (NRT) and aerobic interval training (AIT) on selected inflammatory markers, body composition and aerobic capacity in middle-aged obese men. **Methods** Sedentary volunteers were assigned to NRT (n = 12), AIT (n = 10) and control (CON, n = 11) groups. An age and physical activity matched control group of normal weight subjects (NOM, n = 11) were also recruited for baseline comparison. The experimental groups performed 3 weekly sessions for 12 weeks followed by a 4-weeks detraining period. NRT consisted of 40-65 min of weight training with flexible periodization. AIT consisted of running on a treadmill (4×4 min at 80-90% maximal heart rate, 3 min recovery intervals). Blood samples were collected to determine TNF- α , IL-6, CRP, sICAM-1 and adiponectin (ADPN) concentrations at baseline and the end of the training and detraining periods. The concentrations were measured in duplicate by ELISA. **Results** Unpaired t tests showed, at baseline, NOM had significantly higher serum ADPN and lower sICAM-1 than obese subjects, but not for IL-6,

CRP and TNF- α . Two-way ANOVA with repeated measures showed, compared to CON, serum levels of IL-6, CRP, and TNF- α did not change significantly in response to both training, but sICAM-1 decreased significantly. ADPN increased significantly after AIT, but NRT had no effect when compared to CON. ADPN and IL-6 levels significantly worsened after detraining. Aerobic capacity increased significantly more after AIT than NRT, but returned to pre-training levels in the NRT only after detraining. The 2 exercise programs were equally effective at improving body composition but detraining abolished these adaptations. Discussion Increase in ADPN after the AIT was accordance with study of Racil et al (2013) investigating the effects of high intensity interval aerobic training in obese individuals. Recently, it has been shown that ADPN levels remained unchanged after prolonged aerobic training with low to moderate intensity in healthy obese people. Also, Fatouros et al (2005) reported significant increases in ADPN after moderate- and high-intensity RT but not after low intensity training. In this study, more than 80% of a NRT program was performed at low to moderate intensity. Thus, it appears that the intensity is a determinant for a significant increase in ADPN in both training. The effect of AIT on ADPN might be due to the reduction in body weight or increase in aerobic capacity, or a combination of both. The practical applications are that the NRT regimen was not effective for decreasing systemic inflammation in obese men and AIT has better anti-inflammatory effects. References 1- Fatouros IG, et al. EFFECTS OF TRAINING INDUCED FATIGUE ON PACING PATTERNS IN 40 KM CYCLING TIME TRIAL

Skorski, S., Hammes, D., Schwindling, S., Veith, S., Meyer, T.

Saarland University

Introduction: It is known that pacing is important for endurance performance (Abbiss & Laursen, 2008). In some endurance sports, athletes complete several races within a short period of time, resulting in accumulated fatigue. Fatigue affects performance and several physiological parameters (Meeusen et al., 2013), yet it remains unclear if it also influences the pacing pattern (PP). The aim of this study was to analyse effects of fatigue on PP of cyclists during a 40 km time trial (TT). **Methods:** 23 male cyclists completed three 40km TTs on a cycle ergometer. TTs were conducted before (TT1) and after (TT2) a 6-day training period. A third TT was carried out after 72h of recovery (TT3). Training days consisted of 2 cycling sessions; in the mornings: 1h at 95% of individual anaerobic threshold (IAT) or 3x5x30s sprints; in the afternoon: 3h at 80% IAT. 4km split times (min) and rating of perceived exertion (RPE) were recorded during TTs. According to day-to-day variability of cycling TTs (CV ~1.0%; Hopkins et al, 2001) overall performance was expected to decrease >1% between TT1 and TT2 as well as increase by at least the same amount between TT2 and TT3 to ensure states of fatigue and recovery. Only athletes showing these performance changes (10 out of 23; 28.8 \pm 7.6y) were included in this analysis. **Results:** 40km time increased from TT1 to TT2 by 4.1% (\pm 2.5%; $p=0.0007$) and decreased from TT2 to TT3 by 3.9% (\pm 2.2%; $p<0.001$). TT1 and TT3 showed no significant difference ($p=0.95$). PP was significantly different in TT2 compared to TT1 ($p=0.04$) and TT3 ($p=0.04$). The first 4km were significantly slower in TT2 compared to both other trials ($p<0.001$), whereas the last 4km in TT2 were significantly faster than the corresponding section in the other trials. No difference in the PP could be observed between TT1 and TT3 ($p=0.85$). RPE showed no difference between trials over the whole race ($p>0.32$). **Discussion:** Cyclists seem to reversibly change their PP during a 40km TT due to accumulated fatigue. Furthermore, overall performance is significantly reduced in the fatigued state. PP changed at the beginning and the end of the race, which is compatible with the model that pacing includes a combination of anticipation and feedback mechanisms. Participants reduced their power output until premature exhaustion seems unlikely and then increased it for an end spurt. The slower pace at the beginning of the trial might be a response to compensate for the increase in RPE induced by fatigue. **References:** Abbiss CR, Laursen PB.
